Table of Contents

Knowledge Management

S1-1 ERP and productivity: a conceptual characterization
Amol Gore and Pekka Kess

S1-12 Are web based learning management systems sustainable of disruptive?
Bala Maniam and Christina Cross

S1-14 Unleash corporate capability of knowledge management with Web 2.0
Shu-Fang Lin

S1-25 Leadership and organizational learning as antecedents to knowledge management practices
Sanjay Kumar Singh

S1-38 Relationship between Knowledge Management and E-Business Adoption: A Malaysian SMEs' perspective
Alain Yee-Loong Chong, Shu Yi Tang, Keng-Boon Ooi and BinShan Lin

S1-51 The role of TQM and KM in supply chain learning: a conceptual model
Siew-Phaik Loke, Keng-Boon Ooi and Boon-In Tan

S1-61 The relationship of organizational politics with employees' knowledge sharing behavior and Work Engagement
Bindu Gupta

Performance Management

S2-1 The effect of diversifications on the performance and risks of banks and credit unions in Taiwan
Chuang-Min Chao and Chi-An Wang

S2-17 Off-balance Sheet Activities and Bank Efficiencies: The Three-Stage Data Envelopment Analysis with Undesirable Outputs
Chuang-Min Chao and Tsui-Chu Chang

S2-30 A studying of measuring the e-Service Quality of online human resource agency
Qinan K. Y. Lin and Bruce C. T. Ho

S2-31 The effects of project's social capital, leadership style, modularity, and diversification on new product development
Li-Yueh Lee, Shu-Min Li and Shang-Min Chen

S2-43 Foreign investiments and development of life insurance companies case of poland
Adam Sliwinski

S2-44 Business performance improvement through managing intangible assets
Chaichan Chareonsuk and Chuvej Chansa-ngavej

S2-59 HRIS effectiveness using data mining techniques
Jayanthi Ranjan and Vishal Bhatnagar

Table of Contents

(Continued)

Innovation Management

S3-1 An application of analytic hierarchy process to voice over internet protocol selection
Chuvej Chansa-ngavej and Akekachat Srijuntub

S3-20 The tacit signal e-HRM method at organization performance development
Marko Kesti and Antti Syväjärvi

S3-36 The diffusion of innovation and perceived risk for the adoption of alternative energy vehicles
Richard A. Feinberg, Hsin-Ying Wu and Charles V. Trappey

S3-56 Excel course manager (ECM): an electronic classroom management system designed for creating and grading excel assignments and examinations
James K. Fugate, Chuleeporn Changchit and Robert Vokurka

S3-70 Development strategy of service innovation: near field communication system application
Tsui-Yii Shih and Chia-Chang Chan

S3-85 Innovation influence on strategies of Romanian service firms
Cezar Scarlat and Catalin Alexe

S3-95 Requirements for software reuse: an intellectual capital view
Tauno Kekäle and Carmen Cabello Medina

S3-108 The Effect of Variability In Electronic Kanban (e-Kanban) Production System
Wichuta Insalee and Pornthep Anussornnitisarn

Maketing and Acquisitions

S4-1 **Factors predicting SMEs' Success**
Jiraporn Tangkittipaporn

S4-15 **Behavioral agent-based modeling of stock market microstructure**
Mariusz Kicia

S4-27 **Modeling the evaluation of business strategy**
Chinho Lin and Hua-Ling Tsai

S4-47 **Marketing strategy, Channel Brand Equity and performance: evidence from the Taiwan TV shopping channels**
Tsui-Yii Shih

S4-49 **Sources of value creation in acquisitions: a strategic business process reengineering perspective**
Stacy Huey-Pyng Shyu and Leon Tsai

S4-62 **Marketing strategy comparison between international brand and Thai brand for premium coffee business under customers' perspective: case study in Chiang Mai, Thailand**
Chulaluck Pratip Na Thalang

S4-71 **The power of employer's brand**
Dagmara Lewicka

Table of Contents

(Continued)

Investment and Contemporary Issues in Industrial Management

S5-1 **A Study on the individual investors' sentiment and the institutional investors' recommendation behavior in Taiwan**
Chuang-Min Chao and Yi-Ling Huang

S5-10 **Production efficiency: evidence from Taiwanese businesses in China**
Li-Hua Huang, Hsing-Chin Hsiao and Jui-Chih Wang

S5-27 **Market reaction to rating report by foreign institutions: a price and trading behavior analysis**
Chuang-Min Chao and Hung-Yu

S5-37 **The influencing factors of supplier's specifricity investments**
Ya-Jung Wu and Hong-Chun Wang

S5-53 **Determinants of information sharing of mobile phone users**
Chung-Chu Liu

S5-60 **Business ethics and quality management**
Fotis Vouzas and Christina Doufa

S5-73 **Design for Excellence in ICT companies**
Pekka Belt, Tuukka Mustonen, Janne Harkonen, Matti Mottonen, Pekka Kess and Sitthinath Sanpanich

Knowledge Management and e-Learning

S6-1 **Knowledge creation and intellectual capital of banks**
Kuang-Hsun Shih and Hsiao-Chen Chang

S6-21 **Intellectual capital in the public sector: Implement the IC process to formulate community traditional knowledge management strategy**
Pitipong Yodmongkon and Nopasit Chakpitak

S6-37 **Exploring the factors influencing knowledge sharing from the perspective of knowledge flow**
Chinho Lin, Ju-Chuan Wu, Teresa L. Ju and Andrea CP Liu

S6-54 **The relationship between social capital, organizational learning, knowledge integration mechanism, and human capital: a conceptual framework**
Ru-Jen Lin

S6-75 **Using ontology to improve the reusability of inter-organizational knowledge: an collaborative knowledge management network**
Nelson K. Y. Leung, Sim Kim Lau, Joshua Fan and Seung Hwan Kang

Management Information Systems

S7-1 **REVIEW: Interdisciplinary research of options theory and management information systems**
Liang-chuan Wu

S7-21 **A classification model of ERP system data quality**
Anders Haug, Anne Pedersen and Jan Stentoft Arlbjorn

S7-36 **Conceptualizing web-based information systems quality and its impact on customer satisfaction: a multichannel service provider perspective**
Moez Bellaaj, Ines Zekri, Michel Plaisent and Pascal Pecquet

S7-51 **Integration of information technology into the business models of healthcare system**
Yung-Chieh Chien, Pei-Shun Ho, Ben-Jeng Wang and Ching-Rei Kuo

Table of Contents

(Continued)

Strategies in an Organization

S8-1 **The strategic alignment among business strategy, operations strategy, and information systems strategy in organization**
Yue-Yang Chen, Hui-Ling Huang, Che-Wei Hsu and I-Chen Tsai

S8-17 **Performance implications of fit among marketing strategy, manufacturing strategy, and strategic orientation**
Yue-Yang Chen, Hui-Ling Huang, I-Chen Tsai and Che-Wei Hsu

S8-33 **Elements of strategic management of technology in high-tech SME practise**
Kari Sahlman and Harri Haapasalo

S8-52 **On the operationalization of strategic frameworks: an analytic network process (ANP) Approach to porter's five forces model**
Hakyeon Lee, Ran Kwak, Sanghoon Lee, Moonsoo Kim and Yongtae Park

S8-60 **A New model for managers used for positioning their organizations in market place**
Ahmadreza Shekarchizadeh

Enterprise Development and Growth

S9-1 **The role of human resources management as a strategic partner**
Ravee Phoewhawm

S9-21 **Evaluation of entrepreneurship policy for fostering SMEs using a hybrid MCDM model**
Wen-Hsien Tsai, Hsiao-Chiao Kuo and Yu-Wei Chou

S9-40 **A quality loss approach for airline service failure analysis**
Pao-Tiao Chuang

S9-50 **Survey of the shadow economy in slovenia: the demand side of the households**
Bojan Nastav, Štefan Bojnec and Ivo Lavrač

S9-66 **Dynamic Reorder Points for manufacturing execution system: a case study for testing equipment in hard disk drive factory**
Varintorn Boonsiri and Pornthep Anussornnitisarn

Management Change in an Organization

S10-1 **The relationship between critical successful factors (CSFS) and performance of ERP systems implementation-view of implementation phases**
Wen-Hsien Tsai, Shu-Ping Chen and Yu-Shan Shen

S10-2 **Review of business growth studies-focus industries and processes**
Pekka Kess, Matti Muhos, Kongkiti Phusavat and Sitthinath Sanpanich

S10-17 **A case study on emergency strategy**
Scott, S.C. Lung and Chung Lin Ho

S10-34 **A simulation analysis of group technology and job shop manufacturing system**
Surat Triwanapong

S10-44 **The determinants of foreign direct investment in Cambodia: case study of multienterprises**
Sivyong Ho

S10-59 **Barriers and Chalinges in E-Government services: an empirical study in Jordan**
Mohammad Hjouj Btoush, Jawed Siddiqi

Knowledge Management, e-Learning and Human Capital

S11-1 The success factor of e-Learning: the mediate effect of the e-Learner's competency on learning outcomes
Li-An Ho, Tsung-Hsien Kuo and Chien-Ting Lin

S11-17 Development of a project-based cooperative learning environment for computer programming courses
Hui-Chun Chu, Gwo-Jen Hwang and Gwo-Haur Hwang

S11-26 e-Learning in Slovenia
Štefan Bojnec and Ajda Fošner

S11-30 e-Learning: The effects of computer attitude, statistics anxiety, and self-efficacy on statistical software adoption behavior
Kevin K. Chiu, Maxwell K. Hsu and Stephen W. Wang

S11-43 An Investigation into Data Collection Technology in the Construction Industry
Chang-tseh Hsieh and Binshan Lin

S11-56 Technology innovation and open learning environment
Natalija Komljanc

S11-69 Knowledege management implementation in multinational companies – an empirical study in Malaysian MNCs
Tan Nya Ling, Robert J. Nathan

e-Commerce and Business

S12-1 A study for the determinants of customer loyalty perspective in e-Retailing
Bruce C. T. Ho and Faye H. J. Chen

S12-22 An examination of the determinants of loyalty in e-Telecommunication industry
Bruce C. T. Ho and Switch J. C. Su

S12-42 A comparative analysis of Japanese, U.S., and Korean firms on it and management
Kazuyuki Motohashi

S12-58 Effects of knowledge integration and task-technology fit on the implementation of e-business applications: evidence from Taiwanese service industry
Jung-Chi Pai

S12-67 Understanding the mass adoption of third generation mobile communications system in Taiwan
Weichen Teng and His-Peng Lu

S12-82 e-Business and Slovenian SMEs
Viktorija Sulčič and Dušan Lesjak

Table of Contents

Productivity Management

S13-1 A multinomial logit model on Taiwan's corporate recovery from the financial distress
Chuang-Min Chao and Chia-Hsin

S13-18 Improving managerial skills – the results of research done in polish companies
Agnieszka Sitko – Lutek

S13-36 An evolutionary complex system's decision-support tool for the management of operations
James S. Baldwin, Peter M. Allen and Keith Ridgway

S13-54 An exploratory research on supply chain performance measurement framework for the Thai jewelry industry
Achara Satayapaisal and Chuvej Chansa-ngavej

S13-74 Leaner than Thou – Linking lean production, DFMA and production region in the automotive sector
Mikael H. Ehrs and Tauno Kekäle

S13-84 Reducing competence gap and the enterprise's effectiveness
Urszula Skurzynska-Sikora

Quality Management

S14-1 Dimensions of TQM: relation to role ambiguity
Pei-Lee The, Chen-Chen Yong, Veeri Chettiar and Keng-Boon

S14-19 An approach for eliminating redundancy in virtual enterprising
Reggie Davidrajuh and Zbigniew Pastuszak

S14-30 Quality management model for banks-An IPA & BSC integrated approach
Ching-Wen Lin, Fu-Ju Yang and Kai-Lien Chen

S14-50 Effective asset management to improve the satisfaction of mobile telephone customers
Sanjay Ramsingh and M.K.S. Sastry

S14-61 An analysis of factors affecting industrial goods buying decision making in a manufacturing company
Sallaudin Hassan, Abu Bakar and Chong siong Choy

S14-77 Integrated business process and service management
Thomas Gulledge

Table of Contents

(Continued)

Emerging Issue in Operation and Organizational Management

S15-1 Analyzing gaps for ERP introduction: An adoptive learning model
Shing-Jen Song

S15-18 Product quality inspection improvement by attribute acceptance single sampling plan and its computer program application
Natha Kuptasthien

S15-29 A comparative analysis of the behavioral model of wikipeia by social roles
Nai-Ching Yeh, Judy Chuan-Chuan Lin and His-Peng Lu

S15-47 Alliances and acquisitions in high velocity environments: in search for a grounding theory
Hani sarkis, Michel Plaisent and Prosper Bernard

S15-67 Electrical motor business and difficulty managing delivery
Rosemarin Sukhasem, Pornthep Anussornnitisarn and Petri Helo

S15-80 FERN's Decision making: a chaotic perspective
Safawi Abdul Rahman, Khalid Abd. Wahid and Mohamad Shanudin Zakaria

Finance, Enterprise Risk, and New Product Development

S16-1 Why European two tier boards instead of us single board?
Rado Bohinc

S16-22 Corporate governance related lated party trabsaction and bank performance
Chuang-Min Chao and Jia-He Jhuang

S16-32 On the relationship of the off-balance sheet activities and the three risk types of the new baselaccord
Chuang-Min Chao and Yu-Ling Hsiao

S16-42 A rough set-based approach to selection of crucial features in new service concepts
Changyong Lee, Hyeonju Seol, Changho Son and Yongtae Park

S16-50 The impact of collective nature of team members on new product development performance: the organizational routines perspective
Hong-Chun Wang and Ya-Jung Wu

e-Commerce and e-Business

S17-1 The effects of interactivity and hedonic value on WOM and attitude towards the website
Wann-Yih Wu, Shu-Min Li and Chia-Jung Chuang

S17-26 Digitalizing SMES in the ERA of e-Commerce lessons learned from SMES' industry portals design
Jau-Rong Chen, Tzu-Chuan Chou and Jung-Te Wang

S17-38 Internet security, risks and minor guardianship
Augusto Sebastio

S17-46 Assessing the role of age and gender on the propensity to engage in software piracy
Vatcharaporn Esichaikul and Trevor T. Moores

S17-48 Exploring bloggers' motivation and behavior in Thailand
Nuchada Dumrongsiri and Vikanda Pornsakulvanich

Table of Contents

Supply - chain Management

S18-1 Supply chain management practices: its linkage to firm's sales
Za'faran Hassan and Arawati Agus

S18-17 Managing supply chain network in a globally distributed environment
AHM Shamsuzzoha and Petri T. Helo

S18-30 Supply chain analysis of the defence sector
Štefan Bojnec and Ajda Fošner

S18-42 Management and technology: optimizing supply chain efficiency in the apparel industry
Gallayanee Yaoyuneyong and Mary Ann Moore

S18-49 The relationships among and supply chain partners affecting internal operation: perspectives from the high-tech electronic manufacturers in Thailand
Rapee Kanchana, Kris M. Y. Law and Kongkiti Phusavat

Supply - chain Management

S19-1 Technology adoption of mobile learning in language: a study of pod casting in Taiwan
Bruce C. T. Ho and Viola H. Y. Fang

S19-19 Exploring factors affecting nursing e-Learning success based on information system success model
Chung-Feng Liu and Chia – Nan

S19-32 The fast strategy and dynamic decisions in energy industry
Tomi Mäkipelto and Kongkiti Phusavat

S19-46 Environmental management system in European Union (EU): comparative analysis of some case studies
Giovanni Lagioia, Vesselina Dimitrova and Teodoro Gallucci

S19-54 Technology acceptance and related models: an exploratory research for internet banking applications
Mantana Intana and Chuvej Chansa-ngavej

Emerging Issues in Operation and Organizational Management

S20-1 Application of environmental criteria in organizations assessment with AHP method
Agnieszka Leszczynska

S20-12 The impact of ERP systems on information flows in enterprises: a questionnaire survey
Anders Haug, Anne Pedersen and Jan Stentoft Arlbjorn

S20-24 Evaluating product-service systems using system dynamics
Sora Lee, Jieun Kim, Chulhyun Kim and Yongtae Park

S20-35 The structural impact of supply chain management on process performance
Arawati Agus and Za'faran Hassan

S20-58 Customer satisfaction with information technology implementation in a government agency: A survey on royal Malaysian customs
Najmi Mohd. Radzi, Abu Bakar Abdul Hamid and Chong Siong Choy

ERP AND PRODUCTIVITY: A CONCEPTUAL CHARACTERIZATION

Dr. Amol Gore, BRIMS, University of Mumbai, India
dr.amolgore@yahoo.com
Dr. Pekka Kess, IEM, University of Oulu, Finland
pekka.kess@oulu.fi

ABSTRACT

Millions of dollars have been invested in the enterprise applications market with the consideration of ERP systems as key element of an infrastructure that delivers a solution to business, with the hopes of accelerating the productivity growth. As it becomes crucial to mobilize resource capabilities across corporate boundaries, ERP has evolved to include sophisticated modules in e-commerce, customer relationship management and supply chain management.

While there is substantial literature about the general effect of IT and productivity, there is limited specific research on ERP and productivity with ERP as a particular entity. This paper aims to develop a conceptual framework for ERP and productivity that articulates the challenges of ERP in driving productivity. Moreover, this research framework would provide a theoretical ground for advanced enterprise systems conciliation with productivity as it is based on the extensive review of the ERP developments in addition to our prior research.

Keywords: ERP Systems, Productivity, Innovation, Next Generation Enterprise Systems, Agile Networks

INTRODUCTION

Technology is often regarded as the critical dimension of the productivity management models with thrust on innovation (see e.g. Sumanth, 1998; Ark, Kuipers and Kuper, 2000; Hoshi and Jorgenson, 2005). Today, technology and in particular information technology is embedded into most aspects of modern global economic activity. According to Liikanen (2004), information technology is one of the drivers of productivity and is closely linked to innovation. In fact, one of the most important IT-enabled business innovations has been the emergence of enterprise resource planning (ERP) systems.

The ERP systems are developed to provide information backbone needed to support the business decisions. Thereby, ERP is described as software system that integrates application programs in manufacturing, logistics, sales and marketing, finance, human resources and other functions in a firm (Vollmann et al., 2005). Most major companies have implemented ERP systems and are in various phases of ERP maturity. The evolution of the ERP systems has been largely from the material requirements planning (MRP) philosophy to a huge industry today that is expected to grow to $64.8 billion in 2009 as indicated by the recent AMR research. Also, these enterprise systems play a central role in the supply chain management challenges, from integration and collaboration to practices of strategic agile networks.

Although there is substantial literature about the general effect of IT on productivity and some empirical investigations have even attempted to find a relationship between IT

investments and productivity (see e.g. Brynjolfsson and Hitt, 2000; Oz, 2005; Dozier and Chang, 2006; Stiroh and Botsch, 2007), the IT and productivity debate is neither conclusive nor consistent while the ERP and productivity characterization has been obscure as regards the content and the changing status of the phenomenon. There is limited specific research on ERP and productivity with ERP as a particular entity. Moreover, ERP is transforming progressively towards next generation enterprise systems and it is essential to highlight the aspects of productivity in these increasingly consolidating applications. In this paper, our approach is to review the challenges of ERP in driving productivity and to evaluate the productivity links to the next generation applications. This will lead to a conceptual framework that incorporates the factors impacting productivity on implementing ERP systems.

ERP DEVELOPMENT AND PRODUCTIVITY CHALLENGES

While the 1990s focused on the increasing levels of global competition and growing importance of supply chain processes extending across the firms in standard mode of operation (Rondeau and Litteral, 2001), the 2000s further established this form with activated business clusters (see Ketels, 2003; Porter, 2008) and budding agile networks. The clusters stress innovation and productivity improvement whereas the agile networks were proposed to forward similar ideology as a response to uncertain market conditions and ever-changing customer requirements (see Brown and Bessant, 2003; Gore, 2008). Furthermore, the firms recognized the need for strengthening the information systems infrastructure to meet the global directives and achieve customer-oriented information management, thereby investing in ERP systems that promised to deliver on all the fronts. It was not that many of these firms had a choice, because, the dynamics of the new customer-supplier relationships demanded it (Reary, 2000). So, the ERP development can be traced depending on the advances in processes, technology, methodology and organization, depicted as generations of ERP systems (Siau, 2004).

However, the basic ERP's role in driving productivity includes the following responsibilities:

- providing the necessary real-time information so that the employees and managers can optimally run the business
- better integration
- enhanced collaboration
- improved customer service

These responsibilities indicate the necessity of proactively implementing the vision, putting together the information systems strategy with the company strategy, rather than engulfing in the mere mechanics of operating the software. In this context, the debate has been restricted to 'alignment' with the units or in some cases about partnering in planning the organization's future. But, Monat (2006) insists that the IT departments recast themselves and transcend ERP to leadership state in order to maximize corporate productivity. Monat's survey shows that only 6 percent of the companies regard ERP's role as proactive leadership, which means that at least in the early phases of ERP development, the productivity efforts were compromised. This seems likely considering the strategic ERP perspective of business solutions (Shanks et al., 2003; Elbertsen et al., 2006) as opposed to arbitrary installation of new software. Moreover, there is evidence suggesting that ERP had mixed results and the technology had difficulty dealing with the degree of data incompatibility within firms resulting in only partial realization of total information integration (Baily, 2004).

The companies have dealt with the issue of incompatibility in different ways depending on the type of ERP package. There is a broad spectrum of choices and the extent of tailoring efforts have important implications for the risks faced and outcomes realized by companies that implement the ERP systems. The options are off-the-shelf packages, customization, in-house applications, or out-sourcing. But, each option has its pros and cons with regards to costs, implementation time, skills and security. The figure 1 shows the option selected by companies and the productivity results. The study is based on telephone interviews with managers of some companies in Finland. These companies expected ERP to potentially improve inventory control, reduce inventory costs, improve yield, traceability, forecasting and correct sequencing of manufacturing processes.

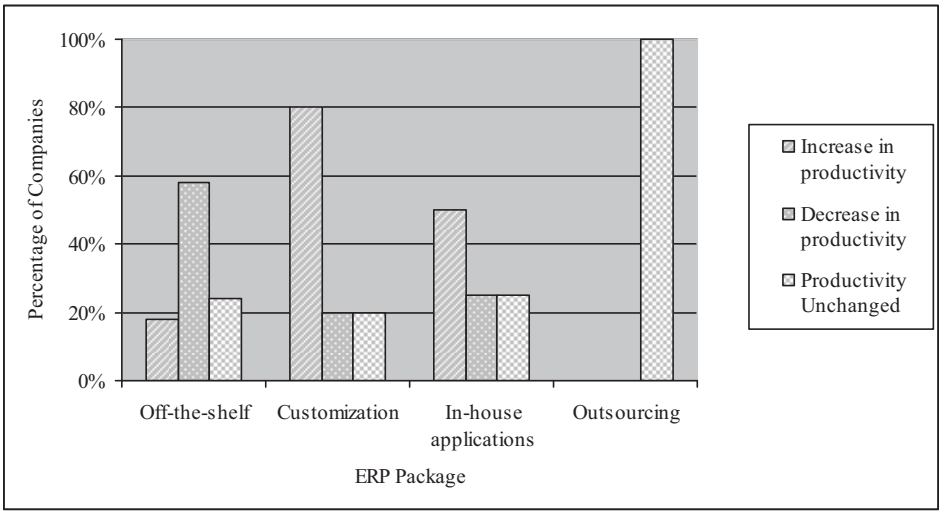

Figure 1 Type of ERP Package and Productivity Effects

Since the sample size in this survey is limited, it is difficult to draw exclusive conclusions but it can be deduced that customized ERP leads to positive productivity outcomes. This result coupled with the modest productivity gains of in-house applications implies that the uniqueness of the organizational processes should normally be captured in the ERP implementation. The pure off-the-shelf implementations fail to comprehend the organization and move away from the goal of providing real-time information, largely negating the productivity. Therefore, the importance of setting parameters in the package to reflect the organizational features and inimitability is underscored. On the other hand, extensive modifications can cause difficulties during upgradation apart from time-consuming and expensive programming, maintenance and post-implementation efforts. According to Zarotsky et al. (2006), the upgradation process can become complex and as risky as the implementation itself. The companies that attempted to build high competitive differentiation to the extent of contemplating legal protection for the resource, actually saw their productivity dip, thus suggesting a trade-off between configuring the system and controllable tailoring risks. Also, the business practices in organizations evolve over time and may not necessarily be efficient but the organization may be unwilling to abandon the practices in favour of the ERP package. Some companies dealt with the trade-off issue by applying 'bolt-on' packages for particular functions or areas that supplemented the organization's existing ERP package. For example, Butler and Meyer (2002) have described the 'bolt-on' for accounts receivable and collection functions that raises the function to the next level. This was seen as a way to attain competitive advantage relative to the companies utilizing the package as-is. So, the 'bolt-on' could be designed to work with the ERP system and provide

industry-specific functionality or even broader expertise such as supply chain management (SCM) and customer relationship management (CRM). According to Grossman (2004), ERP systems have played a critical role in getting organizations to focus on business processes but they have not been as successful integrating processes across the supply chain. The reason could be that the traditional ERP systems did not readily take to e-commerce (Johnson, 2007) and, in order to be internet-ready, they had to be redesigned for being:

- Fully browser enabled
- Available for all corporate users, not just the special few
- Available to trading partners
- Standard data interchange language oriented, rather than proprietary protocols oriented.

In other words, ERP vendors had to completely redesign their applications for a true e-business environment. Most of these are now available as integrated business suites built with open, service-oriented architecture (SOA), web-enabled for e-business. Managers are now focusing more on the internet-enabled collaborative strategies that represent a paradigm shift in the corporate mindset. Earlier, few organizations willingly shared information believing that their own information provides competitive advantage, but, in the collaborative environment, the organizations have to optimize the processes for mutual benefit (Búrca, Fynes and Marshall, 2005). The ability to interact across the supply chain requires crossing the traditional organizational boundaries and inducing visibility in the operations. The exchange of accurate information and progressively trusting business relationships can facilitate enhanced productivity. However, the top management has to view the ERP systems as enabler of collaboration and comprehend the intricacies of collaboration in entirety because, poorly planned efforts at collaboration may be deleterious.

Two other aspects that surfaced from this study were utilization of ERP and organizational changes. The productivity gains come from the ability to apply and utilize the ERP system not just the expensive selection of package, thus drawing parallel to the previous studies of IT and productivity (see Oliner and Sichel, 2002). Research shows that more the understanding of both how day-to-day processes work and the systems capabilities, the more that can be accomplished (Sonde, 2008). However, it takes time to learn and apply new technologies and absorbing ERP in the organization entails transition stages referred to as 'stabilization.' During this period, the competing interests, power transfers, degree of formalization, and appraisal practices remain fluid. The lesson learnt from the ICT sector in Finland is that the productivity impacts of new technologies can be long-delayed. According to Jalava and Pohjola (2007), ICT can be expected to increase productivity by standardizing, automating and outsourcing the work in basically the same way as the assembly line mechanized manufacturing. So, ERP would play the same role as the assembly line did in the transformation of industrial work. The on-going digitalization and outsourcing of business processes could result in the restructuring of the work at global level, consequently bringing about a new wave of productivity growth. Therefore, time is a significant factor that determines the productivity growth achieved specifically by ERP implementation.

ERP AND INNOVATION

There have been some contradictory views suggesting that ERP tends to lock in a certain way of doing things making innovation difficult. However, although acknowledging the dialectical and often complex relationship between ERP systems and innovation, the current research highlights the ERP potential for augmenting knowledge capabilities and leveraging

the enabling elements for innovation (see Srivardhana and Pawlowski, 2007). The ability to harness this ERP potential to drive innovation leading to increased productivity can be the fundamental source of wealth creation in an economy. As the ERP systems are considered from the perspective of enhanced knowledge capabilities they become strongly related to innovation, particularly since innovation today is largely the result of an interactive process of knowledge generation, diffusion and application (Tödtling et al., 2009). The complexity increases when the collaboration with specialized outside partners along with the interplay in the supply chain is conjectured. Dachs, Ebersberger and Pyka (2004) have grouped the different motives for firms to collaborate for innovation as sectoral, strategic and political attributes. Firm's propensity to collaborate is determined by the firm's management of appropriability as well as speed of knowledge generation and utilization processes. Nevertheless, the implication for the organization is in the form of significant investments in training people for ERP systems and it essentially means that the organization is building up intangible capital. Managers have to identify business improvement opportunities and engage knowledgeable people to ensure strategic fit. Sambamurthy et al. (2003) have coined the term 'entrepreneurial alertness' to indicate the management's ability to anticipate strategic opportunities in the marketplace and develop knowledge systems for agility. They define agility as the ability to detect opportunities for innovation and seize those competitive market opportunities by assembling requisite assets, knowledge, and relationships with speed and surprise. According to Berente (2005), the agile firm not only responds to moments of opportunity, but also contributes to them through relentless innovation. The important realization is that sustainable value can be created from nurturing intangible assets thereby fostering an innovative organization. Such organization would achieve high productivity and wealth creating capability. Therefore, retaining people trained in ERP environment is a crucial factor coupled to productivity.

CONCEPTUAL FRAMEWORK

The ERP market experienced hype as the systems were looked upon as key driver of productivity with immense opportunities for strategic and operational development. The vendors steadily brought on the scene a host of solutions ranging from isolated technologies and 'bolt-on' applications to extensively consolidated packages. Later, the hype soured as the traditional ERP faced difficulties for e-business transformation. The response was to expand the system and devise modularized architectures to be gradually adopted into the infrastructure of the ERP systems. However, the companies continue to struggle with productivity because of the challenges posed by a number of entities and particularly because the implementation goes beyond just assimilating sophisticated technologies through multiple modules. The conceptual framework of ERP and productivity illustrated in figure 2 consists of two platforms to be elaborated collectively as follows:

1. The Foundation Platform: Six factors and sub-factors impacting productivity on implementing ERP systems.
2. Elements of productivity in the next generation enterprise systems.

In the Table 1, these platforms are decomposed into a set of factors and subsequently explained in the following.

Foundation Platform

This platform forms the core part of the discussion on ERP and productivity since it includes the standard ERP modules such as financials, sales and distribution, logistics, manufacturing,

quality management and human resources, that are the backbone of the system and maps the ERP maturity.

The first factor namely the type of ERP package is directly linked to productivity since our research indicates that applying any of the extremes viz. off-the-shelf and extensively tailored package produces undesirable effects and often drop in productivity. In fact, the implications can range from loss of data to frequent work stoppages and reduced employee morale. So, the customized ERP with necessary but limited modifications can be prescribed as favourable for productivity improvement.

Then, the factor of 'utilization' refers to the ability to comprehend the system, exploit the features and manage the user acceptance. The gap grows between the capabilities offered by the ERP and the extent to which the system is accepted and effectively utilized by the intended users. This could be due to the misalignment of perceived expectation and rewards between users and managers or intimately tied to the sustained fulfillment of the users' cognitive expectations (Lim, Pan and Tan, 2005). In other words, utilization of ERP system at perfunctory level leaves the productivity unchanged at the best and in all likelihood hinders productivity gains. Hence, greater utilization relates positively to productivity advantage.

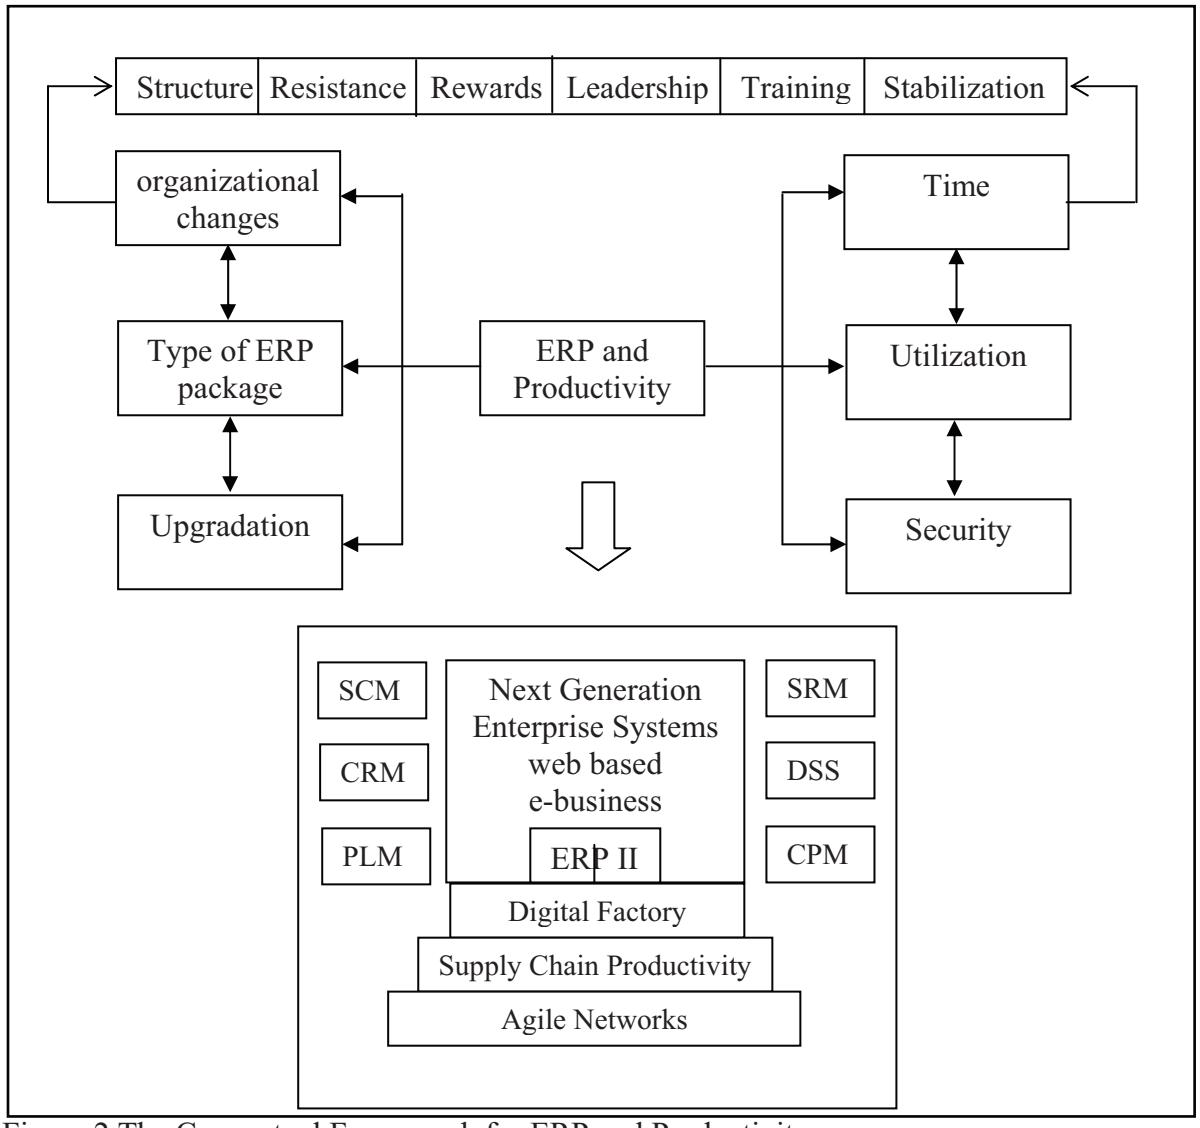

Figure 2 The Conceptual Framework for ERP and Productivity

The organizational changes that follow are closer to organizational restructuring dynamics as the evolutionary change alone becomes insufficient to achieve the ERP benefits (Gore, 2008). Evidence suggests that the ERP paybacks can be realized in a flat organization structure where qualified and empowered employees work with clear strategic objectives. However, the flat, responsive structure does not emerge radically and several transition forms appear instead to take a toll on the productivity. Hence, the management of resistance to change and transformation of reward schemes are the sub-factors in the conceptual framework.

ERP requires users to understand that they are no longer working in silos and this creates resistance due to fear of the unknown and inherent desire to maintain the status quo. This can be tackled by instituting new reward schemes that stress competence and superior performance, not just compliance. According to Bartol and Srivastava (2002), rewards are important for most mechanisms of knowledge sharing and could be made partly contingent on knowledge sharing behaviours as in merit pay, and team-based or company-wide incentives like profit sharing and employee stock options. Such reward schemes provide impetus for productivity growth after ERP implementation.

Platform	Components	Factors	Sub-factors
Foundation	Standard ERP Modules	Type of ERP Package Utilization Organizational Changes Upgradation Time Security	Structure Resistance Rewards Leadership Training Stabilization
Next Generation Enterprise Systems	SCM CRM PLM SRM DSS CPM	Digital Factory Supply Chain Agile Networks	Web based E-business

Table 1 The Platforms in ERP and Productivity Characterization

Time is another factor that has significant bearing on productivity through the sub-factors of stabilization and training. The companies typically require 12 to 36 months to stabilize before productivity can be recorded and ERP being not just software installation but solution for business, the implications could go well beyond the internal value chain processes and encompass the global activities thereby setting new trends in productivity attainment. The leadership has to be responsible for ERP so as to 'own' ERP from a strategic perspective and the top management commitment is imperative in order to take any real strides towards the objectives of the enterprise. In this regard, investment in training the people in ERP systems is foremost activity that is time-dependent and as Finney and Corbett (2007) note, training is the crucial part of ERP implementation or in effect the precursor for productivity. Further, stabilization involves resolving issues after the 'go-live' stage towards post-implementation aspects like upgradation.

Upgradation means to raise the ERP by newer versions or releases of application suites to expand the capabilities of the system and leverage the business value. It is essential to treat

upgradation like a new project since the efforts required depend on myriad of technical, organizational and operational matters. Organizations that underestimate the time and resources needed for upgradation commonly limit the planning time, rush to implement system changes and fail to thoroughly test all facets of the updated ERP environment, thereby causing disastrous impact on productivity (Beatty and Williams, 2006). Hence, upgradation is a key initiative that can be best conducted by the original ERP implementation team so as to reduce the overall cost and time. The users' understanding and 'buy-in' can only result in enhanced productivity.

Elements of Productivity in the Next Generation Enterprise Systems

The second platform comprises of factors that are associated with advanced enterprise systems in which the embedded components are devised to extend the standard ERP functions. The purpose here is to comprehend the productivity facets in the view of the fact that research is continuing in each of these specialized areas.
Once a company becomes a convert to the ERP philosophy, it starts looking ahead to the advent of e-commerce and extended ERP applications. The low cost and ease of use of internet has increased efforts to connect supply-and-demand chains across organizations (Davenport and Brooks, 2004). So, the next generation enterprise systems include supply chain planning, integrated e-commerce, decision support systems and customer relationship management (CRM). According to Møller (2005), ERP II is essentially web-based, componentized ERP, e-business and collaboration in the supply chain.

The SCM module enables planning, execution and coordination of the entire supply network in the changing competitive environment. Two key elements underpinning the success of the e-SCM are collaboration and visibility. All firms involved have to consider collaboration as a strategic asset and an operational priority in order to foster trust among trading partners and the information visibility across the supply chain has to be managed with strict policies, disciplines and monitoring (Búrca et al., 2005). Consequently, productivity needs to be highlighted as 'supply chain productivity' in the context of supply chain management. Supply chain managers then need to be responsible for earning power and productivity of assets in their trust, not just for cost control of these assets (Byrnes, 2005); therefore going beyond the traditional supply management, obligating the supply chain managers to arm with expertise in knowledge generation and change management. Differentiating the company from the competitors by using supply chain capabilities and focusing on return on invested capital (ROIC) management are positively linked to supply chain productivity. Initially, this ideology concentrated on the planning process only within the concept of digital factory. The digital factory is a comprehensive network of digital models, methods and tools – including simulation and virtual reality visualization – that are integrated by a continuous data management system with the purpose of having integrated planning, evaluation, and continuous improvement of all essential processes and resources of the factory in combination with the product (Bracht and Masurat, 2005). The concept essentially enlarged the ERP pitch that today encapsulates the absolute supply chain detail. Moreover, some vendors cater to specialized engineering organizations such as made-to-order or custom-engineering firms with unique supply chain need, to achieve higher productivity gains. However, Koh et al. (2006) contend that in these cases apart from ERP to manage the supply chain, other technologies such as radio frequency identification (RFID), wireless technology and intelligent knowledge-management systems would be more significant for efficient supply chain. Further, the components such as customer relationship management (CRM),

supplier relationship management (SRM), product lifecycle management (PLM), decision support systems (DSS) and corporate performance management (CPM), are productivity boosters. CRM promotes customer identification, interaction and service management thus providing a tool to improve productivity, satisfaction, delivery and decision-making, while SRM facilitates management of supplier relations in their complete life cycle. We appreciate these prevailing perspectives but concur with the school of thought that integration is the essence than just making the technology available for business. The rapid investment in ERP add-ons does not automatically ensure rapid labour productivity growth unless supported by intensive training and motivation. Hence, the research needs to be expanded particularly for architectures in agile networks wherein the entities could be opportunistic or proactively anticipating changes, and for productivity paradigms encompassing customers' operations as well.

CLOSING REMARKS

This paper attempts to establish a conceptual framework for ERP and productivity based on the analysis of ERP research and emerging enterprise system perspectives. The model compiled sets an outline of ERP and productivity characterization that has so far remained obscure in the literature or curtailed to general observations about the IT phenomenon. As the next generation enterprise systems are progressing rapidly, a host of new implications are emerging for productivity together with the challenges of inter-organizational integration. The paper provides insights for interesting future work on productivity in the scenario of digital factories and agile networks.

ARE WEB BASED LEARNING MANAGEMENT SYSTEMS SUSTAINABLE OR DISRUPTIVE?

Dr. Bala Maniam, Sam Houston State University,USA
maniam@shsu.edu
Christina Cross, Sam Houston State University,USA
gba_bxm@shsu.edu

ABSTRACT

A sustainable technology is one that is arrived at through incremental improvements to an existing technology. These products are usually higher quality due to the continuous testing and improvements. An example would be in the camera industry. Leading companies focused on improving the quality of film cameras and offering new features on these cameras that appealed to their core customers. A disruptive technology, however, is a new innovation that does not follow the guidelines of sustainable improvement, but jumps over the current technologies to appeal to fringe customers. This product is in lower quality, but it offers some benefit that can't be found in existing technologies such as cost or convenience that causes some to adopt it. When digital cameras first emerged, their quality was much lower than comparably priced film based cameras. Many in the camera industry did not embrace this new technology because it only appealed to a few customers on the fringe. As customers began to embrace the digital technology, the quality quickly improved and has since dominated the market. Leaders in the industry did not allocate the resources to fully implement the new technology or they disregard it completely because they believed it was substandard and would not last. Still others were willing to give up the customers on the fringe and market to their mainstream customers. Sometimes industries are correct in their beliefs, but sometimes a new technology will begin to improve in quality and will be quickly adopted by mainstream customers. Web based learning management systems appear to have the characteristics of both of these models. (Armstrong, 2000)

Web based learning management systems (LMS's) have enabled many nontraditional students who would not otherwise be able to take classes to further their education. LMS's bridge the gap of both time and space and enable institutions to offer courses that meet the needs of students who are not able to attend face to face classes due to either their proximity to the institution or scheduling conflicts. Offering these opportunities helps institutions reach out to students, for example an adult student may work full time and find it difficult to commute to campus each week. An online course offers them a viable alternative. LMS's also offer the institution alternatives in scheduling. An institution can create economies of scale by offering a hybrid course which is partially online and partially face to face which allows them to schedule two classes in the same time slot.

Offering online courses also brings up additional issues that need to be addressed. A distance learning program needs to be thoughtfully planned out in order to avoid the two extremes of canned courses or courses independently created by faculty who are not experienced in online teaching. Canned courses can lead to an impersonal experience for students; while a

poorly designed course can lead to confusion and frustration. Frustrated students can lead to low retention levels and can stifle a distance learning program's growth.

Web based LMS's have pushed distance learning into exponential growth. Not only had distance education become more mainstream, it is being offered and strongly advertized by higher education institutions for both undergraduate and graduate programs. Web based learning has changed the face of education in that universities now have to compete with other institutions who offer the convenience of a degree that can be obtained completely online. With technology becoming more and more engrained in our lives, students will need to learn this technology in order to become functional in the workplace. Educators are now responsible for preparing students for a career in which they will be expected to use technology that may not even exist today.

This paper will discuss whether web based learning management systems are a disruptive or sustainable technology in the higher education industry. It will first address the evolution of modern distance education from the traditional correspondence type course to modern web based distance courses. It will then discuss how communication and social presence are improving online distance courses and creating a sustainable advantage. Next it will outline new roles for teachers and students in an online environment and the responsibilities that are placed on an administration when adopting an online learning program. Finally, the paper will discuss quality and improvements in online education and conclude.

Unleash Corporate Capability of Knowledge Management with Web 2.0

Shu-Fang Lin, Department of Business and Administration, Yuanpei University,Taiwan.
Lucy_linn@yahoo.com

ABSTRACT

The latest pervasion of Web 2.0 has created more than technical impact to individuals and organizations alike, rather, it has profoundly influenced the way we communicate, learn, work, and live our lives. A surge of growth in adopting Web 2.0 application into the business processes has been witnessed around the globe, and the trend is still on the rise. In knowledge management arena, new space and potentiality for innovation in business process are widened through various forms of Web 2.0 applications. However, due to strategic, managerial and technical reasons, the implementation of Web2.0 application into the organizational learning practice is an area too new to be mature. The situation is even more prominent in Taiwan, where innovation is one of the top concerns for organizations to sustain their competitive advantages.

The present research proposal is aimed at investigating the impact and influence of Web2.0 over the practise of knowledge management, and how can organizations unleash their collective intelligence and gain competitive advantages through leveraging web 2.0 capabilities. Attempts are also made to identify the various reasons behind the resistance of Web2.0 adoption in their knowledge management system. Eight hypotheses are developed to address the issues arising from both the literature and organizational practices, respectively from a strategic, managerial, and technical perspective.

Using case study approach, this research work is to conduct qualitative analysis based on both personal and organization experience of knowledge management facilitated by Web 2.0.

Keywords: web 2.0, organizational learning, SECI, knowledge management

INTRODUCTION

The evolvement in web technologies has been shaping the fashion we communicate, the notion of our society, and ultimately, the way we live our lives. In knowledge management arena, new business paradigms has offered enormous competitive

advantage to those who embrace the new tools that enable contextual, agile and simplified information exchange and collaboration to distributed workforces and networks of partners and customers. The social software technologies emerging through computerization will solidify the web not only as a new business platform, but also as a rich learning, knowledge creation and collaboration environment. With the advent of the Web 2.0 technologies, web-based learning is shifting to new learning community driven requirements, which facilitates novel approaches for flexible, evolving, adaptable, and interoperable community (Spaniol et al, 2008).

With respect to knowledge creation and management, the SECI model developed by Nonaka and Takeuchi has come to be the most widely recognized and accepted all over the world. The SECI model consists of three elements: SECI, ba, and knowledge assets, which interact with each other organically and dynamically. According to the SECI model, organizational learning is mainly a social process and Japanese companies are more competitive because of their collaborate culture. Featuring sharing, community based collaboration, user-generated contents, collective intelligence, Web 2.0 concepts seem to be an ideal fit with Nonaka's SECI approach for more personal, dynamic, and social learning on a global scale. As asserted by Chatti et al (2007), web 2.0 can drive SECI model based learning process. Spaniol et al (2008) argued that Web 2.0 can be used for folksonomy, syndication, participation, knowledge sharing and control.

However, most IT departments today have resisted Web 2.0 tools due to various strategic, managerial and technological reasons. Likewise, the impact and influence of Web2.0 over the practise of knowledge management, and how can organizations unleash their collective intelligence and gain competitive advantages through leveraging web 2.0 capabilities is still under researched. The present research plan is aimed at investigating the impact and influence of Web 2.0 over knowledge management, and attempts are made to provide a framework model for organizations to incorporate web2.0 into their knowledge management practices. The study will base its theoretical foundation on the analysis of case studies. Group discussions and seminars will be held to develop the hypotheses, and questionnaires will be used to collect data and testify the hypotheses.

LITERATURE REVIEW

Web 2.0

Web 2.0 can be described as the "intelligent web" or "harnessing collective intelligence". It refers to a set of economic, social, and technology trends that collectively form the basis for the next generation of the Internet—a more mature, distinctive medium characterized by user participation, openness, and network effects (.O'Reilly, 2005).Through a variety of tools, like blog, wiki, podcasting, rss, sns, and etc, Web 2.0 incorporates a two-way and interactive mechanism to enable individuals contribute to the development and distribution of tools, contents, and software applications over the Internet. In other words, the core values of Web 2.0 include four characteristics: unconstraint, service, externality and user-centered. Dron (2007) points out that the characteristics of Web 2.0 can be explored from several aspects, as follows:

- **Social software and control**
  organic and self-organizing, underpinned by dynamics that parallel natural processes.
- **Contribution**
  Each Internet user has the opportunity to actively provide their knowledge content to the shared domains.
- **Sharing**
  knowledge contents are freely available to others, but secured mechanisms may be enforced to enable the knowledge sharing among legitimate members within specific communities.
- **Collaboration**
  knowledge contents are created and maintained collaboratively by Internet users, who participating in the knowledge contents can have conversations as a kind of social interaction.
- **Dynamic**
  knowledge contents are updated constantly to reflect the changing environment and situation.
- **Reliance**
  knowledge contribution should be based on trust between knowledge providers and domain experts.

Spaniol et al. (2008) identify seven Web 2.0 business-models (peer pioneers,

ideograms, presumes, new Alexandrians, platforms for participation, global plant floor, wiki workplace) that could be used to enhance organization knowledge management. According to Lin (2006), the key success factors of Web 2.0 are content, community, consumer experience, and cross service integration. Abram (2006) notes that the success of Web2.0 should be attributed to the critical feature of interactivity in Web 2.0.

Successful examples of Web 2.0 application include Wikipedia, Blogs, BitTorrent, Google adSense, ebay Reputation, Amazon reviews, Gmail, Google Docs, Goodle Calendar, Google maps, and the list can go on and on.

Web 2.0 and Knowledge Management

Before defining the concept of knowledge management, it is important to define knowledge. Many researchers have defined knowledge from different perspectives. Some define knowledge as experience, concepts, values or beliefs that advances individual's ability to take effective action (Alavi and Leidner, 2005). Others treats knowledge as fact of knowing, an object, as a process, or a capability for action. (Zack, 1999).

Knowledge management is managing the knowledge through a systemic and organizational specified process for acquiring, organizing, sustaining, applying, sharing, and renewing both tacit and explicit knowledge by employees to enhance the organizational performance and create value (Davenport, 2001). Nonaka et al. (1995) identify four steps of knowledge creation processes including: socialization, externalization, combination and internalization (SECI).

- **Socialization** is a process of sharing experiences and then creating tacit knowledge through communication.
- **Externalization** is a process of articulating tacit knowledge into explicit concepts.
- **Combination** is a process of systemizing concepts into a knowledge system through combination of various components of explicit knowledge.
- **Internalization** is a process of embodying explicit knowledge into tacit knowledge for becoming valuable assets.

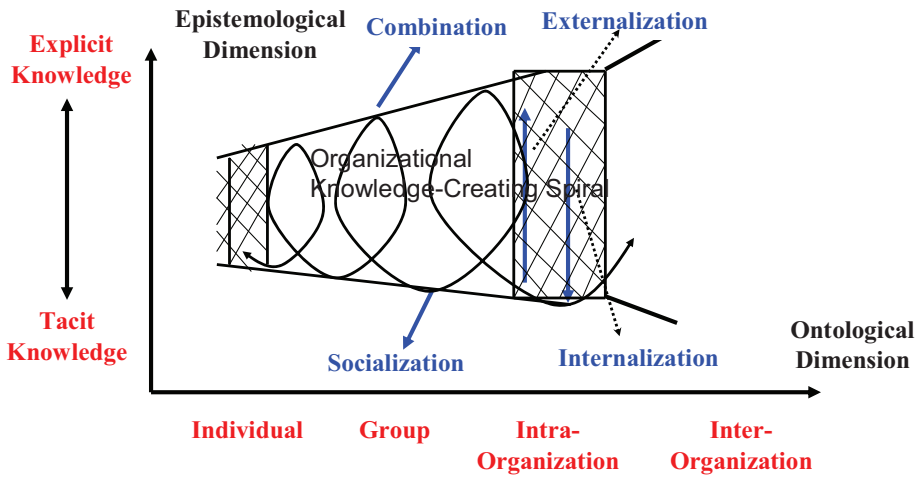

Figure 1 Organizational knowledge-creating spiral by Nonaka and Takeuchi (1995)

The basis of this model is a distinction between two types of human knowledge: explicit and tacit. Explicit knowledge or information is codified, objective knowledge that can be transmitted in formal, systematic language. In contrast, tacit knowledge is not easily codified, difficult to express and subjective. A spiral emerges when the interaction between tacit and explicit knowledge is elevated dynamically from a lower ontological level to higher levels. In short, knowledge can be generated by identifying what knowledge exist in the organization or collecting and importing knowledge from outside or learning from existing knowledge. However, the generation of knowledge to the Web 2.0 can be affected by the individual's perception of usefulness of the Web 2.0 content, as claimed by the technology acceptance model (Davis et al., 1989).

Web 2.0 as a tool appeared in many different forms such as wikis, blogs, social-networking, open-source, open-content, file-sharing, peer-production, and etc. Its application has also gained scientific attention in the area of knowledge management, as Web 2.0 acts as a platform for knowledge creation, knowledge sharing and knowledge utilization. The success factors of Web 2.0 for knowledge creation are built upon the strong emphasis on knowledge networking and community building to leverage, sustain, and share knowledge in a collaborative way (O'Railey, 2005). In other words, the community building enables individuals to share a common language and would be more at ease discussing ideas openly and challenging the ideas of others. Hayduk (1998) also observes that learning are more effectives when knowledge is shared among a self-selected peer group. Though shared knowledge creation space is an important catalyst for knowledge creation, some argue that close tie in a community limit knowledge creation because individuals are unlikely to

encounter new ideas in close-knit networks where they tend to possess similar information (Robertson et al., 1996). Spaniol et al. (2008) also indentify that the use of Web 2.0 as a platform for knowledge creation can result in folksonomies. Users can recognize the use of Web 2.0 as social classification and social tagging, and therefore it is to annotate and categorize the content of knowledge created.

Don (2007) claims that the mass collaboration in Web 2.0 enables organizations to make profits, but the effectiveness of profit generation of the Web2.0 depends on the interactivity among users. Web 2.0 is all about flexible and simple implementations that populate by usage and gain momentum from day one. Highly visible, highly useable and without the complexity that becomes a barrier to use. For some companies that use of wikis, they are becoming so pervasive that they're rivaling traditional knowledge management tools at a lower cost. For example, Web 2.0 is internal wikis that create a place for global employees to collaborate and brainstorm. It's blogs that allow a software development team to stay informed without multiple e-mail threads and attachments. And it's a website that harnesses customers' opinions for improved products and sales.

However, sharing knowledge are often unnatural acts (Davenport,2001; Hendriks, 1999; Wasko and Faraj, 2005; Hars and Ou, 2002). If knowledge is a valuable resource, why should it be shared? If one’s job is to create knowledge, why should he put his job at risk by using his own instead of that of the others? To enter our knowledge into a system and to seek out knowledge from others is not only threatening, but also just plain effort so we have to be highly motivated to undertake such work. If the knowledge manager adopted this principle, we wouldn't take sharing and use of knowledge for granted. Therefore, we wouldn't assume that the deployment of a web 2.0 system will lead to widespread sharing, or that making information available will necessarily lead to its use. We would realize that sharing and usage have to be motivated through time-honored techniques performance evaluation, compensation, for example. Thus, this study proposes that:

With the enabler of Web 2.0, it can be seen that shared ideas and information will be increased rapidly. The integration and capturing of knowledge will the challenge for organizations. Therefore, the ability to integrate and apply specialized knowledge by organization members is fundamental to a firm in creating and sustaining a competitive advantage (Davenport, 2001). Chatti and at al (2007) also point out that organizations have to place attention on knowledge transfer over issues of networking

and collaboration and intelligence search to be benefit from the Web 2.0 technologies.

Social media support a bottom-up building of communities and networks. Effective knowledge management practices need to take a personal, open, and knowledge-pull approach based on small, loosely joined pieces. The main obstacle of the knowledge-pull model lies in the information overflow on the Web. Therefore, we need intelligent search mechanisms for reliable access to information, services, communities, and expertise. Alavi and Leinder (2005) note that the extent to which knowledge should be transferred or can be transferred depends on the interdependency among individuals or communities. If knowledge does not become integrated in the organization, the organizational knowledge transfer will not succeed and lots of resources are in fact wasted. It is important to know the way in which interactivity affect knowledge transfer in an organization.

Web 2.0 challenges the core assumptions about information in the corporation—who gets it, who owns it, and who has power because they have it. And that's a really scary thing for people used to controlling it. These fears help explain why Web 2.0 hasn't quite caught on with the corporate crowd (Daniel, 2007). Enterprises are embracing Web 2.0 as a critical business tool that enables them to share information, create communities and user networks, and glean referrals that build loyalty by showing expertise and responsiveness to their most important asset: their customers. Web 2.0 tools have gained critical mass in the mainstream and even across age ranges, according to a study by Booz Allen released in January 2007 which interviewed a sample of 2600 persons, 42 percent of MySpace users and 41 percent of YouTube users are over the age of 35. Web 2.0 seems to cut across age and gender and—more importantly to businesses—it influences purchase decisions. The study's conclusion: "The need to evolve existing business models by integrating the Web 2.0 environment is urgent."

Also, it is important to note that while there can be enormous business benefits to leveraging Web 2.0, it also imposes unprecedented levels of security risks.

A white paper by websense corporation (2005) discussed in length of these potential risks in the deployment of Web 2.0, such as inappropriate content or applications finding their way on to company computers; the increased possibility of viruses, worms, and malware; and accidental or malicious data loss. More remarkably, it breaks down many of the legacy models around which IT security has been built.

These traditional approaches include securing the perimeter, reactive threat protection, and reputation analysis. Alavi and Leinder (2005) point out that organizational culture has been identified as catalyst or a major hindrance to knowledge creation and knowledge sharing. With the potential risk of Web 2.0 technologies might brining, the organization initiatives to the use of Web 2.0 for knowledge management is crucial.

Based on the literature review and our preliminary studies, we form eight hypotheses, each of which is centered a specific type of influences that web2.0 applications are bringing about to the practice of knowledge management, respectively from strategic, managerial and technical perspectives, as depicted in Figure 2.

From the strategic level, we propose that:

H1: Perceived value of Web 2.0 by the management affects the knowledge management strategy in the organization.

H2: Organization culture is decisive to Web2.0 implementation for knowledge management.

From the managerial perceptive, we propose that:

H3. Management capability of integration will affect the effectiveness of the use of Web 2.0 in knowledge management practices.

H4: Web2.0 KM practices shall be incorporated into the routine processes of business operation.

H5: A reward system which motivates user participation has a significant influence on knowledge sharing and utilization.

Finally, in the technology dimension, the enabling technologies of Web 2.0 applications lay the very foundation of knowledge management platform, we therefore propose that:

H6: Selection of technology affects the effectiveness of knowledge management, as well as the system security.

H7: User-centered experience is critical in enhancing user participation.

H8: Both strong-tie communities and weak-tie communities are important on knowledge creation and sharing.

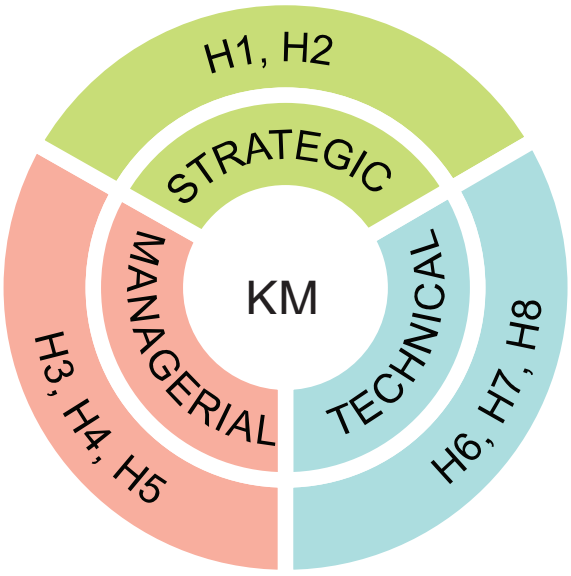

Figure 2 Research model for knowledge management with Web 2.0 technology

Research Method

This study will employ a case study approach, which is the preferable method for analysis in early stage of research on a topic when a fresh perspective is needed (Yin, 1994). Though qualitative approach has been criticized for being less generalizable, qualitative approach can yield thick and rich descriptions of actual events in real-life contexts which uncover and preserve the meanings that those involved ascribe to them (Gephart, 2004). In order to reach the rigor of qualitative approach, this study will also employ a personal case study research design, which aims to provide user point of view on the use of Web 2.0 tools for personal knowledge creation, knowledge sharing and knowledge generation purposes. A personal case study refers to a researcher uses a set of actions to improve the efficiency in certain activities related to the project. In addition, an industrial case study on the influence of application of Web 2.0 technology on organization's knowledge management will be conducted to examine the proposed research hypotheses.

Leadership and Organizational Learning as Antecedents to Knowledge Management Practices

Sanjay Kumar Singh, Institute of Management Technology, India
sanjaysinghdu@yahoo.com

ABSTRACT

The management of knowledge in organizations belonging to different industry segments across the geographic boundary of the nation has become an ultimate business reality. The firms which swear by it have been found to compete effectively even in the volatile business environment. The empirical studies of these firms by the management thinkers have found organizational level variables along with personal and interpersonal level variables of the employees to create significant impact on to the knowledge management processes of the firms which if leveraged results into sound organizational health. This study is an attempt to find out potent organizational level variable(s) affecting the knowledge management processes and also to design a framework to be used by the firms operating in different businesses throughout the globe. The meta-analysis of the findings of several empirical studies, which were conducted by the researchers in different cultural settings, provides an interesting insight in this direction. The author observes that the leadership of the firm along with rigorous practices of the organizational learning mechanisms results into creating as well as management of the knowledge for the competitive advantages of the firms. The observation of the present study was also used to develop a framework of the knowledge management practices but it needs to be validated by the management thinkers and practitioners who have been working in this domain of knowledge. It is hoped that this simplistic framework of knowledge management will lead the firm towards successes.

Key words: *Leadership, organizational learning, knowledge management*

INTRODUCTION

The financial meltdown which the world witnessed in the second half of 2008 has sent deep seated message to the captains of the industry across different parts of the world to compete through management of knowledge. The art and science of knowledge management which is the urgent need of the day depends upon learning on the part of the members to reach at organizational level and this to get significant boost by practicing a significantly different leadership styles. The studies have been carried out intensively in each of the three areas separately but no serious attempt has been made to bring them together on a single platform for business excellence. This inquiry is a conceptual level effort in that direction and believed that it will be of importance to the organizations which have been facing the heat of world's worst financial crisis. It is said that the present financial meltdown and its impact can be successfully attended to by increasing the understanding of different aspects of globalization and interrelationships of various factors and their changes will help organizations to meet the new challenges brought by globalization, whether their primary operation environment is domestic, international, or global (Jokinen, 2005). Moreover, the effect of globalization has been such that

the operating environment of the business which used to reside well within the geographic boundary of the nation up to 1990s has gone away and as a result organizational mindset is of working locally but thinking globally.

The present world scenario makes it imperative to develop global competencies for persons especially in leadership roles in the corporations. McCall and Hollenback (2002) believe that these global competencies should be based on to the global business strategy which to determine what kind of global presence is desirable, how many and what types of international or global jobs, projects, task forces, and other types of interactions exist. It is such that what happens in the small city of the USA, it impacts immediately and significantly to the life of businesses in the Indian subcontinent as well. In other words, these developments suggest that now the context of the business has gone for a sea change and this calls for a fresh look on to the part of the captain of industry to think of global leadership competencies. It is these global leadership competencies which will remain now onward as only competitive advantages for any corporations anywhere. Zahra (1999) says that tomorrow's global marketplace will reward companies which will value entrepreneurial risk taking, invest heavily in developing intellectual capital, promote individual growth, and adopt policies that are environmentally friendly. Hence, to do these arduous jobs of global corporations, the successful competitiveness in 21st century will demand the use of visionary and dedicated leadership.

Organizational Leadership for Learning Organizations:

The construct of Leadership is defined by knowledge, skills, and abilities, rather than by position or title. The core competencies of leadership can be learned, and the learning is a life-long process. It is purely a process by which a person influences others to accomplish an objective and directs the organization in a way that makes it more cohesive and coherent. The leaders carry out this process by applying their leadership attributes, such as beliefs, values, ethics, character, knowledge and skills. Today, CEOs are under constant pressure to find new sources of growth in an increasingly demanding and competitive business environment. Senge (2000) enunciates three core characteristics for a person to be in a leadership role in present day organizations and they are of an architect, a teacher, and a steward. These three qualities helps in clarifying mission, vision and values; specifying strategies, structure and politics; creating efficient learning processes; and helping subordinate continually develop their mental model and system thinking.
The today's CEOs must learn to inspire their organizations to new levels of inventiveness in everything that they do, not just in marketing or new product development (Leavy, 2005). Therefore, it calls for a new kind of leadership role and thinking whereby all the stakeholders are internally energized for continuous renewal in people, processes, and product. Survival and growth of organizations are based on a dramatic shift in leadership. It is no longer the time of a heroic leader – the leader walks in and takes up all the space in the board room. Instead, the job of today's leader is to create space for other people to generate new and different ideas; to encourage meaningful conversation between people: and to assist people in becoming more effective, agile, and prepared to respond to complex challenges (Martin, 2007).

Contemporary organizations in India face continuous challenge for successfully translating quality improvements into sustainable competitive edge. Like people, organization should learn

in order to adapt itself successfully to the ever changing business reality. Therefore, Lietaer (2002) has rightly said that a critical success factor for a firm in the knowledge economy for any kind of competitive advantage is that it should possess ability to learn and exploit its existing knowledge base. Shukla (1997) emphasizes to the importance of organizational learning (OL) in Indian firms surrounded with qualitatively changed business environment due to globalization of Indian economy. In Indian organizations, knowledge about customers is given the most importance and firms put serious effort in identifying the most crucial knowledge and then leveraging it for sustainable competitive advantage (Pillania, 2007). To put it in a more explicit way, it is noted that learning enables an organization to continually expand its "capacity to create its future" (Senge, 1990).

The academicians as well as the practitioners have been constantly engaged in researching about global leadership competencies for the business organizations in the 21st century. It is simply because there is increasing business need for global leaders has been felt but still what specific competencies are required to be a global leader have not been explicitly identified (Morrison, 2000). It has been observed that excellent domestic leaders often have the same qualities as global ones, but that excellent global leaders retain these capabilities even in completely unfamiliar situations (Kets de Vries and Florent-Treacy, 2002). Such an observation made by Kets de Vries and Florent-Treacy (2002) suggest to the author(s) that people with global leadership attributes depict more of the qualities of an emotionally intelligent leaders who remain cool and composed even in tiring situations and deliver to the expectations of all concerned. Boyatzis et al. (1999) contends that emotional competencies such as self-awareness, self-management, social awareness, and relationship management are demonstrated by a person whenever she/he interacts with the world around. Success in the global environment requires more than just knowing about different cultural norms and management theories, but it is putting this knowledge into leadership practice (Carey et al., 2004). McCall and Hollenback (2002) observe that the global executives need to learn how to work cross-culture and it is for the most people an emotional education as well as an intellectual one. The challenges of global work arise in three areas: distance, country, and culture. When the world becomes smaller and the workforce becoming more diverse; the key challenge for leaders is to effectively lead across cultural borders (Dalton, 2003).

The literature reveals that transactional leadership was largely studied until 1970s which believe in reciprocity that the relationships between a leader and followers is based on the exchange of some form of reward. At the same time, it is to mention that the research literatures in the late 1970s and onward started talking of a new kind of paradigm to be referred to as transformational leadership. Here, leadership is perceived as engaging the hearts and minds of others around for getting the work done in more effective way (Burns, 1978). But it is also to state that transactional and transformational leadership do not exclude each other, as a leader can be both (Bass, 1985). The research literatures indicate transformational as well as transactional forms of leadership to be positively associated with processes of organizational learning. Lam (2002) and Sadler (2001) in their studies found transformational leadership to have significantly positive effect on encouraging and emphasizing teamwork spirits and involvement at workplace. Similarly, Bass (1997) and Bass and Avolio (1990) also found in their studies that transactional leadership significantly helps improve the efficiency of organizational learning. Therefore, it

may be deduced that both transformational as well as transactional form of leadership have significantly positive effect on the functioning of learning organization.

The literatures which mention the general beliefs of 1980s and 1990s that organizations need only one knowledge leaders to make the process work is erroneous in the context of present days global world order. On the contrary, the knowledge leadership should be evident throughout the organization and it should operate at a range of levels. The effective organizations rely on leadership than leaders (Hubbard et al., 2002). The role of knowledge leader is to provide strategic visions, motivate others, effectively communicate, act as a change agent, coach others around, model good practices, and carry out the knowledge agenda (Debowski, 2006). The knowledge leaders need to explain the goals of knowledge management so that people can identify their roles in achieving those goals. They need to provide guidance on any changes in processes and priorities needed to reach those goals (Debowski, 2006).

Hubbard et al. (2002) is of the opinion that knowledge leadership, apart from having ability to establish predictable and stable processes, needs to encourage innovation and creativity to responding to opportunities. Therefore, the knowledge leaders must have a good understanding of people, processes, systems and business principles which shape business decisions (Debowski, 2006). The knowledge leader's strategic leadership operates from an understanding of the core business and how it relates to the values of that organization (Maurik, 1999). Therefore, the visionary leadership needs to operate at two levels: tactical and futuristic (Kouzes and Posner, 2002). The enthusiasm, drive, and energy of the knowledge leader play a major role in building a commitment of others. Goleman et al. (2002) also notes that visionary leadership has a strong positive effect on organizational climates, and is particularly important when a clear direction is needed. Hence, the nature of the knowledge management development requires continual support by leaders to ensure that the value and outcomes of knowledge management are held firm in contributors' minds.

Learning organizations: The need of the time

Organizational learning as a concept came to academic literature for the first time when March and Simon (1958) were involved in their pioneering work on understanding the complexities of organizations. Since then many authors have contributed significantly to the growth of this body of knowledge though the road to acceptance has not been a straight one. Unfortunately, both the definition and use of the term organizational learning are still associated with considerable confusion (Edmondson and Moingeon, 1998; Easterby-Smith et al., 1998). Furthermore, the scholars have frequently associated the facilitation of organizational learning with the learning organization (Easterby-Smith et al., 1998). Throughout the 80s and the 90s, organizational learning achieved prominence amongst the ideas influencing management studies. The topic has attracted increasing attention, both in academic circles (Shrivastava, 1983; Levitt and March, 1988) and in business practice (Senge, 1990; Argyris, 1993). One of the main reasons for this is the increasing pressure of change on organizations.

Organizational learning may be considered as long-term activities that build competitive advantages over time and requires sustained management attention, commitment, and effort. In

other words, the role of leadership is prerogative for building a learning organization. A learning organization is an organization skilled at creating, acquiring, and transferring knowledge, and at modifying its behavior to reflect new knowledge and insights (Garvin, 1993). Organizational learning has also been viewed as a process through which an organization continuously acquires new knowledge and adjusts itself to successfully adapt to internal and external environmental changes and to maintain sustainable existence and development (Chen, 2005). To achieve all these important competencies, Garvin (1993) believes that it is time to move away from high aspirations and mystical advices which are being given to managers and move on to clearer guidelines for practices and operational excellence. Such a scenario has had been in place for successful learning organizations like Honda, Corning, and GE which have effectively managed their learning capabilities in such a way to ensure that it occurs by design rather than by chance. Moreover, leading learning organizations also have employees training which have especially been designed for developing/sharpening behavioral skills than technical skills that have a short shelf-life (Kiernan, 1993). The prime example of such an organizational attitude can be noticed at Xerox Company. It has implemented a group training program for all its employees at all levels which has been named as *'Leadership through Quality'* that focuses on how to work in teams and in problem-solving processes (Goh, 1998).

Moreover, there seems to be apparent difficulties with the notion of organization learning as a whole. There is clear evidence that learning does take place in organizations during dynamic interactions amongst individuals, groups, and the organization itself (Akgun et al., 2003; Chan, 2003). The benefits of organizational learning are well recognized in terms of improved innovation (Chanal, 2004), achieving and sustaining change (Boyce, 2003), and in developing competence (Pedler, 2002). For long-term success, organizations should be able to learn continuously, to leverage from the knowledge they capture, to apply it to reality and to increase innovative knowledge (Liedtka, 1999) for competitive advantages. The process of effective organizational learning, by way of sharing information and knowledge among organizational members, enables individuals and organizations to reflect on the consequences of their behaviors and actions, to obtain insights from an environment where they operate, to understand the environment, and hence to interpret the meaning and react to it in more accurate approaches (Jones et al., 2003).

In the new economy, organizations may face learning overload; thus improving organizational learning capability is critical for competitive advantage (Goh, 2003). A strategic learning capability involves "strategically figuring out what an organization needs to know and then taking action to acquire that knowledge (DiBella, 2001). The relationship between organizational learning (OL) and knowledge management (KM) has been best put forward by Garvin (2003) when he says that an organization that learns is an expert organization in creating, acquiring and transmitting knowledge, and modifying its behavior to self-adapt. Organization which learns is expert in five activities: systematic resolution of problems, experimentation of new focuses, use of their own experience and past in order to learn, learning from the experiences and more appropriate practices of other companies (benchmarking), and transmitting the knowledge to the whole organizational quickly and efficiently (Garvin, 2003). In this context, it is pertinent to say that the kind of economy that India is today requires firms to continuously get into the organizational learning mode.

Leadership for smart companies:

The literatures have also found evidence for role of leadership in making an organization a truly learning company. In other words, the smart organization is credited to possess a significantly different leadership style practiced for achieving the set goals. In these organizations, the main task of leaders is to encourage knowledge sharing, supporting learning through mistakes, and creating continuous team learning (Macneil, 2001). Popper and Lipshitz (2000) emphasize that leader can create organizational structure and shape up organizational culture to result in influence through various affairs, actions, and service; thus leadership to actually affect organizational learning. Leadership has also been found to improve the process and the result of organizational learning activities (Lam, 2002). The research literatures indicate transformational as well as transactional forms of leadership to be positively associated with processes of organizational learning. Lam (2002) and Sadler (2001) in their studies found transformational leadership to have significantly positive effect on encouraging and emphasizing teamwork spirits and involvement at workplace. Similarly, Bass (1997) and Bass and Avolio (1990) also found in their studies that transactional leadership significantly helps improve the efficiency of organizational learning. Therefore, it may be deduced that both transformational as well as transactional form of leadership have significantly positive effect on the functioning of learning organization. Leaders are needed to empower all the members of the learning organization by developing a shared vision, providing resources, delegating authority, celebrating successes, and most importantly, by being learning architect (Hitt, 1995).

Organizational learning and knowledge management: Empirical findings

Davenport (1999) also believes this to be the case and maintains that KM is gradually expanding in scope, consuming not only learning organization (LO) but also other emerging concepts such as business and customer intelligence. Spinello (2000) argues that organizational learning and knowledge sharing are intimately connected with each other. The knowing process is composed of sharing, thinking and learning components that have a reciprocity relationship. Knowledge sharing enables managers to keep the individual learning flowing throughout the company and to integrate it for practical applications. Though in a study by Swan et al. (1999), it has been found that there is an apparent decline in interest in the concept of learning organization since 1995 and has been offset by a sharp increase in enquires into KM. Pemberton and Stonehouse (2000) believe that successful learning organizations create an organizational environment that combines organizational learning with knowledge management.

Organizational learning which is also known as generative learning (Senge, 1990) is necessary especially for organizations that are operating in a highly dynamic environment where the rate of knowledge obsolescence is far greater (Wijnhoven, 2001). Organizational learning which results into organizational knowledge is much talked about but little understood (Tsoukas and Vladimirou, 2001). Therefore, thinkers like DiBella (2001) feels that there is a need to “bridge the divide” between knowledge management (KM) and organizational learning (OL). This study is an attempt in that direction to empirically investigate relationships as well as impact of organizational learning on to knowledge management in Indian software firm. A knowledge

management company moves from single-loop learning into what is known as double-loop learning. Double-loop learning occurs when error is detected and corrected in ways that involve the modification of an organization's underlying norms, policies, and objectives (Smith, 2002).

Understanding knowledge management as a practice:

Knowledge seems invisible, but it clearly drives the bottom line (Pascarella, 1997). The value of knowledge is increased when it has a key purpose and focuses on mission, core values and strategic priorities. Knowledge assets, like money or equipment, exist and are worth cultivating only in the context of the strategy used to apply them (Stewart, 1997). Knowledge management is a formal, directed process of determining what information a company has that could benefit others and then devising ways to making it easily available (Liss, 1999). Therefore, the steps in this process include how knowledge is captured, evaluated, cleansed, stored, provided, and used (Chait, 1998). It is unfortunate that very few organizations handles explicit and tacit knowledge effectively for business excellence. Exceptions are learning organizations that are skilled at creating, acquiring and transferring knowledge and at modifying their behavior to reflect new knowledge and insights (Garvin, 1993).

Knowledge management is a process that facilitates knowledge sharing and exchange and establishes learning as continuous process within an organization. Therefore, knowledge management and learning go hand in hand (Lopez et al., 2004). Davenport et al. (1998) defines knowledge management as a process of collection, distribution, and efficient use of the knowledge resource. O'Dell and Grayson (1998) believe knowledge management as a strategy to be developed in a firm to ensure that knowledge reaches the right people at the right time, and that those people share and use the information to improve the organization's functioning. Similarly, Bounfour (2003) defines knowledge management as a set of procedures, infrastructures, technical and managerial tools, designed toward creating, sharing and leveraging information and knowledge within and around organizations.

The literatures have also looked into different forms of knowledge and their leverage for organizational competitive advantage. The knowledge that organizational members have can be broadly categorized into two parts as explicit as well as tacit knowledge and both of them work interdependently and in turn leading organization to the path of successes. Explicit knowledge has been found to be increasing being used as well as emphasized in both practice and literature, as a management tool to be exploited for the manipulation of organizational knowledge. For Scarborough et al. (1999), groupware, intranets, list servers, knowledge repositories, database management and knowledge action networks allow the sharing of organizational knowledge. Similarly, Pan and Scarborough (1999) believe that explicit part of knowledge is systematic and easy to communicate in the form of hard data or codified procedures. In other words, explicit kind of knowledge can be transmitted across individuals formally and easily. On the other hand, tacit form of knowledge is subconsciously understood or applied, difficult to articulate, developed through direct action and experience, and shared through conversation, story-telling, etc. Blumentitt and Johnston (1999) contend that information can be captured and stored in

digital form whereas tacit knowledge repositories reside only in intelligent systems, which are within individuals. Tacit knowledge needs to be considered as "knowledge-in-action" which presumes that this is knowledge that has not been articulated as opposed to explicit knowledge that is readily accessible within the organizational domain (Platts and Yeung, 2000).

On the other hand, the management thinkers and practitioners have also made several attempts to define knowledge by distinguishing between data, information and knowledge (Wiig, 1993). The literature is full of various classifications of knowledge the most widely discussed and quoted among them are the ones developed by Wiig (1993), Nonaka (1994), Edvinsson and Sullivan (1996), Carayannis (1999) and Despres and Chauvel (2000).

Wigg's (1993) KM framework consists of three building blocks and they are: exploring knowledge and its adequacy, assessing value of knowledge, and manage knowledge activity. On the other hand, Nonaka's (1994) SECI model is the most widely discussed theories in KM literature. His KM model was developed from empirical evidences which he gathered in case studies of Japanese firms (Honda, Canon, Matsushita, NEC, Sharp and Kao). For the ICM of Edvinsson and Sullivan (1996), the intellectual capital of any organization has four major ingredients, namely human capital, structural capital, complementary business assets, and intellectual property. In other words, the ICM model is mainly concerned with management of resources for achieving innovation, and commercialization of innovation for monetary benefits. The literatures have also found Carayannis' (1999) views on KM which is slightly different from the other theoreticians in the area of KM and his contribution lies to organizational cognition spiral (OCS) and organizational knowledge network (OK Net) models to KM literatures. Finally, Despres and Chauvel (2000) developed a meta-model that is based on four dimensions of KM, namely, time, type, level and context. They suggested three levels of social aggregation to knowledge: individuals, groups and organizations. It is primarily on the basis of findings of other researchers that they have constructed a theoretical framework of KM, but have been very successful in placing each concept appropriately in connection with others and is completely meaningful.

At the same time, it is also necessary to note that these theoretical frameworks on KM though developed out of simple literature reviews or meta-analysis or live case studies have tried to provide some deeper understanding of managing knowledge across firms in different cultural settings. However, it is contended that none of them can independently claim to unearth the complexity of creating, managing, and using knowledge for any kind of competitive advantages by organizations across culture. Hence, it is asserted that the knowledge management (KM) frameworks of these theoreticians are to an extent industry or culture specific and as a result can not be blindly applied by practitioners.

Leadership, organizational learning and knowledge management: A framework

These research literatures reveal that leadership, organization learning mechanisms and knowledge management practices of the firms are intimately related. In other words, there seems to be a positive influence of one over another and when if implemented by the practicing managers, it will provide a competitive edge to the organizations. The following diagram

summarizes what the above discussed research literatures have to convey to the organizations in operations across culture.

(Proposed by the author)

The diagram as mentioned above states it clearly that the knowledge management practices of a firm is dependent upon learning by the members at an organizational level which to be guided, facilitated, coordinated by the leadership as provided by the top management. Hence, the authors state that learning organization is a result of a particular kind of organizational leadership and which in turn develops a kind of knowledge when managed properly to guarantee corporate success. on the other hand, the authors also note that this framework which has been arrived at conceptually and requires empirical validity before taking them directly to the workplace. At the same time, it is also asserted that though it has not been tested empirically, the authors assume that it may work well in organizations across different industry segments.

CONCLUSIONS

The research paper is based upon the literature review of the past researches conducted across organizations in different cultural settings. The literatures are there in plenty in the areas of leadership, learning organizations and knowledge management practices but no major attempt was noticed to connect them together. After identifying the gaps in the literatures, the authors have put in their efforts to bring to the surface the linkages amongst these three organizationally important variables. At the same time, it is also to note that like other research investigations, this research work has got some limitations which in a way provide scope for another research investigation. It is believed that the findings of this study may be beneficial for the consultants, the practitioners, the academicians as well as the students of the behavioral science discipline.

ABSTRACT

The objective of this paper is to examine the influence of knowledge management on the adoption of e-business in the supply chain of Malaysian small and medium enterprises (SMEs). Questionnaire was distributed to 200 Malaysian SMES with a response rate of 68%. Data were analyzed by employing multiple regression analysis. The results show that knowledge management processes such as knowledge acquisition and knowledge application are significant in affecting Malaysian SMEs' decision to adopt e-business in their supply chain. Knowledge dissemination was found not be significant in affecting the adoption of e-business among Malaysian SMEs.

This study has addressed the previous lack of literatures on the relationship between knowledge management processes and e-business adoption among Malaysian SMEs. Although existing literatures have shown a relationship between knowledge management processes and technology adoption, this study empirically verify an adoption model based on knowledge management processes. Organizations planning to adopt e-business would also be able to applied strategies based on the findings from this research.

Keywords: Knowledge Management, Technology Adoption, E-business, SMEs, Malaysia

INTRODUCTION

In today's business environment, many organizations are seeking to be competitive through the implementation of Information Technologies (IT). With the emergence of Internet, E-Commerce is now a vital tool for companies from supporting business operations to helping them to gain competitive advantages. One application areas of E-Commerce in business include the implementation of e-business tools to the supply chain management (8).

Some of the benefits of e-business implementation in supply chain management include improvements in the speed of response; cost savings; improvements in communications, information and knowledge sharing; reductions in inventory; improvements in efficiency and productivity; harmonization and standardisation of procedures; and better transfer of best practices (44). Although the implementation of E-business in the supply chain has shown many successes in companies such as Dell, Wal-Mart and Cisco (33), the implementation of E-business in supply chain of organizations in developing countries are still relatively a new area of study.

The importance of e-business adoption in supply chain management is well publicized. However, only 30% of Small and Medium Enterprises (SMEs) in Malaysia embraced basic information and communication technology (ICT) primarily as a tool for storing and analyzing proprietary data (29). The Malaysian SMEs is an important part of the Malaysian economy as they contribute to 32% of Malaysia's Gross Domestic Products, 56.4% to the total workforce and 19% to total exports of the country (39). In order for Malaysia to continue its growth and remain competitive to foreign investors, it is important that its SMEs are able to operate efficiently through the adoption of E-business in their supply chain.

Although past studies have tend to look at the adoption of e-business from the technological, environmental and organizational factors (7), there have been a lack of study on the impact of knowledge management on the adoption of e-business tools (25). The barriers to change from traditional business operations to e-business no longer relates to technological prospect such as availability of suitable information systems; but relies on the appropriate management of business related knowledge. The resistance to implement e-business can be related to issues related to lack of knowledge, which obstruct the rate at which SMEs' adoption of e-business (13). Thus, the management of knowledge becomes one of the medium for designing strategic e-business decision.

According to Martin and Matlay (28), knowledge management strategies are considered as an effective and efficient means of successful technological innovation (28). Although studies in the past have supported the claims that knowledge management is important for the technology innovation in an organization (10; 32), many of these studies lack the empirical study on the influence of knowledge management practices on the adoption of e-business (25). Furthermore, many of these studies were not conducted in a developing country as well as SMEs. By studying Malaysia's SMEs, the results generated is more relevant for other developing countries compared to studies conducted in developed or western countries. Thus, this paper aims to investigate if knowledge management practices have an influence on the adoption of e-business in the supply chain of Malaysian SMEs.

LITERATURE REVIEW

Knowledge Management

Knowledge has become one of the critical driving forces for business success (24); hence, the managing of knowledge within the organization has become key focus point for all businesses. Knowledge management (KM) is defined as a process cycle to identify, transfer, store and disseminate the knowledge in order to reuse, awareness, and share and learn it across the organization (31; 43). Previous studies had proposed similar key dimensions for KM model which includes knowledge acquisition, knowledge dissemination, and knowledge application (6; 12; 28). The intention of a KM model is to leverage an organization's superior external performance such as marketplace returns and financial results, to attain superior internal operating efficiencies, and to enhance the quality of life of each individual member of the organization (12). Fink and Floder (14)'s research on impact of knowledge process modeling on SMEs in Europe revealed that the acquisition of knowledge among European SMEs is generated through brain writing, mind mapping and scenario method. Moreover, the intranet with elements of online learning, success stories, and communities of practice are used as a medium for knowledge dissemination. For the purpose of knowledge application, content management system, folder system, database system, document management systems

and project reviews are being used. SMEs in many European countries have established the management of knowledge to a certain extend. On the contrary, many researches and practices on KM focus almost exclusively, on large organizations in Asia. As a result, there is relatively little information available on KM in SMEs. Hence, this study will fill the gap for the understanding of KM among Malaysian SMEs in context of e-business adoption.

KM and E-business adoption

E-business had been promising new avenues for the creation of wealth and business opportunities with its dynamic, rapidly growing, and highly competitive characteristics (2). Papazoglou and Ribbers (36) defined e-business as the conduct of automated business transactions by means of electronic communications networks via the internet and possibly private networks from one end to another end. Organizations worldwide are affected by the emergence of internet and e-business in a broad sense. This is not only the operations and ways of doing business, but also the creation of new sales channels; new occurrences in inter-firm relationships and means of managing business-related information for all organizations appeared (22).

E-business widens the breadth of solutions availability to consumers in almost every industry in the sense that purchasers can now compare and contrast the offerings of providers worldwide. Consequently, there are several e-business issues which in turn require firms to generate distinct knowledge in order to face the challenges and decision to the adoption of e-business in supply chain activities. For example the new consumer value propositions creates new competitive measures where purveyors competitor's profile are no longer bounded geographically and also their business nature and long-established content of strategies have to face profound changes. Moreover, e-business is also significantly reshaping traditional business process in the entire supply chain from product development, customer sales and relationship management to the acquiring of human resource and raw materials procurement (12). The popular e-business way of business operation by Dell Computers as well as IKEA's e-business modelling initiatives had proven the argument's meticulousness (22). In light of this, the emergence and rapid growth of e-business arises the fundamental necessity requisite for both knowledge stock and flow. This is due to the widespread impact on pivotal business domains as trade solutions, rivals, strategies, and business processes of the organization has to be developed, share and leverage extensive knowledge in e-business supply chain context. Besides, proper KM will aid firms in analyzing the effect e-business in competitive environment, strategy, and facets in business operations. Hence, KM efforts in focusing on key current, emerging, and potential trends and patterns in e-business will be able to determine the success or failure in e-business adoption.

Previously, technological adoptions such as EDI and E-commerce adoptions had been extensively researched based on Rogers (37)'s Diffusion of Innovation Theory where the adoption factors lied mainly on relative advantage, compatibility, complexity, trialability and observability; and Tornatzky and Fleischer (42)'s technology-organization-environment (TOE) model where organization, technological and external environment are taken into the adoption considerations (21; 23; 30; 35; 41). Nonetheless, e-business with its constantly changing business temperament and entailment for immense knowledge has made the KM paradigm a major deliberation of the technology adoption (25). Therefore, KM has been included as one of the e-business adoption factors (17). In addition, research outcome revealed that IT investments in the US were increased at a blistering rate of 15% per annum,

as many organizations are envisaging to gain competitive advantage with proper KM in I.T business environment (1). Therefore, the barriers to change from traditional business operations to e-business no longer relates to technological prospect such as availability of suitable information systems; but relies on the appropriate management of business related knowledge. In this regard, this paper will uncover the impact of KM towards e-business adoption among the Malaysia SMEs which small and medium enterprises in developing countries like Malaysia are often neglected for its significance to the global economy.

RESEARCH MODEL AND HYPOTHESES

This study considers e-business supply chain technology implementation in the KM context. KM is contemplated as factor facilitating adoption of e-business supply chain technology among SMEs in Malaysia. Figure 1.0 illustrates the proposed research mode, which hypothesized that KM processes (acquisition, dissemination, and application) affect e-business supply chain technology adoption. The construction of research model and hypotheses are discussed below.

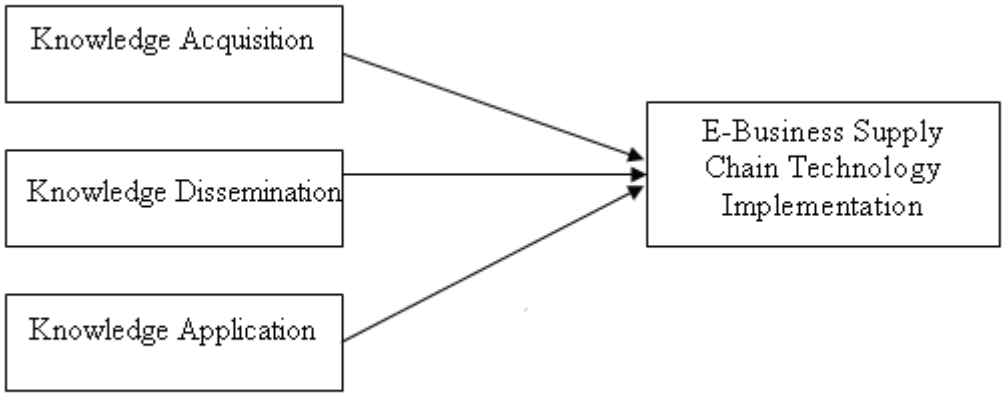

Figure 1.0: Conceptual Model for KM Processes' Influence on E-business Adoption

Knowledge Acquisition

Knowledge acquisition is defined as the first step of KM and it includes business processes that use existing knowledge and the capture new knowledge (16; 25). The process requires rigorous effort and experience in recognizing and capturing new knowledge. The ability to survive and thrive relies, to some extent, an organization's ability to maintain and retain old and new knowledge in the face of complexity, uncertainty and rapid change (11). Hence the acquisition of knowledge is vital to the organization, especially key decisions made based on experience and information which usually shared informally. Cagarra-Navarro (3) described that resources are scarce in SMEs and chief knowledge officer is normally difficult to justify, thus knowledge is likely to be obtained from secondary data like trade journals, sector research, professional magazines, or even personal contacts which is customarily unable to cope with the fast changing business environment. Nevertheless, the acquirement of knowledge in customer-supplier orientation context can be monitored with e-business systems. E-business will enable organizations in determining the relevant customers or suppliers, processes and domain knowledge needed to operate business activities successfully. As a result, the e-business infrastructure involves not only technological initiatives but also is

driven by acquisition knowledge and skills (25). Relationships between knowledge acquisitions capabilities thus are expected to be positively related to e-business adoption. In this regard, the following hypothesis is formulated:

H1: Knowledge acquisition will positively affect e-business supply chain technology adoption.

Knowledge Dissemination

Knowledge dissemination consists of knowledge transfer and knowledge sharing (11). Thus, the focus of knowledge dissemination is on the business processes that distribute knowledge among all individuals participating in the supply chain (25). The process of knowledge dissemination itself is a main challenge to companies. Lack of communication skills and rapid change in information and communication technologies are highlighted as some of the main concerns for knowledge sharing (11). This is due to the lack of capital investment for systematic use of information, developing organization processes and technology development for rapid growth. Notwithstanding, knowledge transfer and sharing is important for improving performance of the firm in the e-business context (25). Furthermore, Darroch and McNaughton (9)'s study on link between KM practices and types of innovation found that knowledge dissemination and innovation have direct linkage between each other. As technology adoptions often yield innovation, it is equitable that knowledge dissemination will have impact on e-business adoption (4). With this perception, organizations will be more enthusiastic and allocate more effort for the e-business initiative. Therefore, knowledge dissemination is expected to be positively associated with the implementation of e-business supply chain technology decision. The following hypothesis is formulated:

H2: Knowledge dissemination will positively affect e-business supply chain technology adoption.

Knowledge Application

Knowledge application is defined as the business processes through which effective storage and retrieval mechanisms enable a firm to access knowledge easily (25). It includes the assimilation of the knowledge generated in the acquisition and dissemination levels (3) and the knowledge is then applied in the routine business activities for performance enhancement. From the technological perspectives, knowledge transfer, knowledge integration and practical application of knowledge are the main elements for developing technological capabilities (25). Based on Cagarra-Navarro (3)'s research, analytical results revealed firms that stimulate and improve organizational knowledge application are more likely to adopt e-business systems and is consistent with the conceptualization of knowledge application as the facilitator of successful technological innovation (16). These findings can also be supported by Lin and Lee (25)'s study outcome which stated knowledge application enables employees to both use existing knowledge and create new that are crucial for e-business adoption. Consequently, firms that stimulate and improve organizational application of knowledge are more likely to adopt new technology, inclusive of the internet-enabled business opportunities. The following hypothesis is formulated:

H3: Knowledge application will positively affect e-business supply chain technology adoption.

METHODOLOGY

Data Collection and Sampling

In order to test the hypothesis in this study, a survey instrument was developed. The survey contained 29 items for measuring the 4 constructs in the questionnaire. Table I shows the sources of the constructs used in this study.

Table 1: Constructs and their sources

Constructs	Number of Items	References
Knowledge Acquisition	5	Cagarra-Navarro (3); Egbu et al (11); Fahey et al. (12); Lin and Lee (25);
Knowledge Dissemination	5	Egbu et al. (11); Fahey et al. (12); Lin and Lee (25)
Knowledge Application	6	Cagarra-Navarro (3); Fahey et al. (12); Lin and Lee (25);
E-business adoption	13	Cassivi (5); Thatcher (40);

The SMEs within Malaysia are randomly selected by referring to the official SMEs list published in Small and Medium Industries Development Corporation (SMIDEC) (2008) (39) website.

In order to ensure that the sample in this study is adequate for regression analysis, we applied the formula from Green (18) who suggested that the sample size (N) should be greater than 50+8m (where m is the number of independent variables) for testing the multiple correlation and N>104+m for testing individual predictors. As there are 3 independent variables in this study, the minimum sample size needed will be 74 (N>50+8*3). As a result, a selection of 200 Malaysian SMEs as the sample size would be acceptable for this research and attaining the rule of thumb criteria.

The set of constructed questionnaire were distributed to 200 SMEs across Malaysia. Questionnaires were disseminated directly to the firms' top management as it is believed that these management level personnel comprise similar level of understanding on organizations' management of inter-organizational relationships and knowledge due to similar level of hierarchy, seniority, experience, and unit affiliations. As a result, feedbacks obtain will provide higher percentage of reliability to the analysis of data.

Questionnaire distribution and collection were completed within six weeks upon date of dissemination. A total of 200 sets of questionnaires were distributed randomly and 147 sets have been successfully collected. However, there were 11 sets of feedbacks which were unusable due to partial respond and missing data. Therefore, data analysis is conducted based on 136 sets of useful feedbacks with 68% of respond rate.

VARIABLE MEASUREMENT

Independent Variables

The independent variables used in the study were derived and modified from existing literatures (See Table I).

A total of 16 questions were developed to capture the KM processes used in this study. A five-point Likert scale (i.e. "1" denoted as strongly disagreed, "2" denoted as disagree, "3" denoted as neutral, "4" denoted as agree and "5" denoted as strongly agree) were used in this study.

Dependent Variable

In order to measure the e-business tools adoption in the supply chain, a list of e-business tools used in supply chain were adapted from Thatcher (40) and Cassivi (5). As Chou et al (8) stated, the current e-business tools used by organizations have ranged from B2B in the 90s to collaborative commerce (c-commerce) tools from 2000s to current. Therefore in order to have a comprehensive list of e-business tools in supply chain, we have included both e-commerce and c-commerce in the supply chain in order to capture the actual e-business adoption in the supply chain by the Malaysian SMEs.

DATA ANALYSIS

Profile of organizations

A total of 136 responses have been successfully collected. Demographics profile of the survey is illustrated in Table 2.0. The organizations are categorized by industry, number of full-tome employees, annual sales turnover, and length of time of the organization.

The industry distribution of the survey respondents is 26.5% manufacturing companies, 25% manufacturing-related companies, and 48.5% of firms in the service industry. Majority of the respondents has more than twenty full-time employees (59.6%), followed by 40 organizations with five to nineteen full-time employees and 11% of the firms consist of less than five full-time employees. From the other point of view, there are 33.8% of SMEs have annual sales turnover exceeding RM1 million, 37.5% between Rm200,000 and RM1 million, and 28.7% less than RM200,000. Demographic of respondents is also sorted by length of time of the organization. There are 11 firms have been operating for over two decades, 21 have been in the industry between ten to twenty years, 24 operate around five to ten years, 36 between three to five years, 28 one to two years, and 16 firms are established less than a year.

Table 2: Respondents Demographics Profile

Variables		Frequency	Percentage
Industry	Manufacturing	36	26.5%
	Manufacturing-related	34	25%
	Service	66	48.5%
Number of Full-time Employees	Less than 5	15	11%
	Between 5 to 19	40	29.4%
	More than 20	81	59.6%
Annual Sales Turnover	Less than RM200,000	39	28.7%
	Between RM200,000 and RM1 million	51	37.5%
	More than RM1 million	46	33.8%
Length of time of organization	Less than 1 year	16	11.8%
	1 to 2 years	28	20.6%
	3 to 5 years	36	26.5%
	5 to 10 years	24	17.6%
	10 to 20 years	21	15.4%
	Above 20 years	11	8.1%

Normality Test

Before conducting the multiple regression analysis for this study, it is important that the data in this study are normally distributed. As the data for this study is greater than 50, Kolmogorov-Smirnov's test is applied to test for data normality (19). The significant level for the Kolmogorov-Smirnov test shows a P value of 0.074 which is more than 0.05, hence normality is assumed.

Scale reliability

In order to ensure the precise measurements for this study, the data collected from the survey is tested for reliability as noisy data can be difficult to interpret (20). The construct of measurement for data reliability is tested using Cronbach's alpha coefficient. The reliability coefficient of 0.70 or higher will be considered "acceptable" in research situations. Hence, the standard of Cronbach's alpha 0.70 will be applied to variables of this study as to be accepted or deleted. Table 3.0 shows the reliability coefficients for the variables used in this study. As the cronbach's alpha coefficients for all the variables are greater than 0.70, the data used in this study are reliable.

Table 3: Reliability Analysis

Constructs	Cronbach's Alpha
E-business Tools	0.923
Knowledge Acquisition	0.758
Knowledge Dissemination	0.806
Knowledge Application	0.725

Multiple Regression Analysis

Multiple regression analysis was applied to test the hypotheses in this study. Table 4 shows the result of the multiple regression analysis. Durbin-Watson statistic is used for testing autocorrelation (38). As a rule of thumb, a Durbin-Watson statistic has to be in the range of 1.5 to 2.5, meaning that a notion may be rejected as data are autocorrelated instead of assuming independence of observations (15). The Durbin-Watson for this study falls between the acceptable range (1.769) indicating no autocorrelation problem in the data. Hence, error terms are assumed to be independent and non-autocorrelated.

In order to avoid the occurrence of multicollinearity, tolerance indicator is suggested to be more than 0.1 and variation inflation factors (VIF) to be greater than 10 (34). The VIF and Tolerance value shown in Table 4 shows that there is no multicollinearity problem as the predictor variables have tolerance of greater than 0.10 and VIF value of lesser than 10.

The F-statistics produced (F = 27.358) was significant (P < 0.05) thus indicating that there is a statistically significant relationship between the KM processes and the adoption of e-business in supply chain by Malaysian SMEs. The coefficient of determination R^2 was 38.3 percent indicating that the KM processes significantly account for 38.3 percent in the adoption of e-business among Malaysian SMEs.

Table 4: Multiple Regression Analysis

Predictor variables	Beta	t-value	Sig.	Tolerance	VIF
Knowledge Acquisition	.361	3.602	.000	.466	2.144
Knowledge Dissemination	.002	.020	.984	.428	2.335
Knowledge Application	.316	3.073	.003	.442	2.261

Overall model F= 27.358, $p<0.01$, $R^2 = 0.383$, Adjusted $R^2 = 0.369$; Durbin-Watson test = 1.769

The result shows that knowledge acquisition ($p < 0.01$) and knowledge application ($p < 0.05$) are both significant in influencing the adoption of e-business while knowledge dissemination ($p > 0.05$) is not significant in influencing the adoption of e-business. Therefore H1 and H3 are supported while H2 is rejected.

DISCUSSION

Knowledge acquisition surfaces as the most significant factor for influencing e-business supply chain technology implementation in this study. This has made the determinant parallel with previous studies (11; 27) where conceptualization of knowledge acquisition is facilitator for successful technological adoption. Business competition is becoming more intense in this day and age. This had push organizations to acquire pervasive data and information in order to be sustainable in the market. Consequently, SMEs are also yearning to expand their knowledge about their own business capabilities as well as to gather external information in areas like economy, technology, financial, and so on. In regard of this, knowledge acquisition becomes strong focus in all business aspect. Alternatively, e-business is able to provide accumulation of information. This will highly raise the aspiration for e-business implementation. Therefore, for SMEs that are demanding for knowledge acquisition will positively accept the decision for adoption of e-business supply chain technology. This

resulted in creating the significant impact of knowledge acquisition towards e-business implementation.

Knowledge application is found to have an influence on the adoption of e-business among Malaysian SMEs. As cited in Lin and Lee (25) and Cagarra-Navarro (3), e-business differs from many previously studied areas of IT adoption as it integrates intra- and inter-organizational business processes. Consequently, e-business supply chain technology is able to facilitate knowledge to be acquired internal and externally and provide SMEs to both use existing information and create new knowledge. This will enthusiastically encourage SMEs to implementation e-business technology. Hence, the factor becomes significant to explain the adoption of e-business in this study as knowledge application allows SMEs to generate and exploit information rapidly and effectively

Knowledge dissemination is found to be not significant in influencing the adoption of e-business among Malaysian SMEs. The result can be caused by Malaysian SME's reluctant to share information. This is similar to study found in Lin and Lee (25)'s study whereby they found that Taiwanese firms are reluctant to share information as employees are afraid to share knowledge for the fear that their colleagues will be promoted at their expense. Knowledge within many Malaysian SMEs are also confidentially treated. Any widespread sharing of this knowledge is perceived to reduce the company's competitive and sustainability. Thus although knowledge dissemination is important for the success of e-business adoption (7; 25), the culture of many Malaysian SMEs do not encourage the notion of sharing information.

CONCLUSION

This study developed a research model that examine whether KM processes influence the adoption of e-business in the supply chain of Malaysian SMEs. Through empirical analysis of the data, the result shows that KM processes such as knowledge acquisition and knowledge application in the SMEs have a positive influence on the adoption of e-business among Malaysian SMEs. This study has several implications.

Theoretical implication

Past studies on the relationships between KM on e-business adoption within organizations have mainly concentrated on multinational companies or larger organizations and have neglected to focus on developing countries' SMEs. This is important as unlike developed nations, developing countries' SMEs are only at the early stage of e-business adoption or are starting to adopt e-business. As countries such as Malaysia moved from manufacturing focused towards service focused, it is important that many of their organizations are implementing technologies such as e-business in their supply chain.

Outcomes from this study insinuated that KM processes such as knowledge application and knowledge acquisition have significant impact in explaining e-business adoption for supply chain. Past studies have mainly focused on studying technology adoption using variables such as environmental, organization attributes as well as innovation's attributes. This study offered empirical evidence to confirm the validity of the research model which focuses on KM processes, and also contributed to the growing literature on rapid changing technology adoption.

Managerial implication

In managerial perspective, indentifying the major determinants of KM processes for e-business adoption among Malaysian SMEs is important for SME from various industries which are constantly searching for ways to improve business in the current volatile economic environment.

Large organizations that have collaborations with SMEs can also aim to improve the adoption of e-business adoption with their partners through improving the KM processes between them.

Limitations

There are several limitations in this study. Firstly, as this study focused only in Malaysia, the results from this study need further testing in other developing countries before the model can be generalized to all developing countries. Secondly, as with many adoption studies, not all adoption factors can be included in this study. Future study can include national culture to conduct a multi-country comparison study. Lastly, this study only focused on SMEs in Malaysia. Future study can include both SMEs and larger organizations to compare if the results are different between them.

ABSTRACT

Firms today focus on their supply chain management (SCM) in order to improve the product quality and lead time due to intensified global competition, shorter product life cycle and increased customers' expectation. This has caused many firms, even leading firms, to react by continually building superior knowledge as their own competitive advantage capabilities. Knowledge management is particularly relevant to every stage in SCM because regardless of the phases of the supply chain process, making decisions at the right time depends largely on the quality and timeliness of the data. While integrated supply chain aims to create value through learning, firms must recognize their practices and capabilities as critical factors of resource management and effective learning. Here, the total quality management (TQM) is presented for the purpose of understanding the association between quality management and knowledge management in supply chain learning (SCL). This study provides a basis for developing a model to advance KM, TQM and SCL research literatures. The practical implication of this study could be useful for business managers, who want to enhance SCL through implementing KM and TQM concepts that support their organization's SCL efforts. This study makes a significant contribution by developing a proposed model as a methodological example which can be useful for tracking the degree of KM and TQM effects on SCL. Organizations could use this framework to do a pre-test baseline measurement, and then periodically re-assess the effects of any KM and TQM change.

Keywords: Total Quality Management (TQM), Knowledge Management (KM), Supply Chain, Learning (SCL)

INTRODUCTION

Stiff global competitions, rapid introduction of short-life cycle products and increased customers' expectation have forced the companies not only to focus more on their SCM (Tan, Lyman and Wisner, 2002) but also to invest in close relationships with firms that possess complementary resources and skills as to effectively compete in the marketplace (Dyer and Singh, 1998). Understanding how firms can achieve competitive advantages has interested management scholar for a long time, particularly in the areas on how strategic plan and business policy of a firm can add and create value to its supply chain. Motwani, Larson and Ahuja (1998) argued that firms compete in global markets have to periodically study their supply chain in order to continuously benefit from savings in terms of cost and time. Although SCM does not seem to be a quick fix for every business situation, a firm's synergies can be greatly leveraged if the supply chain is successfully implemented and managed (Ellram, 1990).

Kehoe and Boughton (2001) stressed that the efficiency and timeliness of information transfer are key to enhance supply chain operation since accurate information exchange increases operational efficiencies and market responsiveness. Knowledge-based businesses which enable instant responses with real time information will contribute greatly to the companies' competitive advantage (Neef, 1997). Knowledge management also benefits the companies in quality and productivity improvement (McCampbell, Clare and Gitters, 1999). Researchers have found that, under demand uncertainty, an effective information sharing and ordering coordination greatly improves supply chain performance in cost savings, inventory reduction and increased customer satisfaction (Lee, Padmanabhan and Whang, 1997; Zhao, Xin and Zhang, 2002). A learning environment is therefore needed for members in a supply chain to ensure optimal value creation through effective partnership as highlighted by Motwani et al. (1998, p.352):

> "Strategic partnerships (information sharing and other firms of linkages that involve shared processes or activities that enhance intellectual capital) between supplier and customer value chains are an important source of competitive advantage, with advances in information technology creating new opportunities to jointly optimize the total industry value chain across multiple organizations".

Greater market performance has been linked to a higher level of process knowledge application spanning the supply chain (Claycomb, Dröge and Germain, 2001). According to Carlile (2004), learning takes place at individual level and subsequently passes through different boundaries to flow to higher levels of aggregation: the group (such as team and department), the organization and the dyad. Learning, therefore, can be an intra-firm or an inter-firm processes (Bessant, Kaplinsky and Lamming, 2003). Most learning organizations construct their structures and strategy in order to maximize their own experiences and experiences of others (Maqsood, Walker and Finegan, 2007). Operation strategies that well-integrated with knowledge unleash the creativity and innovation of the supply chain members as these companies start to collaborate by embracing SCM and act as an integrated entity (Maqsood et al., 2007).

While recognizing the role of knowledge as a source of competitive advantage (Nonaka, 1994; Spender and Grant, 1996), building a learning organization is neither an easy task (Schien, 2002) nor a natural feature of business networks (Bessant et al., 2003). Firms are challenged to learn and to keep pace with new opportunities and threats beyond their boundaries (Bessant et al., 2003). Specifically, learning efforts in the supply chain need to be more integrated and systematic due to the advances in e-business solution, increased customer expectation and customization (Preiss and Murray, 2005). Building on this notion, this paper attempts to understand the relationships among KM, TQM in SCL.

Given the above reasons, this paper begins by describing how researchers and practitioners have addressed the association between KM and SCL in the work context. Then, the linkages between TQM and KM are reviewed followed by the association between TQM and SCL. The review of literature leads to the development of propositions for this study and then followed by the proposed conceptual model. Finally, we discuss managerial implications for this study.

LITERATURE REVIEW

Knowledge Management (KM) and Supply Chain Learning (SCL)

A crucial concept in contemporary business management relates to the knowledge creation and application. To face the ever presence of challenges in the business world we have witnessed a paradigm shift in firms from focusing on management of physical goods to intangible assets such as knowledge (Nielsen, 2005). The traditional factor of competitive production is losing their significance when knowledge emerges to become the greatest determinant in achieving competitiveness in this century. Values and synergies that created via the KM efforts are powerful particularly in the area of innovation enhancement.

Collins, Dunne and O'Keeffe (2002) described knowledge as a strategic asset of a firm. The concept of knowledge, in fact, appears as early as in 1960s. Polanyi (1966) distinguished explicit knowledge from tacit knowledge. According to Duffy (2000), the explicit knowledge is documented and made public, structured, fixed-content, externalized and conscious. It can be verbally captured and shared through information technology and electronic media (Duffy, 2000; Smith, 2001). The explicit knowledge is also known as the academic knowledge or "know-what" which is commonly based on established work processes (Smith, 2001). On the other hand, the tacit knowledge is more intangible and resides in the individual mind, behavior and perception (Thorne and Dutnell, 1997; Duffy, 2000). Tacit knowledge is practical, action-oriented knowledge or "know-how" based on practices or acquired by experience (Duffy, 2000; Smith, 2001).

Learning is central to the study of knowledge management because it serves as an important block for knowledge transfer. Most literature distinguishes individual learning and organizational learning (Dahlgaard-Park, 2006). Spekman, Spear and Kamauff (2002) argued that learning concerns the acquisition of new insights/ knowledge that contributes to the firm's improvement whereas organizational learning focuses on the "accumulation of the knowledge of all the company managers, it encompasses also the learning systems and other processes developed by the company to influence behaviors of others, to establish norms that support a learning environment, and to endure that the knowledge acquired is passed from member to member (p. 43)". Similarly, Simon (1991) stated that organizational learning can happen through either "learning from its members" or "ingesting new members who have knowledge the organization didn't previously have". Lam (2000) identified a four-fold typology in understanding the complexity of learning in relation to different organizational forms and levels of analysis as one of the first conceptual frameworks in organizational learning literature. Learning for a simple dyadic relationship between two players in a supply chain can be very different from learning for a network relationship where there are multi firms involved. Bessant et al. (2003) thus developed a matrix to recognize the different modes in which the supply chain learning can be enabled. Although Spekman et al. (2002) did not provide a specific definition on SCL, they utilized two measures, guided partly by Hamel (1991), to reflect the relative magnitude to which supply chains encourage and/or provide supports to the learning process: (1) the extent to which there is supply chain structure that supports a learning environment such as structures for ideas generation and sharing across the supply chain, and (2) the extent to which attitude and behaviors within supply chain encourages learning process such as ideas sharing and supported experimentation.

Claycomb et al. (2001) classified knowledge applied to facilitate exchange within the supply chain into: (1) upstream, between the firm and its suppliers, (2) within the firm itself, to enhance its operation and (3) downstream, between the firm and its customers or distributors. Highlighted on the concepts of "know-what", "know-how" and "know-why", Fahey, Srivastava, Sharon and Smith (2001) illustrated the key knowledge issues on the SCM process to help managers in producing value to their customers (see Table 1).

Table 1: Key Knowledge Issues on the SCM Process (adopted from Fahey et al., 2001)

Know-What	• What changes are needed within the supply chain to lower costs and increase responsiveness? • What significant changes are realigning your vendor or customer relationships (pricing, billing, ordering, processing, etc.)? • What areas of the supply chain can benefit from e-business enablement? • What types out outsourcing relationships within SCM have been successful?
Know-How	• How do you use supply chain transparency to make more informed operational decisions? • How do you enable communication and collaboration across the supply chain while protecting confidentiality and privacy issues? • How can you leverage your relationships with vendors, partners, and competitors to make SCM processes more effective? • How can you improve your outsourcing relationships? • How have key competitors leveraged collaboration capabilities in your markets? • How can you draw value from the transactions performed across your supply chain?
Know-Why	• Why has the supply chain become an even more important piece of your market intelligence? • Why is it necessary to reevaluate your SM processes? • Why is that your outsourcing is not as efficient and smooth as needed?

While the supply chain partners have long taken the advantages of technology to streamline their operations and to reduce lead-time, new strategy today extended to the usefulness of information sharing and knowledge in supporting collaboration and decision making (Eisenhart, 2001). Spekman et al. (2002) also demonstrated that the principles of knowledge as a competitive source where it could be extended from individual firm to the whole supply chain. Application of KM in operational contexts not only allow greater understanding on customers, suppliers and competitors but also guide the design of products and services, planning and control of performance achievement (Armistead, 1999). More importantly, KM facilitates and encourages learning, unlearning and relearning among the supply chain members. Therefore, based on the above discussion, the first proposition is:

Proposition 1: The higher level of KM will lead to higher level of SCL in the organization.

Relationship between TQM and Knowledge Management

The notion of TQM, or total quality management traced its origin from Feigenbaum in 1950s. (Slack, Chambers and Johnston, 2004, p.719.) He defines TQM as:

> "an effective system for integrating the quality development, quality maintenance and quality improvement efforts of the various groups in an organization so as so as to enable production and service at the most economical levels which allow for full customer satisfaction."

A review of literature discussing the relationship between TQM and KM behaviour suggests that there are strong links between these two relationships, particularly in daily business and operations (Huang and Lien, 2005). Many researchers have recognized this point of view and have tried to link TQM and KM together (Ju et al., 2006; Molina, Montes and Fuentes, 2004; Yang, 2004). The practical philosophy of TQM can be defined as "understanding and discovering" a better processes, while KM concentrates on previously invented or identified methods of accomplishing certain tasks and setting them as best practices (Prajogo and Sohal, 2006; Hsu and Shen, 2005; Janpen, Praneetpolgrang and Horadal, 2006). According to Zetie (2002), the concepts of TQM and KM are closely linked and are all aspects of a much more fundamental concept of organizational development. He further emphasized that the recognition of the relationship between TQM and KM has both theoretical and practical significance. From the theoretical point of view, the implication is a possible broader use of explanatory models developed in a specific context. On a more practical level, it increases the implementation options for those seeking to bring about organizational change (Ju et. al., 2006).

Both TQM and KM approaches are the work-processes of organizational improvements (Janpen et al., 2006). According to the review of the prior empirical study on TQM, researchers have classified TQM construct in several ways although they are complementary to each other (Prajogo and Sohal, 2003). Thus, difficulty of achieving consensus on the components and dimensions of TQM arises due to the inconsistency in the past research (Hoang, Igel and Laosirihongthong, 2006). A comprehensive review of TQM literature proved that the TQM concept could be anchored into leadership, strategic planning, customer focus, and people management (HRM) (Shenawy, Baker and Lemak, 2007; Reed, Lemak and Mero, 2000). According to MacNeil (2001), top management could add significantly to the improvement of core competencies through their role as facilitators of organization learning in the workplace, specifically by establishing a knowledge management activities climate in which employees are encouraged to apply their explicit and tacit knowledge to problem-solving situations. Researchers have acknowledged that the success of leaders promoting knowledge management environment (e.g. Macneil, 2001; Bryant, 2003; Davenport and Volpel, 2001). Liebowitz (1999) reported that one of the keys for driving the success of KM is to have a clear and well-planned strategy. With this strategy, it provides the fundamentals for how a firm can deploy its capabilities and resources to achieve its KM objectives. O'Dell, Wiig and Odem (1999) further stressed that customer focus strategy is to capture knowledge about customers, understanding of customers' needs and using the knowledge within the organization to counteract customer problems. In an empirical study, Stankosky and Baldanza (2001) concluded those understanding customers' requirements and problem well is vital and this is one main factor of continued improvements and innovations to the organizations. In a very interesting study, Lin (2007) found that people usually enjoy helping others and to improve self knowledge efficacy. With senior management support and proper organizational rewards knowledge sharing processes and superior innovation could be further enhanced. Indeed, various researchers in the literatures have emphasized the importance of HRM as a way to improve the transfer of knowledge, especially in the form of technology know-how (e.g. Sparkes and Miyake, 2000; Zander and Kogut, 1995) as both HRM and KM have grown more sophisticated and multifaceted (Gloet and Berrell, 2006; Yahya and Goh, 2002). Therefore, the second proposition is as follows:

Proposition 2: The greater emphasis on TQM concepts will lead to a higher level of KM in the organization.

Relationship between TQM and Supply Chain Learning (SCL)

Learning is necessary in an organization as the world, in particularly the business world, is ever changing at a rapid pace. Simply, learning is acquiring new techniques, knowledge or technology. It could be from experiences or sharing of knowledge from external inputs. In an organization, learning becomes even more complicated as it encompasses many dimensions. Sohal and Morrison (1995) opined that TQM, if practiced as philosophy with a set of techniques, can be an effective vehicle for organization learning. Similarly, TQM involves multi-disciplinary approach including management science, organization theory, production management, cultural anthropology, psychology and organizational development (Easterby-Smith, 1997).

SCM plays a key role in the success of a business organization. Learning organization is seen to be skilled at creating, acquiring and transferring knowledge and the results should be changing the behavior and practices within the organization from the new knowledge acquired (Garvin, 1993). He also pointed out that commitment to organization learning is vital to ensure ever improvement to getting something new as the outcome through learning, be it a new product or a new process; all requires new knowledge and new perspective. SCM is not just a cost centre to an organization but it could be a source of competitive advantage if it is managed effectively and efficiently. The benefits are many, such as higher ROI (return on investment), lower cost and higher returns to shareholders (Spekman et al., 2002). The purpose of SCM could be summarized as a focus on satisfying end customers, to manage the supply chain efficiently and to have the chain flexibly. The activities of supply chain include purchasing and supply management, physical distribution management, logistics and material management (Slack et al., 2004). Due to its complexity, SCM technology and techniques continue to develop and evolve. To improve and excel in SCM, the practitioners are aware that they need to learn the latest technology and techniques in order to perform better or at least to be on par with the contemporary peers in order to be competitive. This is known as part of the formation of a learning organization philosophy. Based on observations and theories discussed, TQM has a positive role to play in the organization learning where SCM is one of the key components for improving organizational management. Thus we propose that that:-

Proposition 3: The greater adoption of TQM practices will lead to higher the level of SCL in the organization.

CONCEPTUAL RESEARCH FRAMEWORK

Based on the above review of the literature, the following conceptual model is proposed demonstrating the relationships among TQM, KM and SCL. The model is shown in Figure 1.

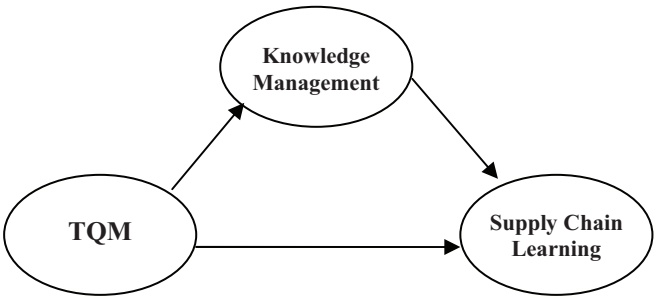

Figure 1: Conceptual Research Model

IMPLICATIONS

The conceptual model contributes to the body of knowledge for both academics and practitioners. From the theoretical perspective, this study contributes to the body of knowledge in TQM, KM and SCL, and provides a proposed conceptual model with an initial insight of what may be a valuable connection between these concepts. The proposed conceptual model in this study develops the SCL concept from KM and TQM perspectives. The impacts of KM and TQM to SCL are developed. The contributions of KM and TQM are described through a literature review. Three major propositions are proposed. First, the higher level of KM will lead to higher level of SCL in the organization. Secondly, the greater emphasis on TQM concepts will lead to a higher level of KM in the organization. Thirdly, the greater emphasis on TQM concepts will lead to a higher level of SCL in the organization. As argued by Spekman et al. (2002) that shared culture is a pre-requisite for learning, this proposed framework assumes the presence of a conducive learning culture or shared culture in the organization is needed to instill knowledge management programmes. SCL is crucial to the competitiveness of any organization that participates in and manages the supply chain regardless of whether they have formal TQM or KM programmes. If the organizations realized the importance of SCM as an integral part of their business successes, and would be willing and making efforts to improve, these organizations would be deemed to be in a better position to learn and acquire new ideas. On the other hand, the concept of learning and improving SCM would motivate organization to build a culture of KM and to adopt TQM practices. In order to fully comprehend the proposed framework, further exploration is still needed to know the strength of association among the three concepts in the model.

From to the practical point of view, the study could be useful for senior management to review their TQM and KM programs on regular basis in order to gain a sense of how these two concepts can influence SCL within their organizations. This study is also vital and beneficial for senior management of companies practicing TQM and KM who wants to address SCL in the work context could benefit from the proposed framework. It is believed that this proposed framework will provide valuable insights about the association among TQM, KM and SCL. Numerous benefits, ranging from cost reduction to the knowledge transfer and creation of synergies throughout the entire supply chain, are expected if TQM and KM are implemented effectively to facilitate the SCL.

CONCLUSION

In conclusion, the purpose of this paper is to provide a thought model for examining and understand the relationship among TQM, KM and SCL. This proposed conceptual model will serve as the catalyst for future research. Further research should be conducted using multivariate analysis to test and validate the model. Currently the authors are designing the questionnaire to collect data from respondents in various sectors to validate the proposed model shown in Figure 1 and its three propositions. The results shall be reported in the future article. Hopefully the model could advance the study in this area and provide a channel for both practitioners and academicians to understand better of the relationships among TQM, KM and SCL.

THE RELATIONSHIP OF ORGANIZATIONAL POLITICS WITH EMPLOYEES' KNOWLEDGE SHARING BEHAVIOR AND WORK ENGAGEMENT

Dr. Bindu Gupta, Institute of Management Technology, Ghaziabad, India
bindugupta@yahoo.com

ABSTRACT

Politics is an inevitable fact of organization life. Political behavior in an organization is mostly covert and subject to differences in perception. The presence of organizational politics is a situational indicator based on individual interpretations of the organizational climate that is expected to influence employee behavior. If employees perceive a highly political organizational atmosphere, all behavior in the organization will be interpreted in that light. The objective of the present research was to test a model of the relationship between employees' perceptions of organizational politics and their tendency to engage in knowledge sharing behavior and their work engagement. It conjectures that if employees perceive more politics in organization, they are less likely to be involved in knowledge sharing behavior and will be less engaged. It also examined the influence of organizational politics on job satisfaction and intention to quit. Data were collected from 114 full-time employees. Results indicated that employees' perceptions of organizational politics significantly influence work engagement, job satisfaction and intention to quit and unrelated to knowledge sharing behavior.

Keywords: Organizational politics, Knowledge sharing, Work-engagement, Job satisfaction, Intention to quit

INTRODUCTION

Organizations are inherently political place. Organizational politics is an elusive phenomenon that represents some unique domains of organizational culture and climate (Shaker, 1987; Frank, 1993). It is common to find organizational members engaging in influence attempts to protect or further their interests. The role of power in organizations is often viewed normatively as a negative or distorting force (Mintzberg, 1989). These critiques are particularly applied to the overt politicking behaviour associated with attempts to secure privileged access to decision-making and resources, or achieve control over others (French & Raven, 1959; Kipnis et al., 1980; Pfeffer, 1981). It is often considered dysfunctional because it has the potential to disrupt organizational efficiency and effectiveness (Kacmar et al., 1999). Some scholars stated bluntly that "politics in organizations is basically a negative process" (Block, 1988). According to Ferris and King (1991), organizational politics describe a dark side of workplace activity, implying that political behavior may lead to functional as well as dysfunctional outcomes for individuals, groups, or organizations. Organizational politics yield a competitive disadvantage by diluting company-level performance (Eisenhardt & Bourgeois, 1988). Various behavior like discrediting one's rival at work in order to get ahead, not sharing useful information with other employees in

order to increase one's power over them, and doing favors for the boss to secure a high salary increase are labeled as political behaviors in organization.

There have been two alternative approaches to understand the politics in organization. The first approach treats organizational politics as a simple aggregated measure of influence tactics by employees in organizations (e.g., Kipnis et al., 1980). The other approach is more cognitive analysis as proposed by Lewin (1936); it suggests a perceptual measure of organizational politics named a Perceptions of Organizational Politics Scale (e.g. Ferris et al., 1989). Political behavior in organization is mostly covert and subject to differences in perception (Drory and Romn, 1988; Kacmar et al., 1999). Lewin (1936) reported that people's attitudes and behaviors are determined mostly by their perceptions of reality and not reality per se. Workplace politics may best be conceived of as a state of mind rather than as an objective state (Gandz and Murray, 1980). These researchers and observations imply that the presence of organizational politics is a situational indicator based on individual interpretations of the organizational climate which is expected to influence employee behavior. The perception of a politically charged atmosphere reflects actions taken by individuals that are beyond the parameters of accepted organizational behavior (Mintzberg, 1983, 1985). If employees perceive a highly political organizational atmosphere, all behavior in the company will be interpreted in that light and studies have indicated they have an immanent effect on organizational climate and on a variety of work outcomes (Kacmar and Ferris, 1991; Ferris and Kacmar, 1992; Folger et al., 1992; Ferris et al., 1996; Vigoda, 2000a, 2000b). Organizational politics could result in several work outcomes, such as job anxiety, job involvement, job satisfaction, turnover and absenteeism (Ferris et al., 1989). Other studies have examined the effect of organizational politics on organizational commitment, loyalty, innovation, tension-and stress related factors, job performance and organizational citizenship behaviors (Bozeman et al., 1996; Cropanzano et al., 1997; Drory, 1993; Kacmar et al., 1999; Parker et al., 1995; Randall et al., 1999; Vigoda, 2000a, 2000b). This study focuses on two unexamined and most desired behavior in today's context namely knowledge sharing behavior and work engagement and two widely studied behavior namely job satisfaction and intention to quit.

Political behavior in organization is defined as influencing others to get what you want (Porter et al., 1981). Mintzberg (1983, p. 172) defined politics as informal, parochial, typically divisive and illegitimate behavior that is aimed at displacing legitimate power. It also has been defined as an intentional social influence process in which behavior is strategically designed as to maximize short-term or long-term self interests (Madison et al., 1980; Gray & Ariss, 1985; Ferris et al., 1989). According to Farrell and Peterson (1982) political behavior in organizations are those activities that are not required as part of one's organizational role but that influence or attempt to influence, the distribution of advantages and disadvantages within the organization.

Knowledge Sharing

Knowledge had become the most important kit for competition and survival under the business climate in 21st century (Ling, 2003). While traditional economies used to rely on tangible assets such as land and capital, today's economy has evolved to treat knowledge as the primary production factor on which competitive advantage rests (Beijerse, 1999). Once created, knowledge cannot be imitated or substituted, which makes it a key strategic asset resource to all

businesses (Cabrera and Cabrera, 2002).The growing use of knowledge in businesses contributed to the emergence of the theory of knowledge management (Aranda and Fernandez, 2002), which is currently one of the hottest topics in information technology and management literature. Knowledge management is aimed to enhance organizational competence and allow adequate people with adequate information technology at right time. As the complicated features of current business environment had increased rapidly, how to exert the capabilities of knowledge management to enhance organizational competence is exactly the critical crisis we have to face now (Liao, 2003).

Knowledge can be defined as a combination of experience, values, contextual information and expert insight that help evaluate and incorporate new experience and information (Gammelgaard and Ritter, 2000). Knowledge exists in documents and repositories, as well it becomes embedded in people's minds overtime and it is demonstrated through their actions and behaviors. The process of knowledge management involves several activities. The most commonly discussed activity in the process of knowledge management is knowledge transfer (knowledge sharing) (Ford, 2001). Knowledge sharing is critical to a firm's success (Davenport and Prusak, 1998) as it leads to faster knowledge deployment to portions of the organization that can greatly benefit from it (Syed-Ikhsan and Rowland, 2004). Traditional knowledge management emphasis was placed on technology or the ability to build systems that efficiently process and leverage knowledge. In order to make knowledge sharing happen within and among organizations, several researchers have focused on the study of different mechanisms and initiatives which could act as facilitators such as information and communication technologies (Dalkir, 2005; Davenport, 2007), whereas in other cases, personal interaction between individuals is the key (i.e. "people-focused" knowledge management) (Wiig, 2004). But later it was realized that the effectiveness of the system is affected more by its users which led to the new model of knowledge management which involves people and actions. It aims at creating an environment where employees are willing to share knowledge rather than hoarding it. Knowledge transfer requires that an individual or a group cooperate with others to share knowledge and achieve mutual benefits (Syed-Ikhsan and Rowland, 2004; Al-Alawi, 2005). By interacting and sharing tacit and explicit knowledge with others, the individual enhances the capacity to define a situation or problem, and apply his or her knowledge so as to act and specifically solve the problem (Nonaka *et al.,* 2006). Trustworthiness and mutual understanding constitute the basis for higher approachability and improved communication, and therefore for more intensive knowledge sharing (Andrews & Delahaye, 2000; Coleman, 1988; Empson, 2001; Husted & Michailova, 2002; McEvily et al., 2003; Newell & Swan, 2000). Moreover, greater commitment to organizational goals is seen as stimulating the sharing of knowledge that helps in achieving these goals (Leana & Van Buren, 1999).

However, there are many factors in organization which inhibit knowledge sharing and organizational politics, considered to be unavoidable reality in organization, which may hinder knowledge sharing. Politics consumes time, restricts information sharing, and creates communication barriers (Eisenhardt and Bourgeois, 1988). High levels of politics may inhibit knowledge sharing in several ways. First, environments perceived as political may be interpreted as inequitable, resulting in employees feeling that there has been a violation of the 'social contract' between the employer and employee (Cropanzano, Howes, Grandey, & Toth, 1997). The social contract is a mixture of economic and social exchanges (Organ & Konovsky, 1989),

and perceptions of politics impact both of these exchanges. When others receive personal benefits from what is perceived as successfully employed political tactics aimed at building social networks, individuals may view the outcome as unfair (Ferris, Frink, Beehr, & Gilmore, 1995) and feel distrustful of both the political actor and the person rewarding the actor's behavior.

Further, individuals in situations perceived as political may engage in self management behavioral. They may inhibit the development of effective social relationships. In contexts that are perceived as highly political, people are unlikely to want to go out of their way to help others by sharing knowledge, as any energy that they dedicate to others may be perceived as taking away from their efforts to promote self-interests. If employees stop interacting with each other, the organization may not be as efficient as it would be if the workers communicated fully with one another. This potentially negative organizational outcome is consistent with theory and research that has demonstrated a negative relationship exists between perceptions of politics and a variety of organizational outcomes (Kacmar & Baron, 1999).

The present research suggests that employee propensity to engage in knowledge sharing behaviors is strongly influenced by the organizational context. If the organization is highly political in nature, individuals are likely to engage in self-promotional activities. Therefore, a highly charged political context is argued to inhibit the display of knowledge sharing behaviors.

Work Engagement

Engaged workers are energetic, are positively connected to their work and feel they are doing their jobs effectively (Koyuncu et al, 2006). It is considered to be a persistent and broad affective cognitive state. Schaufeli et al (2002) view it as a positive, fulfilling work related state of mind that is characterized by vigor, dedication and absorption. Vigor implies high level of energy, the willingness to invest energy in one's work and persistent in difficult time. Dedication is characterized by high levels of work involvement and feelings of pride and challenge from one's work and absorption imply deep concentration in one's work the sense that time passes quickly and one is reluctant to leave the work (Schaufeli et al., 2002). It is important to study engagement because it is linked to positive individual and work related outcomes (Maslach et al., 2001). Work engagement has been linked with positive organizational behavior like, optimism, trust and engagement (Kahn, 1992; Leiter, 2005 ; Schaufeli and Bakker, 2004a; Schaufeli et al.,2003). Researchers have examined the impact of different organizational variables on work engagement. In a multi-sample study, Schaufeli and Bakker (2004b) found that job demands (workload, emotional demands) were positively related to burnout, but not to engagement, and job resources (social support, supervisor coaching, feedback) were positively related to engagement and negatively related to burnout. In a study of employees from an insurance company reported that high work demands and high control were associated with higher engagement (Demerouti et al. 2001). Mauno et al. (2005) reported an association of high time pressures with higher levels of engagement. The present study conjecture that the politics in the organization will influence negatively influence the work engagement.

Job Satisfaction

Job satisfaction is probably the most widely studied variable in the area of organizational behavior. It is defined as "the pleasurable emotional state resulting from the appraisal of one's job as achieving or facilitating the achievement of one's job values" (Locke, 1969, p. 316).Studies have reported that organizational politics has negative effect on less job satisfaction (e.g., Cropanzano et al., 1997; Ferris et al., 1989; Kacmar, et al., 1999; Poon, 2002). Job satisfaction is associated with fairness in decisions such as incentives, promotion, salary, and resource allocation. When employees perceive that these decisions are not fair and more influence my organizationally unsanctioned means employees feel dissatisfied. Previous research suggested that in highly political organization, rewards may be tried to relationships, power and other such less objective factors, and not specifically related to work performance (Kacmar and Ferris, 1991). The study hypothesize that work place politics will negatively influence job satisfaction. Further it explore the impact of different dimensions of organizational politics on job satisfaction.

Intention to Quit

Intention to quit refers to employees' thoughts of quitting their present job. While actual quitting behavior is the primary focus of interest to employers and researchers, intention to quit is argued to be a strong surrogate indicator for such behavior.. Intentions to leave may be regarded as the last stage in a sequence of withdrawal cognitions, ranging from thinking of leaving to intending to search for alternative employment (Tett & Meyer, 1993). Heightened levels of organizational political demands have been suggested as being predictive of employees' intention to quit their job (Ferris et al., 1989) and researches indicate that perceived organizational politics is significantly related to turnover intention (e.g. Cropanzano et al., 1997; Poon, 2002; Kacmar et al., 1999; Randall et al., 1999), hence this study also conjecture the negative relationship between organizational politics and intention to quit and examines the impact of different dimensions of organizational politics on intention to quit.

METHOD

Sample and Procedure

To test the proposed research model, we adopted the survey method for data collection. Data were gathered by means of questionnaires that were sent through electronic mail. Overall 300 questionnaires were mailed, and 114 usable questionnaires were received, with a response rate of 34.2 percent. The respondents came from 10 organizations from diverse industries, with Manufacturing, Finance, Computers, Engineering and Telecom etc. The participants were lower (81%) and middle level executives (19%). The average age of executives was 26.75 years (SD = 4.06), average experience 3.94 years (SD = 3.38), average experience in current organisation 2.34 years (SD = 3.38), and average experience in present position 2.22 years (SD = 1.37). With respect to the level of qualifications, 72.8 percent were graduates from various streams, (i.e., commerce, science, computers, arts, management, electrical, textile etc); and 27.2% were post-graduates from management, science etc. Male respondents accounted for 79.8 percent of the population and 20.2 percent were the females. Married respondents were 25.4 percent and 74.6 percent accounted for unmarried respondents.

Measures

Knowledge sharing behavior.

It was measured using four items adapted from the work of Lee (2001). Employees were asked to respond how frequently they share their knowledge with others in organizations on 5-point scale (1- very rarely, 5 very frequently). The coefficient alpha for the scale was .67.

Perceptions of Politics

Perceptions of organizational politics were measured with instrument developed by Ferris and Kacman (1992). It is 31-item measure that examined various aspects of political behavior in organizations. Employees responded on 5-point likert scale the extent to which they agreed with each statement as it reflected their present work environment (1 – strongly disagree, 5 – strongly agree). The coefficient alpha for the aggregate measure of politics perceptions was .81

Work engagement

It was measured using scales developed by Schaufeli et al. (2002), and Schaufeli and Bakker (2004a). It included three aspects of work engagement, namely vigor (6 items), dedication (5 items), and absorption (6 items). Respondents indicated their agreement with each item on five-point Likert scale (1 – Strongly disagree; 5 – Strongly agree). The scale has high reliability coefficient (alpha) of .87.

Job Satisfaction

It was measured with four items (e.g., "I find real enjoyment in work"). Respondents indicated their levels of satisfaction indicating the degree of agreement with these items on five- point Likert scale (1- strongly disagree; 5 – strongly agree). The scale showed a reliability coefficient of .69.

Intention to quit

It was measured by three items (e.g., "I think a lot about quitting my job"). Subjects indicated their agreement on five point scale (1 – Strongly disagree; 5 – Strongly agree). The scale has reliability coefficient (alpha) of .92.

Analysis

Data were analyzed using descriptive and inferential statistical techniques. For organizational politics questionnaire factor analyses was done. Later the descriptive statistics, correlations and reliability coefficients were computed for each measure. Hypotheses were tested using regression analysis.

RESULTS

Factor Analyses

Before conducting factor analyses, sampling adequacy test was computed using Kaiser-Meyer-Olkin (KMO) statistic. All the items were found to have KMO value higher than .60. The KMO statistics for the sample data set was .69 and Bartlett test showed that nonzero correlations existed at the 0.000 significance level.

Thirty-one items of perceptions of politics were subjected to item analysis. Based on item analysis 16 items were selected for further analysis. These sixteen items were subjected to principal components analysis with varimax rotation. Five factors emerged with eigen values greater than 1.0 and these factors explained 62.45% of variance.

Two rules were used to select items that best represent each of the factors. First, all selected items had to have a factor loading greater than 0.50, the point at which loadings are considered to be practically significant (Hair et al. 2006). Second, items had to clearly load on one factor; items with similar loadings on both factors were not included. Because all items loaded above 0.50 on their intended factor and had relatively low cross-loading, there is evidence of factorial validity for the measure used. The first factor was named as "supervisor behaviour", factor 2 as "co-worker and clique behaviour", factor 3 as "go along to get ahead" and factor 4 as "organization practices and policies". Factor five had only one item so it was not used for further analysis. The cronbach alpha reliability were 0.80 for factor 1, 0.70 for factor 2, 0.60 for factor 3 and 0.59 for factor 4.

Descriptive Statistics

The means and standard deviations for all variables are presented in Table 2. The correlations among study variables are reported in Table 3.

Table 1 : Factor loadings for Perceptions of Politics Questionnaire

Items		Fcator 1	Factor 2	Factor 3	Factor 4
S1item1	Favoritism rather than merit determines who gets ahead around here.	.641	.222	.209	.004
item14	When my supervisor communicates with me, it is to make himself/herself look better, not to help me.	.561	.051	.022	.176
item20	I have seen people deliberately distort information requested by others for purposes of personal gain, either by withholding it or by selectively reporting it.	.522	.187	.330	.183
item24	The rules and policies concerning promotion and pay are fair, it is how supervisors carry out the policies that is	.806	-.053	-.118	-.287

Items		Fcator 1	Factor 2	Factor 3	Factor 4
	unfair and self-serving.				
item27	Whereas a lot of what my supervisor does around here (e.g., communicates and gives feedback, etc.) appears to be directed at helping employees, it is actually intended to protect himself/herself.	.737	.294	.190	.167
item28	The performance appraisals/ratings people receive from their supervisors reflect more of the supervisor's "own agenda" (e.g., likes and dislikes, giving high or low ratings to make themselves look good etc.) than the actual performance of the employee.	.698	.189	.376	-.137
item5	There are "cliques" or "in-groups" which hinder the effectiveness around here.	.362	.581	.201	-.096
item13	As long as the actions of others don't directly affect me, I don't care what they do.	.000	.730	-.103	.104
item21	Managers in this organization often use the selection system to hire only people that can help them in their future or who see things the way they do	.184	.693	.069	-.036
item22	I have seen changes made in policies here that only serve the purposes of few individuals, not the work unit or the organization.	.143	.605	.178	-.259
item9	There has always been an influential group in this department that no one ever crosses.	.083	.270	.784	-.216
item10	Generally, people who have left this organization did so because they realized that just working hard was not enough to get ahead.	.224	-.153	.724	.193
item3	You can get along here by being a good guy, regardless of the quality of your work.	.162	.127	-.096	.795

* Correlation is significant at the 0.05 level (2-tailed).

Regression Analysis

Multiple regression analysis was used to test the relationships between employees' perception of politics and employees' behavior and attitude toward work and organization.

The results of regression analysis for employees' perception of work place politics and employees' knowledge sharing behavior were not significant implying that knowledge sharing is not influenced by employees' perception of politics in organization.
The results of regression analysis for employees' perception of work place politics and work engagement significantly support the overall model with F value of 3.50 ($p < .010$) (Table 4). Adjusted R square (.08) indicates that the variance in work engagement is substantially explained by employees' perceptions of politics. Among the four dimensions of politics, organization practices and policies ($\beta = -.281$, $p < .003$), has significant negative effect on work engagement of employees. Other dimensions of politics were found to be unrelated to work engagement.

Table 4: Results of Regression Analysis for Work Engagement as Dependent Variable and perception of politics as Independent Variables

	Sum of squares	Degrees of Freedom	Mean Squares		
Regression	3.38	4	.85	3.50	.010(a)
Residual	26.29	109	.24		
Total	29.67	113			
=.11; Adjusted R-Square = .08					
	Standardized coefficient				
supervisor behaviour	.028	.265	.792		
co-worker and clique behaviour	.147	1.427	.157		
go along to get ahead	-.043	-.435	.665		
organization practices and policies	-.281	-3.074	.003		

The results of regression analysis for employees' perception of work place politics and satisfaction significantly support the overall model with F value of 5.27 ($p < .001$) (Table 5). Adjusted R square (.13) indicates that the variance in satisfaction is substantially explained by employees' perceptions of politics. Among the four dimensions of politics, three dimensions of perception of politics namely supervisor behavior ($\beta = -.223$,$p < .034$), co-worker and clique behavior ($\beta = -.23$,$p < .024$), and organization practices and policies ($\beta = -.230$,$p < .011$), have significant effect on satisfaction of employees.

Table 5: Results of Regression Analysis for Satisfaction as Dependent Variable and perception of politics as Independent Variables

	Sum of squares	Degrees of Freedom	Mean Squares		
Regression	7.17	4	1.79	5.27	.001
Residual	37.06	109	.34		
Total	44.23	113			
=.16; Adjusted R-Square = .13					
	Standardized coefficient				
supervisor behaviour	-.223	-2.148	.034		
co-worker and clique behaviour	.229	2.285	.024		
go along to get ahead	-.171	-1.784	.077		
organization practices and policies	-.230	-2.587	.011		

Table 6: Results of Regression Analysis for Intention to quit as Dependent Variable and perception of politics as Independent Variables

	Sum of squares	Degrees of Freedom	Mean Squares		
Regression	12.23	4	3.06	4.46	.002
Residual	74.72	109	.69		
Total	86.956	113			
=.14; Adjusted R-Square = .11					
	Standardized coefficient				
supervisor behaviour	.267	2.533	.013		
co-worker and clique behaviour	.013	.127	.899		
go along to get ahead	.164	1.689	.094		
organization practices and policies	.060	.666	.507		

The results of regression analysis for employees' perception of work place politics and intention to quit significantly support the overall model with F value of 4.46 ($p < .002$) (Table 6). Adjusted R square(.11) indicates that the variance in intention to quit is substantially explained by employees' perceptions of politics. Among the four dimensions of politics, supervisor behavior

(β = .267, p <.013) has significant positive effect on satisfaction of employees. Other dimensions of politics were found to be unrelated to intention to quit.

DISCUSSION

Everyone in the organization work to achieve certain objectives. These objectives may be concrete such as incentives, promotion etc or abstract such as status attainment etc. In the process of achieving these goals, employees in the organization may engage in political behavior to protect or enhance their own interests, particularly as when face scare resources and increasing competition. Given the fact that organizational politics is inevitable reality of workplaces, it becomes necessary how employees perceive politics in organizations and different dimensions of organizational politics. If employees perceive a highly political organizational atmosphere, all behavior in the organization will be interpreted in that light. The perceptions individual have about the political nature of their work environment will influence the way they do their jobs and affect how they feel about their organization, senior and co-workers.

The present study was in an attempt in this direction. It examined the organizational politics in culture characterized by high power distance and high on collectivism. This study found the perceptions of organizational politics include four factors namely, "Supervisor behavior", "Co-worker and clique behavior", "Organizational practices and policies", and "Go along to get ahead". The first there factors were found to related to employees' behavior and attitudes. "Organizational practices and policies" dimension was negatively related to work engagement. Employees' job satisfaction is negatively influenced by Supervisor behavior, co-worker and clique behavior and organization practices and policies. Supervisor behavior significantly influences intention to quit. These findings are in congruence with the findings of earlier studies examining the influence of organizational politics on employees' work attitudes and behaviors (e.g. Farris et.al 1989).

Knowledge sharing behavior was found to be unrelated to the perception of politics in organization. The reason of knowledge sharing unrelated to perception of politics may be the level of respondents in organization. Most of the participants of the study belonged to lower levels where politics is less compared to higher level. Other explanation may be employees have more reasons to share knowledge rather than not to share it. Today's' organization motivate the employees with various systems and process like knowledge sharing portals, incentive programs and recognition etc.

In the study respondents reported low politics in their organization as mean score on all the dimensions is less than 3.50. The reason of low score on politics may be that most of the employees belong to lower level in organization, where employees are more involve in technical work related to their function and do more individual task and less dependent on other employees. Rewards are more based on individual performance and more based on explicit outcomes. As the employees moves up in the hierarchy they are more interdependent and resources become scare. Organizations are like pyramid where positions are lesser compare to lower levels. Employees are higher level are more involve in planning and job become more unstructured unlike lower level. Studies have indicated that politics as more prevalent among

higher and middle managerial levels than among lower and non-managerial levels (Farris et al., 1989; Fandit and Ferris, 1990; Gandz and Murray, 1980).

There are some limitations in our research that should be mentioned. The sample size was not large enough therefore, the study needs to be replicated using a larger sample of employees. This research has only collected cross-sectional data, and it is not appropriate to infer strong causal relationships between variables. Collecting longitudinal data may be a better approach for future research. Another limitation is the use of self-reported measures when employees provided data on both independent and dependent variables. It is possible that the relationships among the independent and dependent variables were inflated due to common method variance. Further, in the present study most of the respondents were from lower levels. Future study need to include respondents from middle and higher levels also and re-examine the relationship between perception of organizational politics and knowledge sharing in organizations. Studying the organizational politics across level will help to understand differences in perceptions of employees. It will help to managers to identify which dimensions of organizational politics influence employees' attitude and behaviour, so corrective measures can be taken to minimize the negative impact of organizational politics. Managers can put more efforts into streamlining the communication channels, inspiring participation of employees, effectively linking the rewards with performance, and using fair decision-making procedures in work place.

THE EFFECT OF DIVERSIFICATIONS ON THE PERFORMANCE AND RISKS OF BANKS AND CREDIT UNIONS IN TAIWAN

Chuang-Min Chao, National Taipei University of Technology, Taiwan
Chi-An Wang, National Taipei University of Technology, Taiwan
Spiceandy84@hotmail.com

ABSTRACT

Due to the competitiveness become more serious than ever in financial industry, financial organizations are doing more and more diversification to earn more operating income. But different studies and researches usually came out vary results. This study examines the banks and credit unions, two important types of financial organizations in Taiwan's economy, doing diversification would give what kind of impact to their financial performance and risk. We choose 36 banks and 27 credit unions in Taiwan and collect 4-year period data from 2005 to 2008. There are two different diversification variables- Herfindahl-Hirschman index and Non-interest income to operating income ratio. Then we use Hansen's (1999) Panel Threshold Regression Model to test if there are thresholds when financial organizations do diversifications. We find when banks and credit unions do more diversification it would influence their Risk-adjusted rate of ROE and Z-score significantly. So making decisions of doing diversifications becomes a very important idea for management of banks and credit unions. The findings can help researchers to understand that different types of financial institutions may optimally choose different degrees of diversification, which sheds some light on the inconsistent findings in the literature regarding the relationship between diversification and firm values.

Keywords: Diversification, Panel Threshold Regression Model, Non-interest Income, Performance, Insolvent Risk

INTRODUCTION

For the recent decades in Taiwan, financial industry, which includes banks and credit unions, has always been playing a very important role in the economic development. Banks and credit unions are the intermediate organizations that bring money borrowers and lenders together. And the traditional income sources of these two financial corporations are the interest income. After the government adopted the policy of liberalization and internationalization in the recent years, financial industry of Taiwan has undertaken several impacts. The most important one is the number of financial corporations boosted significantly.

Because of that, the environment has become more competitive than ever.

The serious problem of the financial environment has existed for years. Banks and credit unions in Taiwan then reduce their lending interest rates and enhance saving interest rates in order to strengthen themselves and take up more customers. But that will lead to the consequences of decreased income. Because the profit decreased and the risk rose, banks and credit unions try to diversify their scope of products and services, and to use information technology to create various earning sources. Via diversification, they expect to discover wider range of businesses and to achieve the scope economy.

Commercial banks offer many financial products and services, such as, credit card, cash card, trust fund, derivative financial products, securitization financial products, financial planning services, etc., to make their income sources vary. On the other hand, credit unions in Taiwan usually provide simple business services such as lending money to household unit and small and medium enterprises. As the competition arises, they also perform certain diversifications, such as the credit card of the National Federation of Credit Unions and the insurance services.

The diversification of banks and credit unions means that they not only do their traditional interest-earning activities, but also bring out more non-interest activities to earn non-interest income. So we take the ratio of non-interest income to total income as the proxy variable to measure the degree of diversification. When the non-interest income increases, the degree of diversification increases as well. Moreover, Herfindahl-Hirschman Index (HHI), which is a common used diversification ratio, also gives people sign to know whether the degree of banks and credit unions diversification is high or low. Here HHI is also calculated by the non-interest income. So non-interest income is a very important element for us to measure the diversification.

Should banks and credit unions diversify their portfolios across different industries or even broader economic sectors and geographical regions, or should they focus on a few related fields? The focus versus diversification issue is important in the context of banks and credit unions as they are affected by several regulations that create incentives either to diversify or to focus their portfolios, i.e. the imposition of capital requirements tied to the risk of the banks and credit unions' assets or asset investment restrictions. Hence, policymakers should be especially interested to see whether or not banks benefit from diversification.

As long as banks and credit unions earn more from the non-interest income, it is always interesting to know whether diversifications would have a positive or negative influence on their revenue and risks. In recent years, some researches of banking diversification came out

with different conclusions. And there has been little study regarding the diversification effect on the credit unions in Taiwan. The purpose of this study is to examine the diversification effect on the performance and risks of banks and credit unions respectively. Then we compare the difference between these two parties, and give suggestions and conclusions.

The remainder of the paper is organized as follows. Section 2 reviews the prior literature and Section 3 explains describes the dataset, variables, and the methodology that we adopted. We present empirical results in Section 4 and offer concluding remarks in Section 5.

LITERATURE REVIEWS

Diversification in banks and credit unions can be viewed as three-dimensional: across financial products and services; through geographic expansions, and through a combination of geographic and business line diversification. Nevertheless, the concept of financial organizations is still the same. Studies of cross-functional mergers provide mixed results.

From a theoretical standpoint, the decision to diversify income sources is desirable for both efficiency and risk management. The joint production of a wide range of financial services should increase a bank's efficiency (Klein and Saidenberg 1997). Thus, generally speaking, diversification across new types of services should enhance profitability.

When researchers consider risk, it is generally believed that diversification of income sources—that is, the shift from interest to non-interest income—should reduce total risk. Here, the idea is simple: since activities that generate non-interest income are thought of as uncorrelated, or, at least, imperfectly correlated, with those that produce interest income, diversification should stabilize operating income and give rise to a more stable stream of profits.

Empirical research has examined the issue of diversification benefits from several standpoints and through different methodological approaches. In spite of what economic theory postulates, namely, a positive relation between diversification and profitability, it has produced evidence that is by no means clear cut. An exhaustive survey of the literature on bank product mix and bank risk goes beyond the purpose of this paper (for such a survey see, for instance, DeYoung and Roland 2001). Here, we are interested only reviewing the most recent papers and comparing the findings for the U.S. and the EU. In fact, most of the studies that we review deal with U.S. banks (DeYoung and Roland 2001; Stiroh, 2004; DeYoung and Rice 2004; Stiroh and Rumble 2006), but to the best of our knowledge, only a few papers focus on the experience of European banks (European Central Bank 2000; Smith et al. 2003)

and none of them uses econometric methods.

Stiroh (2004), considering U.S. banking data between 1984 and 2001, finds that in the aggregate, industry-wide level, the correlation between net interest income growth and noninterest income growth increased in the 1990s; moreover, that non-interest income is much more volatile than net interest income, Further, that the lowering of operating revenue volatility, which occurred in the 1990s, can be traced directly to the declining volatility of net interest income. Finally, Stiroh finds that at the bank level, risk-adjusted returns are negatively associated with non-interest income shares.

DeYoung and Rice (2004), using data for U.S. commercial banks between 1989 and 2001, find that marginal increases in non-interest income were associated with higher profits, more variable profits, and on net, a worsening of risk–return trade off.

Stiroh and Rumble (2006), in a study on U.S. financial holding companies for the 1997–2002 period, find that there is no link between diversification and performance, but that there is a large negative relation between non-interest share and performance.

Smith et al. (2003) analyze the variability of interest and non-interest income and their correlation, for the banking systems of the 15 EU countries during the 1994–1998 period. For each country, Smith considers commercial, savings, cooperative, and mortgage banks on the one hand and large and small banks on the other, and study the correlation of income sources. They find that in the majority of the cases, the increased reliance on activities that generate non-interest income has stabilized profits.

Mercieca, Schaeck, and Wolfe(2007) took ROE and ROE to measure the performances of banks, HHI to measure the risk and degree of banks' diversification, Z-score to measure banks' insolvent risks. They research annual data for small European banks for the period 1997–2003 from bank scope and classify small banks as credit institutions with an asset size less than €450 million and no multi-bank affiliation. They find that when non-interest income increases, it doesn't help significantly with the small banks' performances, but with positive influence to large banks' ones.

As far as we are aware, Esho et al.'s (2005) and John Goddard, Donal McKillop, John O.S. Wilson (2007) are the only two empirical investigations of the impact of diversification on the financial performance of credit unions. Within Esho et al.'s research, over the period 1993–2001 an increased reliance on fee income generating activities was associated with increased risk. Credit unions with more highly concentrated income streams tended to have

higher risk and returns. Those with a higher proportion of total income from interest on residential loans, and a lower proportion of income from interest on personal loans, had significantly lower risk and returns. Credit unions that diversified by increasing the share in income of transaction fees on loans and deposits, matched by a reduction in the income share of interest on personal loans, experienced higher risk and lower returns.

And John Goddard, Donal McKillop, John O.S. Wilson (2007) collect the data from National Credit Union Association and Callahan & Associate's 5300 Call Reports between 1993 to 2004. And use the cross-sectional data to do the regression and analysis the financial performances. They adopt 6 indicators, they are ROA, ROE, σ_{ROA}, σ_{ROE}, risk-adjusted ROA(RAR_{ROA}), and risk-adjusted ROE (RAR_{ROE}). The result shows that if the credit unions' portfolio is similar, increasing non-interest income will increase the volatility of returns. And larger credit unions are more benefit from the diversification. Small ones should just focus on what they originally do.

METHODOLOGY

This section discusses the methodology that we apply on this paper. Firstly, it briefly review the building procedure for Panel Threshold Regressions based mainly on Hansen (1999), thereafter turning to the empirical specification.

Panel Threshold Regression Model

Threshold regression models allow individual observations to be divided into regimes based on the value of an observed variable. Firstly introduced into univariate time series context (TONG, 1983), the seminal paper of Hansen (1999) introduced the econometric techniques appropriate for threshold regression with panel data. Allowing for fixed individual-effects the PTR model divides the observations into two or more regimes depending on whether a threshold variable is smaller or larger than a threshold value, and these regimes are distinguished by differing regression slopes.

Hansen (1999) provides a two-regime balanced panel structural equation as follows:

$$y_{it} = \mu_i + \beta_1' x_{it} I(q_{it} \le \gamma) + \beta_2' x_{it} I(q_{it} > \gamma) + e_{it} \quad (2.1)$$

where y is the dependent variable and x is the vector of independent variables. Term is the cross-sectional unit of state, t is the year of observed data, μ_i is the individual-specific means, q_{it} is the threshold variable, and I(.) is the indicator function. This equation can be rewritten as:

$$y_{it} = \mu_i + \beta' x_{it}(\gamma) + e_{it} \quad (2.2)$$

where $\beta = (\beta_1', \beta_2')$ and $x_{it}(\gamma) = \begin{bmatrix} x_{it} I(q_{it} \le \gamma) \\ x_{it} I(q_{it} > \gamma) \end{bmatrix}$ (2.3)

Let Y, X, and denote the data stacked over all individuals:

$$Y^* = X^*(\gamma)\beta + e^* \quad (2.4)$$

and the coefficient β estimated by OLS:

$$\hat{\beta}(\gamma) = (X^*(\gamma)' X^*(\gamma))^{-1} X^*(\gamma) Y^*$$

and the sum of squared error (SSE) is:

$$S_1(\gamma) = \hat{e}^*(\gamma)' \hat{e}^*(\gamma)$$

$$= Y^{*'} \left(I - X^*(\gamma)(X^*(\gamma)' X^*(\gamma))^{-1} X^*(\gamma)' \right) Y^*$$

where

$$\hat{e}^*(\gamma) = Y^* - X^*(\gamma)\hat{\beta}(\gamma)$$

It is important to determine whether the threshold effect is statistically significant. The null hypothesis of no threshold effect (linearity) is:

$$H_0 : \beta_1 = \beta_2$$

Rejecting implies that there is one threshold at least. Hansen (1999) suggests the F test is:

$$F_1 = \frac{S_0 - S_1(\hat{\gamma})}{\hat{\sigma}^2} \quad (2.5)$$

where S_0 is the SSE obtained from the estimative of (2.1) under the null hypothesis of no threshold, S_1 is the SSE obtained from the PTR estimative of (2.1), and $\hat{\sigma}^2$ is the residual variance of the PTR regression.

It is possible that the model includes more than one threshold. We first employ the F_1 test to assess the null hypothesis. If this null hypothesis is rejected, then at least one threshold is ensured. We then continue testing the null of one threshold against the alternative of two thresholds – that is:

$$F_2 = \frac{S_1(\hat{\gamma}_1) - S_2^r(\hat{\gamma}_2^r)}{\hat{\sigma}^2} \quad (2.6)$$

where γ_2 is the second threshold. A significant F_2 implies the rejection of the null of one threshold. Therefore, we can repeat this procedure to test the null of more thresholds. The critical values are computed based on the bootstrapping method. If the model exists with a threshold effect, then the next step is estimating the threshold value $\hat{\gamma}$. Hansen (1999) provides a method to form an asymptotic confidence interval for $\hat{\gamma}$ which is to form the no-rejection region $c(\alpha)$:

$$LR_1(\gamma) = \frac{S_1(\gamma^*) - S_1(\hat{\gamma})}{\hat{\sigma}^2} \tag{2.7}$$

$$c(\alpha) = -2\log(1-\sqrt{1-\alpha})$$

where $S_1(\gamma^*)$ and $S_1(\hat{\gamma})$ are the residual sum of squares given the true threshold γ* and $\hat{\gamma}$ estimated, and $(1-\alpha)$ is the set of values of γ such that $LR_1^r(\gamma) \le c(\alpha)$, respectively. If two thresholds cannot be rejected, the confidence intervals can be set in the same way:

$$LR_2^r(\gamma) = \frac{S_2^r(\gamma) - S_2^r(\hat{\gamma}_2^r)}{\hat{\sigma}^2} \tag{2.8}$$

where $S_2^r(\hat{\gamma}_2^r)$ is defined in (2.6).

Sample Selection and Data

We use financial data from Taiwan Economic Journal, and Market Observation Post System database of regional banks and credit unions in Taiwan. The samples used in this study are the 36 banks and 27 credit unions in Taiwan from 2005 to 2008. Those banks are selected because they have the complete 4 period data for 4 years. So we exclude some banks those don't have complete data. Beside that, the credit unions in Taiwan are all selected. We use annual data so there are 252 data.

Variables

Dependent Variables: Risk-adjusted rate of ROE, Z-score

(1) Performance Variable: Risk-adjusted rate of ROE (RAR_{ROE})
ROE is mean value of return on equity. It is the ratio of net income (after loan-loss provisions) to net worth or capital, defined as the sum of reserves, undivided earnings, loan and investment loss provisions, accumulated unrealized gains on securities and uninsured secured capital. For each bank and credit union, we calculate the average ROE over the quarters in a bank or credit union's lifetime or a given year. For each bank and credit union, we also calculate the standard deviation of σ_{ROE} over the same lifetime or year to measure the total volatility of profits. These variables define risk-adjusted return on equity, RAR_{ROE}. The equation is as follows:

$$RAR_{ROE} = \frac{ROE}{\sigma_{ROE}}$$

(2) Risk Variable: Z-score

Z-score is used to measure risks in this study due to that learning the insolvent possibility when banks and credit unions take diversification activities is crucial for investors. Take the year 2008 as an example, a large proportion of financial crises and bankruptcies arose from those companies that took too much financial leverage activities. And financial leverage activity is similar to diversification activity in some aspect. So we take Z-score to measure the risk of banks and credit unions.

The regulator may not care about the actual level of risk but put their eyes on a bank's distance to default. It's a potential criticism of an asset return volatility risk which is usually used to measure a bank's bankruptcy probability (Bouwman, 2004). How closer to failure is generally measured by an index which is called Z-score, introduced by Altman (1968). The Z-score estimates the number of standard deviations below the mean by which profits would have to fall before equity becomes negative. Boyd and Graham (1986) adopt the following equation to examine the risk of failure at large BHCs that diversified into non-banking activities during the 1970s and early 1980s,

$$Z_i = \left(\left\{\sum_{j=1}^{n}\left[2\pi_j/\left(A_j + A_{j-1}\right)\right]\right\}/n + \left\{\sum_{j=1}^{n}\left[\left(E_j + E_{j-1}\right)/\left(A_j + A_{j-1}\right)\right]\right\}/n\right)/S_r$$

where π is net income after taxes, A is total assets, E is total equity, Sr is the standard deviation of π/A, and the subscript j denotes the time period. High values of Z-score are associated with low probabilities of failure and the Z-score approach is frequently used in banking studies.

Threshold Variable: DIV

Both of Threshold Variable that we use the same variable to analyze the degree of diversification is because we want to know at what certain level of diversification will influence our dependent variables. We define Threshold Variable as DIV. And the DIV variable can be two as follow:

(1) Herfindahl-Hirschman index (DIV_{HHI})

The early studies on non-financial industries diversification were based on SIC codes with segmental accounting data. But the degree measurement of SIC-code classification for banks is not granular enough and is not consistent across countries. Moreover, segmental reporting is not consistent across banks and across time (Elsas, Hackethal, Holzhäuser, 2006) Instead, we use an adjusted Herfindahl-Hirschman index to measure revenue diversification. Various authors have applied a similar measuring method (see, e.g., Acharya et al. 2002; Stiroh & Rumble 2003; Stiroh 2004). Equation below shows how this study constructed the

diversification index.

$$HHI_i = 1 - \left(\left(\frac{INT}{TOR} \right)^2 + \left(\frac{COM}{TOR} \right)^2 + \left(\frac{TRAD}{TOR} \right)^2 + \left(\frac{OTI}{TOR} \right)^2 \right)$$

The variable definitions are as follows: INT denotes gross interest revenue, COM denotes net commission revenue, TRAD denotes net trading revenue, OTI denotes all other net revenue and TOR denotes total operating revenue. Denominator TOR is equal to the sum of the absolute values of INT, COM, TRAD and OTI, and we use gross interest revenue so that our diversification measure is not unduly distorted by the profitability of the bank's interest business. We use accounting data from the TEJ database which consistently reports gross numbers for the other revenue categories.

We subtract the sum of squared revenue shares from unity so that HHI increases in the degree of revenue diversification, the higher values of HHI, mentioning the degree of diversification is much higher. By definition HHI can take on values between zero (the bank and credit union is fully specialized in only one business areas) and 0.75 (the bank and credit union generates a fully balanced revenue mix from all four business areas).

(2) Non-interest income to operating income ratio (DIV_{NIOIR})

This is a simple way to measure the degree of diversification that banks and credit unions take. Adopting this ratio basically let us see through the characteristics of bank and credit union industry. Banks and credit unions are the intermediate organizations that bring money borrowers and lenders together. So the traditional income sources of these two financial corporations are the interest income. When banks and credit unions do more non-interest activities, they will have more non-interest income. The equation of calculating the Non-interest income to total income ratio is as follows:

$$DIV_{NIOIR} = \frac{Operating\,Income - Interest\,Income}{Operating\,Income}$$

Operating income of banks and credit unions can easily separate into two major elements: interest income and non interesting income. When non-interest income arises, that means this organization take more actions on diversification.

Other Variables

We put ten variables in our panel threshold regression model in order to analyze the relationship between other variables and the dependent variables. Those variables are collected from the annual financial reports of banks and credit unions in Taiwan. And the ten other variables are: overdue loan rate(OLR), liability to net value ratio(LN), loan growth

ratio(LGR), operating expense to operating income ratio(EIR), equity to asset ratio(EAR), branch number(BN), asset scale(AS), allowance for uncollectible accounts to overdue loan ratio(AOR), capital ratio(CR), and loan ratio(LR).

Empirical Model

When defined all of the variables, we construct the panel threshold regression model as bellow equation:

$$ROE_{it} = \mu_i + \beta_1 DIV_{it-1} I(DIV_{it-1} \le \gamma_1) + \beta_2 DIV_{it-1} I(DIV_{it-1} > \gamma_1) + \theta_1 OLR_{it-1} + \theta_2 LNR_{it-1} + \theta_3 LGR_{it-1} + \theta_4 EIR_{it-1} + \theta_5 LR_{it-1} + e_{it-1} \quad (2.9)$$

$$Z_{it} = \mu_i + \beta_3 DIV_{it-1} I(DIV_{it-1} \le \gamma_2) + \beta_4 DIV_{it-1} I(DIV_{it-1} > \gamma_2) + \theta_6 BN_{it-1} + \theta_7 AS_{it-1} + \theta_8 OLR_{it-1} + \theta_9 LNR_{it-1} + \theta_{10} AOR_{it-1} + \theta_{11} CR_{it-1} + e_{it-1} \quad (2.10)$$

The DIV variable here can be DIV_{HHI} and DIV_{NIOIR} respectively. When the primary models are constructed, we use GAUSS program and use the bootstrap 300 times, in order to get the F-Statistics and p-value. If the p-value is less than 5%, we continue to do the double threshold test. The models are as follows:

$$ROE_{it} = \mu_i + \beta_1 DIV_{it-1} I(DIV_{it-1} \le \gamma_1) + \beta_2 DIV_{it-1} I(\gamma_1 < DIV_{it-1} \le \gamma_3) + \beta_3 DIV_{it-1} I(\gamma_3 < DIV_{it-1}) + \theta_1 OLR_{it-1} + \theta_2 LNR_{it-1} + \theta_3 LGR_{it-1} + \theta_4 EIR_{it-1} + \theta_5 LR_{it-1} + e_{it-1} \quad (2.11)$$

$$Z_{it} = \mu_i + \beta_3 DIV_{it-1} I(DIV_{it-1} \le \gamma_2) + \beta_4 DIV_{it-1} I(\gamma_2 < DIV_{it-1} \le \gamma_4) + \beta_3 DIV_{it-1} I(\gamma_4 < DIV_{it-1}) + \theta_6 BN_{it-1} + \theta_7 AS_{it-1} + \theta_8 OLR_{it-1} + \theta_9 LNR_{it-1} + \theta_{10} AOR_{it-1} + \theta_{11} CR_{it-1} + e_{it-1} \quad (2.12)$$

EMPIRICAL RESULTS

We must examine the number of threshold for equation (2.9) and (2.10) to check if banks and credit unions do diversification could bring what influence to their financial performances and risks. If the single threshold effect exists, we continue to examine equation (2.11) and (2.12) to find the double threshold effect. We have two dependent variables-RAR_{ROE}, Z-score; two diversification variables-DIV_{HHI}, DIV_{NIOIR}. So there will be four threshold testing combinations: (1) RAR_{ROE}, DIV_{HHI}; (2) RAR_{ROE}, DIV_{NIOIR}; (3) Z-score, DIV_{HHI}; (4) Z-score, DIV_{NIOIR}.

Table 1, 2, 3, 4 show the results and the bootstrapped critical values for single, double, and triple threshold effects for the four threshold testing combinations respectively. Through 300

bootstrap replications for each of three bootstrap tests, we find the tests for single threshold F_1 almost all are significant with bootstrap p-value0.0200, 0.0133, 0.1400, and 0.0467. The tests for double threshold F_2 are all statistically significant with p-value of 0.0300, 0.004, 0.0033, and 0.0400. And the tests for a triple threshold F_3 are insignificant with p-value of 0.9033, 0.9267, 0.9667, and 0.9833. Statistics F_1 and F_2 exceed the critical values at the 5% significant level, but is smaller than the critical value at the 10% significant level.

As can be seen, the threshold model (2.9) and (2.10) have three regimes, suggesting the possibility of two thresholds. We next examine the threshold values after confirming the threshold effect. Table 5, 6, 7, and 8 show the estimated two threshold values for the four threshold testing combinations respectively. These minor confidence intervals show the efficiency of estimation. Hence, there are three regimes in this case. These three regimes are

referred to as low, middle, and high if their DIV_{HHI} or DIV_{NIOIR} fall below γ_1, within the ranges γ_1-γ_2, and exceed γ_2, respectively. These show the location of the threshold values and their 95% confidence interval by computing the LR test mentioned above. According to the threshold test results our double threshold regression model from the model can be expressed as model (2.11) and (2.12).

CONCLUSION

Within this study, we can learn the trend of diversification of banks and credit unions

throughout the years, both of these two types of financial organizations enhance their degree of diversification. That means they do more non-interest income activities to earn more of their operating income. That is why the two diversification ratios, DIV_{HHI} and DIV_{NIOIR}, are increasing.

The panel threshold regression model can find the relationships of variables under different regimes and efficiently estimate results powerfully, by using the bootstrapping technique. After running the Panel Threshold Regression Model, we can clearly know when banks and credit unions in Taiwan do diversification, then that would definitely influence their financial performance and risk. Here we use RAR_{ROE} to be the performance variable and Z-score, risk variable. Because the single and double threshold tests are both significant, there are three regimes of banks and credit unions' diversification level. Under certain level, that would come out different influence to their financial performance and insolvent risk. So making decisions of doing diversifications becomes a very important idea for management of banks and credit unions.

The findings can help researchers to understand that different types of financial institutions may optimally choose different degrees of diversification, which sheds some light on the inconsistent findings in the literature regarding the relationship between diversification and firm values. And for banks and credit unions, they can evaluate their conditions to meet the exact one in our research, then, decide what degree of diversification they can do to enhance their performance and reduce risks.

Off-balance Sheet Activities and Bank Efficiencies: The Three-Stage Data Envelopment Analysis with Undesirable Outputs

Chuang-Min Chao, National Taipei University of Technology, Taiwan
Tsui-Chu Chang, National Taipei University of Technology, Taiwan
tsuichu@hotmail.com

ABSTRACT

This study evaluates bank efficiencies in Taiwan using the three-stage DEA proposed by Fried, Lovell, Schmidt and Yaisawarng(2002), and accounts for the impact of the OBS activities on bank efficiencies. In the first stage, the slack-based DEA with undesirable outputs is applied to obtain the initial efficiency. In the second stage, the stochastic frontier approach is used and the stage 1 slacks are regressed against a set of environmental variables and statistical noise. In the third stage, the inputs and outputs are adjusted to account for the environmental effects and the statistical noise identified in the second stage, and the stage 1 model is used again to re-evaluate bank efficiencies. The data consists of 36 banks for the three-year period from 2005 to 2007 in Taiwan. The results demonstrated that the main influence of environmental factors on efficiency is macroeconomic variables. Besides, after purging the environmental effects and statistic noise, the efficiency of banks in the third stage is significantly greater than in the first stage.

Keywords: Efficiency, Off-balance sheet activities, Three-stage data envelopment analysis, Undesirable output

INTRODUCTION

In recent years, the financial deregulation and innovation have changed the product mix of banks. Banks are active in developing new forms of financial products like the off-balance sheet (OBS) activities. During 2002 to 2007, the nominal value of the OBS activities expanded rapidly in Taiwan, with an increase of nearly 246%. As a result, the non-interest income, of which a large portion is from the fee-based the OBS activities, has increased from 16% in 2002 to 22% of the total income in 2007(Table 1). It indicates that the OBS activities play an important role in the banking operations. Thus, it is important to include these activities in the evaluation of the bank efficiencies.

Previous researches regarding the evaluation of the bank efficiencies seldom take the OBS activities into account. Recent studies using data envelopment analysis (DEA) or stochastic

Table 1

The nominal value of the OBS activities and the ratio of non-interest income to total income

Year	The nominal value of the OBS activities	The ration of non-interest income to total income (%)
2002	2,939,564	16.15%
2003	3,663,615	23.86%
2004	6,259,222	26.43%
2005	6,623,675	22.76%
2006	8,910,494	19.36%
2007	10,183,951	22.41%

Notes: The nominal value of the OBS activities are the aggregate of loan commitments, guarantees, letter of credit issued, and liabilities trusted. The unit of the OBS activities are in NT$ million.

frontier approaches (SFA) begin to include either non-interest income (Roger, 1998; Drake, 2001; Tortosa-Ausina, 2003) or the OBS items (Isik and Hassan, 2003; Casu and Girardone, 2005; Liu, Yeh, and Chiu, 2005) as additional output factors. Additionally, other studies(Clark and Siems, 2002; Isik and Hassan, 2003; Liu, et al., 2005) argue that omitting the OBS activities in the estimation of bank efficiencies may result in under-estimating the actual bank outputs, which may lead to biased conclusions. Therefore, this study is going to take the OBS activities into account when evaluating the efficiency of banks.

The purpose of this study is to evaluate bank efficiencies in Taiwan using the three-stage DEA proposed by Fried, Lovell, Schmidt and Yaisawarng(2002), and to account for the impact of the OBS activities on bank efficiencies. The OBS activities, such as the fee-based services, guarantees, commitments, and derivative securities, can earn the non-interest income for banks on the one hand, but may increase the operational risk on the other hand. Banks want to make more profit but to avoid risks. Therefore, we divide the outputs into the desirable outputs and the undesirable outputs. The revenue contribution of the OBS activities is defined as the desirable output, which is proxied by the non-interest income. While the risk side of the OBS activities is defined as the undesirable output, which is proxied by the nominal value of the OBS activities. Additionally, a lot of researches relating to the efficiency of financial institutions (Chang, 1999; Park and Weber, 2006; Chen, Yu, Chang, and Hsu, 2007) treat non-performing loans as the undesirable output. Non-performing loans are an undesirable by-product of the loan production process, and they are unavoidable. Thus, non-performing loans are also the undesirable output in this study.

The contribution of this study is as follows. First, no previous researches have divided the OBS activities into desirable output and undesirable output. Second, according to the literature of the three-stage DEA, no one use the slack-based DEA with undesirable outputs in the first and third stage of the three-stage DEA. In this study, the three-stage DEA is applied to purge the environmental factors and statistical noise, and this study also divides the OBS activities into the desirable output and undesirable output.

The rest of the paper is organized as follows: Section 2 reviews the relevant literature. Section 3 outlines the methodology of the three-stage DEA, and introduces the model this study used. Section 4 presents data and variables. Section 5 discusses the empirical results, and Section 6 concludes the study.

LITERATURE REVIEW

The impact of the OBS activities on the bank efficiencies

The OBS activities, such as the fee-based services, guarantees, commitments, and derivative securities, are contingent assets and liabilities, which remain only in the notes to financial statements. Although the OBS activities are not make into a list of balance sheet, they will influence the cash flows of banks in the future. Therefore, recent studies think the OBS activities should be took into account when evaluating the efficiency of banks.

Clark and Siems (2002) employ the distribution free and stochastic frontier estimation methods to derive the cost and profit X-efficiency of banks, and investigate the impact of the OBS activities on the measurement of X-efficiency. They also examine the relationship between X-efficiency scores, bank size, and the composition of the OBS activities. The results indicate that the estimation of economic cost and production cost X-efficiency increase with the inclusion of the OBS measure, whereas the estimation of profit X-efficiency is largely unaffected. Further, the OBS activities can help to explain the differences between banks in the evaluation of cost and profit X-efficiency.

Isik and Hassan(2003) utilize DEA to measure Turkish bank' efficiencies fist, and then employ the Malmquist total factor productivity change index to examine productivity growth, efficiency change, and technical progress in Turkish commercial banks during the deregulation of financial markets in Turkey. They also investigate the influence of omitting the OBS activities on the efficiency of banks. The results show that the financial deregulation indeed improves the performance of Turkish banks, and productivity growth is mainly driven by efficiency increases rather than technical progress. The results also point out that

exclusion of the OBS activities may lead to biased conclusions, especially against the banks that are active in these non-traditional activities.

Liu, et al. (2005) adopt the stochastic cost frontier method to explore the impact of the OBS activities on the efficiency of Taiwan's banks during 1998 to 2001, and compare the cost inefficiency with or without the OBS activities. The results suggest that omitting the OBS activities result in under-estimating the cost efficiency. In addition, large banks have higher cost efficiencies, and have an ability to develop the OBS activities.

Casu and Girardone (2005) employ Malquist total factor productivity index to inspect the influence of the OBS activities in the definition of output on European banks' productivity. The results demonstrate that inclusion of the OBS activities increases the estimated productivity, and exclusion of the OBS activities may lead to under-estimate the productivity.

Pasiouras (2007) adopts DEA to estimate the efficiency of Greek commercial banks in the period of 2000 to 2004, and considers the effect of credit risk and the OBS activities. The loan loss provisions are as an extra input item to represent the credit risk of banks, and the OBS activities are as an additional output to explain the fact that banks are active in these non-traditional activities recently. This research also investigates the determinants of efficiency utilizing Tobit regression analysis. The results indicate that the loan loss provisions as an input increases the efficiency scores, but the OBS activities as an output do not have a significant impact. Additionally, capitalization, loan activity, market power and the number of branches have a positive and significant impact on efficiency.

To summarize, most of the studies investigates the impact of the OBS activities on banks' efficiency by adopting DEA or SFA. However, no previous researches have divided the OBS activities into the desirable output and the undesirable output. Therefore, this study divides the OBS activities into the desirable output and the undesirable output. The revenue contribution of the OBS activities is defined as the desirable output, which is proxied by the non-interest income. While the risk side of the OBS activities is defined as the undesirable output, which is proxied by the nominal value of the OBS activities.

The efficiency of financial institutions with the undesirable output

In the estimation of producers' performances, the earliest study which take undesirable outputs into account is Pittman (1983), and then Färe, Grosskopf, Lovell and Pasurka (1989) develop a non-linear DEA program to handle the situation that the desirable outputs are increased and the undesirable outputs are decreased.

Chang (1999) utilizes a non-parametric approach to incorporate risk into the measurement of technical efficiencies of the major financial intermediaries in rural Taiwan, and analyzes the relationship between risk and efficiency. Risk indicators are treated as undesirable outputs, including non-performing loans, allowance for loan losses, and risky assets. The results suggest that incorporating risk as an undesirable output has significant impact on the efficiency of credit departments of farmers' associations.

Park and Webber (2006) use directional technology distance function of 1992 to 2002, and the non-performing loans are treated as undesirable output. The results show that Korean banking industry experiences productivity growth which is mainly due to the fact that technical progress is more than enough to offset efficiency declines.

To summarize, in the study of evaluating the efficiency of financial institutions with the undesirable output, most studies treat non-performing loans as the undesirable output. Non-performing loans are an undesirable by-product of the loan production process, and they are unavoidable. However, no studies examine the effect of the OBS activities on the efficiency of financial institutions. Thus, non-performing loans and the risk side of the OBS activities are treated as the undesirable outputs in this study.

Three-stage DEA is used in estimation of financial institutions' efficiencies

Three-stage DEA is proposed by Fried, et al. (2002). They think the performance of producers is influenced by the environmental factors, managerial inefficiency, and statistical noise. Thus, in order to get the correct efficiency scores and ranking, the managerial inefficiency should be isolated from environmental factors and statistical noise.

Pastor (2002) adopts three-stage DEA to obtain the measurements of efficiency adjusted for risk and environment, and decomposes the bad loan into its two components: one part is caused by the bad risk management and another is caused by exogenous economic and environmental factors. The results suggest that about 80% of bad loan is due to internal factors of firms, while the rest is due to exogenous conditions of firms.

Drake, Hall, and Simper (2006) evaluate the technical efficiency of Hong Kong financial institutions during the period of 1995 to 2001 by using three-stage DEA. The results indicate that the Hong Kong banking industry is indeed affected by external factors, like macroeconomic and housing market factors.

Chen, Yu, Chang, and Hsu (2007) extend three-stage DEA proposed by Fried, et al. (2002) to

improve the measurement of productivity growth. The directional distance function with undesirable output is used in the first stage, and non-performing loans are treated as the undesirable output. In the second stage, SFA is adopted to regress the estimated output slacks against the environmental variables. After eliminating the influence of environmental factors and statistical noise, the Malmquist-Luenberger productivity index is applied to measure the productivity growth.

Chiu and Chen (2008) employ the three-stage DEA to estimate the efficiency of 29 banks in Taiwan during the period of 2002 to 2004. In the first stage, super slacks-based measure (SBM) is used to obtain the initial efficiency scores. SFA is then adopted to estimate the external environment risk effects in the second stage. Finally, in the third stage, they reuse the SBM model again to evaluate the efficiency which eliminates the effect of environmental factors. The results show that external environmental variables do influence the efficiency of domestic banks.

To sum up, in the previous studies of measuring the efficiency of the financial institutions by using the three-stage DEA, only Chen, et al. (2007) account for the undesirable output in their three-stage DEA model. Nevertheless, the model they used is the directional function with the undesirable output, while the model we used in the first and third stage is slack-based measure (SBM) with undesirable outputs proposed by Cooper, Seiford, and Tone (2007).

METHODOLOGY

The three stage DEA is employed to measure the efficiency of banks in Taiwan. In the first stage, the slack-based DEA with undesirable outputs is applied to obtain the initial efficiency. In the second stage, the stochastic frontier approach is used and the stage 1 slacks are regressed against a set of environmental variables and statistical noise. The goal is to purge the influence of environmental variables and statistical noise on the input and output slacks. In the third stage, the inputs and outputs are adjusted to account for the environmental effects and the statistical noise identified in the second stage, and the stage 1 model is used again to re-evaluate bank efficiencies.

In the first stage of the three-stage DEA

The model we used is proposed by Cooper, et al. (2007). They modify the slack-based measure (SBM) model proposed by Tone (2001) so as to account for the undesirable outputs.

$$\rho^* = \min \frac{1 - \frac{1}{m}\sum_{i=1}^{m} \frac{s_{io}^-}{x_{io}}}{1 + \frac{1}{s}\left[\sum_{r=1}^{s_1} \frac{s_r^g}{y_{ro}^g} + \sum_{r=1}^{s_2} \frac{s_r^b}{y_{ro}^b}\right]}$$

subject to

$$\begin{aligned} x_o &= X\lambda + s^- \\ y_o^g &= Y^g\lambda - s^g \\ y_o^b &= Y^b\lambda + s^b \\ L &\le e\lambda \le U \\ s^-, s^g, s^b, \lambda &\ge 0 \end{aligned} \tag{1}$$

Where λ is the intensity vector, and L and U are the lower and upper bounds of the intensity vector, respectively. The output matrix Y is decomposed into (Y^g, Y^b) where Y^g and Y^b denote good (desirable) and bad (undesirable) output matrices, respectively. The vector s^- and s^b correspond to excess in inputs and bad outputs, respectively, while s^g expresses shortage in good outputs.

In the second stage of the three-stage DEA

The dependent variable is the input and output slack obtained from the first stage, and the objective of this stage is to eliminate the influence of environmental variables and statistical noise on the input and output slacks.

$$\begin{aligned} S_{ij} &= f^i(Z_j;\beta^i) + v_{ij} + u_{ij} \\ S_{rj} &= f^r(Z_j;\beta^r) + v_{rj} + u_{rj} \\ i &= 1,2,...,m;\ r = 1,2,...,s;\ j = 1,2,...,n \end{aligned} \tag{2}$$

Where S_{ij} and S_{rj} are the *j*-th firm of *i*-th input and output slack, respectively. Z_j is the *k*-th environmental factors of the *j*-th firm, and β^i and β^r represent the estimated parameters. The v_{ij} and v_{rj} are error term which assume $v_{ij}, v_{rj} \sim N(0, \sigma_v^2)$, and independent of the u_{ij} and u_{rj} where they are nonnegative random variables accounting for managerial inefficiency which assume $u_{ij,}\, u_{rj} \sim N^+(u\ , \sigma_u^2)$.

$$X_{ij}^A = X_{ij} + [\max_j\{z_j\hat{\beta}^i\} - z_j\hat{\beta}^i] + [\max_j\{\hat{v}_{ij}\} - \hat{v}_{ij}] \tag{3}$$

$$Y_{rj}^{g,A} = Y_{rj}^g + [z_j\hat{\beta}^r - \min_j\{z_j\hat{\beta}^r\}] + [\hat{v}_{rj} - \min_j\{\hat{v}_{rj}\}] \tag{4}$$

$$Y_{rj}^{b,A} = Y_{rj}^{b} - [z_j\hat{\beta}^r - \min_j\{z_j\hat{\beta}^r\}] - [\hat{v}_{rj} - \min_j\{\hat{v}_{rj}\}] \quad (5)$$

After regressing against a set of environmental variables, the initial input and output have to be adjusted. The equation (3), (4), and (5) are used to adjust for the environmental effects and statistical noise. Where X_{ij}, Y_{rj}^{g}, and Y_{rj}^{b} are the initial input, desirable output and undesirable output, respectively. X_{ij}^{A}, $Y_{rj}^{g,A}$, and $Y_{rj}^{b,A}$ denote the adjusted input, desirable output, and undesirable output, respectively. The equation of $[\max_j\{z_j\hat{\beta}^i\} - z_j\hat{\beta}^i]$ and $[z_j\hat{\beta}^r - \min_j\{z_j\hat{\beta}^r\}]$ are in order to let producers in the same operating environment, and the equation of $[\max_j\{\hat{v}_{ij}\} - \hat{v}_{ij}]$ and $[\hat{v}_{rj} - \min_j\{\hat{v}_{rj}\}]$ are in order to let producers in the condition where is not affected by statistical noise.

In the third stage of the three-stage DEA

Stage 3 is a repetition of stage 1, with observed input (X_{ij}), desirable output (Y_{rj}^{g}), and undesirable output (Y_{rj}^{b}) replaced with adjusted input (X_{ij}^{A}), desirable output ($Y_{rj}^{g,A}$), and undesirable output ($Y_{rj}^{b,A}$), respectively. The input and output of this stage is eliminated from the effect of environmental factors and statistical noise, so the efficiency scores this stage obtained is got rid of the influence of the environmental factors and statistical noise.

EMPIRICAL RESULTS

DATA AND VARIABLES

The data used in this study consists of 36 banks for the three-year period from 2005 to 2007 in Taiwan. There are three inputs and five outputs. The input factors are interest expense and non-interest expense. The output factors include three desirable outputs (i.e., non-interest income, deposits and total loans) and two undesirable outputs (i.e., the nominal value of the OBS activities and the non-performing loans). Moreover, five environmental variables are employed in the second stage of the three-stage DEA, including the number of years that the bank has been operating, branches in city, economic growth rate, growth rate of money supply and unemployment rate. Drake, et al.(2006) point out that the primary external influence on efficiency in the Hong Kong banking industry is the macroeconomic cycle. Thus, we choose three macroeconomic variables in this study. Table 2 shows the description of variables.

In the first stage, initial input and output should be used to calculate the initial efficiency scores. Table 3 shows the summary statistics of efficiency scores in the fist stage for the period from 2005 to 2007. The efficiency scores obtained from the first stage is not adjusted

Table 2

The description of variables

Symbol	Variable	Definition	Unit
Inputs			
X1	Non-interest expense(NIE)	Operating cost–interest expense	NT$ hundred millions
X2	Interest expense(IE)		NT$ hundred millions
Desirable outputs			
Y1	Non-interest income(NII)	Operating revenue–interest income	NT$ hundred millions
Y2	Deposits(DE)	Checking deposit, demand deposit, time deposit, and negotiable certificates of deposit	NT$ hundred millions
Y3	Total loans(TL)	Short-term loans and long-term loans	NT$ hundred millions
Undesirable outputs			
B1	The nominal value of the OBS activities(OBS)	loan commitments, guarantees, letter of credit issued, and liabilities trusted	NT$ hundred millions
B2	Non-performing loans(NPL)		NT$ hundred millions
Environmental variables			
Z1	the number of years that the bank has been operating (YEAR)	The number of years that the bank was established to the end of 2007	
Z2	branches in city (CITYBR)	The number of branches in Taipei and Kaohsiung in Taiwan.	
Z3	economic growth rate (EGR)		%
Z4	growth rate of money supply(M2)		%
Z5	unemployment rate (UR)		%

by the environmental factors and statistical noise. The average of efficiency scores in 2005, 2006, and 2007 are 0.747, 0.61, and 0.572, respectively. The standard deviations of efficiency scores in 2005, 2006, and 2007 are 0.285, 0.352, and 0.371, respectively.

In the second stage, input and output slacks should regress against a set of environmental variables. Table 4 shows the stochastic frontier estimation results in the second stage. The number of years that the bank has been operating has a negative and significant impact on the non-interest expense slacks and the total loan slacks. The branches in city is significantly and

slack. The results also indicate that the main influence of environmental factors on efficiency is macroeconomic variable, and this is consistent with Drake, et al. (2006).

After regressing the input and output slacks against the environmental variables, the input and output are adjusted for the influence of environmental variables and statistical noise. The efficiency obtain from the third stage is eliminated from environmental variables and statistical noise. Table 5 shows the comparison of stage 1 and stage 3. After adjusting for the influence of environmental factors and statistical noise, the mean efficiency scores increase. This study utilizes Wilcoxon signed ranks test to investigate the differences between the stage 1 and the stage 3, and the results is also presented in Table 5. According to the Table 5, it is found that there is a significant difference between efficiency scores of the first stage and the third stage under the significant level of 0.05. It means that after purging the environmental effects and statistic noise, the efficiency of banks in the third stage is significantly greater than in the first stage.

CONCLUSION

In this article, we use three-stage DEA propose by Fried, et al. (2002) to measure the efficiency of banks in Taiwan, and account for the impact of the OBS activities on bank efficiencies. In the first stage, the slack-based DEA with undesirable outputs is applied to obtain the initial efficiency. In the second stage, the stochastic frontier approach is used and the stage 1 slacks are regressed against a set of environmental variables and statistical noise. In the third stage, the inputs and outputs are adjusted to account for the environmental effects and the statistical noise identified in the second stage, and the stage 1 model is used again to re-evaluate bank efficiencies. The data consists of 36 banks for the three-year period from 2005 to 2007 in Taiwan.

The results demonstrated that the main influence of environmental factors on efficiency is macroeconomic variable. Besides, after purging the environmental effects and statistic noise, the efficiency of banks in the third stage is significantly greater than in the first stage.

A STUDYING OF MEASURING THE E-SERVICE QUALITY OF ONLINE HUMAN RESOURCE AGENCY

Qinan K. Y. Lin, Dr. Bruce C. T. Ho
Institute of electronic commerce, National Chung-Hsing University, Taiwan
Qinan624@gmail.com

ABSTRACT

Research Background –
The Internet has significantly expanded the definition of e-commerce. Recently, the development of online Human Resource (HR) agencies attracts extensive attention in Taiwan. Through still in the infancy, the usage of job searching shows great potential for improving the overall effectiveness of online HR agencies.

Research Purpose –
The age of e-commerce opens numerous possibilities that will extend the understanding of electronic service quality. Beginning in the 2000s, researchers studying service quality began to shift the primary focus of research from the physical dimensions of customer service to the virtual dimensions of electronic service. This paper aims to develop a scale that could be used to measure the service quality of online HR agency and to understand the underlying service quality dimensions.

Design/Methodology/Approach –
The main data collection instrument used in this study was questionnaire. A survey based on website was conducted to test our model. The data was collected from users of online HR websites in Taiwan. The questionnaire extended items to assess the service quality of online HR agency by referring to the e-service quality scale and modified its items. The questionnaire comprises two sections. The first section gathers information from the users' perception of the service quality of online HR agency services. The second section collects information including the respondents' gender, age, education, occupation, time spent online, and frequency of using online HR agency.

Findings/Results –
Within the internet environment, service quality dimensions are different from the physical environment. Therefore, we adapted an e-service quality model in this study as the foundation. Such a theory is only the starting point, requiring explanation in terms of cause and effect. In this paper, we validated that online HR agency can be analyzed by a five-dimension service quality constructs involve efficiency, system availability, privacy, personalization, and responsiveness. These research results underscore the importance of electronic service quality.

Originality/value–
In the last decade of electronic commerce development, we have seen mounting evidence of the usefulness of website designers' incorporating strategies into their website building process. However, theories need to be tied to empirical operations and empirical data. In this paper, the service quality of the online HR agency in Taiwan was measured by an integrated framework. The method was proved more suitable than the previous studies that based on the traditional service quality model. Such an examination may lead to a better understanding of variables that affect CRM performance.

Keywords: e-service quality, online HR agency, B2C website

ABSTRACT

Due to the rapid advanced information technology and the complicated business environment, firms are facing more and more competitive situations. To overcome this issue, companies try to create new products to stay competitive advantage. This study aims to explore the effects of projects' social capital, leadership style, modularity and diversification on new product development (NPD) performance. Therefore, the research objectives of this study are (1) to develop a comprehensive research framework to integrate the social capital, project leadership style, modularity, team member diversification, and NPD performance; (2) to identify the interrelationships between social capital, project leadership style, modularity level, and team member diversification on NPD performance; (3) to investigate the different level of social capital and project leadership style on NPD performance; and (4) to investigate the different level of modularity and team member diversification on NPD performance.

Using the 500 senior leaders of NPD teams from different manufacturing firms in Taiwan, this study concludes the following five conclusions, (1) higher level participating style of leadership and higher level of social capital generate better NPD performance, (2) higher level of selling leadership style and social capital create better NPD performance, (3) higher level of telling leadership style and social capital facilitate better performance in design change frequency and innovation, (4) higher level of delegating leadership style and social capital enhance better performance in product prototype development and launch proficiency, technological core competency, and innovation level, and (5) higher level of modular of new product leads to better NPD performance. Managerial implications are also illustrated.

Keywords: NPD performance, modularity, leadership style, social capital, project team diversity

RESEARCH BACKGROUND AND MOTIVATIONS

In the dynamic business environment, firm should efficiently innovate new product or new process to fit market demand. In many cases, new product is a direct result of firm innovation. Higgins (1995) contends that innovation will create extreme values towards the organizations and can be regarded as a secret weapon for firms to acquire competitive advantage. Although new product development (NPD) seems to be the only choice for firms to become competitive, it is a risky work. Cooper and Kleinschmidt (1987) estimate that failure rate of the new product is about 75%. Gallo (1992) further argues that, in the grocery industry, the

failure rate for new product is estimated to be 80 to 95 percent. Thus, the NPD process is difficult because there is less synergy between the needs of the project and the firm's existing skills and resource base. In addition, there is a high degree of uncertainty concerning customers' needs and competitor's actions.

In the process of creating new product, several key issues are essential. These include project leader's leadership styles and skills, organizational culture, team member readiness and experience in NPD, team's relationship with other units, etc. In addition, NPD team members with different backgrounds could agitate different idea and may consequently increase the probability of success. Furthermore, according Yli-Renko et al. (2001), social capital can accelerate the probability of NPD success through increasing the freedom of knowledge-sharing. It can agitate different ideas through members' interaction. Finally, as the needs for firms to be able to deliver high quality products at low cost has long been recognized, many companies have adopted modular architecture instead of integrated architecture to achieve rapidly response. The needs of consumer have also become more diversity. New product adopts modular architecture which component could partial upgrade, maintain, repair, and disposal to exchange different function and form for diversity needs (Nevins and Whitney,1989).

Although there are plenty of studies argues for the importance of project leadership, social capital, modularity, and team member diversities for NPD performance. However, none of these studies have tried to integrate these variables together and identified the interaction effects of these variables on NPD performance. Based upon the above research background and motivations, the research objectives of this study are to firstly develop a comprehensive research framework to integrate the influences of social capital, project leadership style, modularity levels, and team member diversity on NPD performance. This study also aims to test the research framework through empirical data.

LITERATURE REVIEW AND HYPOTHESES DEVELOPMENT

The Influences of Social Capital and Project Leadership Styles on NPD Performance

According to Bardach (2001), "Leadership is a means for diagnosing and implementing improvements in the operating subsystem of the Inter-organizational collaborative capacity, inducing resource contribution, nurturing an ethos of interpersonal trust and organizational pragmatism". Farris (1988) suggests that true leadership involves much more than effectively managing a group performing a task.

In the NPD team, leader is a key role in the team. He/she uses the knowledge, leadership, empathy, and ability to persuade followers to devote all themselves for achieving goals. Optimal leadership in a NPD team should not only encourage team members to work under diversity of member expertise, limited resources and time pressure but also have competences to handle both technical issues and behavior issues. Based on the above discussions, this study suggests that leadership style has a significant impact on NPD performance. The following hypothesis is proposed:

H1: Team leader's leadership style has significant effect on NPD performance.

Social capital is a set of social resources embedded in relationship (e.g., Burt, 1992; Loury, 1997). Some scholars have brought up social capital to facilitate inter-unit resource exchange, product innovation (Gabbay and Zuckerman, 1998; Hansen, 1999; Tsai and Ghoshal, 1998; Nahapiet and Ghoshal, 1998) and cross-functional team effectiveness (Rosenthal, 1996). This

study tries to view social capital from the perspectives of relational and informational flow. In the process of new product development, the project team requires a great deal of multiple information sources. Social interactions among team members who are strongly tied to each other are likely to develop a shared understanding of the utility of certain behavior. In a highly social capital environment, team members could share different knowledge, emotion, value, and information by formal or informal interaction. According to Laumann, Galaskiewicz, and Marsden (1978), network position is like a set of nodes (e.g., persons, organizations) linked by a set of social relationships (e.g., friendship, overlapping membership) of a specified type. If NPD project team stands on a core network position, this project team is able to interact with outsiders to get more information. In the process of new product development, the NPD team should integrate many factors such as different objects, knowledge, information, team member skills, etc. to create a successful new product. Based on the above discussion, the following hypothesis is developed:

H2: Social capital of the NPD team has significant effect on NPD performance

According to the contingency approach of leadership, an effective leadership style should be contingent upon several environmental factors. ……..???

H3: There is an interaction effect of project leadership style and social capital on NPD performance. NPD team having a higher transformational leadership approach and a higher level of social capital tends to achieve significantly higher NPD performance.

The Influences of Modularity Level and Team Member Diversity on NPD Performance

Modularity refers to "the degree to which a system's components can be separated and recombined" (Schilling, 2000). New products with higher levels of modularity mean that the component could independently operate without affecting others. Product modularity is the practice of using standardized product modules so they can be easily reassembled/ rearranged into different functional forms, or shared across different product lines. Since NPD project team needs to integrate many detailed processes to efficiently create value, it could be very complicate if the products need to be modified to fit the changes of customer needs. The change of one component or feature may require extensive redesign of the product. Therefore, the application of module concept can be very helpful to save a lot of cross functional communication, coordination and simplify the NPD process. Besides, product prototype uses modular design that taking individual blocks inlay in the new product will largely increase product variety for diversity consumer and can achieve economies of scale to reduce the cost of production. Based on these reasons, the following hypothesis is proposed:

H4: The levels of modularity that apply to the new product has significant effect on NPD performance

As mentioned earlier, information and knowledge are very important to promote new product development. In any NPD project, it needs multiple source of information to create value of the new product. NPD project member diversification will intensify different ideas, cognitions, and views to develop new product. Appropriate diversification is helpful for NPD team. In light of these reasons, the following hypothesis is proposed:

H5: Team member diversification has significant effect on NPD performance

As previous section, this study believes that team member diversification will accelerate modularity in NPD project because of multiple source of information or knowledge. This study believes that the interaction of team member diversification and the application of modularity will accelerate NPD performance. So, the following hypothesis is proposed:

H6: There is a significant interaction effect of NPD team member diversification and modularity on NPD performance.

RESEARCH DESIGN AND METHODOLOGY

Research Framework

Based on the above literature and hypothesis development, a research framework including five major constructs and their corresponding interrelationships is developed as shown in Figure 1. This research framework is used for further empirical validations in the later sections.

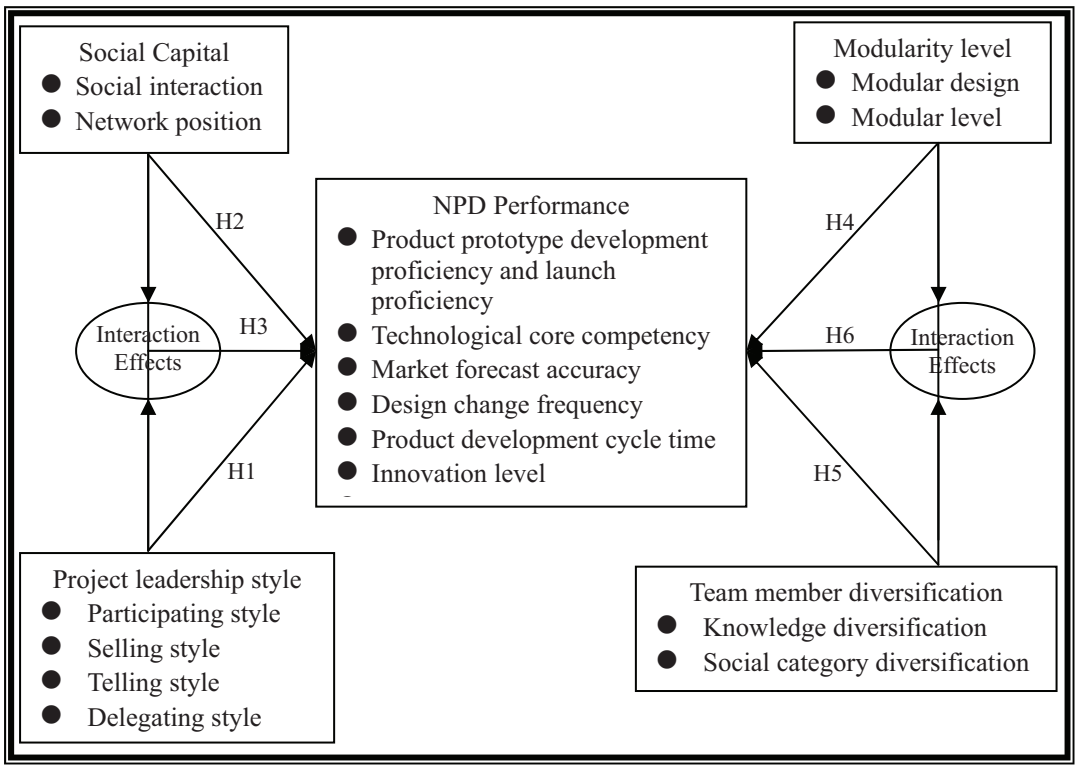

Figure 1 The Research Model

Questionnaire Design and Sampling Plan

There are five constructs to be measured in this study: (1) project leadership style; (2) social capital; (3) NPD performance; (4) modularity level; and (5) team member diversification. A preliminary version of this questionnaire is adopted from previous studies with some modifications based on the specific requirements of this study. Inter-judge reliability is conducted through the judges of one professor and two Ph.D. students major in marketing. Questionnaire items with low inter-judge reliability (i.e., item with two of the three judges disagree with the content) were deleted from the questionnaire items.

A sampling plan is developed to ensure that certain types of respondents are included in this study. This study selects 500 senior leaders of NPD teams from different manufacturing companies in Taiwan. The sampling frame is obtained from "The manager directory in Taiwan (2006)" published by *China Credit Information Service Inc.* As this study chooses senior NPD leaders who have participated in a successful NPD project, they are highly likely

to be the most knowledgeable about the topics in the questionnaire. The respondents are asked to express their perceptions on NPD performance, social capital, team member diversification, modularity level, and project leadership styles based on a specific NPD project that they participated. SPSS 13.0 is employed to analyze the data and to test the hypotheses.

RESULTS AND DISCUSSION

Descriptive Analysis

Descriptive analyses are conducted to provide information about the characteristics of respondents. Table 1 shows the basic attributes of the sample firms. These attributes includes five major items in the study: (1) industry, (2) history, (3) capital, (4) annual sales, and (5) number of employees.

Table 1 Characteristics of Sample Firms (n=95)

Reliability of the Research Construct
Interrelationships between Research Variables

Effect of Project Leadership Style on NPD Performance

According to Sherman, Berkowitz, and Souder (2005), NPD performance can be measured by product prototype development and launch proficiency, technological core competency, market forecast accuracy, design change frequency, product development cycle time, and innovation level. Hersey, Blanchard, and Johnson (1996) suggest that project leadership style can be divided into participating, selling, telling, and delegating style. In order to test hypothesis 1, regressions with ordinary least squares (OLS) estimation method are employed on the full sample data. Table 2 presents the results of the regression using six factors of NPD performance as the dependent variables. The regression results suggest that, product prototype development (regression model M1-1) and launch proficiency is significantly influenced by participating style (β=0.388, $p<0.05$) and delegating type (β=0.166, $P<0.05$).

Table 2 Effect of Project Leadership Style on NPD Performance

Dependent Variable / Independent Variable	Product prototype development and launch proficiency (npdf1)	Technological core competency (npdf2)	Market forecast accuracy (npdf3)	Design change frequency (npdf4)	Product development cycle time (npdf5)	Innovation level (inf)
	M1-1	M1-2	M1-3	M1-4	M1-5	M1-6
Participating style (lsf1)	0.388***	0.3**	0.153	-0.165	.309**	0.166
Selling type (lsf2)	0.131	0.225*	0.180	0.069	0.054	0.071
Telling type (lsf3)	0.094	-0.089	-0.055	***-.404	0.075	.207**
Delegating type (lsf4)	0.166*	0.019	-0.019	0.066	0.030	0.075
R^2	0.289	0.251	0.099	0.165	0.126	0.098
Adj-R^2	0.258	0.217	0.059	0.128	0.087	0.058
F	9.163	7.527	2.462	4.443	3.230	2.452
D-W	2.111	2.117	1.485	1.874	1.781	2.015

In addition, technological core competency (regression model M1-2) is significantly influenced by participating style (β=0.300, P<0.01), and selling style (β=0.225, P<0.001,). The significantly positive coefficients indicate that the levels of participating style and selling style all contribute to the level of technological core competency. Furthermore, none of the independent variables has a significant influence on market forecast accuracy (regression model M1-3) as shown in Table 1. The design change frequency (regression model M1-4) is significantly influenced by telling style (β=-0.404, P<0.01). This result may suggest that a telling leadership approach will result in less design change frequency from product prototype development to volume production. The product development cycle time (regression model 1-5) is significantly influenced by participating style (β=0.309, P<0.01). The significantly positive coefficients indicate that the levels of participating leadership contributes to the level of product prototype development cycle time. Finally, innovation level (regression model M1-6) is significantly influenced by telling style M1-6 (β=0.207, P<0.05) The significantly positive coefficients indicate that the levels of telling style contribute to the innovation level. Based on these, hypothesis H1 is partial supported.

The Effects of Modularity Level on NPD Performance

Table 3 presents the effects of the modularity level on NPD performance, it is suggested that NPD performance is significantly influenced by modular design and modular level. The significantly positive regression coefficients indicate that degree of modular design and modular level can contribute to the factors of NPD performance. The results indicate that both modular design and modular level have significant influences on product prototype development and launch proficiency (β=0.226-0.229, p<0.05), and product development cycle time (β=o.211-0.260, p<0.05). Modular level is positively related to market forecast accuracy (β=0.186, p<0.05) and innovation level (β=0.239, p<0.05), but negatively related to design change frequency (β=-0.315, p<0.05). Therefore, hypothesis 4 is supported.

Table 3 The Effects of Modularity Level on NPD Performance

Dependent Variable / Independent Variable	Product prototype development and launch proficiency (npdf1)	Technological core competency (npdf2)	Market forecast accuracy (npdf3)	Design change frequency (npdf4)	Product development cycle time (npdf5)	Innovation level (inf)
	M2-1	M2-2	M2-3	M2-4	M2-5	M2-6
Modular design(mlf1)	.229**	.357***	0.176	0.050	.26**	-0.095

R^2	0.145	0.116	0.092	0.090	0.155	0.048
Adj-R^2	0.126	0.096	0.072	0.070	0.137	0.028
F	7.774	6.015	4.649	4.522	8.442	2.339
D-W	2.048	1.886	1.600	1.657	1.930	1.905

Effect of Social Capital on NPD Performance

Table 4 presents the results of regressions of NPD performance, while using all six factors of NPD performance as the dependent variables. The results indicate that social interaction (scf1) is positively related to product prototype development and launch proficiency, technological core competency (β=0.387, $p<0.05$) and market forecast accuracy (β=0.368, $p<0.05$), while network position (scf2) is positively related to product prototype development and launch proficiency (β=0.312, $p<0.05$), product development cycle time (β=0.228, $p<0.05$) and innovation level (β=0.37, $p<0.05$), but negatively related to design change frequency (β=-0.368, $p<0.05$).

Table 4 Effect of Social Capital on NPD Performance

Effect of Team Member Diversification on NPD Performance

Table 5 presents the influences of NPD team diversification on NPD performance. The results indicate that for all six regression models, both knowledge diversification and social category diversification do not have significant impacts on the factors of NPD performance, including product prototype development and launch proficiency, technological core competency, market forecast accuracy, design change frequency, product development cycle time and

innovation level. Since previous studies have shown a significant relationship between teams member diversifications and NPD performance, this issue may be subject to further validations.

CONCLUSION AND SUGGESTION

The major objective of this study is to identify the interrelationships among social capital, leadership style, modularity, and team member diversification on NPD performance. Based on the results of this study several conclusions and implications based on these conclusions are drawn.

The first conclusion is that higher level participating style of leadership and higher level of social capital will bring better NPD performance. That means NPD leaders who adopt participative leadership style will result better performance in product prototype development and launch proficiency, technological core competency, market forecast accuracy, cycle time, and innovation if the NPD members are willing to interact with other members. Participating style has no effect on reducing product design change from product prototype to volume production. It's possible that participating leadership style let members to heavily participate project goals, it inevitable will face divergence in opinions. When members have divergence in opinions, it could result product design continuously change to fit different opinions of the team members. It is suggested that NPD leaders should try to enhance member interactions and share multiple sources of information in NPD project. These results are consistent with Nieto, Shim and Lee (2001) who conclude that project leaders differ not only in the general level of influence but also in how to mix various influence tactics, in the R&D project, leader adopts relational behaviors will get higher output.
The second conclusion is that higher level selling style of leadership and higher level of social capital will lead to better NPD performance. But, selling leadership style seems do not influence significantly the design change frequency and product development cycle time. It is suggested that when followers have no ability and willingness, the leader should adopt selling leadership. At that same time, leader should increase followers formally or informally to interact and share multiple source of information in NPD project to get higher NPD performance. These results are consistent with Sashittal (1998) and Olson et al. (2001).

The third conclusion is that higher level of telling leadership style and higher level of social capital will bring better performance in design change frequency and innovation. But it seems that more telling style will lead to bad performance in product prototype development and launch proficiency, technological core competency. Hersey, Blanchard, and Johnson (1996) suggest that, when the followers are unwilling and not capable to work, the project leader should use telling leadership style to lead project members to get better performance. Base on these results, project leaders adopting higher telling leadership style in NPD project may cause staff's bad feeling, and result in bad performance in product prototype development and proficiency and technological core competency. In the process of innovation, telling leadership style has significant effect on NPD performance, but the explain variance is small. It's possible that there are other factors that have been neglected from the model. In fact, there are many factors that will effect innovation. In the process from prototype design to volume production, the multiple source of information can make employees to make fewer mistakes and decrease the frequency of design change. These results are consistent with Howell and Higgins (1990) who state that leader adopts older of leadership to more closed-end project will lead more performance of new product development.

The fourth conclusion is that higher level delegating leadership style with higher level of social capital will bring better performance in product prototype development and launch proficiency, technological core competency, and innovation. Hersey, Blanchard, and Johnson (1996) suggest that when followers have ability and willingness to work, leaders should adopt delegating leadership style to followers. Leaders should increase social capital when they face the project members who are in the highest level of readiness. In the early stage of new product development, leader delegates authority to followers who have ability and willingness that will satisfy their achievement-oriented performance. These results are consistent with Sydow et al. (1998) who conclude that social capital on network processes and effectiveness will speed up NPD performance from structurationist perspective.

The fifth conclusion is that NPD adopting modular design will lead to higher performance on prototype product development and launch proficiency, technological core competency, market forecast accuracy, and product development cycle time. That means that NPD project leader could try to use modular design to development new product. If project team has some previous successful experience, project team may just change some modular to create really new product. Because of the past experience, project team will have better understanding of market to assure the forecast market and to reduce product cycle time. At the same time, the key to successful product modularization is product architecture, a scheme by which functional elements of a product are allocated to structurally independent physical components (Ulrich, 1995; Sanchez, 2000). In the process of designing product architecture, project team members must know the core function of product that could acquire competency to reach diversity functional modules.

The last conclusion is that modular level of new product will lead to better NPD performance except for technological core competency. Potential benefits of modularity include: economies of scale, increased feasibility of product/component change, increase product variety, reduce order lead-time, decoupling tasks, and the ease of product upgrade, maintenance, repair, and disposal (Nevins and Whitney, 1989; Pahl and Beitz, 1988; Corbett *et al*., 1991). These results are consistent with Nieto and Phal and Beitz (1988), Chen and Liu (2004), Huang (2000) and et al. who conclude that modular architectural approach has been an important perspective in product innovation research. The manufacturing industry is

undergoing a major paradigm shift that is taking it from traditional manufacturing into a world of agile manufacturing. An agile corporation should be able to rationalize its manufacturing facilities and produce a large variety of products at lower cost in time. Designs of modular products and reconfigurable processes are crucial to agile manufacturing. Modular product design is becoming a focus and is frequently stated as a goal of good design practice in current engineering areas.

The study results can not confirm that team member diversification has significant effect on NPD performance. This study divides team diversification to two aspects: knowledge diversification and social category diversification. There are different results if we adopt different aspect. Team member characteristics, team cohesion, and environment will affect performance by member interaction (McGrath, 1964). In the process of team member interaction, characteristics of person and task interacts job and team characteristics, just consider personal characteristics is not enough (Salas, 1992). It should combine with task characteristics and personal characteristic. Team member diversification comes from different background, which generates different faith in team and may result many conflicts which reduce team performance (Wiersema and Bantel, 1992). Good and Nelson (1971) suggest that the same years of service have more chance to produce social interaction and team cohesion than diversiform seniority. In the diversification of background function, industry diversification and expertise diversification will have negative effect in communication of information (Smith, 1994).

Although the results of this study are fruitful and the results may contribute to the existing literature for further validation, several suggestions could be made for academicians and business practitioners.

First the model test is conducted in the manufacturing industry in Taiwan. Although this approach enables us to conduct an in-depth study and controls for a considerable amount of environmental ‘noise’ in an important industry, it might limit our ability to generalize our findings. Although this should be subject to further empirical verification, we do not see any a-priori reasons why the effects observed would be different in other industries.

Second, research may use experimental research to confirm the results of this study. For example, business simulations could be adopted to reflect a real environment, and to manipulate different situations of team members. Third, the response rate of this study is very low. This study collects sample data through mail survey. It takes time and efforts to get the answers from the respondents. However, for the respondents, they don’t have pressure to answer the questionnaires. For the future research, the reasonable response rate should be maintained to support the quality of the data.
Even though most of the framework and the relationships between variables have been proved to be significant, the comprehensive model using LISREL test seems to indicate that there are still plenty of rooms to revise and modify results of this analysis and further validation may be required.

Hersey, Blanchard, and Johnson (1996) brought up situational leadership model that a successful leadership style should consider the ability and willingness of followers. In this study, it suggests that further studies can measure the maturity of follower to fit leadership. Further studies should try to find the best leadership model amount leadership style, social capital, and follower’s maturity or characteristic on NPD performance.

Finally, in this study, team member diversification has no effect on NPD performance. This study sums up diversity value to represent diversification. It uses arithmetic average which assumes that different category has the same weight. Further study may find fair weight to show reasonable formula on behalf of team member diversification.

FOREIGN INVESTMENTS AND DEVELOPMENT OF LIFE INSURANCE COMPANIES. CASE OF POLAND.

Adam Sliwinski, Warsaw School of Economics, Poland
adamy@poczta.onet.pl

ABSTRACT

The main aim of this paper is to demonstrate the relationship between changes in the ownership structure and the development of life insurance companies in Poland. The simple regression model is used to reveal the relation. The findings of this study, that the solvency ratio, overall indebtedness ratio, premiums retention ratio and profitability ratio on technical activity and sales are positively related with the changes in the share of foreign capital and especially that the claims ratio is negatively related, suggest that foreign investments have greatly influenced the development of the life insurance industry in Poland during the transition period.

Key words: ownership structure, insurance, performance

BUSINESS PERFORMANCE IMPROVEMENT THROUGH MANAGING INTANGIBLE ASSETS

Chaichan Chareonsuk, Shinawatra University, Thailand and
Chuvej Chansa-ngavej*, Shinawatra University, Thailand
chuvej@shinawatra.ac.th

ABSTRACT

This paper aims to establish empirically the interrelationship of three elements of intangible assets: learning and growth, internal business process and external structure and the business performance. The cause-effect relationships between intangible assets and business performance were investigated in companies of various business sizes, business sectors and age of business establishment. A total of 3,084 questionnaires were distributed to the top management of member companies of the Thai Chamber of Commerce. Responded questionnaires were screened for completeness and reliability. The number of qualified responses were 304 and the data were analyzed using the Structural Equation Modeling technique.

The three elements of intangible assets were found to be independent. The type of business, i.e. non-service and service sectors, has not been found to yield significantly different result. However, the cause-effect relationship results of the business size and the age of business establishment are significantly different. Moreover, the commonly assumed cause-effect relationships were confirmed, i.e. the element of learning and growth has influence on internal business process, the element of internal process has effect on external structure and the element of external structure, in turn, has effect on business performance. It was also found that the element of internal process has direct effect on business performance as well.

These findings will enable top management in each size of business, business sector and age of its company to understand the cause-effect relationships and importance of elements of intangible assets (learning and growth, internal business process and external structure) and business performance. Now that the cause-effect relationships are positively identified, long-term strategies for intangible asset management may be formulated and recommended to management. Budget allocation and management can now be more properly focused and controlled to increase sustainable competitive advantage.

Keywords: Intangible assets, Balanced Scorecard, Business Performance, Structural Equation Modeling, business strategy

INTRODUCTION

The current economic crisis has spread over all business sectors. Some businesses have had to close down and gone bankrupt. Profit and loss are normally used as the main financial performance indicators in the balance sheet and annual financial reports. However, annual financial reports might not reflect and influence the crafting of long-term strategies. Financial profit alone could not guarantee the long term survival of companies under economic crisis and a drastically dynamic business environment.

The investment of tangible assets such as equipment, machineries, building, etc, is also recorded in the balance sheet. Whereas the cost of expenses in brand building, customer database, training, product development, information technology, etc, are usually treated as part of the operation cost and marketing expenses. This simple accounting record mechanism has no linkage with long-term strategies and budget allocation. Intangible assets have been widely studied during the last decade.

Intangible assets are defined as non-financial assets without physical substance that are held for use in the production or supply of goods or services or for rental to others, or for administrative purpose (Epstein and Mirza, 2005). Intangible asset is an accounting term, while intellectual capital is a term used in the management field. They both refer to the same thing. Since an increasing share of market value in this era is not represented by inventory or physical assets.

Investments in intangible assets are usually not documented in a proper and systematic manner because of data non-availability. Consequently, reasonable estimates of the future performance potential of an organization could not be provided to the management. It is intriguing to note that the cause-effect relationships between marketing, production and human resource and financial performance have not so far been made operational. Prior to the knowledge era, business lived in the world of tangibles, which worked well with the traditional accounting practices. However, things are different in today's world of intangibles. Modern management style and strategic crafting have adapted in response to global competition and volatile economic environment. The industrial age management has been replaced by the knowledge age leadership, with corresponding transformational effects on the economy and workplace. The focus on tangible assets in industrial age has made a paradigm shift to intangible assets in the knowledge age. As a consequence, issues concerning intangible assets are now more widely researched and practiced. Intangible assets are of increasing importance for the corporate value creation processes of all kinds of organization.

To be sustainable, companies need to understand and be able to manage intangible factors, including organizational learning and growth, internal process and external structure. The intangible assets are the competitive edge over competitors. Ittner (2008) suggested several previous studies provide at least some evidence that intangible asset measurement is associated with higher performance, however, many are limited by over-reliance on perceptual satisfaction or outcome variables, inadequate controls for contingency factors, simple variables for capturing complex measurement practices, and the lack of data implementation practice. In this paper, the balanced scorecard strategy map (Kaplan and Norton, 2004) is used to provide a framework to illustrate how strategy links intangible assets to value creating processes. The measures in the four perspectives are linked together by cause-effect relationships. The company builds the core competence and training to support the internal process. The internal process creates and delivers the customer value proposition. When the customers are satisfied, the sales and profit are delivered in terms of financial performance.

This paper explores the cause-effect relationship of intangible assets, learning and growth, internal process and external structure to business performance. The model is an attempt to refine and extend the balance scorecard strategy map. A total of 3,084 questionnaires have been distributed to the top management of the Thai Chamber of Commerce. The subjects are in various business size, business sector and age of business establishment. The questionnaire

responses were screened for completeness and reliability. The number of qualified responses was 304, which was the total number of responses used in the analysis. The Structural Equation Modeling technique was the analytical tool applied in this empirical investigation. The model fit testing process is illustrated in Figure 1. The initial step in the analysis of the data focuses on examining the frequency distribution and the meaning and standard deviation for each item or variable considered in this research. The next step in data analysis is to assess the validity of measures. Here the study uses item-total correlation, confirmatory factor analysis and the Cronbach alpha coefficient. The initial data analysis and reliability and correlation analyses are performed using the SPSS statistical package. Furthermore, the structural equation modeling EQS program (Bentler, 1995) is used to perform the confirmatory factor analysis, discriminant validity tests and testing of the structural model.

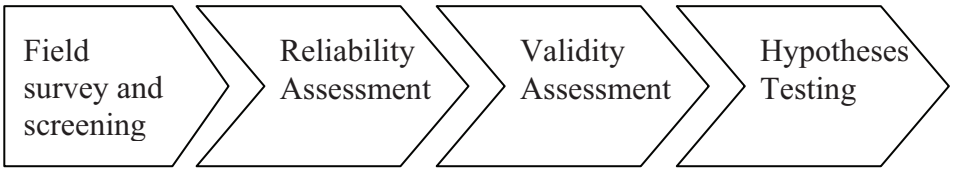

Figure 1. Model fit testing process

LITERATURE REVIEW

During the last two decade years, several studies, Kaplan and Norton (1992), Sveiby (1997), Edvinsson and Malone (1997) and Bontis (2000), have variously attempted to categorized intangible assets. There are common categories of intangible assets as follows:

- Customer/ External structure/Relation capital
- Internal process/ Structural capital
- Learning and growth/human capital/Competence structure

There are several intangible assets indicator in each intangible assets element. By using the categories developed by Hall (1993), Sveiby (1997), Roos et al. (1997) and Shaikh (2004) reviewed and classified the intangible assets into a framework of internal structure, external structure, and employee competence as shown in Table 1.

Table 1. Framework of Intellectual Capital/Intangible assets Indicators

External structure	Brands Customer loyalty Customer satisfaction
Internal structure **or** **Internal Process**	Process Improvement Innovation Information technology
Employee competence **or** **Learning and Growth**	Know-how knowledge Competencies Engagement

The balance scorecard is the most well-known approach that can be used for converting intangible assets into tangible outcomes although its original intent was not meant to be the measure for intangible assets, as discussed by Marr and Adams (2004) and Mouristen et al. (2005). Seggie et al. (2007) made an argument for the balanced scorecard to be the measurement tool in marketing to measure non-financial assets and provide the organization with a long-term perspective. The balance scorecard is at least partially forward-looking and partially geared toward the long-term performance of the firm. The balance scorecard concept has been examined the performance measurement of bonus plan in major financial services firm. Ittner et al. (2003) recommended that the future research on balance scorecard adoption and performance consequences must move to encompass the entire implementation process.

Kaplan and Norton (2004) developed the balance scorecard strategy map to explain the relation of learning and growth, internal process and customer perspective. The concept of cause-effect relationships separates the balanced scorecard from other performance management systems. The measures appearing on the scorecard should be linked together in a series of cause-effect relationships to tell the organization's strategic story. Increasing promotional expenses will lead to the increase in brand value. Increased brand value will lead to higher sales revenue. The investment of human capital will create the continuous learning and growth in the organization. When the employees have more experience and knowledge, they can create the internal process which serves and fulfills customer satisfaction. The profit and revenue are the final outcomes of this causal chain.

Heskett et al. (1994) explained the linkage of the above model that investment in employee training leads to improvement in service quality. Better service quality leads to higher customer satisfaction. Higher customer satisfaction leads to increased customer loyalty. Increased customer loyalty generates increased revenues and margins. There are linkages among learning and growth, internal process, customer, and financial performance. Olve et al. (1999) reported that Halifax applied the balance scorecard in business and found the relation that if we have the right staff, we will get "doing the right thing" and customers will be delighted. When the customers are delighted, we will get more business.

There are many functions involved in aligning the intangible assets with strategies. Each function has to build its own intangible assets in order to deliver and convert them to financial performance. Chareonsuk and Chansa-ngavej (2006) found that most of companies in the Stock-Exchange of Thailand have functional organization structure.

The intangible assets are linked to performance. The balanced scorecard has been widely used in formulating business strategy. Green and Ryan (2005) proposed the framework of intangible valuation areas for facilitating the systematic and repeatable identification of intangible assets balanced scorecard. It is designed to align the value drivers of intangible assets with its business strategy. Understanding the value of its intangible assets helps a business to develop, sustain and enhance its mission effectiveness and competitive advantage. Chareonsuk and Chansa-ngavej (2008) proposed the framework for intangible assets management in business and industrial organization. The framework refines the strategy map concept in the balanced scorecard approach for use in intangible assets management. Intangible assets belong to different functional departments. They must be carefully monitored and properly nurtured by the organization. Intangible assets depend not only on the type of functional departments but also the type of industries.

The data that could be gathered on the issues of intangible assets could be divided into two types as shown in Table 2.

Table 2. Intangible assets relationship analysis methods

Methods	Advantage	Disadvantage
Direct way : Financial quantitative data	Direct analysis from reliable financial data	Difficulty to obtain the financial data in some countries.
Indirect way : Questionnaire	Widely distribute to all industries in any conditions.	The results are highly susceptible to the questions' design and the respondent's attitude. (Chen et al. 2005)

There is some difficulty in obtaining data of intangible assets in financial reports for direct testing of the relationship. Thus, there are several empirical studies using the questionnaires as shown in Table 3.

Table 3. Previous Empirical studies

Studies	Methodology	Empirical Finding/ Result
Bontis et al., 2000	Questionnaire 107 respondents both service and non-service industries. Analyzed by structural equation modeling and Partial Least Squares	Intellectual capital has a significant and substantive relationship with business performance regardless of industry sector.
Carmeli and Tishler, 2005	Questionnaire 99 respondents of general management of local authority in Israel. Use multivariate analysis approach, robust canonical analysis (RCA)	Intangible organization elements (managerial capabilities, human capital, perceived organizational reputation, internal auditing, labor relations and organizational culture) have a significant positive effect on the performance of the organization.
Nagar and Rajan, 2005	Marketing and customer satisfaction survey 87 retail banks. Analyzed by linear regression.	Customer relationship activities link to business performance.
Chin et al., 2005	Gather financial data of 1,386 samples companies listed. Trademark value estimation by Seethamraju (2003).	Trademark/Brand is positively associated with firm's performance.
Wang and Chang, 2005	Gather data from 131 IT firm in Taiwan and analyzed the model by partial least square (PLS) method	Human capital has no direct effect on performance. Innovation, process and customer capital have direct effect on performance. Human capital directly affects innovation and process capital. Innovation and process capital further influence performance.
Chen et al., 2005	Gather data from 4,254 registered companies and analyzed the hypotheses by statistic testing.	Intellectual capital has a positive impact on financial performance.
Cabrita and Vaz, 2006	53 banks (253 samples) in Portuguese banking were tested using PLC testing model	Intellectual capital is significantly related to the organizational performance.
Moon and Kym, 2006	200 questionnaire analyzed and using SEM (AMOS) for model testing	Human capital has a positive effect on relational capital and that both human and relational capital affect structural capital
McKeen et al., 2006	90 respondents in US, and analyzed the hypotheses by PLS method	Knowledge management has direct relation to organizational performance. Organizational performance has direct relation to financial performance. No direct relation between knowledge management and financial performance.
Liu and Tsai, 2007	Questionnaire 560 manager from Hi-Tech companies in Taiwan. Statistic *t*-test and ANOVA are used.	Knowledge management has a positive effect on business performance.
Cheng et al., 2008	Directly obtain financial data of 56 companies and analyzed 23 indicators by Tobit's model	Innovation, customer, human and contract capital have some impact on intangible assets.

RESEARCH DESIGN AND METHODOLOGY

The cause-effect relationship is urged in strategic mapping (Kaplan and Norton, 2004). There are also several researchers, i.e. Huselid and Becker (1997), Hitt et al. (2001), Liu and Tsai (2007), studies the relationship between learning and growth and business performance The hypotheses model is constructed in Figure 2.

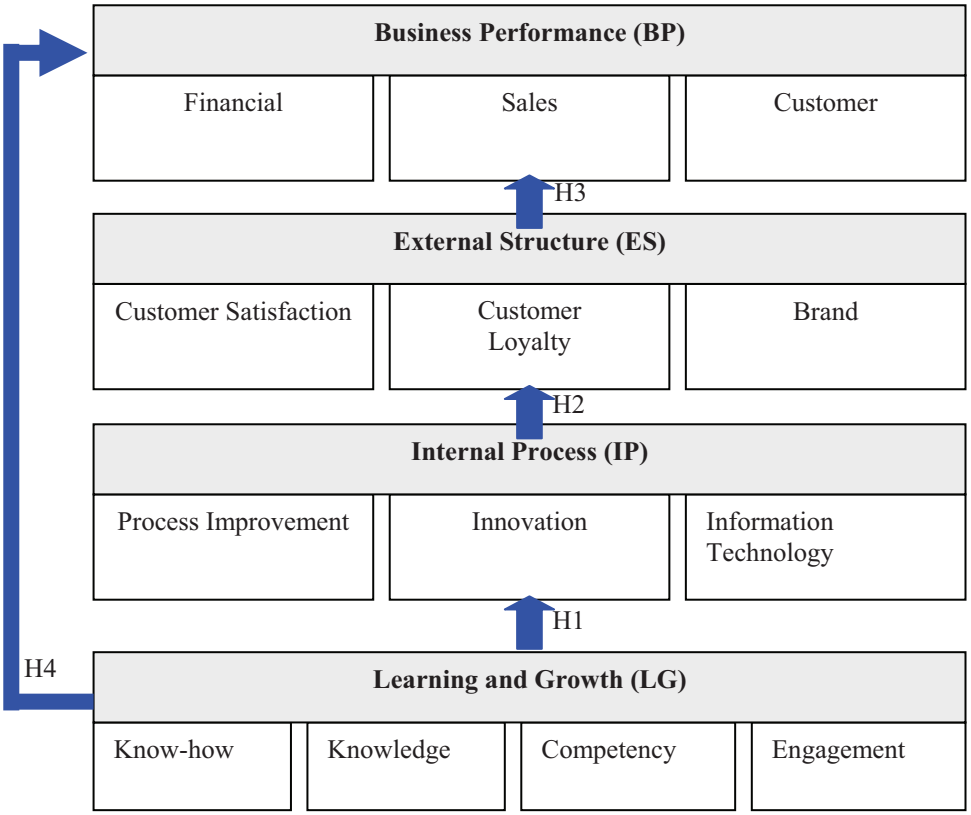

Figure 2 Research Hypotheses Testing Model

H1 : Learning and Growth is positively related to Internal process

H2 : Internal process is positively related to external structure

H3 : External structure is positively related to business performance

H4 : Learning and growth is positively related to business performance

There were several studies on the testing and accepted criteria. Accepted criteria in each statistical testing of previous studies, Steenkamp and Trijp (1991), Nunnally and Bernstein (1994), Ferguson et al. (2005), Hair et al. (2006) and Byrne (2006) shown in Table 4.

Table 4. Accepted criteria in each statistical testing

Testing	Purpose	Accepted criteria
Reliability assessment	Questionnaire consistency	Cronbach's alpha exceed 0.7 Item-total exceed 0.4
Convergent validity	Scale correlation with other measures of the same construct	CFI (Comparative Fit Index) exceed 0.9 NNFI (Non-Normed Fit Index) exceed 0.9 RMSEA (Root Mean Square Error of Approximation) lower than 0.05-0.08 AOSR (Average off-diagonal absolute standardize residual) lower value to zero, better fit *t*-value exceed 2.0 at $p<0.05$ Standard loading exceed 0.6
Discriminant validity	Construct different from the other construct	$\chi 2_{\text{constrained}} - \chi 2_{\text{unconstrained}} > 3.84$, $p<0.05$ correlation+2 (std. error) < 1
Hypotheses	Model fit	$\chi 2/_{df}$ Ratio between 1-3 CFI exceed 0.9 NNFI exceed 0.9 RMSEA lower than 0.05-0.08 AOSR lower value to zero, better fit *t*-value > ± 2.58, $p<0.01$ *t*-value >± 1.96, $p<0.05$ *t*-value > ± 1.65, $p<0.1$

Prior to doing the hypotheses testing, there are several testing steps as described in Figure 1. The detail of empirical result in each step is explained as follows:

Step 1: Field survey and Screening

Questionnaire was the primary source of data of this paper. An appropriate design of the questionnaire is crucial to ensure the success of the study and the achievement of the research objectives. The questionnaire in this paper is constructed by using the step-by-step procedure as illustrated by Churchill (1995). The questionnaires in each intangible assets indicator are adopted from the literature on the measures of intangible assets to business performance and constructed into a total of 68 questions. The questionnaire has to be clear and has simple wording before being dispatched and distributed to top managements of registered member companies in the Thai Chamber of Commerce. The members of the Thai Chamber of Commerce are in various types of industries and size of companies. They have reliable financial and general information. The questionnaires have been distributed to 3,084 members. There were 361 respondents. Some of them have incomplete information. The qualify respondents are only 304 which are used in further analysis. The next step of model testing procedure which is shown in Figure 1 is reliability assessment.

Step 2. Reliability Assessment

Cronbach's coefficient alpha provides an overall indicator of the correlations among a set of items used to measure a construct. It ranges from 0 to 1 (Hair et al., 2006). In general marketing and management fields, the Cronbach's coefficient alpha are accepted at minimum of 0.70 (Nunnally and Bernstein, 1994). However, before evaluating the reliability of scales, item-total correlations were initially calculated to purify the measures. The principle of this procedure is to indicate which items that do not belong to the content domain of the constructs. The items which exhibited item-total correlations below 0.40 were then eliminated from further analysis (Nunnally and Bernstein, 1994). There is only one question removed because it has lowest item-total correlations, 0.3. The Cronbach's alpha in this paper is shown in Table 5.

Table 5. Overall reliable assessment result

Intangible assets element	Intangible assets indicator	Cronbach's Alpha
Learning and Growth	Know-how	0.80
	Knowledge	0.72
	Competency	0.83
	Engagement	0.79
Internal Process	Process Improvement	0.79
	Innovation	0.85
	Information	0.81
External Structure	Customer Satisfaction	0.88
	Customer Loyalty	0.73
	Brand	0.88
Business Performance	Financial Performance	0.92
	Sales performance	0.93
	Customer fulfillment	0.87

All Cronbach's alpha are higher than 0.7. Therefore, on the basis of these preliminary analyses, each items seems to make a good contribution and sufficiently reliable. All questionnaires in each intangible assets element are consistent and reliable.

Step 3: Validity assessment

There are two types of validity assessment, convergent and discriminant validity. The convergent validity is to analyze the scale correlate positive with other measures of the same construct. Two models are tested in convergent validity analysis. The first model comprises 10 intangible assets indicators measuring 3 first order constructs/intangible assets those being learning and growth, internal process and external structure. Using the structural equation modeling, EQS program, all diagnostic indicators for the measurement model were satisfactory and suggested a goodness fit, (CFI 0.99, NNFI 0.98, RMSEA 0.08, AOSR 0.03, the lowest t-value 17.03 and lowest standard loading 0.82). The second model assesses the existence of a multi-dimensional business performance which is conceptualized and operationalized as a higher order construct composed of three first order dimensions those are financial performance, sales performance and customer fulfilling performance. Also, all diagnostic indicators for the measurement model were satisfactory and suggested a goodness fit, (CFI 0.96, NNFI 0.95, RMSEA 0.09, AOSR 0.05, the lowest t-value 8.3 and lowest

standing loading 0.63. Thus, the intangible assets indicator in each constructs/intangible assets is positive correlate with other indicators in the same construct. The knowledge, know-how, competence and engagement are positive correlate in learning and growth. Process improvement, innovation and IT are positive correlate in internal process. Customer satisfaction, customer loyalty and brand are positive correlate in external structure. Lastly, financial, sales and customer fulfillment performance are positive correlate in business performance.

The discriminant validity analysis is to analyze the degree of each construct variable different from other construct variable. In this study, there are 4 construct variables which are learning and growth, internal process, external structure and business performance. Structural equation modeling was utilized in the present study to assess the presence of discriminant validity among the study measures. The result of discriminant validity analysis is shown in Table 6.

Table 6 Discriminant Validity Analysis

Intangible assets elements	Learning & Growth	Internal Process	External Structure	Business Performance
Learning & Growth				
Internal Process	0.88 (0.02)[a] 141.51[b] 63.21[c]			
External Structure	0.79 (0.03) 105.71 54.72	0.88 (0.02) 85.12 30.23		
Business Performance	0.55 (0.06) 198.99 71.90	0.55 (0.05) 139.26 37.43	0.67 (0.05) 158.86 44.64	

Note: Entries below the diagonal show (a) ø coefficients, reflecting correlations among constructs and standard error in the parentheses (b) difference in chi-square from fixed (ø =1.00) model and free (ø estimated) model (c) chi-square for free model

The results in the above table indicate that, in all cases the pairs of construct variables were not collinear, which provide the evidence of discriminant validity. The each pair of difference constrained and unconstrained chi-square models is greater than 3.841 at p <0.05. In addition, each pair of constructs a confidence interval was calculated around the estimated correlation by using twice the standard error. Thus, both chi-square difference tests and confidence intervals assessment provide evidence of discriminant validity among the study constructs. Each construct variable is difference from other constructs. In this study, the intangible assets indicators in each construct variables (learning and growth, internal growth, external structure and business performance) do not correlate with each others.

Step 4. Hypothesis testing result

The result of 304 respondents in various business sectors, ago of business and size of business. The testing results in Figure 3 are simulated by EQS program.

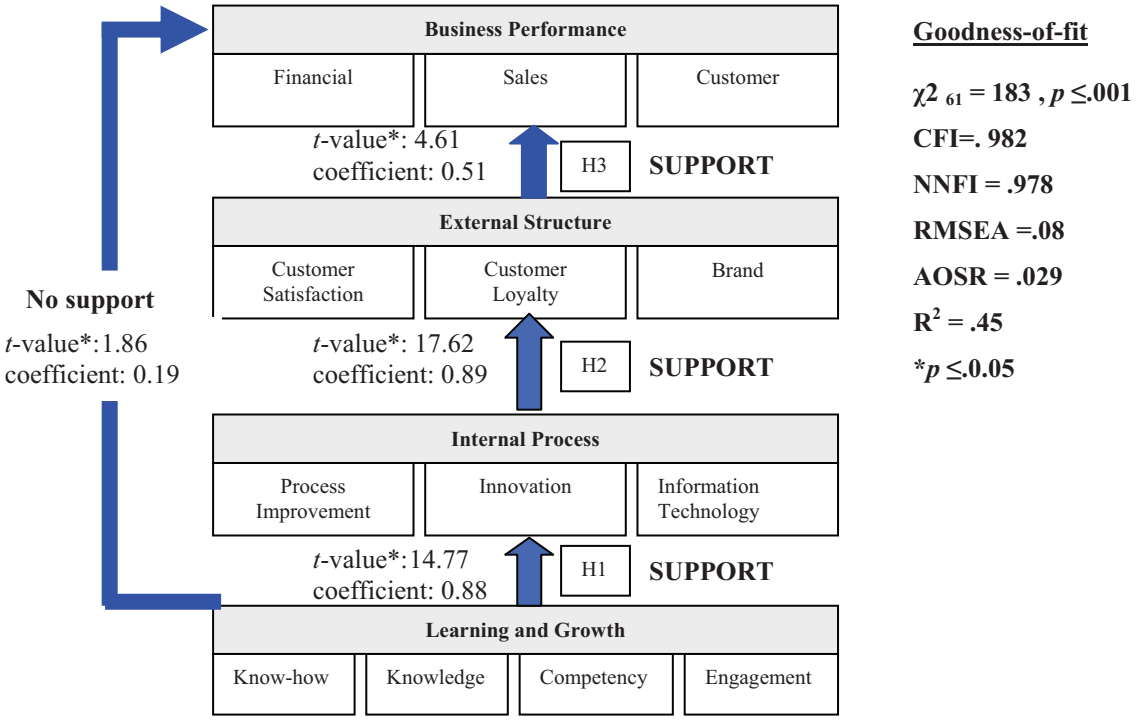

Figure 3. Structure model result

All diagnostic indicators show significant evident goodness-of-fit statistic, CFI=0.982, NNFI=0.978, exceeding 0.9. The RMSEA is equal to 0.08 and a small AOSR. With the large sample size, 304 respondents, the significant chi-square and degree of freedom ratio is acceptable. The model fits relative to the goodness-of-fit statistic result. All hypotheses are supported except the relationship between learning and growth and business performance at $p \leq .0.05$. This structural model solution produces an R^2 value of 0.45 which suggests that the structural model explains 45 percent of the variance in business performance. It has very strong explanatory power for this model compared with the previous studies in Carbrita and Vaz (2006) 0.44, Wang and Chang (2005) 0.43 and Bontis et al. (2000) 0.37.

CONCLUSION

Intangible assets are involved in all levels of value chain in business. The foundation of intangible assets in business is learning and growth. The knowledge, know-how, employee competence and engagement are the intangible assets in learning growth which are positive effect to internal process (process improvement, innovation and information technology) which is the same result as Wang and Chang (2005). The internal process is expended positive effect to external structure. Finally, external structure affects business performance. The learning and growth is the primary foundation factor to lead the business performance. The three elements of intangible assets are independent as illustrated in the validity testing. The linkage of three elements is confirmed the strategic mapping of the balance scorecard. The hypotheses testing does not support the cause-effect relationship between learning and growth to business performance. The learning and growth element has indirect effect to business through the value chain in balance scorecard, internal process and customer proposition.

MANAGERIAL IMPLICATIONS FOR INDUSTRIAL MANAGEMENT

No strategic recommendations were noted from past researches. Management practitioners need not only cause-effect relationship of the model testing results but also long term strategies in their business. When the top management or strategist realizes the cause-effect relationship of those three intangible assets, the recommendation strategies are discussed in the Figure 4. The recommended long-term strategies are retrieved from the high score question in each intangible assets indicators. Understanding the value of intangible assets help a business to develop sustainable and enhance its mission effectiveness and competitive advantage.

Intangible assets are the strategic key for long term profit prospect and sustainable competitive advantage. The setting of key performance index and investment has been allocated and monitored by the above guideline strategies. When the top management has crystallized strategies, they have good management and monitoring. Creating a culture of measurement-driven intangible assets and business performance helps top management understand how to drive the greater return from intangible assets investment.

ABSTRACT

Organizations that are enlightened enough to recognize the importance and value of their data often have difficulty in actually realizing that value. Their data is often disconnected, inconsistent, and inaccessible. They have valuable, untapped raw data that is hidden in the reams of transactional data they collect daily. Information sharing among departments and functions is difficult. Unlocking the intelligence trapped in mountains of data has been, until recently, a relatively difficult task to accomplish effectively. HR data primarily concerns transactional processing-getting data into the system recording it for reporting purpose. Understanding the Human Resource (HR) data is vital to any firm's effective HRIS.

This paper studies the adoption of Data Mining techniques on HRIS (Human Resources Information System) in any organization and presents Data Mining with respect to HRIS effectiveness.

Keywords: Data Mining; human resource information systems; HRIS; human resource data; HR data; employees.

INTRODUCTION

Rapid technological advancements, globalization, move towards knowledge-based economy and a host of other trends are changing the face of any organization. This yields to have a major impact on the role of the human resources (HR) department [40]. An important innovation within the human resources management (HRM) function is the use of Information Technology (IT), which has led to the development of computer-based Human Resources Information Systems (HRIS). In fact, HRIS as described by [27] is the backbone of contemporary HRM function.

Studies have also reported that for organizations which have adopted HRIS, the investments are small and usually address tactics and administration rather than strategy. Tactical HR applications typically refer to transaction processing for payroll and benefits administration while strategic applications make organizations more effective and competitive, especially in knowledge management and workforce planning. In many organizations, the focus of the HRIS is on administrative efficiency. However, as organizations seek to grow and compete in the rapidly evolving knowledge-based economy, the pressure continues to grow for HR to play a strategic role in the organization [46]. The growing link between HR and business strategy has organizations looking to their HR professionals for innovative programs and practices to build a more competitive workforce.

The core and major challenges the corporate face in today's competitive environment is management of large volume of data filter the useful data and transform the filtered data into

useful knowledge. For this purpose, many firms have heavily invested in IT to help them to manage their business decisions more effectively and gain a competitive advantage. By implementing from Enterprise Resource Planning (ERP) to Customer Relationship Management (CRM), Supply Chain Management (SCM), and E-Commerce applications, the firms have taken a big step in automating their business processes [31]. Today all firms immediately respond replying as 'My People' when asked to specify the most important resources in their organizations. While lip service is given to the key human resource asset, surprisingly in reality, little time or effort is given into directing, conserving and leveraging that human resource asset. Data Mining, also called as knowledge discovery in large data, enables firms to make calculated decisions by assembling, accumulating, analyzing and accessing corporate data. Tools like query and reporting tools, On-Line Analytical Processing tools (OLAP), and Decision Support System (DSS) are used in Data Mining applications.

These organizations have been constructing their IT systems with nonintegrated single-point solutions. (For example, they have different departmental data warehouses built on different platforms using combinations of tools, some nonstandard, some with expired maintenance support, and some prebuilt in a tool purchased from a vendor no longer in business.) Implementing quick-fix solutions can become a software maintenance quagmire. With hindsight, even presumably researched software system purchases can still result in redundant tools, data inconsistencies, duplication of effort, and ultimately high IT operating expenses, with unintended barriers blocking systems from cleanly communicating among themselves. All organizations are reaching a point where it is important for computers to talk to other computers.

The concept and role of HRIS have increased parallel to business related technological advancements. All firms have realized and recognized that in a knowledge-intensive, innovative-or-die world; Human Resource Information System's role can not be limited to just administrative work of hiring and firing but has lot to do more. The HRIS also called as Human Resource Management Systems (HRMS) have become full fledged business advisors, beyond employee advocates. But while HRIS have appeared in increasing numbers as the cost of computing power has declined, many systems seem to have been acquired simply because they were affordable and not because organizations sought to use the computer as a means to more effective human resource management.

[25] described an understanding of how the Human Resource (HR) and the Information Technology (IT) management should complement each other for improved communication and competitiveness. [39] Emphasized on importance of organizational theory that makes difference while implementing Data Mining in an organization.

In a global competitive world, top management requires more and more information from their Human Resource (HR) departments. The management wants hard data on turnover, hiring, comparisons of compensation and benefits, ethnic, gender and cultural distributions to evaluate trends, anticipate possible changes in the workforce or the environment. It is necessary for HRIS to become more strategic, and more concerned with the quantifiable data. The objective of the paper is to highlight the role of Data Mining for effective HRIS.

The rest of the paper is organized as follows: In section II, related research is presented. I broadly describe the concepts of Data Mining in section III. Section IV discusses HRIS. Section V explains the techniques of Data Mining. Section VI describes effective HRIS using Data Mining. Section VII concludes the paper.

RELATED WORK

The concept of Data Mining is not explored more in context of HRIS. The work by [34] described the three major techniques of Data Mining namely Association, Clustering and Prediction on Human Resource (HR) data. [37] Presented the importance of Data Mining in Human Resource Information Systems and described thoughtful issues of HRIS with respect to Data Mining.

[43] Showed HRIS implementations lead to cultural considerations in any organization. [51] Described conflicts between information systems approaches and HRIS initiatives. [2] Mentioned that it is unfortunate that in the past many organizations have not gone beyond the automate strategy in HRIS developments.

[28] Explained the role of Data Mining applications on strategic and competitive advantage [41] points out on the patterns in human behavior to some extent for helping to predict how people will react to certain events. [36]) briefly discuss on the regression techniques, neural network applications in personnel performance and retention in Human Resource (HR) and personnel selection. [35] Stressed on the importance of information collection, transforming such information to patterns, for supporting decision making. [32] Mentioned the need for Data Mining for capturing knowledge in communities, for analyzing the co-occurrences of concepts, rules extractions, ontologies, classification grids etc. For HR effectiveness, investments in HR [30] are must for competitive advantage. [50] Presented various HR policies conceptualized by managers in an organization. [47] Suggested models for holistic knowledge framework in organizations. [23] stress on the value of performance measurements in organizations. [42] proposed the impact of training on the workforce for effectiveness in enterprise applications.

[53] described that Human Resource (HR) professionals are now able to give more time to strategic business decisions as the development of technology has allowed for the automation of many transactional HR processes. [3] Opinioned that the firm should put forward the organizational resources and capabilities that are usually rare, valuable, non-substitutable, and imperfectly imitable and these resources form the basis for a firm's sustainable competitive advantage. [8] Mentioned that HRMS create a sustained competitive advantage for decision making by hiring and developing talented staff and synergizing their contributions within the resource bundle of the firm.

[35]) suggest that some firms may use the data only for administrative purpose, some may transform this data into useful information, and some may analyze the patterns on the obtained information for support in decision making. [51] Described conflicts between information systems approaches and HRIS initiatives. It is unfortunate that as mentioned by [2] that in the past many organizations have not gone beyond the automate strategy in HRIS developments.

DATA MINING

Data Mining is the process of extracting information from large data sets through the use of algorithms and techniques drawn from the field of Statistics, Machine Learning and Data Base Management Systems [19]. Traditional data analysis methods often involve manual work and interpretation of data that is slow, expensive and highly subjective [18]. Data mining techniques track the data of the organizations that have thousands of employees a multitude of employment related information, extract the patterns contained in these HR databases by providing some insights like employee retention details, compensation planning, projecting risks and opportunity identifications and assessments.

In HR systems, for effectiveness, lots of data consolidation need to be done. Data Mining has a direct impact on the analytical results that will drive business decisions [5]. In understanding the employee, the complexity has increased dramatically because many departments, many employees, and many sophisticated tools have emerged in organizations. But with Data Mining, one can predict how likely someone will do something we are interested in, in real time [10]. It uses the extracted useful information from large data bases to make critical business decisions [10].

The applications of HRIS using Data Mining give opportunities to generate adhoc or standardized reports from specific sets of data. Researchers have established that [28] Data Mining applications when implanted effectively can result in strategic planning and competitive advantage. Data Mining as pointed out by [54] can be performed on a number of different databases and data repositories that include relational data, transactional data, data warehouse, web data, data streams, flat files, time series data etc. Data Mining includes various queries, reports and decision support tools based on historical data of the organization and can even predict for future perspective.

Organizations tend to write off Data Mining techniques since statistical analysis is routinely performed in all departments. The difference between Data Mining and Statistics is that Data Mining automates the statistical process resulting in several tools [5] Statistical inference is assumption driven in the sense that a hypothesis is formed and tested against data. Data Mining, in contrast is discovery driven. That is, the hypothesis is automatically extracted from the given data.

Some key employees unexpectedly quit in organizations, so how does a firm quickly fill the vacated positions. What do the organizations need to change and who should do it? Any firm's current workforce members are aging and set in their ways. There are patterns in why employees leave and these profiles can be applied to predict our current employees most likely to leave. The heart of the HRIS deals with retaining good employees and effective workforce planning to predict the needed number and types of skill sets of employees and expenses to meet future workload requirements. The reports received from HRIS describe various HR based reasoning like

- The groups of employees most likely to leave within the coming years.
- The reasons why employees have left in the past—measured by type of reason.
- Categories of people leaving by job type.
- Scores1 of individual employees (by name and employee ID number) in the high-risk category predicted to voluntarily leave.
- Current employees most likely to leave, broken down into categories, such as high, medium, or low risk, with the likely causes for their departure.
- Current top performers in the high-risk category and the percentages of reasons that historically caused separations of comparable positions and performers.

HUMAN RESOURCE INFORMATION SYSTEMS (HRIS).

HRIS in organizations collect basic personal and work related data in order to conduct basic HR transactions [35]. [29] give the core elements of Human Resource Information System comprising of HR application, recruitments, payroll, work flow management, reporting and analytics. HRMS can assess the best methods to meet future business objectives and learning needs of an organization with the help of DSS [17] by enabling the employees and managers to make fast, accurate, and informed personal and business decisions. [20] Provided information on reports pertaining to each HR activity like recruiting and placements, labor relations, compensation benefits that are regularly generated. [4] Founded that small firms are less likely to adopt HRM practices than medium or large firms. [33] Described the importance of Human Resources in enterprise systems. As per studies conducted [46] it is clear that for organizations which have adopted HRIS, the investments are small and usually address tactics and administration rather than strategy. However, as organizations seek to grow and compete in the rapidly evolving knowledge-based economy, the pressure continues to grow for HR to play a more strategic role in the organization [46]

[21] provide examples that include pay and benefits as a percent of operating expense, cost per hire, return on training and turnover cost. Mostly data obtained from HRIS do not provide an opportunity to seek additional relationships and patterns. For example, to assess the value of an employee who stays with the organization for an extended period of time, HR functions should provide information on the value of hiring than evaluating the cost of hiring etc.

The role of Data Mining in HRIS is to integrate various HR applications, collect data at various points in the HR databases, and use effective tools for making information available for effectiveness. Other role can be developing and improving intranet based applications for streamlining the processes, for improved predictions of employees' performance management, coordination and work flow management. Say, a separate process can be there for recruitment and selection, separate process for application tacking systems, in-house recruitments, process for training and development, performance management and also separate process for developing Employee Relationship Management. These systems help in consolidating the information across the enterprise to do everything from adhoc reporting to the analysis of complex relationships and workforce trends.

We can perform some of the interactive analytical modeling on HR data. We can detect trends and patterns in employee data which helps to further to improve the organizational culture and organizational decisions. The Decision Support Systems (DSS) can combine information from other functional areas within the firm, such as customer service and marketing, to help support HRIS decisions [9].

Generally patterns generated through Data Mining should be understood, should be valid on new or test data with some degree of certainty, potentially useful and novel. If one is searching long enough in any data set, it is possible to find patterns that appear to hold but are not necessarily statistically significant or useful [18]. A pattern will be interesting if it validates a hypothesis that the user sought to confirm. Data Mining is relevant to rank the discovered patterns according to their interestingness and filtering out the uninteresting ones ([15]. [7] Suggested that the choice of the Data Mining algorithm depends on the intended use of the extracted knowledge. Allocating man power based on demand projections requires careful task relevant data. According to the seasonal variations in demand, temporary man power can be hired to maintain service levels. The demand levels vary within one working day also, that can be used to allocate resources accordingly. Data quality may be insufficient if data is collected without any specific analysis in mind [19]. A careful process with respect to missing or noisy data is required. Whether the HRIS simply automates existing processes or supports transformational change will depend on the way it is designed and developed.

DATA MINING TECHNIQUES.

Data mining and analysis tools are designed to explore large quantities of data for comprehensive analysis to discover hidden relationships and uncover unknown patterns, trends, associations, or anomalies for the purpose of proactive or computer-automated decision making. These tools provide the ability to go beyond merely reporting *what has happened* in a business or organization to discovering *why it has happened*. They are also useful for deriving meaningful and accurate predictions. The superior data mining and analysis tools simplify and streamline both the data preparation time and the analysis process. The beauty of the data mining tools is that they enable organizations to create unique value on top of an asset they already have: their raw data. That is, the casual analyst is empowered with statistical, visualization techniques to extract the underlying business knowledge from vast deposits of data, exploit the data for predictive variables to yield validated findings, and conclusions, possibly optimize their decisions, and finally present the results in actionable forms such as customer segmentation models. Data mining provides a graphical user interface (GUI) that is designed such that analysts with only moderate statistical competencies can drive through the data mining and analysis process, while the quantitative expert can optionally go behind the scenes to fine-tune and tweak the analytical process. For example, nontechnical users can easily examine large amounts of data in multidimensional histograms to graphically compare their analyzed results derived from alternative scenarios and assumptions. The benefit is that the time delay from data access to action is dramatically shortened—and the results can be deployed across the Internet.

Associations, Mining frequent patterns.

These methods identify rules of affinities among the collections. [26] Mentioned that patterns occur frequently during Data Mining process. A frequently occurring subsequence such as staff movement and work attitude tend to have patterns in their performance. Another example in HRIS can be the claim forms submitted by the employees to the medical insurance of the organization. Every claim contains a set of medical procedures that were performed on the given employee during one visit. By defining the set of items to be 'the collection of all medical procedures that can be submitted' and the records to correspond to each claim form, the application can find, using association function, relationships among the medical procedures that are often combined together. Research shows [45] that association rules are essential beyond market basket analysis.

One can use association rules for application tracking mechanisms in recruiting, identification of patterns in employee benefits, analysis of staff movements etc.

Classification and Prediction.

The classification and prediction models are two data analysis techniques that are used to describe data classes and predict future data classes. A credit card company whose customer credit history is known can classify its customer record as Good, Medium, or Poor. To predict whether a certain employee will show a certain type of behavior implies an assumption that the employee belongs to certain type of employee group and will therefore show the certain kind of behavior. Extensive research has been done [6] on classification and decision trees.

The models of decision trees, neural networks based classifications schemes are very much useful for business decisions. Classification works on discrete and unordered data, while prediction works on continuous data. Regression is often used as it is a statistical method used for numeric prediction. While doing effective decision making for employee selection, selection of individuals to fill available jobs becomes clear and meaningful only when there are more applicants than jobs. Primary emphasis should be made on the selection measurement accuracy and predicative efficiency. Simple or multiple regressions is the basic prediction model that enables a decision maker to forecast each individual's criterion status based on predictor information.

There are procedures available to choose appropriate cutoff scores in employee selection processes. [49] Showed through case studies how neural network technology is useful from different areas of business. One can predict the likelihood of success in any HR process. Prediction and classification techniques are used in employee attrition rates(what type of employees are most likely to leave, most likely shift etc), factors to attract new customers, trends of movements of successful and unsuccessful trainings methods, predicting the percentage accuracy in employee performance etc.

Clustering.

It is a method by which similar records are grouped together. Clustering is usually used to mean segmentation. An organization can take the hierarchy of classes that group similar events. Using clustering, employees can be grouped based on income, age, occupation, housing etc. In business, clustering helps identify groups of similarities; characterize customer groups based on purchasing patterns, etc. An organization may segment the employees and discover clusters of potential employees on the basis of attributes (type of seminars, training programs attended and number of vacations availed etc). In HRIS, clustering can be applied to employees having similar characteristics, grouping top performers, analysis of workforce attrition and segments related to retirement facilities, compensations, benefits, allowances. Data Mining also provides summary information: various multidimensional summary reports, statistical summary information (data central tendency and variation).One can use historical data to build models of fraudulent behavior and use Data Mining to help identify similar instances. Good research is done [52] [38] [1][14][12] with respect to Data Mining in machine learning and large data sets.

EFFECTIVE HRIS USING DATA MINING.

In a global competitive world, the loss of an employee or an under-performing team of employees may literally make the difference between success and failure. With these circumstances, it is no wonder that top management has needed more and more information from their Human Resource departments. They demand hard data, information on turnover, hiring, comparisons of compensation and benefits, ethnic, gender and cultural distributions [13].

One can access aggregate reports on position vacancies, salary patterns, performance details, etc. Organization can identify the overall training budget if it wants to know what kind of impact it is having on the company. Data Mining can identify patterns of successful employees who have participated in the training programs, their further progress after training programs, their work performance, their promotions and progress after training programs etc. The generated patterns will be crucial to further training investments for the employees. [29] Mentioned the concept of HR analytics. Data Mining tools focus on [29] historic data and report past events, attempt to focus on trend forecasting in order to highlight areas requiring management attention. Such an approach can be very powerful when combined with a balanced scorecard approach to defining and monitoring key performance indicators in HR, although there is a significant overhead in setting up and maintaining such tools.

Researchers have shown that there is much significant relationship between employee attitude and employee performance [16] [44] [48] mentioned that in today's competitive environment where it is necessary for organizations to have effective HRM practices, the HRIS can support the recruiting, selection and training efforts of the organizations as well as monitor who is leaving the organization and for what reason. Data Mining can identify which segments groups are most successful, which offices and locations have responded to training well, which employee responds to what training etc. it is more economical to retain an existing employee than to acquire a new one. To develop effective employee retention programs it is vital to analyze the reasons for employee attritions.

For example, usually the impact(s) of a change, a training program or a pay increase for a group of employees have historically been projected is always based on educated opinion and not on statistical benchmarks. Often, these opinions turn out to be wrong. When that happens, significant investment has been made with no resulting benefit to the corporation. Newly trained workers may leave to join the competition. A pay increase may have no effect on turnover. To respond to the new demands and the increased visibility of HR management, HRIS seeks a strategic role by turning to Data Mining methods.

Another important factor to consider in the Data Mining process is interpretation of questionnaires pertaining to qualitative data of employees. For example, a pattern may be detected using Data Mining tool pertaining to an employee having the highest compensation level and extended long length of service. The interpretation may be different. Can we conclude that if employees stay long they will have higher compensation or they stay longer only for higher package? Domain knowledge is required along with expertise to interpret the cause and effects of the relationships generated by these patterns. As each company has its own HR data, the interesting relationships in patterns depends the company's competing market, growth cycle stage, integration of various HR applications etc.

We can build a model that identifies employees and their characteristics, who are frequently, been involved in particular, work assignments and tasks. There are some decisions that involve mathematical modeling and analysis which the management must take. Like, what is the proper size of the labor force in a large manufacturing organization? How many people should be hired to handle a significant new influx of demand or a large new contract? This involves mathematically rigorous conviction because the factors that influence productivity are usually not known very well. A properly designed analytical and mathematical model, using appropriate sufficient data could help managers to make better decisions about the level of human resources needed in a market characterized by significant changes in demand. Figure.no.1 shows how raw data in any organization transforms into optimized strategic business decision. The information process scenario is true to any HRIS. Rule based what-if scenarios, forecasting techniques based on analytical data can be applied to HRIS modules.

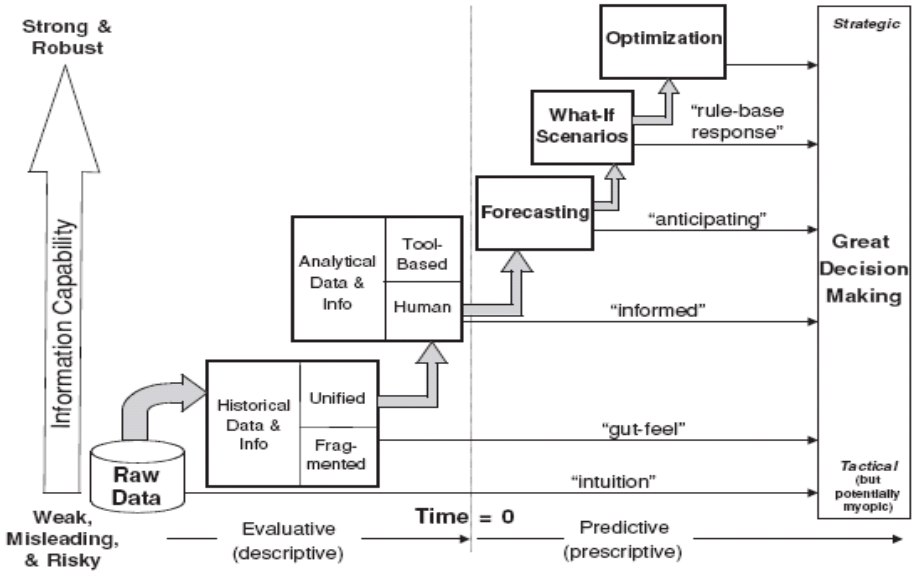

Fig.1 Data transformation into optimized business decisions (adopted from Cokins Gary (2004).

An important innovation within the human resources management (HRM) function is the use of information technology (IT), which has led to the development of computer-based human resources information system (HRIS). In fact, HRIS is the backbone of contemporary HRM function [27]. A HRIS is used to acquire, store, manipulate, analyze, retrieve and distribute pertinent information regarding an organization's human resources. Table 1.0 describes the difference between data, information and patterns of information that can be studied in an organization. The information capability based on know what, know how and know why is also provided.

	Process	Data	HR Reports	Training data	Employee Data
	Processing information in HRIS	**Information**	specializations data cross classified by training name, by employee name, by year	Training data cross classified by year, by course, by research project, by top performance.	Employee data-cross classified by top performance , training undertaken by year.
		Patterns of information using Data Mining	data showing interesting relationships or out of control categories; showing effectiveness in these data;	data showing interesting relationships or out of control categories; showing effectiveness in these data;	data showing interesting relationships or out of control categories; showing effectiveness in these data;
		Know-what	Ability to respond to a query; ability to assess symptoms of courses cancelled, correlations using statistics; identifying the best and popular training programs	Ability to respond to a query; ability to assess symptoms of training based on performance; correlations using statistics; identifying the best practices using expert systems.	Ability to respond to a query; ability to assess symptoms of employee' performance; correlations using statistics.
		Know-how	Ability to diagnose, analyze complex relationships using expert systems, Multi variate analysis of Variance using Statistics	Ability to diagnose employee attrition, analyze complex relationships using expert systems, Multi variate analysis of Variance using Statistics. Build competency and performance measurements tools.	Ability to diagnose students failures; Multi variate analysis of Variance using Statistics
		Know-why	Analysis of New programs, new employees , interdisciplinary work and thrust areas.	Employee communities of practice, personal assistance, group support systems, conference/seminars for sharing information.	Ability to deal with anomalies, interactive effects; use intranet based group support systems for assignments seminars, webminars and video conferences

Table 1.0 Representation of data and patterns of information in HRIS.

The power of data mining component, the robust analytical intelligence, is now available to business users in a compelling, easy-to-use format that is integrated with users' normal workflow. Feedback from analytics leads to corrective actions that positively impact business operations. Feedback guides decision-making, leading to actions that improve business performance. Rather than just reporting data, data mining HRIS introduces forecasting, modeling, and optimization capabilities for decision support. Analytics do not change the way people do business—they enhance how they do it. Data Mining tools are deployable across all levels of an enterprise, from top to bottom, and can be applied immediately to specific day-to-day business issues, such as with a customer call center, where information about each customer (e.g., account balance)

should ideally not only be current in real time but also suggestive of what action to take and why. The data mining tools deliver key metrics and precisely tailored information directly to casual users and decision makers. While enterprises will increasingly require these tools, complementing these capabilities with Data Mining applications substantially increases the overall value of their enterprise information and drives both sizeable productivity improvements across functional areas as well as profitable revenue enhancement. The primary goal of data mining in HRIS is to meld analytics with management functions so that data mining become an integral part of how managers and employee teams perform their job. Hence, successful implementation of data mining tools needs to focus first on specific business needs (i.e., supply chain management, customer churn detection and reduction, etc.).

CONCLUSION

In this paper, I have presented an interpretive perspective of techniques of Data Mining in HRIS by which organizations make sense of their vital HR data. I have also described Data Mining techniques with respect to HRIS. Organizations need to use HR data for strategic effectiveness. Data mining transform HR data into useful information and patterns to achieve competitive advantage. Careful and proper consideration and preparation of HR database, applying Data Mining Techniques will create an opportunity for firms to develop their competitiveness and effective decision making. I studied through Data Mining methods, once can measure the individual transactions and factors influencing an employee. Not all HRIS provide [24] integrated analytic features needed for compensation planning and decision support, such as the ability to also see related real-time competitive market salaries. Instead, they focus on database administration and record keeping related to compensation activities such as payroll, merit pay increases, and benefit enrollment. Migration and effective use of web-enabled integrated compensation design and analysis capabilities are still in their infancy [24]. The use of analytical HR software in all enterprises worldwide is very few.

We conclude that Data Mining on HRIS gives a better understanding of employee relations and improved employee satisfaction and higher probability of attaining competitive advantage. As the technology and techniques of Data Mining advance, organizations are able to collect, store, process, analyze and distribute an ever-increasing amount of HR data. Data and information are rampant in HRIS, but knowledge is scarce. As a result, most organizations today are governed by managerial intuition and historical reporting. However, we believe organizations are slowly moving to the knowledge age, where decision makers will leverage Data Mining technologies to augment intuition in order to allocate scarce enterprise resources for optimal performance. With proper preparation and consideration, HR databases together with data mining create an opportunity for organizations to develop competitive advantage.

APPLICATION OF ENVIRONMENTAL CRITERIA IN ORGANIZATIONS ASSESSMENT WITH AHP METHOD

Dr Agnieszka Leszczynska, Maria Sklodowska Curie University, Poland
leszczynski1@poczta.wp.pl

ABSTRACT

An imperative to protect the environment leads to changes in the manner of activity and in the evaluation of a company. The results of the pro-environmental management of companies include green supply chains. Their effectiveness depends on the choice of particular links of a chain, considering not only efficiency indicators, costs, but also indicators concerning environmental management. The paper proposes the environmental criteria that may be used to evaluate companies and their products. Next, the procedure of expert assessment of companies using AHP method is presented. The evaluation is based on the general and particular environmental criteria, selected by a decision-making company from the group suggested by the author.

Keywords: environmental criteria, supplier assessment, AHP

"Traditional" measures of supply chain assessment

Increasing competition makes companies look for development opportunities by improving the management of supply chain both inside a company and along the line of contact of a company with its environment. Changes in a company management are oriented towards control and monitoring of the connections with outside partners, openness in cooperation, and synchronization of production processes, cooperative connections and market mechanisms (Piątkowski, Sankowski, 2005). A particular emphasis is placed on the development of effective connections, i. e. companies analyze costs they incur and effects of every activity in the chain generating value for a client, and strive to make possible improvements to increase profits. The result of such an approach is comprehensive assessment of cooperating companies.

According to the "traditional" approach, evaluation of cooperation partners is based on the logistic indicators representing empirically observable and measurable states of affairs which as adequately as possible describe the logistics aim or the aim system (Twaróg, 2003). These indicators are usually used to set aims and evaluate their implementation; however, they may also be applied in evaluation of the current data in order to monitor changes, play an advisory and control role (Kowalska, 1998). The traditional logistic measures can be most generally

divided into: the measures to assess the completion of a logistic process in the consecutive logistic chains, and the costs of logistic including:

- the measures to assess the efficiency of logistic activities (according to the flow stages),
- the measures of a company's own and external supply services,
- the measures to assess the duration of logistic activities in consecutive logistic chains.

The most popular of them include:

- price of a purchased product/service,
- product quality, supply quality,
- transfer time (time of delivery),
- punctuality of delivery,
- size of a maximum one-time lot,
- costs of transport, order handling, packaging,
- reliability and regularity of connections,
- scale of wastage,
- possibility to minimize the stored stock, e. g. using JIT,
- variability in time (flexibility of supplies),
- reliability of a supplier determined on the basis of one's own or others' experience,

financial condition of a supplier.

Because companies are characterized by specific requirements, expectations and preferences, the applied criteria undergo further internal differentiation (Bykowski, 1999). The comparison of offers is based on the scale methods, graphic methods.

The criteria mentioned above are used to assess potential cooperation partners and rationalize current activities in the area of logistics. The aim here is, first of all, to reduce costs, e.g. by adjusting the flow of materials along the logistic chain, and to increase the client's benefit, e.g. by increasing precision of delivery or reduction of transaction costs. These measures are thus supposed to be the basis in a decision-making process; they should provide companies with adequate sets of information needed to increase their competitiveness.

The criticism of traditional logistic measures and indicators follows from the fact that such measures are not strategic in character, and the connection between short-term measures and long-term results is not sufficiently clear. Moreover, most measurement systems are inflexible and do not take into account changes occurring in companies and their environment. This concerns also green supply chains whose development requires redesigned or completed system of traditional logistic measures. The next paragraph presents the concept of green supply chains. First, a set of environmental criteria that may be used in the supply chain management was presented, followed by a proposal of a possible application in economic practice.

Green supply chains

The development of the concept of sustainable development and increasing environmental requirements made ecological issues an essential component of contemporary companies management. This applies also to the function of logistics which includes establishing and development of green supply chains. Generally speaking, the concept of green supply chains is an organizational philosophy to make profit and reach market goals by reducing the environmental risk and impact and by improving the ecological effectiveness of a company and its partners (Zhu, Saris, Lai, 2008). Its gist is to incorporate the component of "greenness" into the traditionally understood supply chain, including provision, production and distribution. A broader understanding of the concept includes also product design and liquidation. Thus, the range of green supply chains encompasses designing environmentally friendly products, production using clean technologies, environmentally friendly packaging and transport, adequate procedures of product liquidation (remaking, recycling), etc.

The essential goal of green supply chains is a shared responsibility of cooperating companies for environmental results. Therefore, their participants promote reducing an impact on the environment by their own company and their partners. As a result, it is possible: 1) to reduce costs/benefits of environment-related activities, 2) to determine possible ways of reducing waste, 3) to reduce or eliminate waste inside a company (Handfield et al., 2002). Application of the concept of green supply chains to selected internal functions may also lead to: 1) using environment-friendly materials, 2) modernization of production process to make it cleaner, 3) ecolabelling, 4) ecological improvement of packaging and transport processes. An effect of such activities is an increase in the environmental results of a company, reduction of the risk of incompatibility with regulations and of environmental fines.

An assessment of suppliers by a company from the vantage point of the activity ecologization consists in making sure of the fact that materials and products suppliers provide are environmentally friendly and produced in the environment-friendly processes. Thus two main directions of "greening" the supply chain are related to evaluation of the environmental results and activities of suppliers and the latter's commitment to their improvement. The first direction consists in selection of criteria to assess suppliers (at the moment of evaluation). Another direction surpasses the routine assessment and monitoring, and consists in giving support to educational programs, creating environmental teams, implementation of environmental systems. The range of implementation of the green chain concept depends on the way it is perceived (it may be limited to a company's environment or incorporated into its internal functions) and on the level of ecological commitment of the company (on whether a company shows a pro-active approach to environmental management).

Environmental criteria of the company assessment

The main problem accompanying the development of green supply chains is determination of indicators to assess individual links of the chain. The logistic indicators described above, used in evaluation of the effectiveness of companies' logistic activities, do not provide sufficient information on environmental activities undertaken by companies, their environmental results, etc. Therefore, basing exclusively on the traditional logistic measures and indicators seems to a large extent insufficient in the case of green supply chains. Simultaneously, the research shows that one of the biggest problems encountered in the supplier evaluation and selection was which metrics to use to evaluate "greenness" (Handfield et al., 2002).

A solution to the above problem is to use the indicators related to environmental results, such as: the cost of environmental fees, CO_2 emission level, fuel consumption, water consumption, dangerous waste etc. This approach – no doubt the simplest – is based on the quantitative criteria. However, these measures were not always the most important metrics in terms of their impact on the environment.

Extending the group of criteria related to environmental results makes it necessary to include also the qualitative criteria in the evaluation process. This is a consequence of a multidisciplinary character of the environmental management concept, of the need to assess the effectiveness of logistic processes, both statically and dynamically, and also to evaluate the quality of services provided by business partners. Therefore, this paper proposes the multicriteria evaluation of suppliers on the basis of two groups of ecological criteria: 1) related to a company, 2) related to a product (Fig. 1).

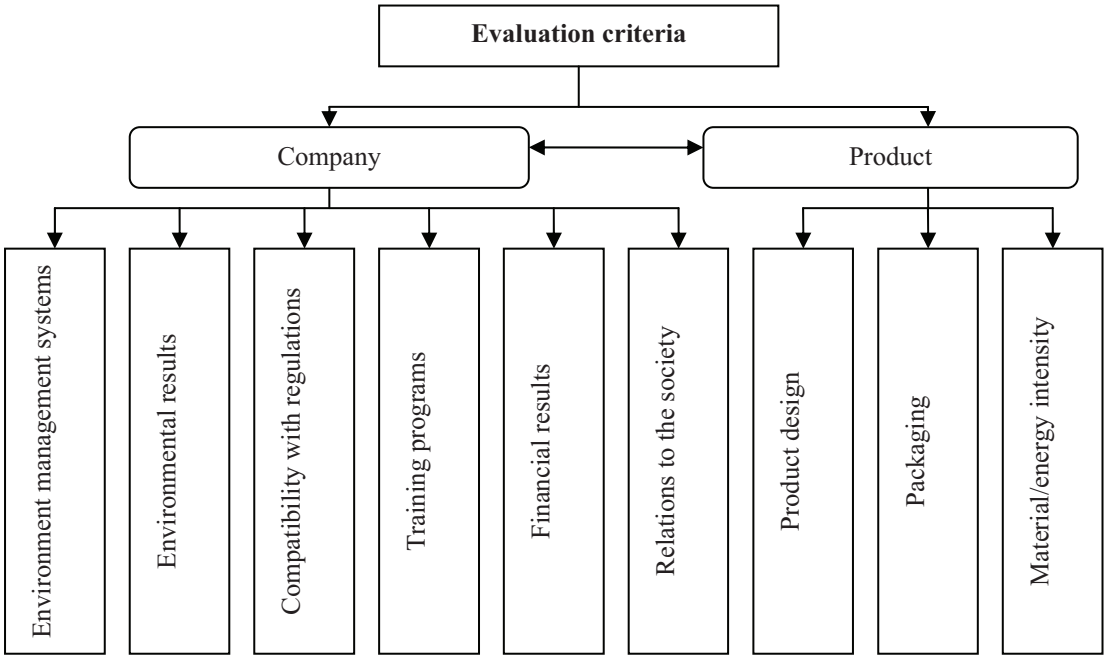

Fig.1. The proposed categories for environmental evaluation (Leszczynska, 2008)

The environmental evaluation of a company depends on the level of its "greenness", and covers: training programs, compatibility with regulation requirements, environment management systems, environmental results, financial results, and relations to the society. The assessment of products concerns the level of the product "greenness" and is determined by product design, packaging of the product, material/energy intensity; the number of categories may increase. The indicators used in each category are presented in Table 1.

Tab.1. The characteristic of environmental categories

Category	Description	Examples of the indicators
Environmental results	The category indicates the emission level, the size of generated waste and the range of use of natural resources.	Energy consumption Water consumption Quantity of waste
Environment management systems, environmental programs	The category refers to the extent to which the supplier's processes has been certified by the third party in the form of systems, i. e. ISO 14000, EMAS, and programs, goals and tasks related to the environment protection.	The scope of implementation of the environment management system The number of implemented pollution preventing initiatives The number of management levels with a definite environmental responsibility
Compatibility with the regulations	The category evaluates the extent to which the supplier's activities comply with environmental regulations (laws).	The time of reaction to environmental incidents Number of/ costs related to environmental fines, penalties
Training programs	The category focuses on the implementation of training programs related to environmental protection.	The number of hours of employee training on the advantages of …
Financial results	The category includes financial results related to the environmental aspects and activities of the company.	The costs related to environmental activities Return on capital invested in environment-improving initiatives
Relations to the society	The category determines involvement in the local environmental activities and contacts with the society/media	The number of enquires, commentaries on environmental issues The number of publications on the results of the company's environmental activity
Product design	The category determines the level of the supplier's involvement in designing environment-friendly products and in redesigning the existing products to eliminate the use of dangerous materials, or to meet the expectations of the so called „green clients".	The number of products planned for dismantling, recycling The number of products with instructions for environmentally safe use
Packaging	The category focuses on pro-environmental packaging, i. e. returnable, recycled, reusable packaging.	The share of recoverable secondary materials in protective elements
Material/energy intensity	The category determines the quantity of necessary materials (energy), including pro-environmental materials (i.e. recycled) in the production process.	% of materials coming from renewable resources in total materials Energy used per product unit

The criteria (indicators) used to evaluate cooperating companies may depend on the level of environment management in the company, on the goals of evaluation (decision-making process, obligatory documentation). For example, a company using the reactive strategy based on compatibility should focus on the indicators related to the degree of compatibility with legal requirements. On the other hand, a company adopting an innovative environmental strategy should take into account all the proposed categories. Moreover, the choice of logistic measures adequate for a given company should guarantee that they fulfill their proper function (advisory and/or operative). Therefore, the evaluation of a supply chain links on the basis of environmental criteria should be preceded by an analysis of the indicators referring to: the scope of tasks to be implemented, number and processing capacity, costs, etc.

The evaluation of supplier performance with AHP method

AHP method (*Analytical Hierarchy Process*) combines purely subjective expert evaluations with the objective analysis of decisions concerning hierarchically organized partial relations and connections among factors describing an analyzed problem. The method derives from the views of Saaty (Saaty, 1990) on the role of subjective evaluations, opinions in decision making. The subjectivity leads to ascribing different weights to partial parameters of each variant, which results in diversification of evaluation criteria. In this aspect, the method is analogous to the utility function (Kubiesz et al., 2008). In AHP method, decisions are analyzed in the framework of comparative or diagnostic evaluation, which leads to computation of the priority vector for the decision set or to application of the utility function the value of which is the basis for assessing dissimilarity of an analyzed problem. Thus the method adopts the multicriteria approach, based on the compensation strategy in preference modeling and assuming the comparability of variants, it takes into account the specific character of psychological processes of hierarchical and relational evaluation. Simultaneously, the method supports articulation of a decision maker's preferences and their use in the process of assessments aggregation. Modeling is used when unequivocal functional relationships among the problem components are not known and when the problem is described by a hierarchical structure of factors (criteria).
The evaluation of variants of an analyzed problem leads to a synthesis of partial results of those variants, described by a hierarchical set of criteria. The basis of AHP method is a hierarchical structure of goals, where the overriding goal is at the top of the hierarchy. The intermediate goals (criteria) are expressed by respective criteria of a lower level. Thus the structure of the problem of company-supplier performance evaluation takes the following form (Fig. 2):

- overriding goal – evaluation of suppliers' performance according to environmental criteria. Evaluation is performed by a decision-making company. In the author's study, it was a medium-size company producing chemicals, fertilizers, ethanol, titanium white;

- main criteria – the criteria selected from the group of the proposed environmental categories; seven criteria used in this study are presented in Table 2;
- partial criteria – the indicators chosen to evaluate the main criteria; the indicators used in this study are listed in Table 2;
- variants – the companies under evaluation. In this study: three companies (potential suppliers) active in chemical business.

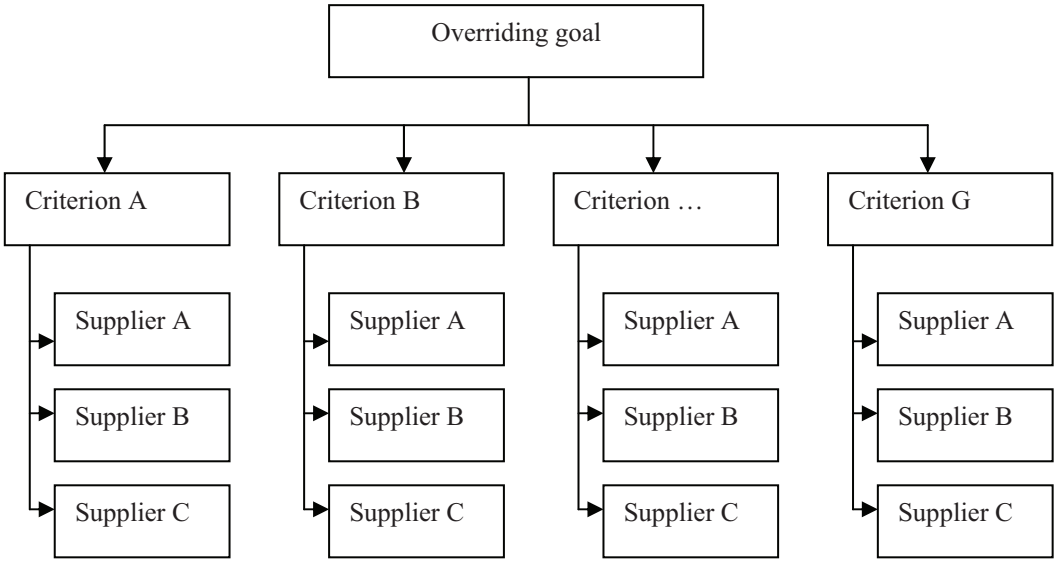

Fig. 2. Hierarchical structure of the problem

The procedure includes the comparison of all the factors in pairs to establish their mutual relationships. As a result, a matrix of subjective assessments is created, reflecting a degree to which a given company-supplier meets the relevant ecological criteria. The companies are evaluated on a conventional 1-7 scale.

Tab. 2. Criteria/indicators for evaluation of selected companies

Criterion	Indicators	Criterion symbol
Environmental results	Ammonium nitrogen, sulfates, COD, BOD_6, water consumption	A
Financial results	Environmental fees paid last year: water consumption, sewage disposal, emissions, waste storage	B
Environmental programs	Number of environmental programs planned for implementation in the next 3 years	C
Training programs	Number of employees trained last year in courses on ecological issues / general number of employees	D
Compatibility with regulations	Number of environmental audits performed last year	E
Relations with the society	Participation in pro-environmental initiatives in service of the society	F
Product design	Number of recyclable products/ general number of products	G

Analysis of the evaluation results

The analysis of the results was performed according to the specific AHP procedures. The first step was establishing, by the decision-making company, the relative importance of the selected criteria by evaluation of relationships between them, using the importance assessment technique. In this way, the matrix of comparisons for the degree of criteria preference was created on the basis of the company's preferences (Tab. 3).

Tab. 3. Matrix of the relative importance of the criteria

	A	B	C	D	E	F	G
A	1/1	7/1	2/1	5/1	3/1	2/1	5/1
B	1/7	1/1	1/5	3/1	1/3	5/1	5/1
C	½	5/1	1/1	5/1	5/1	3/1	3/1
D	1/5	1/3	1/5	1/1	2/1	1/5	1/7
E	1/3	3/1	1/5	½	1/1	1/5	1/5
F	½	1/5	1/3	5/1	5/1	1/1	2/1
G	1/5	1/5	1/3	7/1	5/1	½	1/1

The subsequent steps were the following:

- the relative importance of the criteria was decimalized,
- the square of the matrix was found,
- the values of elements of the new matrix were summed,
- the matrix of weights was found by sum normalization,
- consecutive iterations were performed on the basis of the above partial operations.

The weight vectors for the consecutive iterations of the performed operations are presented in Table 4.

Tab. 4. Results obtained for the selected criteria

Criterion	1st iteration	2nd iteration	3rd iteration	Order of criteria
A	0.297648	0.294767	0.296339	1
B	0.171752	0.140031	0.145734	3
C	0.232148	0.234428	0.234539	2
D	0.03294	0.039977	0.038389	7
E	0.067484	0.073089	0.072935	6
F	0.108947	0.117155	0.114516	4
G	0.08908	0.100553	0.097548	5

Next, the results obtained by each company-supplier for the selected indicators were collated (Tab. 5). The described procedure was used to determine the companies' preferences according to the criteria, and the number of criteria was reduced to the three most important: environmental results (1), environmental programs (2), financial results (3).

Tab. 5. Results of the suppliers for the selected environmental criteria

Index	Company A	Company B	Company C
Ammonium nitrogen [mg NH_4/l]	1.56	3.28	0.96
Sulfates [mg SO_4/l]	7.2	95.7	35.6
COD [mg O_2/l]	376.8	102.4	118.8

BOD_6 [mg O_2/l]	182.2	76.7	41.9
Water consumption [m^3]	4469917	128300540	57428933
Environmental fees [PLN]	56211234	33749916	48372391
% of trained employees	40	60	10
Number of planned environmental programs	8	5	1
Number of environmental audits	1	1	1
Participation in pro-ecological initiatives	2	1	1
Number of recyclable products [%]	33	60	33

Source: the author's own specification based on the information obtained from the companies.

The ranking of the preferred variants (companies) from the point of view of the individual criteria was put together on the basis of the computed (according to the previously described procedure) preference vectors (Tab. 6).

Tab. 6. Results of the generalized preferences

Environmental results	Environmental programs	Financial results
0.229505	0.64863	0.246801
0.121864	0.229505	0.436758
0.64863	0.121864	0.316441
2nd iteration	2nd iteration	1st iteration

The synthesis and interpretation of the solution is presented in Figure 3.

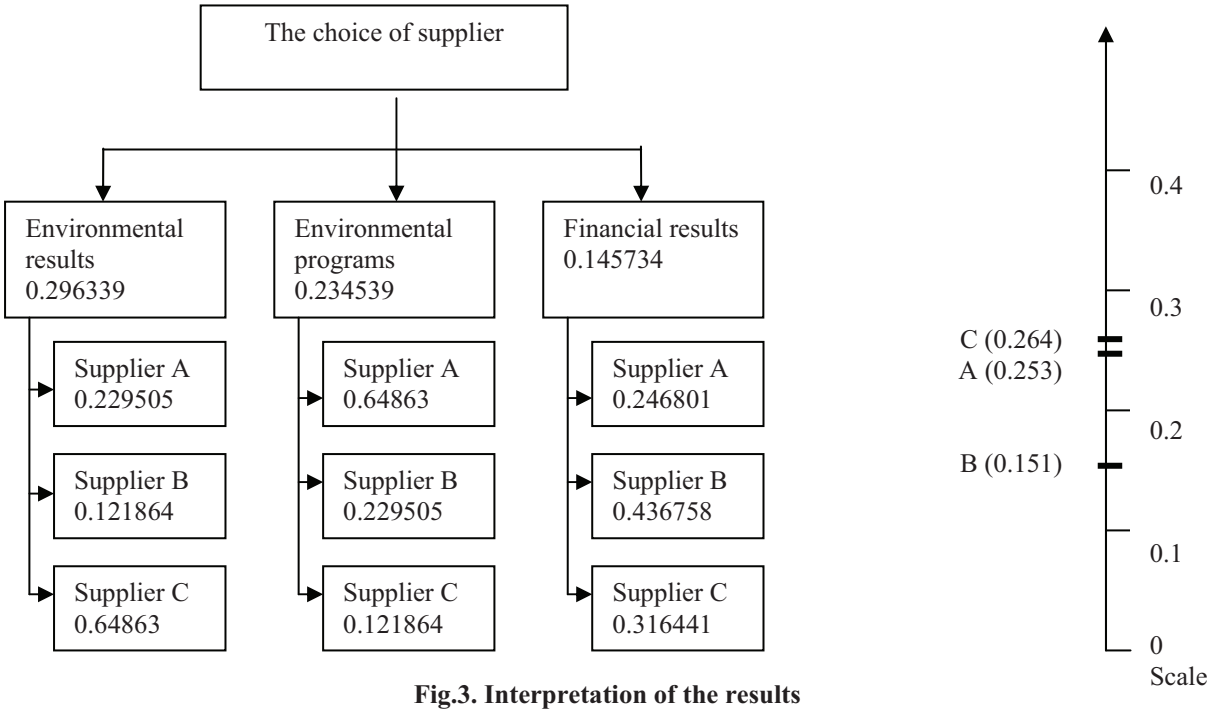

Fig.3. Interpretation of the results

CONCLUSION

The development of green supply chains results from a growing awareness and meaning of the environmental issues. Establishing of such chains entails the necessity of evaluation and

choice of suppliers who can proactively contribute to their company's environmental strategy and whose products and services meet or exceed government environmental regulations. This paper presented how the environmental measures/indicators can be used to evaluate links of green supply chains. The environmental criteria useful in evaluation of companies and products were proposed. The set of criteria may be extended by adding the logistic measures/criteria traditionally used by a company. Thus environmental indicators may be regarded as the ones complementing such "traditional" indicators as: proportion of orders accepted for realization, quality and time of delivery, flexibility of supplies, information openness etc.

The criteria presented in the paper were used to assess external suppliers. However, the presented indicators can also be used to evaluate a company's internal units. The identified indicators therefore satisfy the need for indicators that are useable both for an extended supply chain and for individual companies involved. The criteria were verified with AHP method, which was used to quantify the individual companies-suppliers.
Generalizing the study results, it should be stressed that the presented solution may be an efficient analytical tool in a decision process. This is due to the fact that AHP method makes it possible to determine the decision-maker preferences and to use them in the process of assessments aggregation. It may therefore be used in a multicriteria evaluation of cooperating companies on the basis of selected criteria.

A limitation of the presented solution is poor availability of the data. Resolving these types of issues is not an easy task. Much of the information needed for assessing environmental criteria is simply not available. In addition, companies are reluctant to give information on their internal activities. Other limitations result from the procedure of the AHP method application, and include a considerable subjectivism of judgments, necessity to meet the requirements of the method (e. g., possibility to perform operations on matrices).

ABSTRACT

The impact of ERP systems on the information flows of companies is an aspect often mentioned in ERP literature, but not a topic that has received much detailed attention. Based on existing ERP literature, this paper discusses the concept of ERP system integration in relation to how well the information flows in a company are organized around the ERP system. To investigate the level of ERP system integration in practice, the paper presents the data from a questionnaire study. The paper rests on the premise that ERP systems are designed as enterprise-wide repositories for master and transaction data, for which reason the intended utilization of an ERP system would imply that such companies are always capable of finding the necessary information when needed. However, data from the questionnaire indicates that this is not the case for many companies.

Keywords: Enterprise resource planning, ERP systems, Information flows, Information management

INTRODUCTION

Many companies have engaged in the use of ERP systems as a means to improve their competitiveness. Kumar et al. [16] describe the key underlying idea of ERP systems as "using information technology to achieve a capability to plan and integrate enterprise-wide resources, i.e. by integrating the applications and processes of the various functions such as design, production, purchasing, marketing, and finance". Basically, the popularity of ERP systems can be attributed to their promise of improving operational efficiency and business efficiency [8;13]. For many years, ERP projects have led to substantial tangible benefits (e.g. inventory reduction, less personnel needed, and reduced IT costs) and intangible improvements (e.g. improved internal processes, better customer service, strategic enhancements) in different areas of organizations [1;3;5;10;26]. On the other hand, achieving the expected benefits of the ERP system is by no means a guarantee in ERP projects. There are many examples of organizations that have not been successful in obtaining the intended benefits, in spite of making large investments in ERP projects [5;18;26]. Even worse, many ERP projects have failed and implied financial difficulties for these companies [20;28]. In fact, some research has indicated that ERP implementation projects commonly do not fulfil their initial objectives and operations often suffer from ERP related problems [11;17].

Although the implementation of an ERP system can produce significant performance benefits, achieving effective integration remains problematic because of the numerous technical and organizational challenges, such as the required standardization of work

processes, norms, skills, and outputs [2;12;15]. As formulated by Davenport [4], "an enterprise system, by its very nature, imposes its own logic on a company's strategy, organization, and culture". Because of the many built-in complexities in ERP projects, a significant amount of literature focuses on the management of ERP projects [11]. An important aspect in this context is redesigning the information flow structure of the company, i.e. defining how information processes should be altered to utilize the ERP system. The transition to using an ERP system (or extended use of an existing ERP system) affects the information flows in a company in a number of ways. From a principal perspective, the proper use of an ERP system as a common repository for enterprise data implies that relevant information can be retrieved by relevant persons. In other words, information flows should to a much greater extent pass through an enterprise-wide software system, rather than between individuals or groups in the form of oral messages, paper, emails, and local software systems. Guiding the information flows through a centralized and common channel ensures that information is always present when needed. This obviously implies a wide range of positive effects for a company, such as avoiding errors, shorter lead times, better basis for decision making, less redundant data, etc. Thus, such a transformation of the company appears to be something that should be a prioritized goal to any company. However, the question is if this actually is what happens in practice? Unfortunately, it seems that this topic is not something that has received much detailed attention in ERP literature [23]. Thus, this paper presents a questionnaire study carried out to investigate this question.

The remainder of the paper is organized as follows. Section 2 contains a review of relevant literature concerning the impact of ERP systems on the information flows of a company. Next, section 3 deals with the concept of ERP system integration. Hereafter, section 4 describes the method applied for investigating the impact of ERP systems in companies. Section 5 presents the empirical data from a questionnaire study, which are analysed and discussed. The paper ends with a conclusion in section 6.

LITERATURE REVIEW

This section investigates relevant literature in the context of analyzing the impact of ERP systems on the information flows of the company.

Effects of ERP systems on information flows

Mohania and Bhide [21] argue that the growth of organizations invariably leads to creation of multiple isolated data sources that are disconnected from each other, which leads to reduced efficiency. They further claim that the information integration problem has become the biggest pain point for enterprises today. Vayghan et al. [27] describe the concept of 'information silos', which means that data are redundantly stored, managed, and processed in different silos with different policies and processes. Thus, inconsistency often occurs. Vayghan et al. argue that enterprises need to move away from the 'information silo approach' and towards integrated management systems and architectures for data, processes, and policies.

ERP systems have been marketed as a panacea for dealing with lack of data integration, i.e. that replacing inadequately coordinated legacy systems by an ERP system should imply that most data quality problems would disappear [4;14;18]. However, it is important to perceive ERP as more than integration of IT systems, but to a great deal also business integration, i.e.

defining how the functional units of a company are linked to one another through data/information and processes. In other words, implementing an ERP system implies data and process integration. Organizational information processing theory suggests that ERP systems fit organisations where the interdependence is high and differentiation is low [8]. Thus, Gattiker and Goodhue [8] argue that there is a tendency towards organisational subunits that are highly interdependent to substantially benefit from an ERP system, while subunits that are very different from the other subunits may incur costs from dealing with suboptimal business processes or dependence on employee workarounds. The great danger of having a low fit between some organisational units and the ERP system is that such units use other software than the ERP system for some operations, and thus the purpose of information integration in the company is counteracted. To limit such negative impacts, the information flows of all relevant business units should be thought into the ERP solution.

One of the primary goals of managing the information flows in ERP projects is to ensure that the ERP system provides the needed data to relevant users and that data are of adequately high quality. In this context, Vayghan et al. [27] describes three important data-specific challenges: (1) establish trusted data sources; (2) integrate information; and (3) improve data quality. For the first challenge (establishing trusted data sources for enterprise-critical data), they argue that this becomes a major challenge if: the ownership of data is fragmented in many areas; there are multiple sources for the same data; existing data are undocumented and tightly coupled inside monolithic applications; and subject matter experts in these areas are in short supply. For the second challenge (problems of integrating information), they describe this as being caused by: platform dependencies; organizational issues; tight coupling with business processes; and the lack of business data standards. For the third challenge (improvements of data quality), they argue that this is increasingly difficult: when dealing with a large amount of data where data fields are not standardized; if there are multiple ways of capturing the same data; and if data is copied in many places.

The importance of information flow management

To highlight the importance of aligning the information flows of a company with their ERP system, this issue can be related to the type of benefits that an ERP system produces. Shang and Seddon [24] provide a classification of ERP benefits into five groups: 1) operational (cost reduction, cycle time reduction, productivity improvement, quality improvement, and customer services improvement); 2) managerial (better resource management, improved decision making and planning, and performance improvement); 3) strategic (supporting business growth, supporting business alliance, building business innovations, building cost leadership, generating product differentiation, and building external linkages); 4) IT infrastructure (building business flexibility, IT cost reduction, and increased IT infrastructure capability); and 5) organizational (supporting organizational changes, facilitating business learning, empowering, and building common visions). For all these types of benefits, the precondition is that the necessary information can be found in the ERP system. The more frequently information cannot be found, the less are the benefits of the ERP system.

Markus et al. [19] differentiate between three distinct phases in the ‘ERP experience cycle’: 1) project phase (configuration of ERP software and roll out in organization); 2) shakedown phase (the company makes a transition from 'go live' to normal operations); and 3) onward and upward phase (the company captures the majority of business benefits and plans future steps). In all three phases it is important to ensure that the information flows of the company

are aligned with the ERP system. However, the 'battle' is not lost if this alignment is not achieved instantly. Although the adequate alignment of the information flows with the ERP system is not achieved during the project phase, it can later be achieved during the shakedown phase. In the onward and upward phase, a focus on ensuring that healthy information processes are maintained is important in order not to lose the benefits obtained.
Another danger in ERP projects, besides not getting the required data/information into the ERP system, is that the data stored in the ERP system may be incorrect. Incorrect data is a problem that does not only affect the context in which they are used, but also may have much wider ranging consequences if data errors are carried throughout the system [9]. According to Häkkinen and Hilmola [11] marginal data inaccuracies (e.g. 1-5 percent) may not necessarily represent a major problem in manufacturing, but such inaccuracies will have direct effects in terms of lost sales and operational disruptions in the after-sales organizations. However, ensuring that the data stored in the ERP system is correct is an easy task. According to Knolmayer and Röthlin [14], capturing and processing master data involves several risks of errors, which can emerge from: inappropriate information system architectures, insufficient coordination with business processes, inadequate software implementations, or inattentive user behaviour. Knolmayer and Röthlin give the example that if an employee does not find required master data within reasonable time, the employee may be tempted to swiftly create duplicate data in order to continue his business tasks. Other common sources of errors, which may contribute to misunderstandings or data redundancy, are mistyping names, addresses, and other data fields.

ERP SYSTEM INTEGRATION

In literature there seems to be general agreement on the meanings of the terms 'data' and 'information', while the meaning of the term 'knowledge' is much debated (see e.g. [7;22;25]). However, in this paper the focus is on data and information. Davenport and Prusak [6] define data as "discrete, objective facts about events" and information as data transformed by the value-adding processes of contextualisation, categorisation, calculation, correction and condensation. Similar definitions of data and information are provided by Zack [29], "data represent observations or facts out of context, and therefore not directly meaningful. Information results from placing data within some meaningful context, often in the form of a message". In a similar vein, Newell et al. [22] define data as "providing a record of signs and observations collected from various sources" and information as when "data are presented in a particular way in relation to a particular context of action".

Much of the information passing through a company has relevance for others than the ones initially sending it and the ones receiving it. An ERP system can be the medium that ensures that such information is stored and made accessible to others. Therefore, an important focus of ERP projects is to force this communication of important information through the ERP system. To highlight the difference between structured and unstructured information flows, Figure 1 illustrates a scenario where structuralization of information flows implies that all relevant employees have access to the information they need. In the scenario on the left side of Figure 1, Actor-1 passes on information to Actor-2, while Actor-1 and Actor-2 fail to recognize that this information is also needed by Actor-3. In the scenario to the right, Actor-1 communicates to Actor-2 through an ERP system (i.e. stores data that Actor-2 finds), which enables Actor-3 to use this data as well. The type of data/information in focus in the described scenarios could be transaction data (e.g. invoice payment, receiving of ordered

items, etc.), master data (e.g. item name, debtor credit limit, etc.) or various business information (e.g. budgets, project plans, etc.).

Using the two scenarios illustrated in Figure 1, three archetypical information flow configurations can be defined with respect to ERP system integration, as shown in Figure 2. In Figure 2, the circles represent persons and groups, while the arrows represent communication of business information. As seen, the higher percentage of relevant information, which is exchanged through the ERP system, the more integrated the ERP system is. This measure indicates how well information is shared in an organisation, i.e. the higher the integration of the ERP system is, the greater the chance of being able to find needed information for the users of the system. Thus, 'full enterprise system integration' may at first glance seem to be the solution to all information problems. However, just because information is accessible, this does not mean that it is useful. The stored data also has to be of adequately high quality, i.e. correct, unambiguous, consistent, etc.

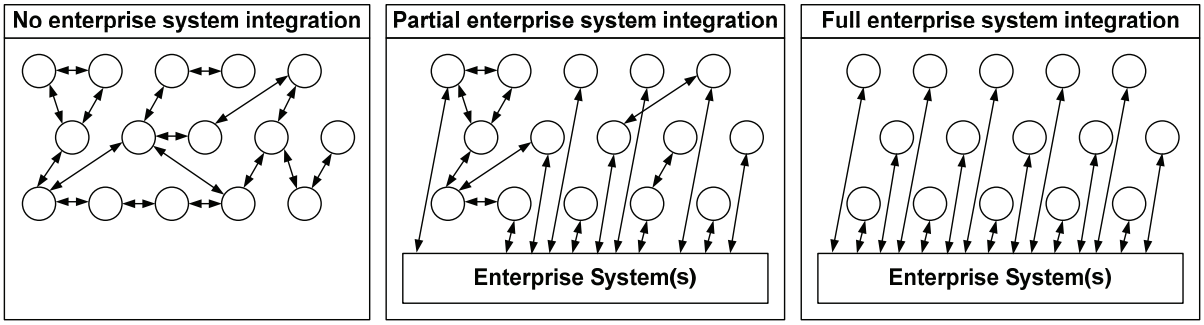

Figure 2: Levels of enterprise system integration (lines symbolize information flows)

RESEARCH METHOD

In 2008, a questionnaire study focusing on supply chain management was carried out. Part of the questionnaire had a focus on information systems within and across companies. The data from this part of the study are presented in this paper.

The questionnaire survey was conducted by distributing questionnaires to 110 of the participating companies at a Danish supply chain meeting ("The Supply Chain Day") arranged by the Danish post office "Post Danmark". This resulted in 49 completed questionnaires. The data were cleansed for companies not having an ERP system and for incomplete responses. This left 37 useable answers divided into 23 manufacturers, 10 wholesalers and 4 retailers. To be able to make a reasonable comparison of companies, it was decided to focus only on the companies of the type 'manufacturers'. This choice was made based on the assumption that such companies in general deal with greater challenges of data management because of dealing with both purchased/produced components and end-products. Table 1 shows the sizes of the remaining companies, divided into small companies (1-49), medium sized companies (50-249), and large companies (250 and more).

Size	1-49	50-249	250-	Total
Number	5	8	10	23

Table 1: Company sizes

RESULTS AND DISCUSSION

The questions about information management were organized into three areas, which are presented in the following sub-sections:

- Product development and production planning
- Deliveries from suppliers
- Deliveries to customers

Product development and production planning

To investigate the extent of the information management problems during product development and production planning, the respondents were asked to estimate how often needed information cannot be found and how often misunderstandings occur because of inconsistent information. Table 2 shows the frequency of needed information that cannot be found during product development and production planning and Table 3 shows the frequency of misunderstandings because of inconsistent information during product development and production.

Frequency/Company size	1-49	50-249	250-	Total
1. Never	20.0 %	12.5 %	20.0 %	17.4 %
2.	40.0 %	75.0 %	50.0 %	56.5 %
3.	40.0 %	12.5 %	30.0 %	26.1 %
4.	0.0 %	0.0 %	0.0 %	0.0 %
5. Very often	0.0 %	0.0 %	0.0 %	0.0 %

Table 2: Frequency of that needed information cannot be found

Frequency/Company size	1-49	50-249	250-	Total
1. Never	0.0 %	12.5 %	0.0 %	4.3 %
2.	100.0 %	37.5 %	60.0 %	60.9 %
3.	0.0 %	50.0 %	30.0 %	30.4 %
4.	0.0 %	0.0 %	10.0 %	4.3 %
5. Very often	0.0 %	0.0 %	0.0 %	0.0 %

Table 3: Frequency of misunderstandings because of inconsistent information

The data show that for the majority of the companies, there do not seem to be great problems in relation to the handling of information during product development and production. In the dataset, 17.4 percent do not experience that information cannot be found, and 56.5 percent chose the rating '2'. For the remaining 26.1 percent who gave the frequency rating '3', the frequency of experiencing that information cannot be found cannot be considered satisfactory. A similar picture is shown from the frequency of misunderstandings occurring because of missing information, although happening a bit more frequently, i.e. 30.4 percent placed this at the frequency '3' and 4.3 percent at '4'. However, the problematic 26.1 percent in Table 2 and the 34.7 percent in Table 3 may be explained by other factors than just poor ERP system usage, since other systems often also are used together with an ERP system for the management of product and production information.

Deliveries from suppliers

To investigate the extent of the information management problems during the process of managing deliveries from suppliers, the respondents were asked to estimate how often needed information cannot be found and how often misunderstandings occur because of inconsistent information. Table 4 shows the frequency of that needed information cannot be found during the process of handling deliveries from suppliers, and Table 5 shows the misunderstandings because of inconsistent information during the management of deliveries from suppliers. In the questionnaires handed out, examples of the types of information in focus were included, i.e. amounts, quality descriptions, prices, item numbers and similar.

Frequency/Company size	1-49	50-249	250-	Total
1. Never/almost never	20.0 %	12.5 %	44.4 %	27.3 %
2.	80.0 %	75.0 %	33.3 %	59.1 %
3.	0.0 %	12.5 %	22.2 %	13.6 %
4.	0.0 %	0.0 %	0.0 %	0.0 %
5. Very often	0.0 %	0.0 %	0.0 %	0.0 %

Table 4: Frequency of that needed information cannot be found

Frequency/Company size	1-49	50-249	250-	Total
1. Never/almost never	20.0 %	0.0 %	22.2 %	13.6 %
2.	40.0 %	87.5 %	44.4 %	59.1 %
3.	40.0 %	12.5 %	33.3 %	27.3 %
4.	0.0 %	0.0 %	0.0 %	0.0 %
5. Very often	0.0 %	0.0 %	0.0 %	0.0 %

Table 5: Frequency of misunderstandings because of inconsistent information

The data show that 27.3 percent of the companies never experience that they cannot find the information needed during handling of deliveries from suppliers, while 59.1 percent rated this '2'. Only 13.6 percent experience not being able to find the needed information at a frequency of '3'. The frequency of misunderstandings because of inadequate information rated '3' is a bit higher, i.e. 27.3 percent. Therefore, the data show that it is only a smaller part of the companies which have problems during supplier handling. In these cases, however, there is a strong indication of unsatisfactory ERP system integration, since ERP systems are intended to hold all relevant information related to suppliers and purchases.

Deliveries to customers

Next, the extent of the information management problems during the process of managing deliveries to customers was investigated. In the context of management of deliveries to customers, Table 6 shows the frequency of lost information, Table 7 shows the misunderstandings because of inconsistent information and Table 8 shows the frequency of how often the delivery times are not kept because of inconsistent information. In the questionnaire handed out, examples of the types of information in focus were given, i.e. completed orders, ongoing orders, time of delivery, order size and similar.

Frequency/Company size	1-49	50-249	250-	Total
1. Never/almost never	20.0 %	0.0 %	20.0 %	13.0 %
2.	60.0 %	62.5 %	60.0 %	60.9 %
3.	20.0 %	12.5 %	10.0 %	13.0 %
4.	0.0 %	12.5 %	10.0 %	8.7 %
5. Very often	0.0 %	12.5 %	0.0 %	4.3 %

Table 6: Frequency of that needed information cannot be found

Frequency/Company size	1-49	50-249	250-	Total
1. Never/almost never	20.0 %	12.5 %	0.0 %	8.7 %
2.	60.0 %	50.0 %	70.0 %	60.9 %
3.	0.0 %	12.5 %	10.0 %	8.7 %
4.	20.0 %	25.0 %	20.0 %	21.7 %
5. Very often	0.0 %	0.0 %	0.0 %	0.0 %

Table 7: Frequency of misunderstandings because of inconsistent information

Frequency/Company size	1-49	50-249	250-	Total
1. Never/almost never	20.0 %	12.5 %	10.0 %	13.0 %
2.	60.0 %	37.5 %	60.0 %	52.2 %
3.	20.0 %	25.0 %	10.0 %	17.4 %
4.	0.0 %	25.0 %	20.0 %	17.4 %
5. Very often	0.0 %	0.0 %	0.0 %	0.0 %

Table 8: Frequency of not keeping promised time of delivery because of inconsistent information

Table 6 shows that 13.0 percent never experience that they cannot find the information needed during handling of deliveries to customers, 60.9 percent gave the rating of '2', while 26 percent gave a rating from 3 to 5. In Table 7, 29.4 percent of the companies gave a rating from 3 to 5. Assuming that ratings of 3 to 5 are problematic, the data show that for more than a fourth of the companies there are problems in the handling of information related to deliveries to customers. With regard to being able to keep the promised time of delivery because of inconstant information, as seen in Table 8, for 17.4 percent this happens at a frequency of '3', and for 17.4 percent it happens at a frequency of '4'. The data from this part of the questionnaire indicate that these around 35 percent of the companies have unsatisfactory ERP system integration, since ERP systems are intended to hold all relevant information related to deliveries.

Information problems across processes

In order to show how many companies experience information problems in any of the three processes, in Table 9 is found a summation of the total number of the companies who in any

of the three processes (i.e. product development and production, deliveries from suppliers, and deliveries to customers) experience that needed information cannot be found.

Frequency of that needed information cannot be found in: product development and production; deliveries from suppliers; and/or deliveries to customers	Companies
1 Never	13,0.%
2	39.1 %
3	34.8 %
4	8.7 %
5 Very often	4.3 %

Table 9: Frequency of that needed information cannot be found in any of the processes

Assuming that ratings from 3 to 5 of how often the needed information cannot be found can be classified as being problematic, about half of the companies (48%) have information management problems in spite of having an ERP system.

Forms of communication

To investigate possible reasons for problems of managing information, the companies were asked to tell how often different forms of communication are used. Table 10 shows the way information is communicated during product development and production planning, and Table 11 shows the way information is communicated during the process of handling deliveries from suppliers.

Frequency of communication form	Email	Software	Printed documents	Handmade documents	Speech
1. Never	13.0 %	4.3 %	8.7 %	52.2 %	17.4 %
2.	13.0 %	8.7 %	30.4 %	21.7 %	26.1 %
3.	26.1 %	13.0 %	17.4 %	17.4 %	30.4 %
4.	17.4 %	17.4 %	26.1 %	8.7 %	17.4 %
5. Very often	30.4 %	56.5 %	17.4 %	0.0 %	8.7 %

Table 10: Product development and production planning: communication forms

Frequency of communication form	Email	Software	Printed documents	Handmade documents	Speech	EDI
1. Never	0.0 %	45.5 %	8.7 %	72.7 %	18.2 %	50.0 %
2.	0.0 %	18.2 %	30.4 %	18.2 %	9.1 %	9.1 %
3.	8.7 %	18.2 %	21.7 %	0.0 %	50.0 %	18.2 %
4.	21.7 %	9.1 %	34.8 %	4.5 %	13.6 %	22.7 %
5. Very often	69.6 %	9.1 %	4.3 %	4.5 %	9.1 %	0.0 %

Table 11: Deliveries from suppliers: communication forms

With regard to the way information is communicated during the product development and production process, the majority of the companies very often use software to handle this communication, i.e. 56.5 percent. However, the numbers also show that a significant part of this communication is in the form of printed documents, handmade documents and speech. These numbers provide a possible explanation to the problems reported with regard to not being able to find the needed information in this process. In the communication in connection with handling the deliveries from suppliers, email is by far the most used means of communication, i.e. 69.6 percent stated 'very often'. However, information is also to a large extent exchanged by speech, which may be part of the explanation for the amount of lost and inconsistent information reported.

CONCLUSIONS

In much literature ERP systems are described as a technology that promises integration of business information across the business units of a company. However, also much literature points out that this does far from always happen in practice. One of the main obstacles is that such a transformation requires great alterations of the information flows of the company to insure that information passes through the system and not past it. To deal with this topic, this paper discussed how ERP projects can transform the way that business information flows through a company. The paper presented three archetypes of enterprise system integration: 'no integration', 'partial integration', and 'full integration'. These types are relevant in the sense that the degree of ERP system integration in many ways is decisive for the amount of benefits that a company can achieve from an ERP project.
Having defined different levels of ERP system integration, a question to be raised is that although many companies manage to implement ERP systems into daily operations, do they actually achieve a satisfactory ERP system integration, i.e. a proper restructuring of the information flows within the company? To investigate this issue, the paper presented a questionnaire study from where the companies of the type 'manufacturer' and the ones that use ERP systems were selected, in all 23 companies. The data from these companies indicate that about half of these companies have problems in managing their business information, in spite of having an ERP system. However, the data from the conducted study should be received with some reservations. First, it should be recognized that the amount of data retrieved fitting the selection criteria (i.e. manufacturers with ERP systems) was not very extensive for a study of this kind. Therefore, the study does not give a solid basis for generalization about the quality of information management in Danish manufacturing companies with ERP systems. Another problem of the study is that the way the questions were asked left much to the judgement of the respondents. Also, since only one person from each company filled out the questionnaire, there is a great chance that others in the same organization may have insights into other problems of handling information. Thus, it seems fair to assume that the numbers would have been higher if more persons from each company had answered the questionnaire.

Since about half the companies in the survey reported not being able to find the relevant information at a frequency that seems unsatisfactory, there are some indications of problems related to ERP system integration. This produces two main challenges for future research. First, a more extensive survey needs to be carried out in order to produce better grounds for generalizing. Second, more in-depth studies are needed in order to discover the reasons for the apparent problems of integrating ERP systems in companies.

ABSTRACT

Product-service systems (PSSs) are highlighted as prevailing trend toward integration of products and services for customer satisfaction or sustainability. Many firms have chosen PSSs as an essential strategy to survive in hyper-competition. However, few systematic methods for evaluating PSSs from multi-objective perspectives have been established. This study proposes a systematic approach to evaluation of PSSs using system dynamics from multi-objective perspectives such as customer satisfaction, sustainability, and profitability. System dynamics is a method developed to support the dynamic behavior in complex systems. It can be effectively employed in analyzing PSSs which are complex systems including many stakeholders and objectives interrelated with each other through product life cycle. The proposed approach deals with the properties of PSSs through the general steps of system dynamics simulation procedure. It enables firms who adopt PSSs not only to evaluate and compare alternatives but also to describe and understand the systems' mechanisms and feedback links. A simple case of PSSs providing washing function is presented for illustration of the proposed approach.

Keywords: Product-service system, System dynamics, Evaluation, Customer satisfaction, Profitability, Sustainability

INTRODUCTION

Nowadays, manufacturers are suffering from lack of strategies for satisfying customers. Their agony is how to differentiate them in tough competitive market. One of the new arrival as a solution for this problem is product-service systems (PSSs) (Matthyssens and Buyl, 2005; Baines et al., 2007). By integrating products with services and various enablers, PSSs add value for customers. Moreover, PSSs are focused on in an ecological aspect. By emphasizing the 'sale of use' rather than the 'sale of product', PSSs enable manufacturers to reduce and optimize the use of resources. Increasing concern about environmental effect of economic activities is highlighting PSS as imperative milestone to achieve sustainability (Baines et al., 2007). Therefore, many manufacturers are trying to adopt PSSs for their benefits.

However, there are many barriers to adoption of PSSs. Lack of methods and tools for designing PSSs exists at the core of difficulty. PSSs have distinguishable features from products obviously. PSSs involve dynamics of system including many stakeholders and

objectives that are inter-related each other. That is, PSSs incorporate somewhat complex aims which are minimization of environmental impacts while maintaining enterprises' economical performance and service quality for users (Komoto et al., 2005). These facts lead the needs for new systematic methods and tools for PSSs. As it is already mentioned, systematic methods for designing PSSs have, however, not yet fully established. This implies that there is a lack of methods and tools for concept evaluation of PSSs. Concept evaluation to identify the most promising design concept has been considered very critical as it has significant impact on the downstream development processes as well as on the success of the PSS developed (Zhai et al., 2009). Thus it is much important to establish systemic PSS concept evaluation methodology at the systemic level in practice.

This paper aims to propose an approach to evaluating concept of PSSs by simulating alternatives using system dynamics. System dynamics is a method which was developed to support the dynamic behavior in complex system. It can be effectively employed to analyzing PSSs which are complex systems including many stakeholders and objectives interrelated each other through product life cycle.

Remained of this paper is organized as follows. The basic concept and related studies on PSSs and system dynamics are discussed each in the following sections. After the proposed approach for evaluating PSSs using system dynamics is introduced in the next section, a simple case is presented for the illustration of the proposed approach. Finally, summary and further discussion concludes this paper.

PRODUCT-SERVICE SYSTEM

Product-service system (PSS) is a marketable set of products and services capable of jointly fulfilling user's needs (Goedkoop et al., 1999). The PSS concept aims at minimization of environmental impact with use of alternative production and consumption patterns. There are several definitions for PSS, but it has been generally described as 'a system of products, services, supporting networks and infrastructure that is designed to be: competitive, satisfy customer needs and have a lower environmental impact than traditional business models (Mont, 2002)'. At its core, PSS focuses on the delivery of a 'function' to the customer, instead of sale, ownership, consumption, and disposal of 'products' (Williams, 2006). Actually the approach is to substitute services for products and moving from 'product thinking' to 'system thinking' (Mont, 2003).

Within a traditional paradigm, the relationship between a producer and a consumer is quite simple (Williams, 2006). When the producer sells a product after designing and manufacturing, the consumer buys it. This is the end of producer's roll because the producer has given ownership to the consumer. In contrast, in PSSs, manufacturers' involvement and responsibility is extended from making a product available to purchase to phases of the life cycle that are usually outside the buyer-seller relationship. Therefore PSSs require close integration of all actors within the life cycle of products (Mont, 2002; Mont, 2003). The stakeholders in PSSs interact actively each other forming network, thus the relationships among them are likely to be complex.

This complexity can make firms difficult to design PSSs. In some cases, it will result in an additional cost for communication and a slower market introduction because of the difficulty in explaining (Goedkoop et al., 1999). Although various tools and methodologies have been

introduced for designing PSS (Mont, 2000; Goedkoop et al., 1999; Aurich et al., 2006; MEPSS Handbook, 2004; etc.), still there is lack of critical and in-depth evaluation of their performance in practice and need for in-depth and rigorous research to develop models, methods, and theories (Baines et al., 2007).

Especially, as concept evaluation to identify the most promising design concept has been considered very critical on the success of the PSS (Zhai et al., 2009), many related studies have been conducted. In the first place, some researchers mentioned about what to evaluate. Maxwell and Vorst (2003) identified nine criteria for optimizing PSS: functionality, environmental impact, social impact, economic impact, quality, market demand, customer requirements, technical feasibility, legislation and technical industry specifications. While Thoben et al. (2001) focused on economic impact, market, and customer because they asserted that the goals of PSSs are proposing an attractive package for the customer and standing out from competition, Bhamra et al. (2001) attended to environmental impact and social impact from asserting that PSS involves environmental considerations such as dematerialization and sustainable products.

Looking over studies aiming to propose specific methods or tools, we can identify the two critical factors that most of them are focusing on. The one is economic value based on customer satisfaction and the other is ecological effect based on product life cycle. Caswell et al. (2008) developed a computation model to estimate economic value of service system that could be aligned with PSSs by definition. The model takes into account partners' satisfaction and the additional value which is created by the relationships among the various partners. Tasaki et al. (2006) suggested a quantitative method to evaluate the level of material use and waste generation in lease/reuse systems, using a simple indicator in terms of annual product demand. As a consequence, whether a system shortens or extends the lifetime of products appeared to be the key factor to determining material intensity, not whether the system itself was a lease system or a possession system. Komoto et al. (2005) proposed a methodology to analyze PSS based on discrete event simulation technique. They described the resulting performance of product life cycle as a function of occurrence of the PSS-events and their individual performance.

Although various attempts to deal with evaluation of PSS, there still exist some limitations or problems. Little systematic approach to evaluate PSS from multi-objective perspectives is established. Interrelations among the objectives are scarcely considered even though multi-objectives are estimated. Moreover, they tend to oversimplify the complex systems not fully considering the characteristics of PSSs.

SYSTEM DYNAMICS

System dynamics is a methodology that was specifically developed to support the study of dynamic behavior in complex system. It draws on a wide variety of disciplines to provide a common foundation for understanding and influencing how things change over time. Its central concept is that all the objects in a system interact through causal relationships. System dynamics recognizes the roles of the feedback information and the cause-and effect relationships in creating the dynamic behaviors of the systems, and takes an integrative perspective in modeling the system (Rabelo et al., 2005).

System dynamics modeling is mainly about discovering and representing the feedback

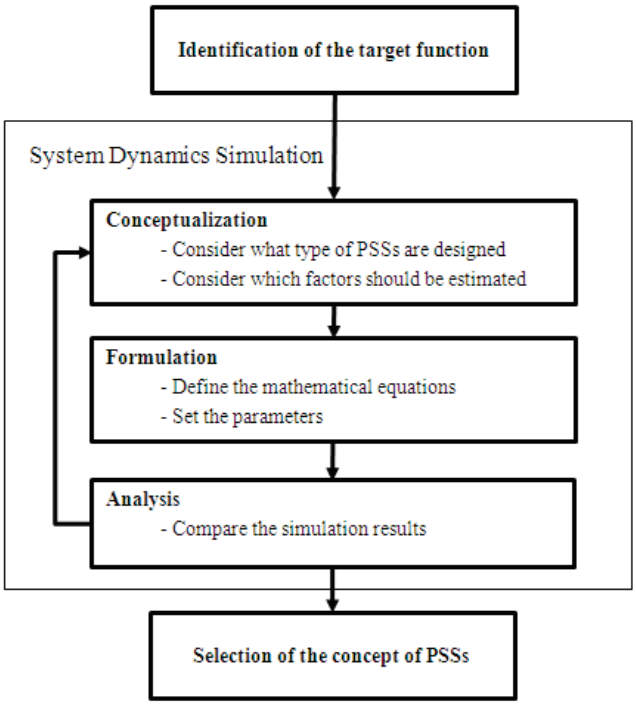
processes (Sterman, 2000; Hjorth and Bagheri, 2006). It determines the dynamics of a system along with stock and flow structures, time delays, and nonlinearities. As a result of these processes, causal loop diagram is drawn. Causal loop diagram is a powerful graphic tool to see the relationships among a system's parts and their interactions with each other. It is composed of a simple node-arrow construct that interlink key system variables by arrows indicating directions of causality. And a series of causal relationships consists of the set of interconnected feedback loops. While attempting to draw causal loop diagrams, we can enhance learning in complex system through not only a better understanding of a system's mechanisms and feedback links, but also modifying decision rules and mental models of the real world (Hjorth and Bagheri, 2006; Sterman, 2000). This has helped many managers to think how a strategy might or might not work, and what kind of consequences emerge. Finally, simulation models based on causal loop diagrams are built and run, which help to analyze system performance under different scenarios.

We found the possibility of system dynamics to be employed successfully in PSSs. As mentioned earlier, PSS is a large and complex system including many stakeholders and transactions. There are multiple driving forces such as customer satisfaction or sustainability, which have interdependence among each other. System dynamics approaches reasonable and actual solution by incorporating various interests and interactions of objects in complex system, and reflecting dynamic behavior. PSSs need long-term feedback during product life cycle. Although that is one of the main reasons many existing approaches cannot be employed to PSSs successfully, system dynamics can deal with this issue satisfactorily. System dynamics has been used in the business to evaluate the impact of business alternatives on the long-term performance of the enterprise (Rabelo et al., 2005). The fact that system dynamics is considered as a powerful methodology to deal with issues of sustainability (Hjorht and Bagheri, 2006) enhances the suitableness of system dynamics for PSSs.

In addition, designing PSSs is iterative process with restructuring business organization. Simulation technique deals with the repetitive tasks efficiently. As system dynamics does not depend on data and has been considered suitable for qualitative parameters in management decisions, it has more powerful in concept evaluation phase. Therefore, system dynamics enables the efficient and effective decision-making during the iteration of concept design process for PSS.

EVALUATING PRODUCT-SERVICE SYSTEMS

In this chapter, we briefly explain the procedure of evaluating PSSs to aid manufacturers to adopt PSSs. Following the general steps-conceptualization, formulation, and analysis-in system dynamics simulation process, we focus on the characteristics of PSSs. Figure 1 depicts the framework of proposed approach.



[Figure 1] Framework for evaluating PSSs concept using system dynamics

Based on the target function that would be offered to customers, manufacturers conceptualize their PSSs concepts. While manufacturers have delivered their offering to customers by selling their products traditionally, the offering is function in PSSs. The delivered form of function varies in integrating way of various service enablers. Generally, there are three types of PSS(Baines et al., 2007) as shown in Table 1. Depending on the PSS type, the stakeholders, their roles, and transactions in system are varied. Therefore, considering the delivering way of target function can be a good starting point for establishing variables to conceptualize PSSs.

[Table 1]Three types of PSS

Type	Description
Product-oriented PSS	promoting/selling the product in a traditional manner, while including in the original act of sale additional services such as after-sales service to guarantee functionality and durability of the product owned by the customer
Use-oriented PSS	selling the use or availability of a product that is not owned by the customer
Result-oriented PSS	selling a result or capability instead of a product

After deciding the delivering way for the target function, defined the estimated factors of the PSSs. As summarized in section 2, several critical factors for designing PSS were identified. Firms are able to consider some of them depending on their purposes. Generally, customer satisfaction and sustainability are considered as main objectives of PSS. And it is no wonder that economical benefit of firms is also included.

The important task in conceptualization step is lining the relationships among the established variables. The core of conceptualization of PSSs in system dynamics exists in finding how the critical factors are connected each other. The stakeholders make complex tangible and intangible transactions, and the critical factors are resulted in these transactions and additional variables. The variables and their relationships are represented in causal loop diagram.

The rough relationship depicted in conceptualization step is defined as mathematical form in formulation step. Many studies have proposed the calculation for each factor. Firms can apply or modify those proposed equations depending on their situation and purpose. Generally, customer satisfaction is calculated from perceived value and paid cost and profitability of firms is calculated from price and cost. In the case of sustainability, there exist various approaches to estimation. In practice, guidelines or regulations from committee or government approach are useful. And then, parameters for simulation are determined

Finally, the model is simulated. Results of each concept are analyzed and compared each other. If necessary, the simulation can be repeated based on several scenarios. As the dynamics of PSS range over product life cycle, change of environment should be fully considered. Additionally, finding uncovered feedback loop provides the opportunity for correcting their strategy and solving their problems. As a nutshell, the results of simulating PSS concepts imply some important insights that are hard to be provided from other approaches for firms. The application of this approach depends on the situation of firms in practice. In the next section, an example is presented for illustration of this approach.

ILLUSTRATIVE EXAMPLE

The proposed approach is applied to a washing machine manufacturer. The firm is faced the issue on whether it keeps the existing business model or not. Traditionally, the firm has sold washing machines to customers. The traditional business model seems that it cannot guarantee the growth of the firm any more. Therefore, new concept of business model as a PSS for providing washing function is proposed. In the new business model, washing function is provided to customers by guaranteeing accessibility to the washing machine owned and maintained by manufacturer. It is called ‘pay-per-use model’ and ‘use-oriented model’ in the classification of PSSs type.

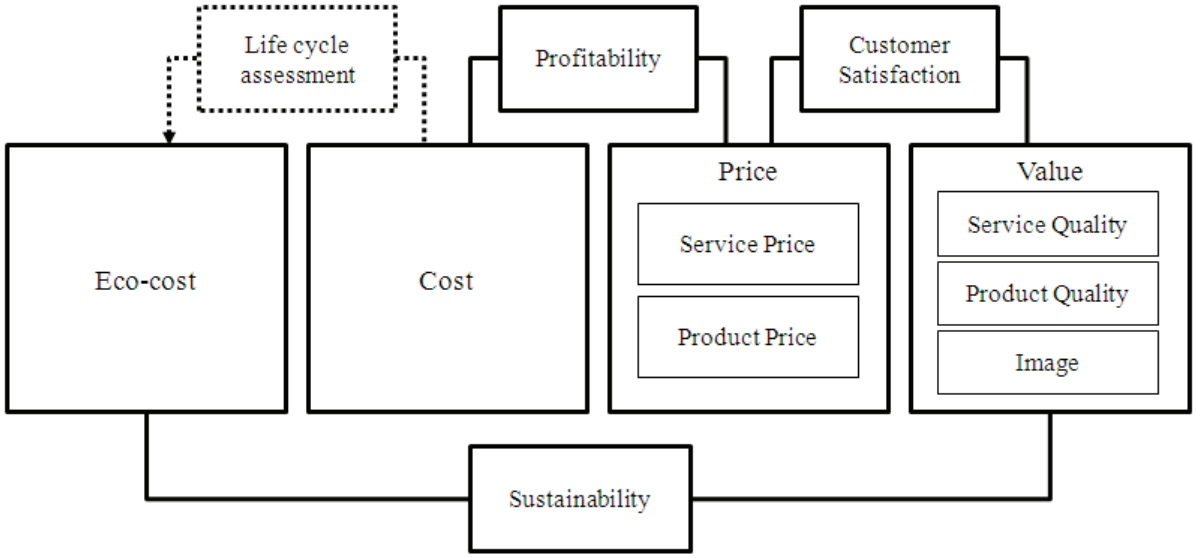
Roles and relevant stakeholders during product life cycle are depicted in table 2. Product model used in each concept is also different. While products in the traditional model are not reused, other products in the alternative would be reused by the manufacturer.

[Table 2] Example of role and responsible part for each concept

Concept		**Traditional model**	**Alternative**
Product model		Household	Community
Role	Manufacturer	Manufacturer	Manufacturer
	Owner	Customer	Manufacturer
	Operator	Customer	Customer
	Maintainer	Customer	Manufacturer

Disposer	Customer	Manufacturer
Reuser	-	Manufacturer

The firm is concerned about the profitability acquired from each PSS concept. Customer satisfaction and sustainability are also main factors to be estimated. Generally, customer satisfaction is considered as the basis of the profitability. In aspects of environment and pollution, government is tightening regulations. Moreover, eco-friendly firm gets more attractive to customers. Based on the physical transaction among the stakeholders, these key factors are estimated. After the variables comprehensively established, the relations among them are mapped. Figure 2, the strategic model for PSS, conceptually shows the relations among the variables.

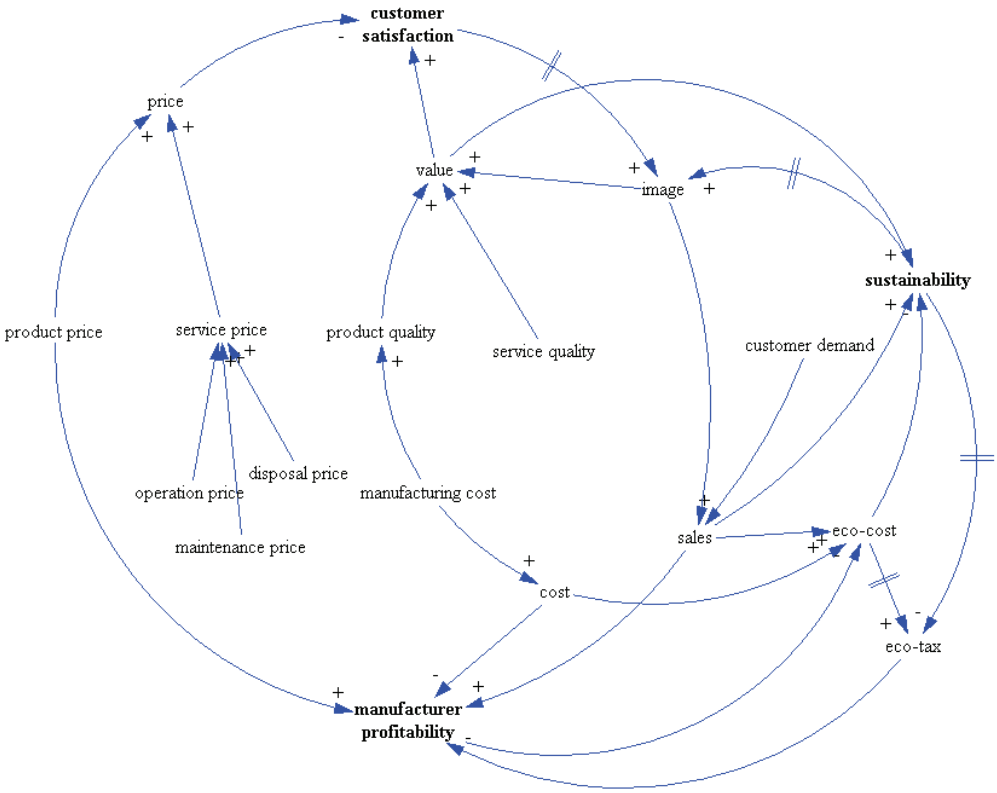


[Figure 2] Strategic model for PSS

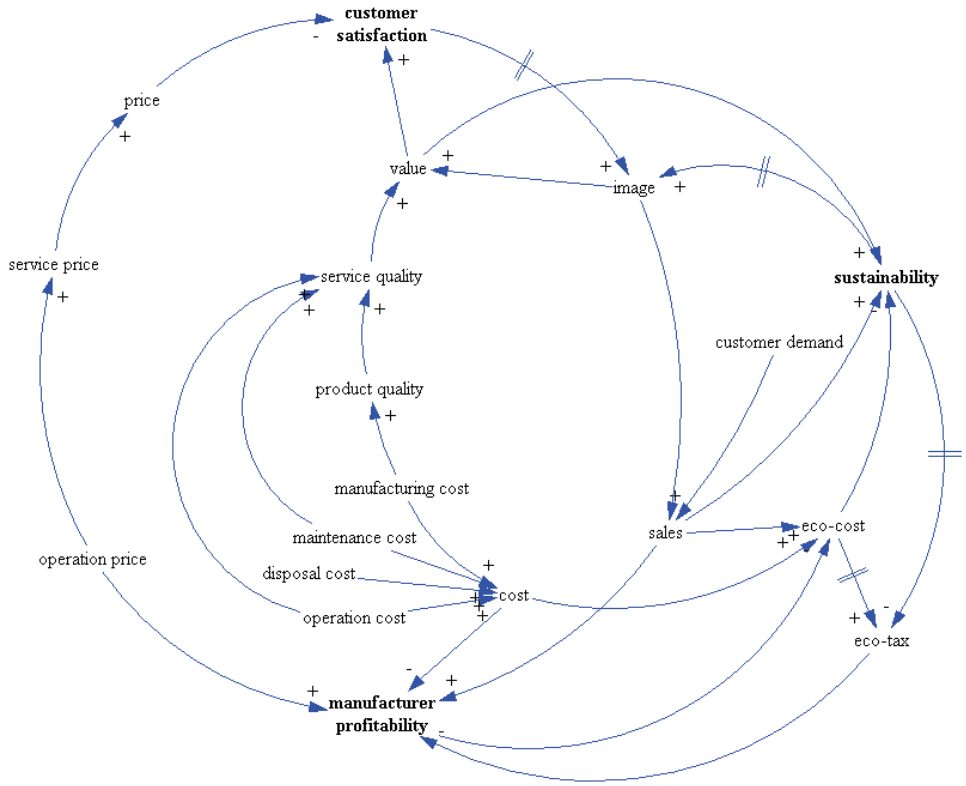
Figure 3 and figure 4 are causal loop diagrams based on the strategic model. While manufacturer get the product price in the traditional model, the operation fee is income of manufacturer in alternative. The service that has been traditionally provided by the third party is provided by manufacturer in alternative. Additionally, some different causal links are identified.

Completing the conceptualization of each model, the relation is formulated into mathematical equations and parameters are set for simulation. Customer's satisfaction is calculated with value divided by price. Manufacturer's profitability is basically calculated from the differences from price and cost. In practice, tax for environmental regulation is included in cost. In this simulation, however, the tax is subtracted from the price as a distinguished item for highlighting the relation between profitability and sustainability. To make this illustrative case to be simple, the equations related with environmental is supposed as very simple form. The tax is calculated based on the sustainability of the system. Sustainability in this simulation is estimated as eco-efficiency (Vogtländer et al., 2001). Eco-cost is proportional to cost. The simplification of mathematical equations in case study is not critical considering the

purpose of this case study and this paper. For each variable, the equation is specifically defined and parameter is set. The products' feature used for setting parameters is depicted in table 3.



[Figure 3] Causal loop diagram of traditional model

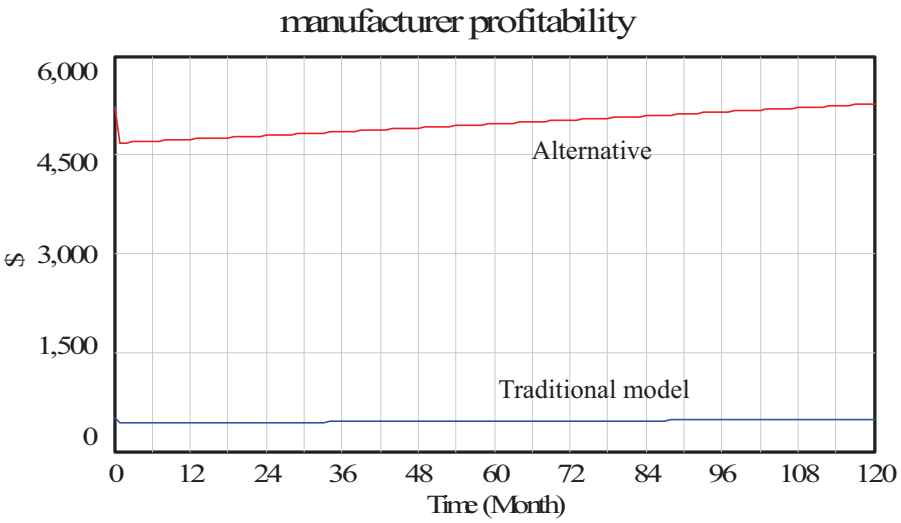


[Figure 4] Causal loop diagram of alternative 1

[Table 3] Feature of product for each model

	Traditional model	**Alternative**
Product type	Household	Community
Price [$]	500	1000
Life time [year]	10	5
Operation capacity [operation/week]	5	100
Capacity [kg/operation]	4	6
Failure rate [/operation]	0.0001	0.0001
Operation cost [$/operation]	0.2	0.3
Operation fee [$/operation]	0.2	0.3
Repair cost [$/failure]	100	100
Repair fee [$/failure]	100	150
Disposal cost [$]	25	25
Reusable	No	Yes
Reuse cost [$]	-	75

Results of the simulations show that level of customer satisfaction and sustainability in alternative are higher than those in traditional model. This leads the rapider increase in manufacturer profitability in alternative than the increase in traditional model shown in figure 5. That is, the performance of new business model is expected to be better than traditional model. Thus, the new PSS concept, ‘pay-per-use model’ is recommended to be adopted.



[Figure 5] Simulation result-manufacturer profitability

CONCULSION

This study proposes a simulation-based approach for evaluation of PSSs. PSSs are large and complex systems with multi-objectives that depend on each other. The proposed approach serves these distinguishable attributes of PSSs using system dynamics. The case of washing machine manufacturer was presented for illustration of the proposed approach. The illustrative case shows the possibility that proposed approach based on system dynamics can be successfully employed in modeling and analyzing PSSs. Analyzing more simulation results on customer satisfaction, sustainability, and other causal variables is listed as ongoing work. That would be more fruitful insights for manufacturers.

However, the refinement of proposed approach is still remained. Each step need to be more clarified and detailed. Further, more abundant and realistic case study is practically useful for lots of manufactures who try to adopt PSSs.

ABSTRACT

Supply chain performance and effective management of supply chain have been increasingly recognized as critical factors in gaining competitive advantage. More and more firms are increasingly making use of SCM to improve their performance. This paper presents the findings of a research which examines the relationship between supply chain management (SCM) practices and process performance in manufacturing companies in Malaysia. The study measures senior management's perception of SCM practices and the level of process performance in the industry. Associations between SCM and process performance are analyzed through methods such as Pearson's correlations, cluster analysis and Structural Equation Modeling (SEM) using 250 respondents' data. The findings suggest that SCM practices have significant correlations with process performance (comprises of processes such as demand management process, customer relationship management process, customer service management process and order fulfillment process). Specifically, process performance has high correlations with SCM practices namely as 'strategic supplier partnership', 'customer relationship performance', 'information sharing', 'lean production' and 'postponement concept' and 'technology and innovation'. The SEM result also reveals that SCM practices exhibit direct impact on process performance. Findings of the study provide a demonstration of the importance of SCM practices in enhancing process performance in Malaysian manufacturing companies.

Keywords: Supply chain management, SCM practices, process performance, business performance, manufacturing companies, changes, Pearson's correlation, cluster analysis and structural equation modeling.

INTRODUCTION

Today's global marketplace offers tremendous opportunities in achieving strategic competitiveness through effective supply chain management (SCM). The environment in which firms operate, today, has changed drastically with the growth in collaboration between competitors as well as business partners, outsourcing and also integrated supply chain systems. As global competition increases, businesses should be more involved in how their suppliers and customers do business. To compete successfully in today challenging business environment manufacturing companies should be able to effectively integrating the internal functions within a company and effectively linking them with the external operations of suppliers and supply chain members. They need to focus on supply chain management practices that have impact on enhancing SCM activities such as where materials come from, how their suppliers' products are designed and assembled, how products are transported and stored and what consumers really

wants. The process of making and distributing products and services to customers is becoming the most effective and efficient way for businesses to stay successful and is central to the practice of supply chain management.

Empirically, the purpose of this study is to present an explicit result on the relationship between SCM and process performance where other researchers have perhaps known or describe them only implicitly. There are studies which suggest that SCM improves performance but, with a few exceptions, rarely support it with statistical evidence. This study is one of few attempts to estimate the effect of implementing SCM programs on process performance. It fills a gap that exists in the literature on SCM in the manufacturing industry in Malaysia.

Since the purpose of this paper is to enhance managerial understanding of supply chain management and process performance in relation to SCM implementations, the main objectives of this paper are:

(1) To empirically investigate relationship between supply chain management (SCM) practices and process performance.
(2) To empirically assess the structural effect of each SCM practice.

This paper explores the possibility of adopting SCM as the basis for enhancing process performance in manufacturing companies. First, this paper proceeds with an introduction, the objectives of the study and the test conducted to obtain the reliable measures of the variables; Secondly, it continue with a brief explanation on the SCM principles and literature review; Thirdly, it describes the conceptual framework consisting of the conceptual model and hypotheses; Fourthly, it discusses the methodology adopted; Fifth, it highlights the results of Pearson correlations, cluster analysis and structural equation modeling. Finally, the results are then discussed and implications highlighted.

SUPPLY CHAIN MANAGEMENT (LITERATURE REVIEW)

Supply chain management includes managing supply and demand, sourcing raw materials and parts, manufacturing and assembly, warehousing and inventory tracking, order entry and order management, distribution across all channels, and delivery to the customer. The term SCM was first used in the 1980s and as such is a relatively new discipline within management theory with tools and concepts still being developed. As with most management subject areas, many definitions have been used to explain the term SCM. The frequency with which the term “supply chain management” (SCM) is used in today’s environment would suggest that it is a well understood concept accompanied by an accepted set of managerial practices. However, definitions of and approaches to SCM vary substantially from organisation to organisation. Schonsleben (2004) defines SCM as coordination of strategic and long-term cooperation in logistics networks (Windischer and Grote, 2003). Tan, et. al. (1998) defines SCM as the simultaneous integration of customer requirements, internal requirements and upstream supplier performance. Quinn (1997) similarly views the supply chain as a set of processes. According to Quinn (1997), the supply chain includes all of those activities associated with moving goods from the raw-materials stage through to the end user. This includes sourcing and procurement,

production scheduling, order processing, inventory management, transportation, warehousing and customer service. It also embodies the information systems which are necessary to monitor all of those activities. Ellram and Cooper (1990) viewed SCM as an integrating philosophy to manage the total flow of a distribution channel from supplier to the ultimate customer. Christopher (1998) defines the supply chain as the network of organisations that are involved, through upstream and downstream linkages, in the different processes and activities that produce value in the form of products and services in the hands of the ultimate customer. Supporters of this approach (e.g. Hakansson, 1982; Wijnstra, 1998) argue that buyer-seller relationships are influenced not only by the characteristics of the product and the organizations involved, but also by the relationships between these organisations and other organisations which are part of the supplier network. SCM coordinates and integrates all of the supply chain activities into a seamless process. SCM links all of the partners in the chain, including departments within an organisation and external companies and information systems providers. A key point in SCM is that the entire process must be viewed as one system (Lummus and Vokurka, 1999). This definition highlights the importance of managing boundaries between business partners. Robinson and Kalakota (2000) view the supply chain quite simply as a "process umbrella" under which products are developed and delivered to customers. From a structural viewpoint, they argue, the supply chain refers to the complex network of relationships that organizations maintain with trading partners to source, manufacture and deliver products. According to this view, an ideal supply chain consists of multiple companies that function as efficiently and effectively as a single company with full information visibility and accountability. The supply chain can be conceptualised in a number of different ways, ranging from network studies through production chains to behavioural analysis of dynamic inter-firm relationships (Hart and Saunders, 1997). Research shows that the development of effective supply chain coordination involves a multidimensional approach to systems integration, encompassing logistical flows, transfer of learning and trust-based relationships (Oliver et al., 1996; Hart and Saunders, 1997).

According to Ganeshan and Harrison (1999), a supply chain is a network of facilities and distribution options that performs the functions of procurement of materials, transformation of these materials into intermediate and finished products, and the distribution of these finished products to customers. Supply Chain Management (SCM) is "the management of upstream and downstream relationships with suppliers and customers to deliver superior customer value at less cost to the supply chain as a whole" (Christopher, 1998).SCM involves integration, co-ordination and collaboration across organizations and throughout the supply chain. SCM comprises determinants such as strategic supplier partnership, customer relationship management, information sharing between SCM partners, lean production, postponement concept and technology & innovation. All these determinants are considered as building blocks of SCM in today's business environment. SCM involves integration, coordination and collaboration across organisations and throughout the supply chain. Supply chain management requires coordination with customers and suppliers. Firms must achieve a relatively high degree of integration before implementing SCM. Supply chain management has the potential to assist the organisation in achieving both cost and a value advantage (Christopher, 1998). To gain competitive advantage, organisations have to adopt supply chain management (SCM) approach and consider the supply chain as a whole. Many researchers claim that supply chain management can result in better supply chain performance (Christopher, 1998 and Christiansee & Kumar, 2000). But very few

empirical studies have been carried to investigate the relationship between SCM and performance.

INDEPENDENT AND DEPENDENT CONSTRUCTS' MEASUREMENT: VALIDITY AND RELIABILITY

In this study, validity and reliability tests were used to select and assess the final items of the independent constructs that would be used for statistical testing. The SCM variables in this study were adopted from prominent studies or sources (Gunasekaran et al, 2003, Kuei et al., 2001, Li et. al, 2002, Hill, 2003, and Vickery, 1999). In this study, SCM was operationalized based upon six different kinds of activities that manufacturers commonly used to integrate their operations with suppliers and customers namely strategic supplier partnership, customer relationship management, information sharing between SCM partners, lean production, postponement concept and technology & innovation. As the initial data analysis, the six SCM variables were subjected to validity and reliability tests before a single score can be calculated to represent each construct. Multi item scales were developed for each construct in the study. Before creating the final scales, the data were checked for normality and outliers.

Table 1: Factor Analysis and Reliability Test

CONSTRUCT	Exploratory Factor Analysis –EFA (Varimax Rotation)			Confirmatory Factor Analysis – CFA		Reliability Test
	Eigenvalue	% of Variance Explained	Cummulative Variance Explained	GFI	CFI	Cronbach's Alpha
SCM	6.192	44.229	44.229	0.978	0.988	0.887
Process performance	4.203	30.022	74.251	0.918	0.971	0.965

Extraction Method: Principal Component Analysis.
Rotation Method: Varimax with Kaiser Normalization (KMO= 0.957)

Exploratory factor analysis, confirmatory factor analysis and Cronbach's reliability analysis were used to select and assess the final items that would be used for hypothesis testing. The critical variables of SCM in this study had content validity because an extensive review of the literature was conducted in selecting the measurement items. The SCM determinants in this study were adopted from prominent studies or sources (Zairi, 1998; Murray, 1997; Mabert, 1992; Richman & Zachary, 1993). As the initial data analysis, the six determinants of SCM were subjected to validity and reliability tests. Exploratory factor analysis was conducted to investigate whether the constructs as described in the literature fits the factors derived from the factor analysis. The result from the factor analysis indicates that the KMO (Kaiser-Meyer-Olkin) measure is 0.957 with significant chi-square value (Barlett's Test of Sphericity = 3192, probability value = 0.000).

The value of KMO in this analysis surpasses the threshold value of 0.50 as recommended by Hair et. al (1998) and all the eigenvalues of the two constructs are above 1.00. All variables or determinants exhibit high factor loadings and almost fall into the designated factors as described by the literature. This result provides evidence to support the theoretical conceptualization of each construct. In addition, confirmatory factor analysis (CFA) or a measurement model using AMOS 5 was employed for examining construct validity of each scale by assessing how well the individual item measured the scale (Ahire et al., 1996). The goodness of fit indices (GFI) and comparative fit index (CFI) of the exogenous determinants exceeded the 0.90 criterion suggested by Hair et al. (1998), hence, establishing the construct validity (see Table 2).

Since data for this study was generated using scaled responses, it was deemed necessary to test for reliability. The reliability analysis was conducted by calculating the Cronbach's alpha for the main constructs. The result shows that the Cronbach's alpha measures for the main constructs exceeds the threshold point of 0.70 suggested by Nunnally (1978). Alpha coefficients for SCM and performance scales ranged between 0.887 and 0.965 after the alpha maximization processes were carried out (Table 1).

CONCEPTUAL FRAMEWORK

This paper explores the relationship between supply chain management and process performance within the context of the Malaysian manufacturing industry. The proposed model, as depicted in Figure 1, is based on two main constructs namely: (i) Supply Chain Management (SCM); and (ii) process performance (PROCESS).

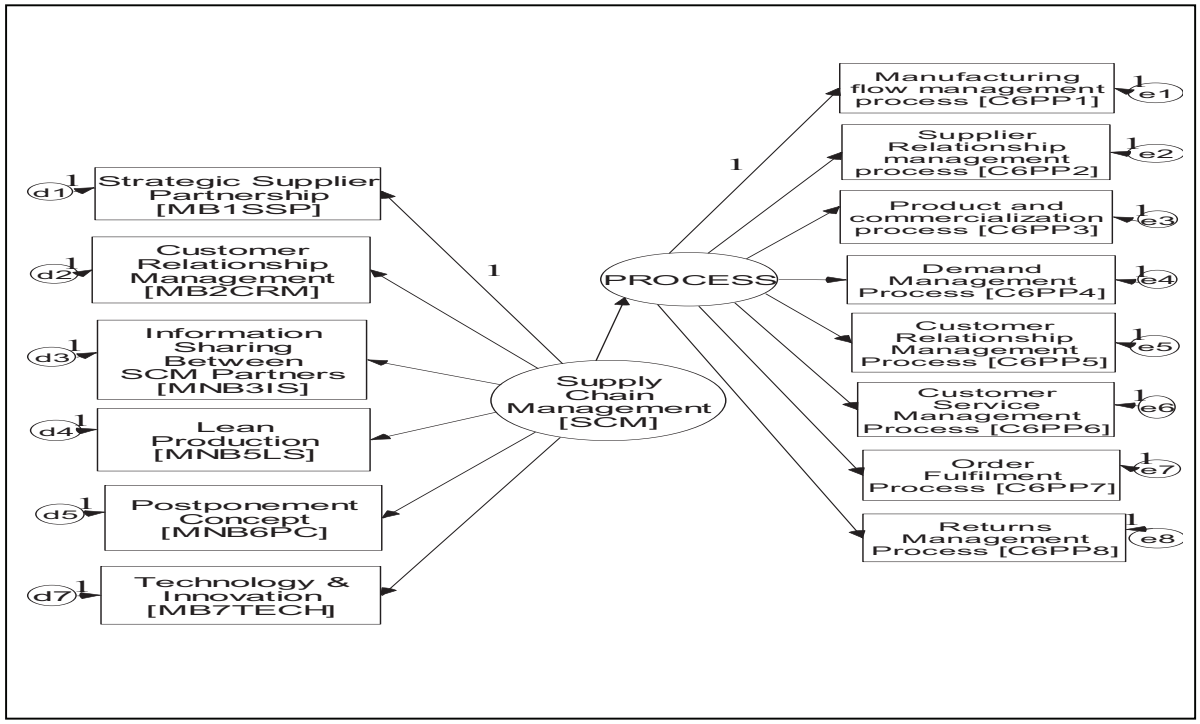

Figure 1: The conceptual model linking SCM and process performance

In this study, SCM represents a manager's assessment of the overall level of supply chain management practices (Davis & Heineke 2005, Mekong capital.com, 2004). In addition to improving levels of performance, SCM has also been shown to provide benefits in terms of outcomes (Inman, 1999, Arnheiter, & Maleyeff, 2005). The model proposed here uses SCM dimensions derived from studies and documented references. Six dimensions of SCM identified from several sources (Davis & Heineke 2005, Mekong capital.com, 2004) were considered to relate to distinctive features of SCM and are therefore incorporated in the present conceptual model. These SCM dimensions are strategic supplier partnership, customer relationship management, information sharing between SCM partners, lean production, postponement concept and technology & innovation

In addition, several studies have identified performance improvement constructs that are commonly associated with SCM (Voss, 1988, *Gunasekaran et al, 2003, Kuei et al., 2001 and Cox, 1999*). Voss (1988) classified performance measures into three groups: market place competitive advantage, productivity increases, and non-productivity benefits. Specifically, this study focus on the impact of SCM on process performance which comprises dimensions namely manufacturing flow management process, supplier relationship management process, product and commercialization process, demand management process, customer relationship process, customer service management process, order fulfillment process and returns management process. Items included in the instrumentation for process performance, include such aspects relating to value chain cost, on-time delivery as well as inventory turnover.

Hypotheses

In investigating the influence of SCM practices on process performance, structural equation modeling is utilized to evaluate and analyze the magnitude and direction of the linkages between those constructs. The main hypothesis proposes that SCM has a positive structural effect on process performance. Conceptually, it suggests that with good implementation of SCM, process performance would be enhanced. Hence, in short, this study tests the following main hypotheses:

H_1: SCM has a positive structural effect on process performance (PROCESS).

In investigating the structural effect of SCM on overall results such as process performance, it is also pertinent to determine the structural loadings of each SCM determinant. Therefore, this study also attempts to test the following additional hypotheses:

H_{1A}: Strategic supplier partnership has a positive structural loading on SCM.
H_{1B} Customer relationship management has positive structural loading on SCM.
H_{1C}: Information sharing between SCM partners has a positive structural loading on SCM.
H_{1D}: Lean production has a positive structural loading on SCM.
H_{1E}: Postponement concept has a positive structural loading on SCM.
H_{1F}: Technology & innovation has a positive structural loading on SCM.

More importantly, this study aims to test the overall SEM model fit based on the main null hypothesis:

H_0 : The overall hypothesized model has a good fit.

For structural modeling, accepting this hypothesis indicates that the model presented adequately reproduce the observed covariance matrix (Bollen, 1989; Joreskog, 1989; Mueller, 1996) and suggesting that the data fit the proposed model.

RESEARCH METHODOLOGY

Sample companies were chosen from the manufacturing industry in Malaysia (the sampling frame was derived from the Federation of Malaysian Manufacturers Directory-FMM). Two hundred and fifty responses were received from a total of 300 sample companies chosen which representing 83 percent response rate. The primary purpose of the research is to gain insight into the benefits of implementing SCM in the manufacturing industry. The goal is to understand and determine measures of SCM that can enhance process performance. Face to face interviews with production or SCM managers were carried out to ensure the information accuracy, validating the outcome of analysis and developing an understanding of practical aspects of SCM principles adoption. To enable respondents to indicate their answers, seven–point interval scales were use for the questionnaire. Several items of SCM, which have been widely referred, were extracted. Similarly, the dependent variable namely process performance also used a seven-point interval scale, representing a range of agreement on statement whether over the past three years these process performance measures are high relative to competitors after implementing SCM practices.

FINDINGS

Correlation Analyses

As a preliminary analysis, Pearson's correlation analysis was conducted to establish associations between SCM practices and process performance. Table 2 exhibits correlation among the SCM variables and process performance measure. On the other hand, Table 3 highlights the descriptive and multicollinearity statistics. The result indicates that the SCM practices have significant correlations with one another and also with process management. In addition, it suggests that those SCM practices complement each other and need to be implemented in a holistic manner. Furthermore, the collinearity test does not indicate any multicollinerity problem. Process performance has high correlations with SCM practices especially with strategic supplier partnership, customer relationship management, information sharing between SCM partners, lean production, postponement concept and technology & innovation. These findings are consistent with several previous studies that proclaimed better organizational transformations as a result of SCM initiatives (*Womack et al., 1990; Womack and Jones, 1996, Lee, Peccei 2008, p4,* Inman, 1999, Arnheiter, & Maleyeff, 2005).

Table 2: Pearson's correlation among variables

SCM variables		1	2	3	4	5	Mean Process Performance
1	Strategic supplier partnership	1.00					.583(**)
2	Customer relationship management	.629(**)	1.00				.526(**)

Notes: *p ≤ 0.05; **p ≤ 0.01 (all *t*-tests are one-tailed)

Cluster Analysis and Friedman's Rank Test

Since process performance is a very importance outcome in this study, therefore the cluster classification performed in this study is based on process performance clustering. This cluster analysis categorized these manufacturing companies into two groups:

(1) "High" process performance achievers
(2) "Average" process performance achievers

Table 4 highlights further information about the cluster groups. From the result, we can also infer that the higher level of SCM implementations are more realized in "High" process performance achievers than "Low" process performance achievers. "High" process performance achievers" put high priorities on lean production followed by technology & innovation, customer relationship management and postponement concept and. Investigating the background of these clusters, the result also indicates that the first cluster ("High" process performance achievers) comprises of large-scaled companies with average employees of more than 1,200 people and average approximated sales turnover of more than RM 1.5 billion. Mean while, the second cluster ("Low" process performance achievers) comprises of smaller companies with average employees less than 600 and average approximated sales turnover less than RM 80 million.

Table 4: Rankings of SCM practices based on process performance using Friedman's Test

SCM	"High" process performance achievers (n=151, chi-square = 81.135, significant=0.000, overall cluster's mean = 5.469)				"Average" process performance achievers (n=99, chi-square = 80.218, significant=0.000, overall cluster's mean = 4.486)			
	Friedman's Test	Rank	Mean	Std Dev	Friedman's Test	Rank	Mean	Std Dev
Strategic supplier partnership	2.82	5	5.0993	1.30450	3.62	4	4.6104	.80699
Customer relationship management	3.81	3	5.6309	.88895	4.56	1	4.9787	.93011
Information sharing between SCM partners	2.82	6	5.0993	1.30450	2.53	6	4.0177	1.21966
Lean production	4.11	1	5.7479	.82535	3.67	3	4.5767	1.06008
Postponement Concept	3.38	4	5.5057	.99679	3.86	2	4.6539	.81407
Technology & innovation	4.05	2	5.7343	.64036	2.76	5	4.0801	1.13977

Structural Equation Modeling

(i) The result of the preliminary model (Model A).

The study postulates that SCM has influence on product quality performance. Given the confirmatory nature of this study, the statistical analysis technique called Structural Equation Modelling (SEM) was utilized. A SEM model was employed to investigate simultaneous linkages that allow a researcher to determine the relative strength of relationships between variables. A two-step approach was employed. First, confirmatory factor analysis was performed to ensure that all the indicator variables used to measure the constructs were reliable and valid. Second, causal relationships between constructs were postulated and tested. The SEM model was evaluated to check if the specified items provided adequate fit. The relationship of SCM practices on process performance is depicted in the preliminary model as shown in Figure 2. In this statistical analysis, we would like the model developed to fit the data, therefore the acceptance of the null hypothesis of the overall model is expected. Hence, in this test of goodness of fit for the structural equation modeling, the probability we are looking for should be higher than 0.05.

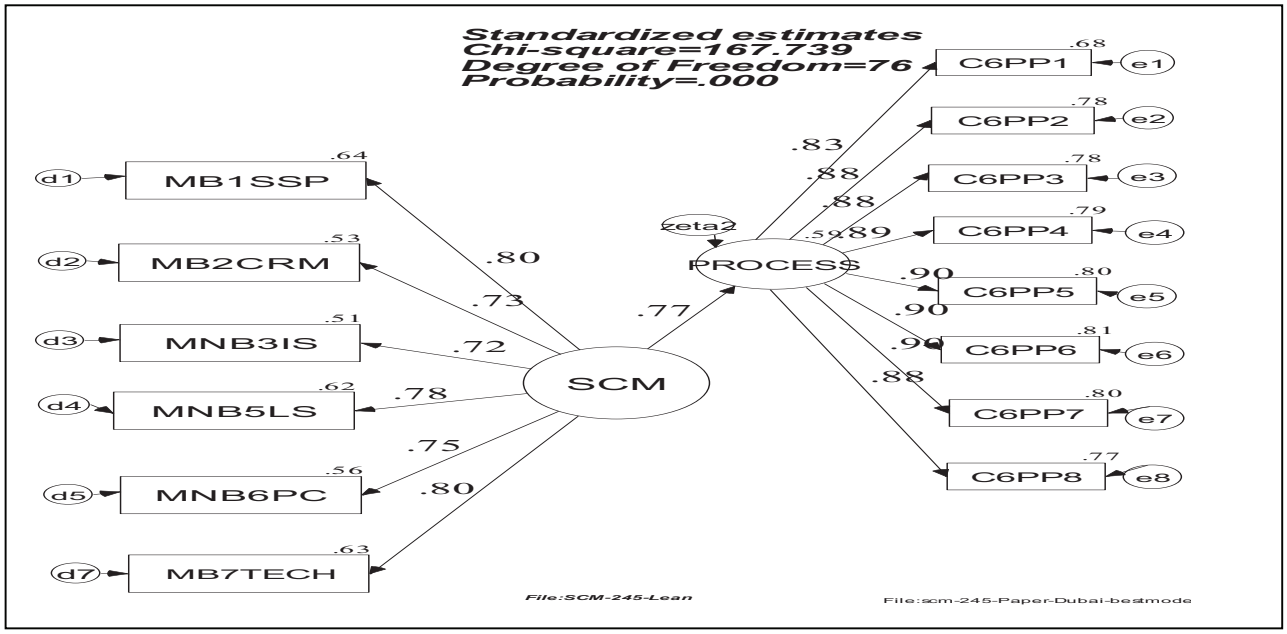

Figure 2: The result of the preliminary model (Model A) showing the structural linkage between SCM practices and process performance.

Unfortunately, the result of the preliminary model indicates that the χ^2 test and the probability value suggest a poor fit. The value of the Chi-square is equal to 167.74 with 76 degrees of freedom and the probability level of 0.000 (Table 5). On the whole, the result suggests that the proposed preliminary model has only a null fit and the data did not adequately fit the model. The unsatisfactory fit may relate to the high levels of random error and the many parameters that must be estimated (Bagozzi et. al 1991).

Table 5: The Measurement Result of the Preliminary Model

Statistics	Model Values	Recommended * values for good fit
Chi square	167.739	-
Probability Level	0.000	≥ 0.05
Degree of Freedom	76	-
χ^2 /df	2.209	≤ 3.00
Bollen (1989) Incremental Fit Index (IFI)	0.971	≥ 0.90
Tucker & Lewis (1973) TLI	0.965	≥ 0.90
Bentler (1988) comparative fit model (CFI)	0.971	≥ 0.90
Normed fit index (NFI)	0.949	≥ 0.90
Goodness of fit index (GFI)	0.912	≥ 0.90

*Chau (1997)

Even though the overall model has an unsatisfactory fit, the contributions of manifest variables in the model as well as the statistical significance of parameters' estimates of SCM and process performance are investigated. Standard errors and probability values are used to determine the precision of each parameter estimate. Parameters whose critical ratios are larger than 2.00 in magnitude are judged to be different from zero (Joreskog & Sorbom, 1989; Sharma, 1996, Mueller, 1996). The result indicates that the parameters have significant relationships and the variables are contributing to the concept. The loadings of the SCM variables (Figure 2) on the main latent construct suggest that strategic supplier partnership (0.798), technology and innovation (0.797), lean production (0.785) and postponement concept (0.750) are among the top variables with high contributions toward the SCM implementation. All SCM indicators exhibit significant critical ratios of above 2.00 (see Table 6). Therefore, we can suggest that strategic supplier partnership, customer relationship management, information sharing between SCM partners, lean production, postponement concept and technology & innovation have positive and significant impact on SCM implementations.

Table 6: The Measurement Result of the preliminary model

(i)Constructs and indicators	Std. Loadings	Std. errors	Critical Ratio	Probability
a. Supply Chain management (SCM)				
Strategic supplier partnership	.798	.068	13.450	0.000
Customer relationship management	.731	.073	12.293	0.000
Information sharing between SCM partners	.717	.106	12.010	0.000
Lean production	.785	.082	13.450	0.000
Postponement concept	.750	.074	12.691	0.000
Technology & innovation	.797	.094	13.705	0.000
b. Process performance (PROCESS)				
Manufacturing flow management process [C6PP1]	.827	.133	11.734	0.000
Supplier relationship management process [C6PP2]	.883	.053	19.112	0.000
Product and commercialization management process [C6PP3]	.882	.054	11.734	0.000
Demand management process [C6PP4]	.888	.060	18.101	0.000
Customer relationship management process [C6PP5]	.896	.060	18.366	0.000
Customer service management process [C6PP6]	.897	.062	18.429	0.00
Order fulfillment process [C6PP7]	.987	.062	18.418	0.000
Returns management process [C6PP8]	.878	.063	17.739	0.000
(ii) Exogenous/endogenous Path				
a. SCM→ PROCESS [H_1 is supported]	.767	.079	11.254	0.000

Specifically, in order to ensure the success of SCM implementation, manufacturing companies need the support and commitment from SCM partners, adopt new technology and innovation in production process and SCM activities, eliminating waste wherever possible through lean production and be flexible in meeting changes needs and demand from customers using postponement concept. Surprisingly, information sharing between supply chain partners is not among top indicators of SCM in manufacturing industry in Malaysia. Probably the logical reason is because the culture of sharing vital SCM informations is not yet widespread in manufacturing companies in Malaysia. In addition, since customer relationship management (CRM) is still a new concept, this could explain why CRM has lower structural loadings on SCM implementations. By examining the structural loadings and their respective critical ratios and probability values, we can conclude two things. Firstly, we can say that strategic supplier partnership, technology and innovation, lean production and postponement concept have higher structural contributions toward SCM in manufacturing companies in Malaysia. Secondly, the

significant critical values indicate that SCM has positive effect on process performance. However, the overall result does not support the overall model fit, which is not uncommon when a measurement model has many items.

(ii) The improvement of the null model (Model B: The Parsimonious Model)

Since the overall result of the preliminary model (Model A) does not allow us to conclude that the suggested preliminary model has a good fit, the study will try to look at the element of standard structural validity for the modification of the overall model to improve its fit and to determine which of the exogenous and endogenous variables that are responsive and have direct causal relations with their latent construct (Joreskog and Sorbom, 1989). In addition, according to Tamini (1998), if the constructs were related to each other, they would all load on a higher order factor loading. Hence in this study, the model will be respecified by examining the exogenous measurements (SCM indicators) and investigating their contributions toward the main latent construct (SCM) and simultaneously the manifest variables of the endogenous construct will also be reexamined. According to Joreskog and Sorbom (1989), a structural loading (λ_{ij}^{s}) is a measure of the extent to which the variation of one indicator explains the variation of the latent variable. The indicator with the highest factor loading is the most valid indicator of its latent variable. High factor loadings are thus good indicators of the convergent validity of constructs. Closer examination of the parameters of the preliminary model (Figure 3) showed that the structural loading of customer relationship management (CRM) and information sharing between supply chain are not as high as the other four SCM variables (strategic supplier partnership, technology and innovation, lean production and postponement concept). This could be an indication that these variables have lower contributions and less responsive toward SCM implementations in manufacturing companies in Malaysia. Even though these variables exhibit significantly positive contributions toward SCM, however, they do not respond to the simple and direct relationship between SCM and process performance. This could mean that these SCM variables may be related to process performance in a more complex manner. As for the endogenous variables, only demand management process, customer relationship management process, customer service management process and order fulfillment process have high loadings and impact on the main latent construct. To improve the result, a second analysis on the respecified model is later performed to achieve a feasible and parsimonious model (Model B) with a more satisfactory fit.

(iii) The result of the final model (The parsimonious model)

The final parsimonious SEM model (Figure 3) exhibits the structural relationship of SCM on process performance after the modification process has been carried out. Note that in this model, two SCM variables namely customer relationship management and information sharing are dropped. Inversely, for the endogenous variables, demand management process, Customer relationship management process, demand management process, customer relationship management process, customer service management process, customer service management process and order fulfillment process high structural loadings and more responsive towards the impact on process performance, and therefore are retained in the revised model. The findings of Model B (the revised and parsimonious model) indicate that the resulting Chi-square value is

28.925 with 19 degrees of freedom and p-value of 0.067 (Figure 3 and Table 7). This supports the null hypothesis that the revised model has a good fit (H_0). The p-value is considerably substantial (p-value > 0.05), in supporting the proposition that the overall model fits the data. In addition, other statistical structural indices such as Bentler CFI (0.994), Bollen IFI (0.994) and Tucker and Lewis TLI (0.990) further suggest that the model has a satisfactory fit (Table 7). Since the probability value and structural modeling indices are well above the recommended level, the model is considered to be a reasonable representation of the data (Hair et al., 1995).

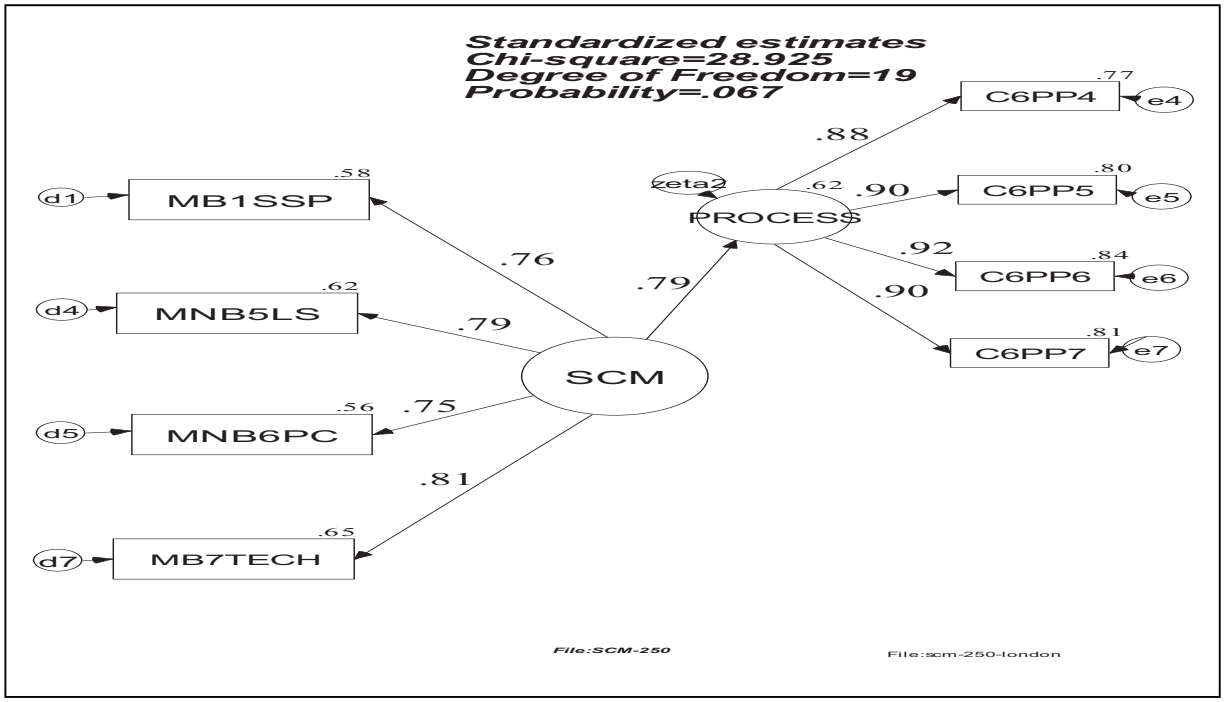

Figure 3: The final parsimonious SEM model showing the structural linkage between SCM practices and process performance (Model B).

Table 7: Measurement Results of the final SEM Model

Statistics	Model Values	Recommended * values for good fit
Chi square	28.925	-
Probability Level	0.067	≥ 0.05
Degree of Freedom	19	-
χ^2 /df	1.522	≤ 3.00
Bollen (1989) Incremental Fit Index (IFI)	0.994	≥ 0.90
Tucker & Lewis (1973) TLI	0.990	≥ 0.90
Bentler (1988) comparative fit model (CFI)	0.994	≥ 0.90
Normed fit index (NFI)	0.981	≥ 0.90
Goodness of fit index (GFI)	0.972	≥ 0.90

*Chau (1997)

The direct structural effect of SCM on process performance (PROCESS) is high (0.79) given the complex causal linkages, suggesting the significant importance of SCM practices especially strategic supplier partnership, technology and innovation, lean production and postponement concept in manufacturing industry in Malaysia (H_{1A}, $H_{1D,}$ H_{1E}, and H_{1F} are supported).. The standardized structural coefficient of SCM on process performance (0.79) is associated with low standard error (0.093) and non-zero critical value (11.295), which indicates that the structural effect between these two constructs, is positive and the relationship is significant (Table 8). Therefore, we have enough evidence to accept the proposition that SCM has a positive structural effect on process performance (H_1 is supported). In addition, we can obviously suggest that SCM practices can help manufacturing companies improve demand management process, customer relationship management process, customer service management process and order fulfillment process.

Table 8: Measurement results of the final SEM model

(i)Constructs and indicators	Std. Loadings	Std. errors	Critical Ratio	Probability
a. SCM (SCM)				
Strategic supplier partnership	.760	.070	12.334	0.000
Lean production	.788	.094	12.333	0.000
Postponement concept	.747	.085	11.655	0.000
Technology & innovation	.805	.109	12.613	0.000
b. Process performance (PROCESS)				
Demand management process [C6PP4]	.876	.048	20.376	0.000
Customer relationship management process [C6PP5]	.896	.041	22.772	0.000
Customer service management process [C6PP6]	.747	.047	22.771	0.000
Order fulfillment process [C6PP7]	.901	.048	21.786	0.000
(ii) Exogenous/endogenous Path				
a. SCM→ PROCESS [H_1 is supported]	.786	.093	11.295	0.000

Looking at the loadings of the SCM variables (Table 8) on the main construct, we can see that technology and innovation has the highest contribution towards SCM and it is followed by lean production, strategic supplier partnership and postponement concept. All of these indicators have significant probability values (critical values ≥ 2.00), giving statistical evidence that their contributions towards SCM construct are significant and positive. Therefore a manufacturing company can enhance its by integrating and implementing SCM strategies and practices.

CONCLUSION AND IMPLICATIONS

Many manufacturing companies have fought the global pressures of competition by becoming increasingly technologically advanced, moving up-market to more value-added products, and upgrading the skills of their domestic work force. SCM provides a vision that focuses everyone in an organization on better improvement. The pursuit of improvement is not only requested by the market but also driven by the need to survive. This paper tries to investigate the structural relationships between SCM and process performance in manufacturing companies in Malaysia. On the whole, we can suggest that SCM has a positive impact on process performance. Initially, the result of the preliminary model indicates that relationship between SCM and process performance only suggests a null fit. Viewing the result of the preliminary model on the relationship between SCM and process performance, the findings suggest a conclusion that there is no firm and direct link between some of the SCM variables and some of the process performance indicators. It should be noted that the model presented in this study reflects linear and direct linkages between SCM and process performance. It could well be that some of the variables of SCM and the indicators of process performance are related in a more complex way. Given that the results of this study show no empirical support for simple structural linkages, it is suggested that these constructs may be related in a more complex manner. However, further investigation on the contributions of each of the SCM variables and process performance indicators signals that some of the indicators are more responsive to the causal relationship between SCM and process performance, which suggests possible direct linkage between them. A revised model was analyzed which retained some of the more responsive manifest variables. The result of the revised and parsimonious model indicates a satisfactory fit.

SCM practices provide a vision that focuses everyone in an organization on SCM improvement. The pursuit of better improvement is not only requested by the market but also driven by the need to survive. This paper tries to investigate the structural relationship between SCM and process performance in the Malaysian manufacturing industry. The associations and effects of the SCM variables were evaluated using correlations, Friedman test and SEM. The results of the study assist in understandings on how SCM practices influence process performance. This study leads to several main conclusions. First, evidences suggested that:

(1) Technology and innovation, lean production, strategic supplier partnership and postponement concept have **positive** and **direct** effects on process performance.
(2) SCM practices have **positive** and **significant direct** effects on process performance specifically demand management process, customer relationship management process, customer service management process and order fulfillment process.

The conclusion emerging from this study is that SCM will ultimately results in positive gains. The results validate some of the key linkages and support beliefs and evidence by researchers of the relationship between SCM and process performance. It is also important to note that this study attempts to enrich the literature review and make a contribution in SCM-related studies. Obviously, its purpose has been to make explicit what other researchers have perhaps known implicitly with solid measurements. The empirical results support long-standing beliefs and anecdotal evidence by researchers about the relationships between the exogenous (SCM) and endogenous results (process performance), and lend credibility to causal hypotheses that

improving internal process leads to improvements in external performance results. This study to some extent helps in resolving controversy about the magnitude and measurements of performance gains from implementing SCM. By strengthening SCM practices, improved performance will likely to occur. This result provides evidence that improving internal practices will positively impact the most important performance measures.

This paper is relevant to practitioners because the findings may reveal important aspects in the implementation of SCM practices, which may provide significant information managers can use to solve implementation challenges and perhaps to improve performance. The paper would be of particular interest to practicing production managers or SCM managers as it suggest what factors should be emphasized to stimulate the adoption of SCM concepts in the Malaysian manufacturing industry. Moreover, the findings may provide support for continued implementation of SCM practices. The result indicates that manufacturing companies should emphasize greater attention to the technology and innovation adoption, waste reduction aspects through lean production and strategic partnership of the SCM practices and a greater degree of management support for SCM programs. Finally, the conclusion emerging from this study is that SCM will ultimately results in positive gains. The results validate some of the key linkages and support beliefs and evidence by researchers of the relationships between SCM and process performance. It is also important to note that this study attempts to enrich the literature review and make a contribution in SCM-related studies. In addition, its purpose has been to make explicit what other researchers have perhaps known implicitly. However rather than being conclusive, this study opens new avenue for future research.

AUTHOR'S BACKGROUND

Arawati Agus is a Professor of Quality and Operations Management at Graduate School of Business, National University of Malaysia (UKM). She received a Bachelor degree in Finance from Southern Illinois University and Master in Management Sciences from St. Louis University. She obtained her Ph. D. in National University of Malaysia (UKM). Her area of research includes Quality Management, Supply Chain Management, Operation Management, Service Quality and Entrepreneurship. Her works have been published in Total Quality Management (UK), International Journal of Management, Singapore Management Review, International Journal of Production Economic, Security Industry Review (Singapore), Journal of Quality and Reliability, Malaysian Management Review and Management Journal (UKM).

Za'faran Hassan is an Associate Professor at the Faculty of Business and Management, Universiti Teknologi MARA. She obtained her BBA at Idaho State University, USA; MBA at Saint Louis University, Missouri, USA; and DBA at National University of Malaysia (UKM). She is an Associate Professor at Universiti Teknologi MARA, Malaysia. Her past administrative experience includes being the Dean of the Faculty of Hotel and Tourism Management, Director for Business Development, as well as Head of the Malaysian Entrepreneurship Development Center at her university. Currently, she is the Head of the Faculty of Business Management's Department of Management, Human Resource Management and International Business. She is an industry member for the Malaysian Productivity Corporation's Consultative Panel of Expertise for Tourism, Member of the Malaysian Institute of Management, and the Academy of International Business, as well as Associate Member of the Centre for Small Business & Regional Research (CSBRR), University of Wollonggong, NSW, Australia. She has presented papers at conferences and also published in various publications, both locally and internationallyShe is also a member of various local and international professional associations such as the Malaysian Institute of Management (MIM), Malaysian Society for Training and Development (MSTD), and the Academy of International Business (AIB). Her research interest includes areas related to Management, Strategic Management, SMEs, Entrepreneurship, Supply Chain Management and Quality Management.

ABSTRACT

This study is conducted to investigate the extent of customer satisfaction of the service delivery process through the implementation of information technology (IT) in the Royal Malaysian Customs (RMC), one of the prominent and technology-pioneering government agencies in Malaysia. Data were collected from two types of customers, i.e. internal (employees) and external (business clients), specifically from the RMC officers in the state of Selangor who use the Customs Information System (CIS) for the transhipment of goods (Customs Form 8-C8) and its business clients who comprise of forwarding agents, importers, and bonded warehouse licensees in the same state. The findings reveal that both types of customers are either indecisive and/or doubtful with the performance of CIS used by the RMC. It can be concluded that it is of paramount importance for the RMC, a government agency that provides service to the industrial population as its core business, to fulfil the satisfaction of both types of customers by provision of improving its service delivery process through the CIS used so as to ensure that the adoption of IT produces desirable outcomes.

Keywords: Information technology implementation, e-government, customer satisfaction, business clients, Royal Malaysian Customs, Malaysia

INTRODUCTION

Malaysia aspires to be a developed country comprising of a community that has an abundance of information and knowledge by the year 2020 in line with the National Vision Policy. With the awareness on the importance of technological knowledge as a catalyst for the development of the nation, the Malaysian government has conceptualized the Multimedia Super Corridor Malaysia (MSC Malaysia) project (for details, see Mohd Fairuz et al., 2008). In addition, the development of Putrajaya (the nation's administrative center within the MSC Malaysia) with state-of-the-art and sophisticated information and communications technology (ICT) and information technology (IT) infrastructure has completed the circle of IT development in Malaysia (Hizral, 1999).

Further, the government has provided a substantial sum of money for the delivery of electronic public services, more popularly known as Electronic Government (E-Government). E-government is referred to as the implementation of ICT to transform the structures and processes of government organizations aiming at performance improvement (Mofleh et al., 2009). It enables the simplification and automation of transactions between citizens and businesses, and even with different government entities (Metaxiotis and Psarras, 2005;

Sprecher, 2000) through multiple channels by using ICT, whose objective is to improve the efficiency, transparency, accountability, and effectiveness of the government (Gil-Garcia and Pardo, 2005; Gorla, 2008). By using ICT, the role of government changes from direct to a more limited involvement, thereby empowering citizens (Yu and Fang, 2005). As a facilitator of good governance (Rose, 2004; Sharma, 2004; Zhang, 2004), e-government thus has the ability to improve democratic, economic, and administrative governance (Gorla, 2008).

Gorla (2008) opines that e-government is becoming increasingly important due to the growth of ICT and Internet penetration. In Malaysia, for instance, the Malaysian Communications and Multimedia Commission reported that the penetration of Internet in 2007 is about half the size of the population (47.8% of 28,294,120 people) as opposed to 3,700,000 users in 2000 (http://www.mcmc.gov.my). This is due to the many initiatives undertaken by the Malaysian government in the development of ICT infrastructure and environment so as to enable the country to move rapidly into the Information Age as part of an important agenda of transforming the country into an information and knowledge-based society by 2020 (Tan et al., in press). Another reason is being the encouragement given to the development of ICT in the country as evident from the Seventh Malaysia Plan (1996-2000). This was the period that saw the inception of the MSC Malaysia (Chong, 2006). In fact investment of ICT in Malaysia has expanded at a rate of 9.2% per annum from RM3.8 billion in 1995 to RM5.9 billion in 2000 (Economic Planning Unit, 2001). About RM7.9 billion was invested on ICT programs under the Eighth Malaysia Plan (2001-2005) such as computerization of government agencies, schools, ICT funding, multimedia applications and developments, as well as ICT research and development. The following Ninth Malaysia Plan (2006-2010) witnesses an allocation of RM12.9 billion for the same programs (Economic Planning Unit, 2006).

Under the e-government initiative, a number of flagship projects have been developed and successfully implemented involving many areas such as smart school, telemedicine and the national smart identity card which involved a budget of RM1.06 billion. Several systems have also been created such as the Smart Transportation System which helps to eliminate traffic congestion in the Klang Valley area on top of imparting important information to traffic users. Other systems include the Project Validation Process, Human Resource Management System, E-Procurement, and the Generic Office Environment. Another measure that had taken place in is the launch of a program 'My-EG', in which a selection of public services is being made available online. From such developments, coupled with the development of broadband wireless Internet access, it can be seen that the Malaysian government is gearing up for change by putting into action a blueprint for the assimilation of IT into its governance structure.

It is therefore not surprising that the Royal Malaysian Customs (RMC), a government agency responsible for the collection of indirect tax and at the same time providing facilities to the commercial and industrial sectors, together with the task of safeguarding the national economy, social and security, is jumping on the IT bandwagon in its effort to prepare the agency towards the realization of Vision 2020. As a matter of fact, the RMC is among the first government agencies that adopted electronic data interchange (EDI) in 1994 as modified from the United Nations/Electronic Data Interchange for Administration, Commerce and Transport (UN/EDIFACT). As part of the e-government initiatives, the RMC introduced the Customs Information System (CIS) through the custom declaration forms in 1992 with manual key-in process designated for four types of forms, i.e. C1 (import), C2 (export), C8 (transshipment), and C9 (import-break bulk). In 1994, the RMC began using the EDI in

addition to CIS for its C1 and C2 forms. In 1997, the EDI and CIS were further augmented with the introduction of a single Electronic Fund Transfer (EFT) system, which was later upgraded to multiple EFT in 2003 which saw the application of EDI and CIS for C8 and C9. In January 2003, the use of EDI and CIS was enforced on the Paperless Export Normal C2 (for non-dutiable goods) form, which was extended to dutiable goods in July of the same year. In January 2004, the RMC introduced the Inter-station Centralization System (C8).

Notwithstanding its popularity, the applicability and practicability of e-government has been extensively debated (Ciborra, 2005; Davison et al., 2005; Holliday, 2002). Davison et al. (2005) for instance opine that it is reasonable to query whether governments really want to make the transition to e-government. This is attributed to the fact that the success of IT adoption in the public sector has not been very clear and/or consistent due to lack of research (Tang et al., 2009). Further, many e-government studies have focused on developed countries (Ke and Wee, 2004; Kolsaker, 2006; Lee et al., 2005) with very few research attempts being undertaken on developing countries. In addition, e-government is an evolving, multidisciplinary topic that involves various stakeholders with multiple value dimensions (i.e. financial, social, and political) (Chirchu, 2008; Yang and Paul, 2005). This led to the lack of clear understanding of managerial practices surrounding the role of central governments in the deployment and development of e-government (Mofleh et al., 2009). On the contrary, IT has been adapted by many multinational corporations (MNCs) and businesses with the key objective to tailor the available and emerging technologies to the specific requirements of those firms in order to increase efficiency and effectiveness of their delivery systems which ultimately help to realize their organizational goals. Matching both the elements is however a difficult task in the public sector which face different sets of priorities and therefore challenges compared to the business sector (Chirchu and Lee, 2005; Davison et al., 2005; Gil-Garcia and Pardo, 2005). This is evident from a study by Ghapanchi et al. (2008) who identified as many as 12 e-government implementation challenges. While the opponents failed to dissuade governments in the use of ICT, they have conveyed a clear message that governments will never be prepared for the change that is taking place if they are unable to link the role of governments as public service providers and the function of IT that is to assist the delivery of service to the citizens.

As such, as a government agency that provides service to the industrial population as its core business and consequently one of the major government revenue generating agencies, it is crucial for the RMC to continuously assess and improve its service delivery system due to the involvement of many of its stakeholders, specifically between the agency, its officers, and the business entities it serves. The relationship between the agency and its business entities is deemed an important determinant of e-government success, as business rather than individual Internet usage has been found to have greater exploratory value as an antecedent to the availability of e-government services (Boyer-Wright and Kottermann, 2008). It is therefore imperative to identify the satisfaction levels of RMC's officers and its business customers toward the use of the CIS. The resulting feedback will serve to inform the service providers on the level of effectiveness of RMC's CIS process, i.e. whether the current IT implementation is adequate, or a reengineering process is required.

It is against this backdrop that this study investigates the impact of RMC's IT implementation on the satisfaction of its officers and business customers. Specifically, feedback is gathered from the RMC officers who are responsible for the approval of dutiable goods movement within the bonded warehouse department and the declarations made by forwarding agents,

importers, and bonded warehouse licensees through the process of declaration and approval of Customs Form No. 8 (C8) using the CIS. Procedurally, the RMC's clearance for C8 is very important to ensure that its business customers receive their goods on time without any delay as this can affect their businesses. As such, it is important to observe the satisfaction of these external customers. In addition, the RMC management must ensure that every stage in the IT adoption has been properly undertaken so that the system will work smoothly. This can be observed from the satisfaction of its internal customers (officers). The implementation of CIS C8 is very important for many reasons, central to the assumption is that with IT implementation, it will facilitate the RMC in providing better services to its business customers. In short, the study is undertaken to provide answers to the following research questions:

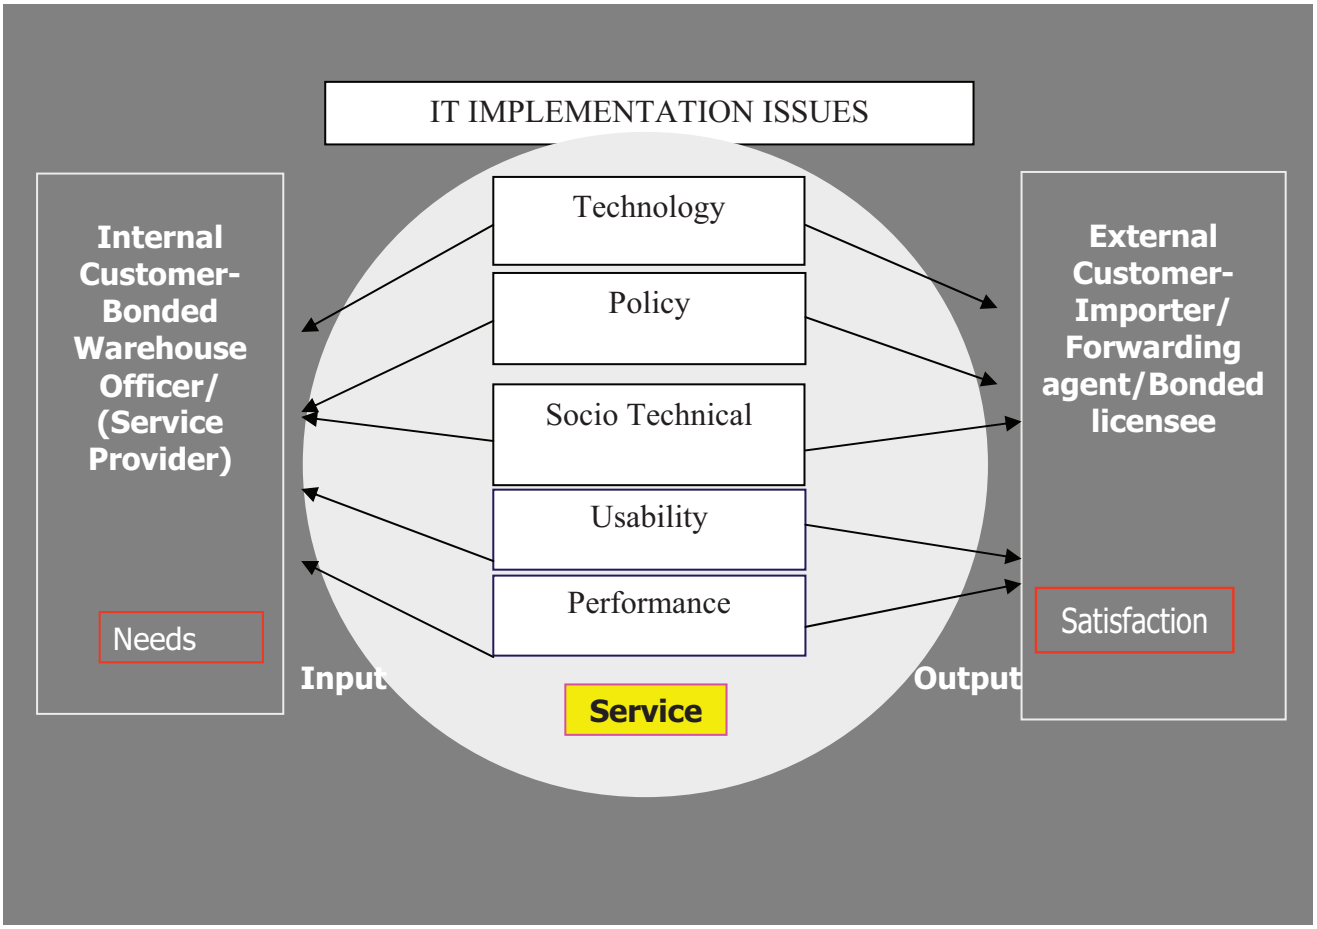
1) What is the level of IT utilization in terms of the CIS C8 declaration and approval process by the internal and external customers within the bonded warehouse department?;
2) What is the level of user satisfaction with regards to the CIS C8 process?; and
3) What are the areas that the bonded warehouse department should focus on to make sure that its IT implementation, specifically the CIS C8 process, is successful?

The rest of the paper is organized as follows. The next section presents the research framework employed in this study. The methodology used is detailed next, followed by presentation of the empirical results. The results are then discussed and implications provided before the paper is concluded.

RESEARCH FRAMEWORK

As Diagram 1 suggests, the RMC bonded warehouse officers provide service to their business customers in terms of granting approval to the transshipment of goods after their customers made declaration on the C8 form through the CIS. In providing the service through the use of CIS, the level of service quality is dependent on a number of factors such as technology, policy, socio-technical, usability, and performance on the part of the RMC as supported by the top management of the agency. At the same time, the same factors are also assumed to be important in fulfilling the needs and satisfaction of the business customers. On top of that, IT support infrastructure is also posited to contribute to the effectiveness of the service delivery. As such, the expected outcome is deemed to be the service realization through the use of the CIS process which will result in satisfaction to both the internal and external customers.

Diagram 1: Research Framework



RESEARCH METHODOLOGY

The research design is quantitative in nature, focusing on soliciting inputs and perceptions of the RMC bonded warehouse officers who are involved, and/or expected to be involved in any effort that will increase the performance and/or capabilities of their business customers, specifically on the C8 approval process through the use of CIS. These personnel comprise of all the RMC bonded warehouse officers from the lowest ranking to the most senior officers in the state of Selangor. This study focuses only on the state due to the fact that Selangor reported the highest revenue collection among all the states in Malaysia, with RM368.5 million collected in 2006 (representing 36% of all the revenues collected), out of which RM8.9 million is contributed by the bonded warehouse department. In terms of the total number of C8 clearance forms processed, the RMC's Annual Report (2005) indicates that Selangor ranked second after the state of Penang with 133,877 forms processed in 2005. Due to the small number of population, getting the involvement of as many RMC bonded warehouse officers as possible in the state is vital. There are currently 10 senior officers and 36 officers working in the department. About 34 officers agreed to take part in the survey.

The external customer is defined as those who are at the receiving end of the service which consists of managers and officers who manned the operations, purchasing, warehouse planning, and marketing departments of the forwarding agents, importers, and bonded warehouse licensees. As of 2007, there are approximately 1250 registered forwarding agents and 95 bonded warehouses in the state of Selangor. In practice, it is not uncommon to find that bonded warehouses seldom change forwarding agents. Moreover, it is not unusual for some established agents to handle a few bonded warehouses at the same time. This feature allowed the research to focus on respondents who are regular and familiar with the C8 declaration process using the CIS. About 35 business clients from 6 bonded warehouses took part in the survey.

Two sets of self-reporting questionnaires were developed and disseminated to both sets of the population. The questionnaires consist of two major sections. Section 1 is meant to solicit the respondents' demographic and psychographic information. Among the questions asked include age, highest education level, the availability of Internet connection, experience with Internet usage, and familiarity with the C8 process and CIS. Section 2 comprises of a series of items gauging the respondents' satisfaction levels on the various CIS implementation issues. About 51 items divided into 7 variables are administered to the RMC officers (refer Table 2), while the forwarding agents, importers, and bonded warehouse licensees were asked 31 questions from 5 variables (refer Table 3). All the questions in this section utilize a 5-point Likert scale, ranging from 1=highly dissatisfied to 5=highly satisfied with 3 scaled as neutral. Descriptive statistics, namely mean and standard deviation scores are used to interpret the data. Table 1 shows the interpretation of the mean scores obtained.

Table 1: Interpretation of the Mean Scores

Mean	Interpretation
1.00 – 1.49	Customer do not have anything that he/she is satisfied with
1.50 – 2.49	Customers' satisfaction at the lowest level
2.50 – 3.49	Indecisive , doubtful (customer doesn't give full attention)
3.50 – 4.49	Customers' satisfaction at a very high level
4.50 – 5.00	Customers' satisfaction exceeding beyond expectation

RESULTS

Demographic Profile of the RMC Officers

All the RMC officers are above the age of 26, with a majority of them possess minimum education qualifications (the Malaysian Certificate of Education or equivalent to GCE 'O' Levels). Many of the respondents have been in service for more than 15 years which explain the age and education level of the officers. About 41% of the officers own laptops, with 67% of them having Internet connectivity and 53% of them have experienced in using the Internet. However, it is interesting to note that the majority of respondents reported that they do not have Internet connection at the office (65%), and they therefore cannot access to the RMC's CIS at their workplace. The majority of the officers are familiar with the C8 process (64.7%) and the CIS (56%).

Level of Perceived Satisfaction of RMC Officers

Table 2 shows the results of descriptive statistics with regards to the satisfaction level of the RMC officers on the various CIS implementation issues. On an overall, the present IT environment scores the highest mean (3.34), followed by the contribution of IT through the satisfaction level of the overall CIS (3.30), the effect of technology and systems on effectiveness (3.21), level of IT usage in organization (3.17), IT in relation to management (3.02), socio-technical (2.99) and IT facilities (2.98). Based on the interpretation provided in Table 1, the mean scores of between 2.98 and 3.34 imply that the officers are indecisive and/or doubtful with the various issues asked upon them.

Similarly, the mean scores for each of the individual items suggest that the responses are within the range of neutral, judging from the mean scores of between 2.62 and 3.59. Only two items, i.e. "IT exposes me to become more creative" and "easy to analyze data" scored above or equal to 3.50. Satisfaction with the browsing speed scored the lowest mean. The responses to these questions corroborate the rates of satisfaction and/or dissatisfaction shown by the officers. About 62% of the officers are satisfied or highly satisfied with the exposure of IT that makes them more creative, while 56% of them are satisfied with the ease of data analysis. About 44% of them are dissatisfied of the browsing speed while 35% of them remained neutral on this item. The standard deviation scores for most of them items are below 1, indicating consistency in the respondents' answers.

Table 2: Descriptive Statistics of Perceived Satisfaction among the Internal Customers

	Descriptive Statistics	No	Mean	Std. Deviation	Very Dissatisfied	Dissatisfied	Neutral	Satisfied	Very satisfied	Missing	Total

Demographic Profile of Business Customers

The majority or 57% of the respondents are holding non-executive positions in their organizations, with 60% of them come from forwarding companies. Many of them range from 36 to 45 years old with the majority of them come from the Malay ethnic background (80%) and having the Malaysian Certificate of Education as their highest education qualification (70%). About 80% of them do not own laptops and 69% of them have no Internet connection at home. However, 74% of them connect to the Internet at their respective offices. The majority or 57% of the clients report that they have experienced in using the Internet. Almost all the respondents claim that they are familiar with the C8 process (91.4%), with 51% of them familiar with the CIS C8 interface. About 77% of the respondents reported that they declare the C8 at the terminal stationed at the RMC's office, while 14% of them perform the declaration at the EDI-enabled facilities outside the RMC's office.

Level of Perceived Satisfaction of Business Customers

Table 3 shows the results of descriptive statistics with regards to the satisfaction level of the forwarding agents, importers, and bonded warehouse licensees on the various CIS implementation issues. Among the variables, the contribution of IT in terms of the satisfaction level of the overall CIS scores the highest mean (3.42), followed by IT facilities (3.38), and the present IT environment (3.37). The variables of the effect of technology and systems on effectiveness and IT in relation to socio-technical interface score the lowest mean of 3.25 each. Again, the RMC customers are rather indecisive and/or doubtful with their responses, judging from the mean scores of between 3.25 and 3.42. However, compared with the mean scores obtained from the RMC officers, its customers seem to record higher satisfaction.

In terms of the individual items, the mean score is within the range of neutral for most of the items, looking at the mean score of between 3.00 and 3.70. Only four items were found to

score above or equal to 3.50. They are "scope of works increases by computing", "able to discuss needs", "effective information delivery", and "sufficient data communication". The satisfaction with browsing speed remains the lowest scored item (mean=3.00). To some extent, some support is found for the rates of satisfaction or dissatisfaction shown by the respondents although many of them rated the items within the range of neutral. The standard deviation scores for most of them items are below 1, indicating consistency in the respondents' answers.

Table 3: Descriptive Statistics of Perceived Satisfaction among the External Customers

	Descriptive Statistics	No	Mean	Std. Deviation	Very Dissatisfied	Dissatisfied	Neutral	Satisfied	Very satisfied	Missing	Total
					Percentage						
Present IT	Faster information	35	3.3	0.98	5.7	14	34	40	5.7		100

DISCUSSION AND IMPLICATIONS

In terms of the demographic and psychographic profiles of the respondents, the findings imply that despite age and education level, the majority of both the types of respondents have experienced Internet usage and are familiar with the C8 process and the CIS. This is probably due to the training provided by the RMC to its officers and customers. However, both groups indicate that the training they received is insufficient, looking at the mean scores obtained for the items measuring sufficiency of training and hands-on knowledge. Among the main areas that warrant attention from the policy makers in this section include the rate of the RMC officers who are unable to access to the Internet and thus the C8 CIS at their workplace. It is also contrary to expectation when the business customers report that they are more familiar with the C8 process than the RMC officers. The level of understanding of the RMC officers and customers toward the C8 CIS is also questionable, judging from the fact that only a simple majority of them understand the CIS.

As far as the mean scores are concerned, the study has successfully achieved its objectives by providing answers to the three research questions. It is obvious that the level of IT utilization among the RMC officers and its customers, particularly through the use of C8 CIS is still low. This is attributed to the lack of an environment and facilities conducive for IT implementation, top management support, and socio-technical conditions. All these have somehow created doubts among the officers on the effectiveness of the CIS utilized which have prevented the officers from using the CIS to a level of their satisfaction. Nevertheless, the majority of the clients who use the CIS at the terminals stationed at the RMC's office claim higher satisfaction levels to the items surveyed, albeit still within the range of neutral. This leads to the answer for the second research question in which both the RMC officers and the customers surveyed are rather indecisive and/or doubtful with the CIS, again with the customers reporting higher satisfaction level compared to the RMC officers. The answers to the first and second research questions have implications on the third question, i.e. what are the areas that the bonded warehouse department should focus on to make sure that the implementation of its CIS C8 is successful.

On an overall, the study lends support to the debates on the applicability and practicability of e-government, specifically on the challenges it inherit from the process of its implementation. This implies a gap between the deliverables conceived and the actual realization of such e-government initiative (Sushil, 2008). It is evident that the implementation of e-government at the RMC is still in its infancy stage, in view that the agency is still struggling with the various hurdles concerning e-government implementation such as personnel, technical, and environmental conditions. These issues are not considered new but are in fact recognized as challenges facing governments in the early stage of e-government initiatives. The results show that the facilities and environment are not friendly enough to spur greater usage of the CIS among the officers. They are facing technical and socio-technical problems such as lack of relevant technical skills due to lack of top management support, training, and shortages of skilled personnel. In fact, the officers and customers seem to indicate that further improvements to the CIS and IT infrastructure such as browsing speed are necessary, in which the latter part contradicts with the ongoing government's efforts in developing sufficient infrastructure bandwidth. These issues have been transferred over to the customers, which resulted in lower levels of usage and satisfaction. To some extent, the findings show that the external customers are more satisfied with the CIS in many ways compared to the RMC's officers. This is probably due to the fact that the officers are able to accurately see the

shortcomings of the system as compared to their customers who have frequently been exposed to positive images of the system by the policy makers. In some ways, the results also imply that the government has been over-emphasizing on building technology infrastructure without really considering the acceptance of the stakeholders. With little top management support, there is an apparent lack of a conducive environment and facilities needed for successful IT implementation. It is therefore not surprising that the RMC officers and their clients cast doubt on their satisfaction levels.

The results imply that it is imperative for the RMC to reassess their CIS implementation from the perspectives of their internal and external customers. The agency can no longer take a neutral stand and must be open to any forms of reviews in order to stay relevant as an important public service provider. The satisfaction of both the internal and external customers must be fulfilled. In this case, the officers play an important role as they are the front liners to the system. Their perception and satisfaction levels will thus leave important implications to their customers.

To be successful in e-government initiative, vision, in-depth planning and implementation strategy are thus essential factors (Gil-Garcia and Pardo, 2005; Sushil, 2008) in order to reduce the associated risks, costs, and the time wasted (Ghapanchi et al., 2008). Central to e-government implementation is the objectives to be achieved, i.e. to improve the efficiency, transparency, accountability, and effectiveness of governments in better serving their constituents through the delivery of quality service. As such, public sector organizations such as the RMC must be prepared to embrace IT wholeheartedly if it is to become efficient and effective service providers and delivery agents to the citizens. The RMC needs to consider improving its internal management and control (Chu et al., 2008) through a change management mentality (Ghapanchi et al., 2008) so that a conducive environment is enabled to fuel growth of the CIS usage. The policy makers must be made to realize that any e-government initiative would be cumbersome without their full support and commitment. They will have to champion such initiative which must be cascaded down to the departmental levels of the RMC. The management of RMC should be made aware of the importance of CIS usage towards success in public service delivery and allocate adequate budget and resources to facilitate the support given to their officers and customers. It is imperative that the resources are used to improve the IT facilities and infrastructure, hire skillful personnel, and to provide periodic training to both the stakeholders. The training programs provide interaction opportunities among the officers, which might help the RMC to identify future improvements to the CIS.

Related to the above, as e-government involves various stakeholders, it is thus imperative that a holistic approach is taken to increase participation and collaboration with the officers, business entities, citizens and even other government entities when a system is designed or needs improvement, such as in the case of the CIS. It is obvious that the CIS needs to be revamped in order to enhance its usability as stressed in the respondents' answers. This is not uncommon as e-government is still evolving and people are still learning how to develop and manage this new technology. As such, Ghapanchi et al. (2008) suggest that e-government strategies should first target the improvement of their operations and processes and also the level of government's ability to cooperate. In this respect, any system is likely to generate development gains when it is closely adapted to the needs and capacities of the various stakeholders (Bhattacharyya, 2008) who might react differently to an innovation and therefore the degree of adaption (Chan et al., 2000). It is worth remembering that improved

interoperability between public organizations as well as between public and private organizations is of critical importance to make e-government more successful (Gottschalk and Solli-Saether, 2008; Reddick, 2008).

Once a system is designed and ready to be implemented, the policy makers and management of public sectors must think of how to increase the acceptance of the system by its stakeholders. Prior studies have identified factors such as perceived usefulness, trust, and persuasion which exert influence on the acceptance and intention to use e-government applications (Akpinar and Ondin, 2008; Tang et al., 2009). As such, any effort towards increasing acceptance of the CIS must be based on these factors. The officers must be convinced that the use of CIS helps them to complete their tasks on time and expose them to become more creative. At the same time, trust must be built with the customers through effective laws and policies. The customers must be able to see that the CIS meets their needs and that the RMC officers are friendly enough to be reached for advice and even suggestions on how certain aspects of the CIS can be further improved. In addition, it has been found that technology characteristics do not significantly influence the intention to use e-government applications. Therefore, it should provide a hint to the policy makers that continuous investment in technology does not guarantee usage, but rather picking the right technology that is able to fulfill the needs of both the internal and external customers is what matters most. More importantly, the technology and its associated facilities must be friendly enough to encourage usage on top of having sufficient bandwidth and technical integration which are deemed important to fulfill processes timely, quickly, and with minimum of wasted time and corruption (Ghapanchi et al., 2008).

CONCLUSION

In view of the rapid development of ICT infrastructure and environment in Malaysia, there is no doubt at all that the nation is prepared to embrace e-government towards achieving better service delivery performance for its citizens, businesses and other government entities (Tsai et al., 2009) despite the presence of many challenges. In fact, the success of e-government initiative in such as developing country like Malaysia has far-fetched implications. As Ghapanchi et al. (2008) put it, such an enabled government is a momentous opportunity for the developing countries to improve and streamline their government's operations, provide breakthrough performance, and reduce their existing gaps with the developed countries. It is therefore hoped that the recommendations provided above shed some lights to the policy makers and stakeholders in adapting appropriate IT strategies for e-government implementation success. Further, the findings can be used to guide future e-government projects in the country as well as other developing countries. From the research perspective, it is hoped that this study would spur more research in this area, especially among the developing countries.

Perhaps one of the major weaknesses of this study is the small sample size. A larger sample size across all the departments within the RMC and/or with other government agencies and diverse business entities may validate the arguments presented in this paper. It is possible for future studies to consider other important factors such as information quality (Burbridge, 2002; Klischewski and Scholl, 2008) security (Holden et al., 2003; Luna-Reyes and Gil-Garcia, 2003; Roy, 2003; Ryoo et al., 2009), technology incompatibility (Garson, 2003; Holden et al., 2003), policy and political pressures (Brown and Brudney, 2003; Edmiston, 2003; Rocheleau, 2003; Roy, 2003), privacy concerns (Edminston, 2003; Holden et al.,

2003), relationships between governments, business entities and citizens (Rocheleau, 2003), social and economical issues (Brown and Brudney, 2003; Edmiston, 2003; Holden et al., 2003) which are likely to generate important findings. In addition, prior research has shown evidence on the possible significant correlations between the IT issues and demographic factors such as age, education level, broadband access, experience in computer, Internet use, and frequency of Internet usage (e.g. Akpinar and Ondin, 2008; Dwivedi and Williams, 2008). An attempt on this may therefore yield interesting discoveries. Finally, this is a cross-sectional study. A longitudinal study is needed to capture the details.

The Effect of Variability In Electronic Kanban (e-Kanban) Production System

Wichuta Insalee and Pornthep Anussornnitisarn

ABSTRACT

Traditional mass production manufacturing is not responsive to changing customer demands. It relies on forecasting future demand and scheduling. Mass production systems often have excess inventory, higher WIP levels, and longer quoted lead-times from order to delivery. (Richard 2001) Just-In-Time (JIT) manufacturing approach has triggered various 'pull production systems' that emphasize the importance of production control that react to actual demand rather than future demand forecasts (Karin 2005).

Pull systems authorize parts to be processed in response to the actual demand arrival, control WIP and observe throughput (Spearman 1990). A pull mechanism can be implemented in many ways. The best known is a Kanban policy (Monden 1983). The Kanban control was originally used in Toyota production lines. In the Kanban control system, Production authorization cards, called Kanban, are used to control and limit the releases of parts into each production stage.

The manufacturing operations to respond to changing customer demand. So, The Information Technology is important to improve operation. Particularly in the automotive industries are utilize e- Kanban for their operation. e- Kanban respond actual demands (right products at the right times and in the right amounts) and make-to-order environment (Debra 2001). The next question is the electronic kanban systems can be implemented in most manufacturing. Surprisingly, the answer is NO. There are many variations and factors to be considering

In this article the production example is automotive manufacturing by refer assembly line at Toyota company .The assembly line have main line and sub-line to serve component to each station at main line . Some factors in this paper were fixed as set up time, Economics, Supplier Capacity, Logistic Lead time, part quality from supplier. The main factors to be considered in this study are demand variation, buffer stock at sub-line(component) to support main line, number of workstation at main line, machine breakdown time variation, processing time variation.

Simulation models are used in this paper to illustrate the mechanics systems by use ARENA10.0. To input variable are factors variation which affect with e-Kanban Production system .The result the factors its effect with WIP level (control policy). So this model can specified which factor are the key of factors to implement in e- Kanban system. Then this model can apply for simulate the variation of factor which effect the e-Kanban system. The decision control policy will be judge which condition can be implemented in the manufacturing. So the result can made decision to management team to improve in their manufacturing. The results show the performance of e- Kanban systems using work-in-process levels, backlog order and station utilizations, are main. Hopefully the result can become preliminary guideline who considering e-Kanban implementation.

RESEARCH BACKGROUND AND MOTIVATION

Traditional mass production manufacturing is not responsive to changing customer demands. It relies on forecasting future demand and scheduling. Mass production systems often have excess inventory, higher WIP levels, and longer quoted lead-times from order to delivery. (Richard 2001) Just-In-Time (JIT) manufacturing approach has triggered various 'pull production systems' that emphasize the importance of production control that react to actual demand rather than future demand forecasts (Karin 2005).

Pull systems authorize parts to be processed in response to the actual demand arrival, control WIP and observe throughput (Spearman 1990). A pull mechanism can be implemented in many ways. The best known is a Kanban policy (Monden 1983). The Kanban control was originally used in Toyota production lines. In the Kanban control system, Production authorization cards, called Kanban, are used to control and limit the releases of parts into each production stage.

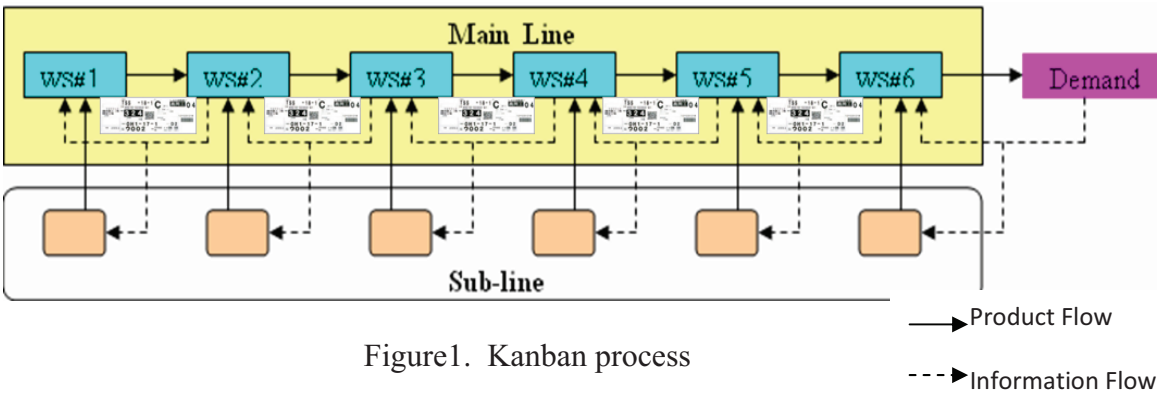

Figure1. Kanban process

The manufacturing operations to respond to changing customer demand. So, The Information Technology is important to improve operation. Particularly in the automotive industries are utilize e- Kanban for their operation. e- Kanban respond actual demands (right products at the right times and in the right amounts) and make-to-order environment. (Debra 2001) The next question is the electronic kanban systems can be implemented in most manufacturing. Surprisingly, the answer is no. There are many variations and factors to be considering.

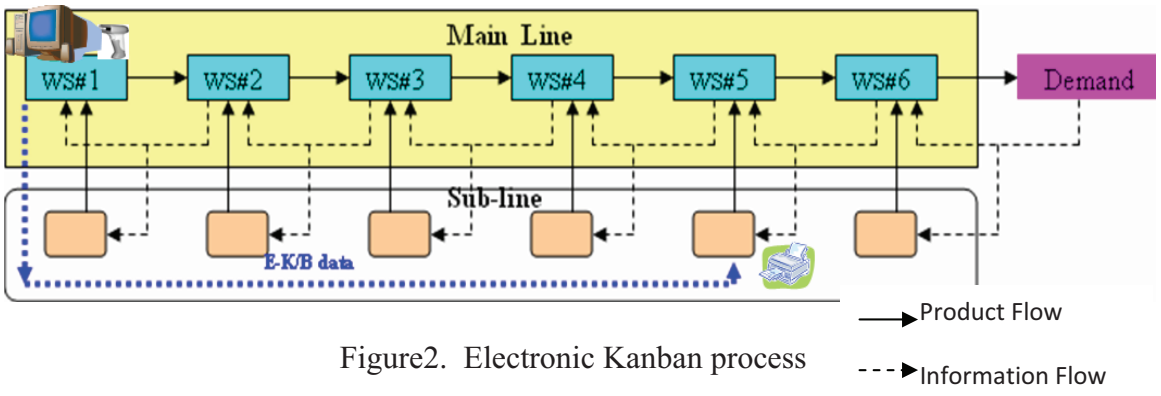

Figure2. Electronic Kanban process

In this study, the production example is automotive manufacturing by refer assembly line at Toyota company .The assembly line have main line 1 line and sub-line to serve component to each station at main line . Some factors in this paper were fixed as set up time, Economics, Supplier Capacity, Logistic Lead time, part quality from supplier. The main factors to be considered in this study are demand variation, buffer stock at sub-line(component) to support main line, number of workstation at main line, machine breakdown time variation, processing time variation.

Simulation models are used in this paper to illustrate the mechanics systems by use ARENA10.0 .To input variable are factors variation which affect with e-Kanban Production system .The result the factors its effect with WIP level (control policy). So this model can specified which factor are the key of factors to implement in e- Kanban system. Then this model can apply for simulate the variation of factor which effect the e-Kanban system. The decision control policy will be judge which condition can be implemented in the manufacturing. So the result can made decision to management team to improve in their manufacturing.

In this study show the results of a simulation study on the performance of e- Kanban systems. The performance measures as work-in-process levels, backlog order and station utilizations, are investigated. Hopefully the result can become preliminary guideline who considering e-Kanban implementation. To explore the potential barriers in other manufacturing plant beside Toyota assembly plant. This study is focus on the impact of variation the performance of e-Kanban system. The purposes of this study are

1. To find out key factors which effect to implement in e-Kanban system in the assembly line
2. To find out variation of factors are impact in the process
3. To simulate factors by generate suitable model

LITERATURE REVIEW

Kanban and e-kanban

Kanban, meaning card or marker in Japanese, is the more widely known and recognized type of pull system. A Kanban pull system is sometimes referred to as the Toyota Production System (just-in-time manufacturing using a Kanban pull system) (Monden ,1981)
A traditional card based kanban system has some limitations that can be improved with an electronic kanban (e-Kanban) system. The kanban system itself includes some nonproductive work caused by card handling. The kanban system is difficult to adjust to production mix changes because the cards have to be collected and replaced with new ones(Richard P. Marek , 2001).

Electronic kanban systems or closely related kanban type systems have been developed during recent years.However, the scientific reports and descriptions of electronic kanban system or their implementation are rare.Several articles describe the advantages of electronic signals over the cards. Some articles notice that electronic kanbans are in use to some extent, but they do not

include more detailed information of the principles and practices utilized. Motor vehicle manufacturers have been the first companies reported to have electronic kanban systems in place. Rover used as early as 1986 an EDI based signaling system used to pull materials from the suppliers.General Motors was reported in 1990 to have bar-code based pull production system. Toyota studied the possibilities of replacing the card based kanban with an electronic system in 1999. Toyota had a working interned based kanban solution in their factories in France and England in the year 2000 to pull materials from suppliers.The suppliers attach a bar-code to each delivered container, which is used for batch identification.After the material is used the bar-code is removed from the container. However, the practice described above has some push control features. The orders or pull signals are sent based on the production schedule, not the realized production or system status. Ford has implemented a simple bar-code based pull production system called SMART. BMW is reported to have an electronic kanban system in place.ERP vendors such as SAP have included kanban functionality in their products. The SAP solution utilizes RFID tags attached to containers to automate batch identification and location tracking. The manufacturing decisions can be made based on accurate information of production batch status.Most of the electronic kanban systems described use RFID-codes or bar-codes in production batch identification.[10] [16] Bar-codes are applied more often to manage material flow between companies, because the containers are used for different batches. RFID tags are more applicable in inter-company situations because the same containers are used many times. The earlier mentioned Toyota example is limited only to pull the materials from the suppliers. Toyota still uses card-based kanbans in its own manufacturing operations.

An e- kanban system has many advantages over the traditional kanban system. It is as simple as the traditional kanban, but signals are transferred faster. Several writers list the advantages of the e- kanban system:

- Removes the problem of lost cards
- The demand need is delivered right time
- Time and effort needed cards handling is minimized
- Fast and effective optimization of kanban cards
- Minimizes the material shortages
- Improves the supply chain transparency
- Helps to analyze the supplier efficiency

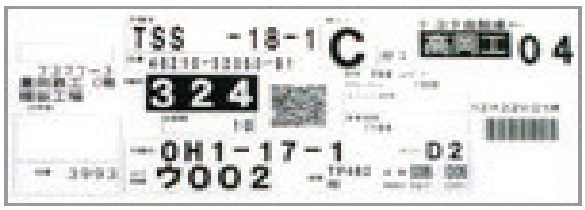

Figure3: Kanban Card

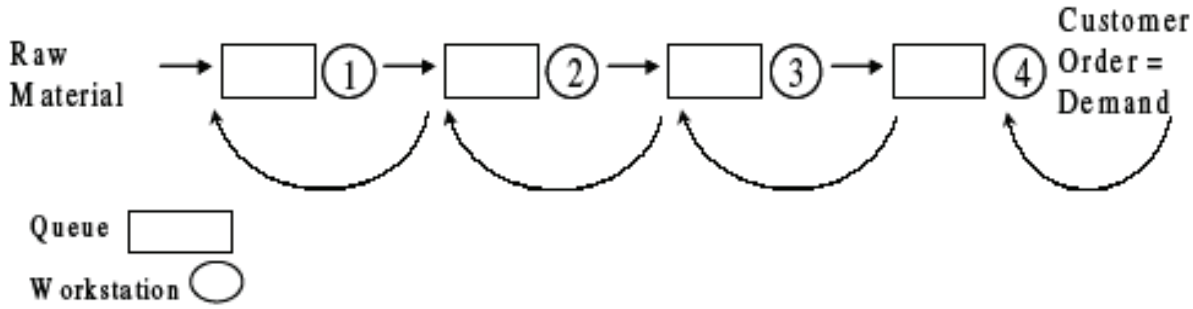

Figure.4: Kanban Pull System

Just-in-time production system

Just-in-time(JIT) system or Toyota production system (TPS). Developed mostly within Toyota and with its suppliers in the 1950s and 1960s, the JIT/Toyota system was largely unknown in the West until the late 1970s. The word got out in 1977 in two English language articles. One, written by Toyota managers, was published in the International Journal of Production Research (Sugimori et al., 1977). The other appeared in American Machinist (Ashburn, 1977).Not much changed until 1981 when JIT/TPS quickly became a hot topic, aired in assorted books, articles, conferences, lectures, and management consultants' advocacy. Today, many industry people who are involved appear to be unaware that what is now called lean manufacturing was in full bloom, notably in the United States, in the early 1980s. A common perception seems to be that the movement began in the 1990s following publication of The Machine That Changed the World (Womack et al., 1990). The following are a few notable markers of the rise beyond Japan of JIT/ TPS/lean in the 1980s:

In recent years, a new production control concept, called Just-in-time production (JIT),has been initiated in Japan by Toyota Company and adopted by many companies around the world to aid management in improving production performance. The basic concept of JIT production control system is to reduce in-process inventories to the lowest level possible by operating the line and each station according to the demand. JIT systems are also referred to as pull systems, since a succeeding station withdraws or pulls parts from the storage of a preceding station only at the rate and at the time it has completed its parts. (Mehmet Savsa ,1995)

JIT production control systems have been reported and described in various professional journals. While some of the papers deal with the general philosophy and review of the JIT systems, others deal with the modeling and analysis aspects of such systems. Among others, Kimura and Terada,Schonberger, Monden, Im [S], Miltenburg and Wijngaard [IS] and Mejabi and Wasserman deal with the basic concept and philosophy of JIT systems. Research in the modeling and analysis area can be classified as: mathematical models, simulation models and case studies. Phlipoom et al. [S], Bitran and Chang, Wang and Wang [lo],Bard and Golany and Li and Co have developed different mathematical models, such as dynamic programming, integer programming and Markovian models to describe the behavior of JIT systems and to

determine the optimum number of kanbans (work-in-process) between stations. However, it has been realized that the development of mathematical models sometimes require restrictive assumptions which may not be realistic. Therefore, some investigators have tried to develop simulation models to describe the behavior of these systems.Huang et al., Schroer et al. [14], Rees et al., Sarker and Harris, Sarker and Fitzsimmons and Sarker, have presented different simulation models and studied JIT systems. Chu and Shih have reviewed and compared several previous simulation studies on JIT production systems. Cadley et al. have studied the impact of implementing JIT in US firms using simulation modeling. Finch and Cox have examined JIT application to a small manufacturing line with a practical application. The best literature review on the subject was carried out by Golhar and Stamm who have reviewed and classified 860 articles related to JIT production control system. Mehmet SavsaP , Abdullah Al-Jawinib ,1995)

Just-in-time systems make use of cards (referred to as kanbans) which are attached to part containers and carry the necessary information with them. A kanban system is an information system to harmoniously control the movement of parts between stations.

In this paper, I present the results of a simulation study on the performance of JIT systems. In particular, the effects of processing time and demand variability, buffer stock of components, Breakdown time variation and the line length (number of workstation) on such performance measures as backlog quantity, work-in-process levels and station or machine utilizations, are investigated.

METHODOLOGY

Data collection

There are many factors that concern e-Kanban system such as demand variation, demand distribution, buffer stock, processing time variation and distribution, number of workstation, breakdown time variation and distribution, product type variation. So that before collect the data researcher interview production manager to screening the factors. The result, the main factors are considered have total 5 factors.

Factor A : Demand Variation
Factor B : Buffer
Factor C : Processing time variation
Factor D : Number of workstation
Factor E : Breakdown time variation

All data is collected from actual data of the year 2008 is used for this research

Design of Experiment

In this experiment, statistical software was applied to design and simulate suitable experiment for the raw data collection in screening process, analyze the result, including design the response surface of experiment to determine the appropriate operating condition for factor effect analysis. The application of statistical software is to analyze and evaluate the results from the experiment.

In the first step, there were many influenced factors that must be considered. Some of them have significant effects on the response variables and some have less or none at all. We could not apply the full factorial design at this step because of the limitation of time and resources. Fractional factorial design was selected at the first step to screen the influenced factors. The fractional factorial design or Taguchi design resolution for this experiment was resolution I designs (3_I^{5-2})= 27 runs. It mean 5 factors,3 levels and no. of run 27 run.For this design, only main factors can be estimated (main effects are all confounded with any order interaction) resolution I .

In the second step, the interaction effects must be considered. Fractional factorial design was selected at the second step by Taguchi's design shown in table 7. This step select two set of interaction factor to be considered. There are AB (Demand and buffer), AC (Demand and processing time), AD (Demand and Line length), BC (Buffer and processing time), BD (Buffer and Line length) and CD (Processing time and Line length) effects. Other factors are fixed when 2 factors interaction be considered.

The level of factor is fixed as below.

Factor A (Demand): Normal distribution with mean 4 min and standard deviation 0.586
Factor B (Buffer): Zero buffer for safety stock
Factor C (Processing time): Constant 4 min/unit
Factor D (No. of workstation): 10 workstations
Factor E (Breakdown time): Mean time and standard deviation time before failure

Results

Initially, the experiments are planned to identify the most important factors of the model. Then, these factors are used as input data for optimization software. Also, this model is optimized using all factors as input data in order to compare the results. The optimization software is ARENA 10.This chapter will run simulation model including the interpretation of the obtained results .Also this chapter has concluded the analysis of factor effect. The response variables are collected the data for each run to 27 runs shown in Figure 6.

Main Effect

The results obtained for each run is shown in table 8. The performance measure for response variable "X" is WIP level by using ANOVA.
It's calculated expected mean square then the next step is to calculate F value. After completing the F value, calculate P value from degree of freedom, depended on the number of replicate, for screening the significant factors.

The main factor effect by *average WIP level* response stand for *"X"* is shown in Figure 7. To determine the main factor effect from P-value its significant at confidential interval 95 % when less than 0.05 respectively. The P-value shows the main factor A, B, C and D effect to average WIP level.

Error	16	0.000103	0.000103	0.000006		
Total	26	0.204933				

Figure 11: Response factor "Z" for main factor effect by using ANOVA

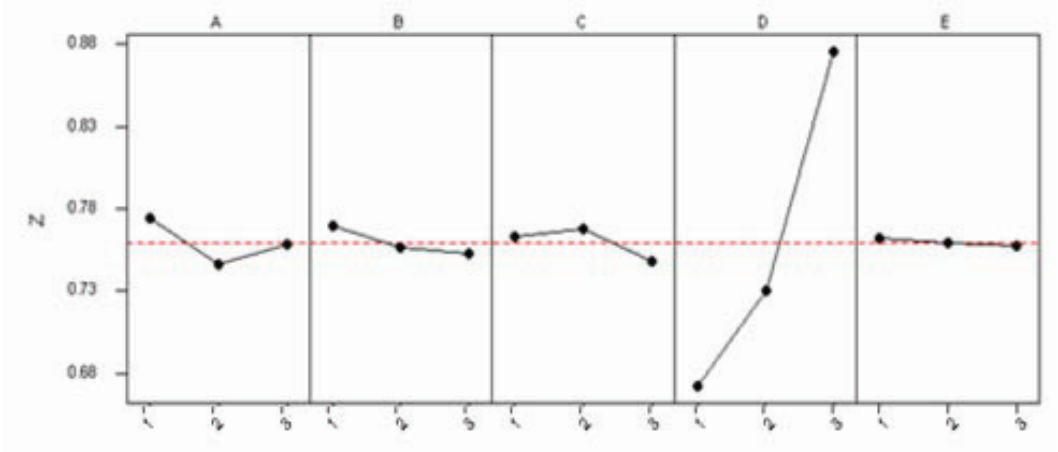

Figure 12: Main effects plot for "Z" average machine utilization

See Figure 12 .It is noticed that factor, B=Buffer at sub-line and C=Processing time variation have negative effect. These factors increase the average machine utilization when they are decreased (level 3). Another factor D= Number of workstation has positive effect that increase the average machine utilization when they are increased (level 3). It's seem factor A=demand variation that can't identify positive or negative effect with average machine utilization .By the way at zero demand variation level is maximize of average machine utilization.

These figure gives a good indication that four factors must be effect to average WIP level , total backlog order and average machine utilization, as demand variation, buffer at sub-line, processing time variation and number of workstations.

However, to have conclusive results, it is necessary to verify the interactions among factors.

Interaction Effect

The two-factor interaction between factor A and Factor B is shown in table Figure 13-16. The ANOVA for response "X" show AB interaction hasn't significant effect. From Figure17&18, it is noticed that the interactions between AB=Demand variation and buffer lead to same results by minimize of average WIP level and total backlog order. Taking into consideration interaction AB it is clear that factors A must be kept at level 1 (zero variation) and factors B must be changed levels.

In the same way, the interactions between AB=Demand variation and buffer lead to maximize of average machine utilization. Taking into consideration interaction AB it is clear that factors A must be kept at level 1(zero variation) and factors B must be changed levels shown in Figure 19.

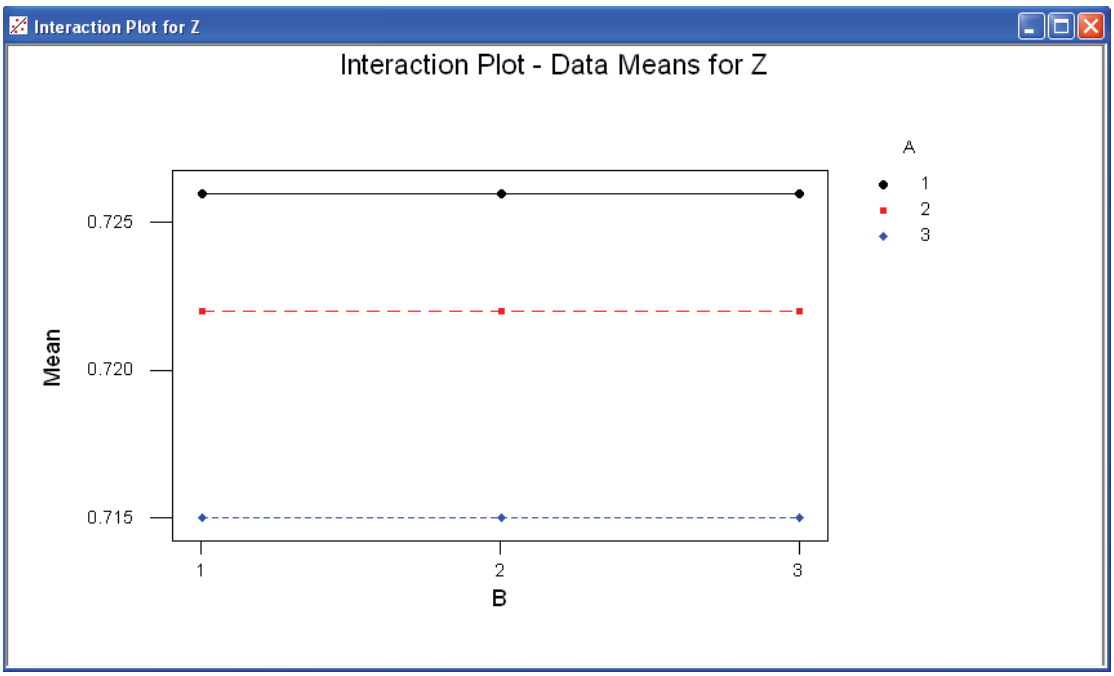

Figure 19: Interaction effect of AB by average machine utilization response

The two-factor interaction between factor B and Factor C is shown in Figure 20-23. The ANOVA for response "X" show BC interaction hasn't significant effect. From Figure 24 & 25, it is noticed that the interactions between BC= buffer and processing variation lead to same results by minimize of average WIP level and total backlog order. Taking into consideration interaction BC it is clear that factors C must be kept at level 1 (zero variation) and factors B must be changed levels.

CONCLUSION

The main purpose of this study was to develop a simulation model, to investigate the effects of different operational factors on the performance of e-Kanban production system. Three performance measures were evaluated under different operational conditions, including average WIP level, backlog order and machine utilization. Furthermore, an experimental design was set up to study the effects of main and interaction of different factors on performance measures.

Main effect

Results of the ANOVA are summarized for all three performance measures (the responses) in Figure 27. The " * " indicates that the effect of the factor was significant at 5%; the (+) indicates that the effect of the factor should set at high level; the (-) indicates that the effect of the factor should set at low level. From the simulation results we observed that the WIP level, backlog order and machine utilization are significantly affected by the variability in demand interval, buffer, processing times and number of workstation. On the other hand the variability in breakdown time does not have a significant effect on response variables

Figure 27: Analysis of variance results of main factor for different performance measures

Factor	Main Factors Performance measures (response)		
	WIP level	Backlog order	Machine utilization
A (Demand interval)	*(-)	*(+)	*(-)
B (Buffer)	*(-)	*(+)	*(-)
C (Processing time)	*(-)	*(+)	*(-)
D (No.of workstation)	*(+)	*(-)	*(+)
E (Breakdown time)			

Note: * significant at 5%; (+) high level of factor should set up or (-) low level of factor should set up

Interaction effect

The two- interaction effects were not significant in all performance cases at significant level 95%. So this system hasn't two-factor effect to WIP level, backlog order, machine utilization.

General Practice

The other company which apply e-Kanban system to use with your own. The results refer from simulation would set factor parameter as,

a. Demand variation should be zero variation, it's closed to constant
b. Buffer should be zero, because buffer its take more space and protect e-Kanban system. So this system will inform production plan to each process in advance
c. Processing time variation should be zero variation, it's closed to constant
d. Line length or number of workstation should be longer. The job of each workstation is decreased so the error should be reduced accordingly. It makes less of impact to the system.

Recommendation

a. By backlog order reduction would has overtime production / add production line or plant (bridge production concept)
b. Some factor in some performance measure its not good result. So increasing replication for running model its quite be good for interpret the result.
c. There is the factor to be considered as number of product type which may effect to performance measure. It's should trial this factor for next study.
d. For complex system simulation, where the simulation itself is very time-consuming, the Factorial Designs make possible some special approaches as response surface methods (Kleijnen 1998) which are recommendations for future works.

ABSTRACT

The aim of this research is to establish the criteria for selecting the most appropriate Voice over Internet Protocol (VoIP) technology using the Electricity Generating Authority of Thailand (EGAT) as the case study company. Seven EGAT experts in telecommunication systems agreed to participate in this research. In-depth interviews with experts were arranged in order to gather expert opinions for refining the criteria from those gathered from past researches and to screen the alternatives for final selection. Analytic Hierarchy Process (AHP) is applied to investigate the priority of the established criteria and evaluate the preference of each alternative. The opinions were collected from the experts using the structured survey questionnaire.

The result of this research indicates that highest priority was given to "benefit criteria" rather than "low cost criteria". Under benefit criteria, intangible benefit subcriteria received priority that was higher than that of tangible benefit. Highest preference was given to the pure IP-PBX VOIP alternative based on the four main criteria ranked in the order of importance from high to low as follows: benefit, low cost, technical feasibility, and low risk. The choice of the most appropriate technology in this case was found to be rather insensitive to changes in the importance of each main criterion. Managerial implications are discussed.

Keywords: Analytic Hierarchy Process, Multiple-Criteria Decision Making, Innovative Technology Selection

INTRODUCTION

Communication system technology is one of the key tools to ensure the system reliability, especially the power system control, of Electricity Generating Authority of Thailand (EGAT), a state enterprise responsible for electricity generation in Thailand. Various communication systems have been installed in EGAT, such as data-communication network, telecommunication network and information system, to support internal operation and core business of EGAT. Communication system division of EGAT has undertaken responsibility for planning, designing, installing, deploying and maintenance every communication system within EGAT.

The communication systems were continuously improved and developed to support core business to ensure availability and reliability, especially regarding electricity generation and transmission system. EGAT has many substations, with power plants and dams located in virtually all provinces in Thailand. Therefore, EGAT's employees dispersedly work throughout the kingdom. Internal communication systems of EGAT, such as the wireless system and the telephone system, can help them to communicate from anywhere at any time.

The telephone system in EGAT is the main communication system used to support both administrative work and power system control.

At present, employees at remote site can communicate with other employees using telephone sets, faxes and modems at headquarters through EGAT's telephony network. However, many pieces of equipment of the telephony system are used beyond its designated life cycle, and thus most of them become inoperable and require a great deal of effort and cost to operate and maintain. Routine maintenance and breakdown repair cost increase, energy use may increase, even more operation time may be required, and more undesirable consequences would follow. Also, the impact of changes in technology is found to vary among different types of assets. In general, the costs per unit of operation, as well as quality and other factors, are favorably impacted by changes in technology, which result in replacement of existing system with new and better challengers. Replacement of legacy system is expected to retain the cost-effectiveness of telephone system, reduce resources for operation and maintenance, and increase productivity.

This study focuses on the evaluation and selection of the appropriate VoIP technology from economic and non-economic perspectives. The technology is planned to replace legacy voice communication equipment at headquarters, control center, and remote sites across its communication network. VoIP is expected to increase employee productivity with integrated voice and data applications such as collaborative multimedia applications and mobile communications solutions supporting both administrative tasks and mission-critical tasks like power system control. The main aim of the research is to establish the set of criteria suitable for the selection of innovative technology for such a technology-intensive firm as EGAT.

METHODOLOGY

Decision making process model of Simon (1977) and AHP model were used to assist EGAT in analyzing the VoIP adoption options. These methodologies can be used to solve the conflicting issues among different viewpoints within an organization. This study integrated the three-phase model of Simon (1977) decision making process into the methodology.

Intelligence phase – Intelligence phase is concerned with identifying an enriched and consensual view of the problem. This was conducted entirely through in-depth interviews with a mixture of face-to-face and telephone sessions. It is important to allow the group of experts the opportunity to discuss, understand, and define the problem fully.

Design phase – Design phase is concerned with identifying or designing list of alternatives and criteria. Data were gained through from literature reviews in order to obtain validated alternatives and criteria. A validated list of alternatives and an initial list of objectives were presented to the seven experts. Experts individually involved in discussions about their opinion on the lists to refine and augment a list of criteria and alternatives of VoIP technology. For complex criteria that cannot be directly evaluated, they are decomposed into a set of sub-criteria, both qualitative and quantitative ones. After that a revised list of alternatives and a refined list of criteria were created, which were presented to the experts to gain approvals. The selection of criteria is described under the Criteria Selection heading.

Choice phase – The Analytic Hierarchy Process served as the foundation of the choice phase. One of the strengths of the AHP is to provide a clear, organized, and logical view of the decision problem.

The data requirement used in this study is described below under the Data Requirement heading. There are two instruments used to collect the required data. The first instrument, described as such, is used in *intelligence phase* and *design phase.* The second instrument, described under another heading, is used in the choice phase.

Data Requirement

The data required for this research were generated by two instruments. The EGAT decision makers and experts on the topic of VoIP responded to these research instruments. The first research instrument in this research used in-depth interview. Each expert responds to questions on a face-to-face basis. The interview was recorded (i.e. typewritten) and respondents were given the opportunity to re-evaluate their original answer. The evaluation of this instrument led to quantifying experts' judgments using the second instrument which is the AHP. It was used to obtain preference weights of validated criteria from EGAT experts. The criteria were composed of tangible and intangible criteria. The result of preference weights was used in ranking VoIP solution of EGAT. The AHP technique has proved useful in eliciting objectives and ranking policy options as well as in checking for consistency of the statements of stakeholder groups. Implementation of this approach requires a complex data elicitation process.

Recruitment of Experts

AHP considers both qualitative and quantitative approaches to research and combines them into a single empirical inquiry. It is to be noted that the AHP approach is a subjective methodology that does not necessarily involve a large number of experts to take part in the process. Generally, in an academic research, a small sample might only provide a rough picture. However, with reference to tacit information about important business decisions, opinions from a small group of key executives of the company are considered to be sufficient for generating reliable and useful results. Sometimes, some very important business decisions involve discretion on the part of only one person, usually the managing director of the company, who is the one and only one to fill in the questionnaire (Cheng & Li, 2001).

A list of potential participants who had strong experience was generated, at least five years, on telephone system of EGAT. The potential participants were contacted for participation in the study. Seven experts involved in decision-making, planning, design, maintenance, and operation of telephony system of EGAT were asked to participate in this study. They were given the complete picture about the objective of the study and specifically the VoIP system evaluation. Profiles of the subjects who agreed to participate in the research are listed in Table 1.

Table 1 Profiles of the experts participating in this research

Expert	Position	Experience (years)		Description of experience
		Telephone System	VoIP System	
1	Engineer, level 5	5	3	Planning and designing of telephone system Preparing bidding document Cooperate with internal customer
2	Engineer, level 7	20	3	Operating and maintain for Hybrid IP-PBX and Pure IP-PBX
3	Engineer, level 7	29	4	Operating and maintain for Hybrid IP-PBX and Pure IP-PBX
4	Engineer, level 8	15	3	Operating and maintain for Hybrid IP-PBX and Pure IP-PBX
5	Section Manager	10	2	Operating and maintain for Hybrid IP-PBX and Pure IP-PBX
6	Section Manager	15	6	Planning and designing of telephone system Preparing bidding document Cooperate with internal customer
7	Engineer, level 10	10	3	Planning and designing of telephone system Preparing bidding document Cooperate with internal customer

Criteria Selection

Because the criteria serve as the performance measures for the application of any multiple-criteria decision making model, their selection is critical for the decision process. A number of specific considerations need to be taken into account, however, in finalizing the choice of the criteria to be used in the application of AHP model. These include:

Completeness – It is important to ensure that all of the important criteria are included. In this connection, the concept of a hierarchically structured value tree (or a layered diagram) is a valuable tool.

Non-redundancy – In principle, criteria that have been judged relatively unimportant or to be duplicates should be removed at a very early stage. However, omission on these grounds should be approached with care.

Operationality – It is important that each alternative should be meaningful and can be judged against each criterion.

Minimum Number of criteria – An excessive number of criteria leads to extra analytical effort in assessing input data and can make communication of the results of the analysis more difficult. A final check to ensure that the number of criteria is not larger than it needs to be is necessary. Complex issues can be addressed effectively by using a hierarchical structure given the inability of human to compare more than seven categories simultaneously. A hierarchy should not contain more than seven elements. Under this limited condition, a

rational comparison can be made and consistency ensured as well (Keeney and Raiffa, 1976; Goodwin and Wright, 1998).

First Instrument

Criteria involved in the VoIP system evaluation need to be identified with great care. These factors are chosen keeping in mind the organizational needs. For this study, the researcher collected empirical data from several experts within EGAT. Instrument was an in-depth interview (face-to-face interview or interview via telephone) guide. The interviews were held at a location selected by the expert participating. Each interview lasted between 45-60 minutes depending on the availability of the expert. A set of criteria extracted from the literature were first proposed to the experts and discussion was made with the experts. Then, each expert could add any other relevant criteria for themselves or remove insignificant criteria. Each expert had to feel that every criterion covered their domain of technology type evaluation. The discussion involved a set of criteria and a series of open-ended questions about

- What are the frequently-used features of existing telephone system in the company?
- What are the telephone/VoIP features that should be deployed in the company?
- What are the technology types of VoIP experienced with?
- What advantages (pros) of the technology types are experienced with?
- What disadvantages (cons) of the technology types are experienced with?
- What are the set of criteria that covered all the evaluation facet of a technology?

Second Instrument

The parameters identified for evaluating the VoIP system were chosen based on the requirements of the organization, as the first instrument. It would have been very easy to rate the VoIP system if all the parameters were of equal importance, but evidently it is not so. Qualitative criteria may be of major importance followed by others. Hence, it becomes essential to know the relative importance of each factor that has been selected.

The results from the first instrument were used to develop the second research instrument. In order to develop the second instrument, each question from the in-depth interview was analyzed to determine all of the VoIP technologies that any of the experts considered viable. The results were that the experts identified three alternatives of VoIP system and four main criteria.

Once the list of VoIP solution was compiled the second instrument was developed which involved a series of pairwise comparisons between the three alternatives. After the research instrument was developed it was tested on employees at the researcher's workplace. None of the employees had prior knowledge of pairwise comparison and thus, had only the instructions that were provided in the instrument to guide them in answering the questions. The employees' lack of prior knowledge about pairwise comparison provided the opportunity to evaluate how well the experts would understand the Instrument's instructions since none of the experts had used pairwise comparison in the past either. The staffs' comments and suggestions for improvement were incorporated into the instrument and it was re-tested on employees at the researcher's workplace. Additional changes based on their comments were incorporated into the research instrument prior to distribution to experts.

The survey or second instrument conducted was based on the analytic hierarchy process. It involved the pair-wise comparison of factors amongst each other. For this, AHP was first explained to the respondents. The survey questionnaire with a detailed explanation of each factor was filled by the respondent. The selected candidates were briefly explained about AHP and especially the comparison matrix that they were required to fill in. They were given examples in order to give a complete understanding about the new concept. The scale of comparison was chosen between 1 and 9, where 1 stood for equal importance and 9 for extreme preference. This scale was also available for reference of the respondents on the first page of the questionnaire included with this paper.

The questionnaire consisted of comparison matrix for the first level in the hierarchy, i.e., the four major criteria, followed by matrices for the sub- criteria at the second and third level. The first comparison matrix requires all the major criteria to be compared among them. The process continues until all the parameters are compared amongst each other. Thus, the comparisons among the entire hierarchy are carried out. The respondents were required to fill in only the top half of the matrix and the lower half was hence darkened. A period of over one week was given to the respondent to fill in the questionnaire.

These filled questionnaires were used to generate the priorities of the factors for evaluation at the various levels. Each filled matrix was checked for consistency; and if it was found inconsistent, then that respondent was further contacted for a discussion to check the inconsistency. It was seen that most of the cases, the inconsistency was only marginal and it was because AHP was new to the respondents. However, discussions proved very fruitful since the inconsistency could be solved. A sample calculation for this procedure has been incorporated. In this study, Expert Choice software was deployed to compute the weights from the responses. The consistency test was used to calculate the inconsistency ratio (IR) of the adoption criteria. All criteria have received consistent responses as their IR value must less than 0.1 (Saaty, 2001).

RESULTS AND ANALYSIS

This revolves around the provision of VoIP technology for Electricity Generating Authority of Thailand (EGAT). A group of seven experts from the communication system division of EGAT was selected, for the purposes of the selection of VoIP technology. In-depth interview techniques were used to select which criteria would be used by the experts. The experts were chosen for this purpose. The experts were chosen according to their experience with evaluation telephone system in EGAT. Table 1 shows the experts' personal profile. The problem statement resulting from the in-depth interviews was "evaluating and selecting the most appropriate VoIP technology for EGAT". Roughly, they gave some recommendations for the definition derived following problems:

- The alternatives of VoIP technology should be enterprise-level solution.
- The system should be high reliability, availability and security.
- The system should be interoperable with the existing system.
- The cost of the system should be acceptable.
- It should be easy to use and maintenance.
- It was expected to enhance productivity of users.
- It was expected to help operation team to work efficiently.

A list of the evaluation criteria of IT/IS and VoIP was developed from the literature review. The criteria were condensed into a set of 28 criteria shown in Table 2 which were presented to the experts.

Development and Execution of the Model

After performing in-depth interviews on the various issues and criteria with seven experts, the initial criteria were then revised and reduced to 26 criteria. With the overall goal being the 'selecting the most appropriate VoIP technology for EGAT', the 26 criteria were categorized into four first level categories: 'benefit', 'low cost', 'technical feasibility', and 'low risk'. The final hierarchy model used in the AHP experiment is shown in Figure 1 with all the relevant criteria. After further discussion with EGAT experts and the set of criteria established, the seven experts decided that the possible technology choices were the pure IP-PBX, hybrid IP-PBX, and open-source IP-PBX.

The seven experts helped prioritize the criteria. They individually executed the analytic hierarchic process on the model with questionnaire. Individual relative weights were allocated to each criterion after a pairwise comparison. If the inconsistency ratio for all the pairwise comparisons was greater than 0.1 the individual expert went through another iteration of the process. Finally the three technologies were compared pairwise to each of the 26 terminal nodes (leaves).

Structuring the Hierarchy

The goal is to select the most appropriate VoIP technology for EGAT. This goal was placed at the top of the hierarchy. The hierarchy descends from the more general criteria in the second level to subcriteria in the third level to secondary subcriteria in the fourth level to the alternatives at the bottom or fifth level. General criteria level involved four major criteria: benefit, low cost, technical feasibility, low risk.

Intangible benefit and *tangible benefit* were placed under the *benefit* criterion in the third level of the hierarchy. Each of these in turn needed further decomposition into specific items in the fourth level. *Intangible benefit* decomposed into seven criteria: *Enhancing end-user productivity, creating new business opportunities, improvement of cooperation, improving in consumer service, aligning with business strategy, improvement of organizational image, and improvement of voice and data system management. Tangible benefit* decomposed into three criteria: *Moves/Adds/Changes cost saving, reduce travel cost to remote sites, and fewer support staff required.* We also located *low start-up cost, low on-going operating and maintenance cost, and low conversion cost* under *low cost.* The seven subcriteria were included for *technical feasibility* in the third level. These are *ease of use/friendliness, ease of implementation /management /maintenance, full suite of communications features & business-enabling applications, multi-vendor interoperability, easy scalability, equivalent voice quality to TDM,* and *high system reliability/availability/security.* Six criteria were also included for *low risk.* These are *enough appropriate skills, low technical infrastructure risk, low trade-off risk, low functional risk, low support risk,* and *low risk of technological changes.*

The decision-making team considered three VoIP technologies for the decision alternatives, and located them on the bottom level of the hierarchy. These are hybrid IP-PBX, pure IP-PBX, and open-source IP-PBX.

Performing Pairwise Comparison

After constructing the hierarchy, pairwise comparisons were systematically performed to include all the combinations of relationships of criteria, subcriteria, secondary subcriteria, secondary subcriteria, and alternatives. The criteria and subcriteria are then compared according to their relative importance with respect to the parent element in the adjacent upper level. Due to the differences among the schedule of the experts and managers, questionnaires including all possible pairwise comparison combinations were distributed to the decision makers.

The pairwise comparison matrix of the criteria and sub-criteria is used to obtain each hierarchical factor weight, in which the eigenvector. After performing all pairwise comparisons by the decision-makers, individual judgments were aggregated using the geometric mean as suggested by Saaty (1990).

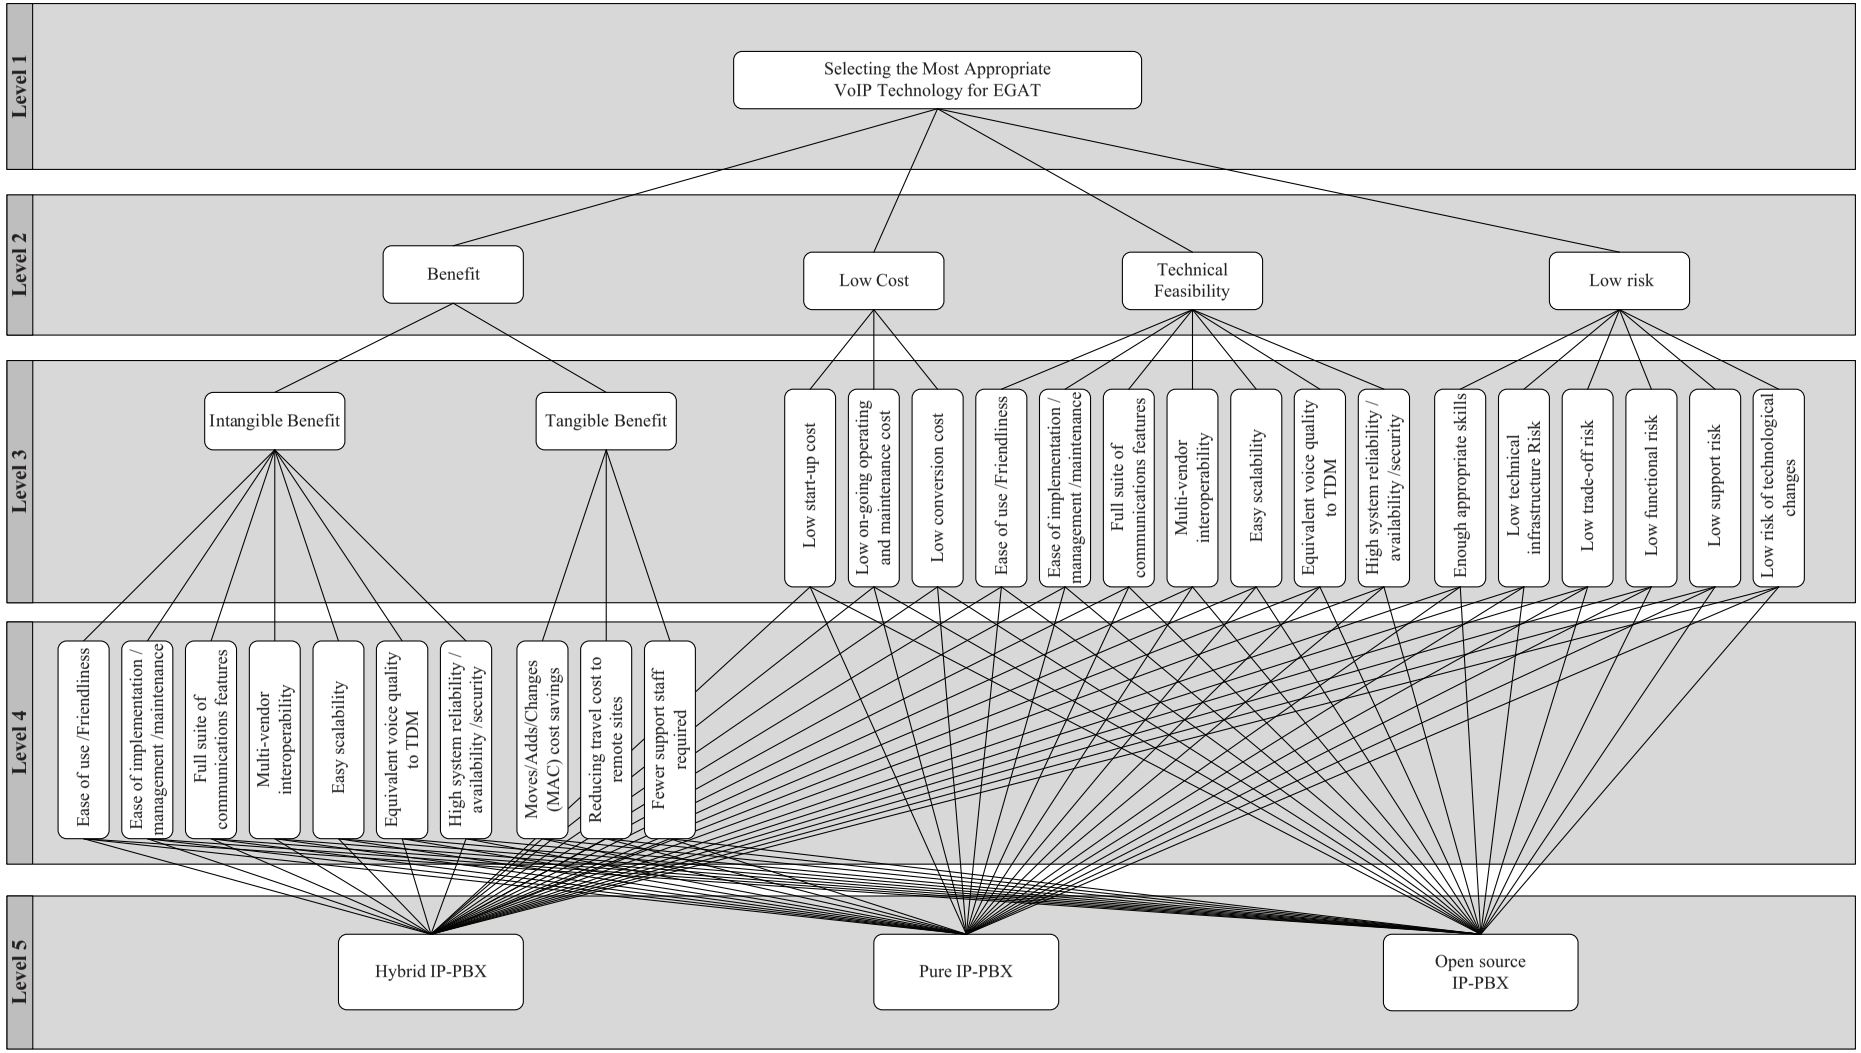

Figure 1 A hierarchical representation of selecting the most appropriate VoIP technology

Table 2 Criteria of AHP model and their definition

Criteria	Definition	References
Level 1 Goal	Selecting the Most Appropriate VoIP Technology for EGAT	
Level 2 criteria		
Benefit	The degree to which EGAT will gain benefit from new tehcnology after deploying VoIP.	Escobar-Perez (1998), Bacon (1992), Walker and Hicks (2004)
Low cost	The degree to which EGAT will payfor the cost to implement new technology.	Jones and Beatty (1998), Iacovou et al. (1995), O'Callaghan et al. (1992)
Technical feasibility	The degree to which new technology meet technical requirement of EGAT environment.	Jones and Beatty (1998), Catchpole, Middleton and Nelson (2001), Pierce (2007), Walker and Hicks (2004), Hoover (2006)
Low risk	The degree to which VoIP will not degrade business process, operation, and customer satisfaction .	Catchpole, Middleton & Nelson (2001), Pierce (2007), Walker and Hicks (2004), Hoover (2006)
Level 3 Benefit subcriteria		
Intangible benefit	It assesses the degree to which new technology will provide potential to affect the technological leap in the future. However, this intangible benefit is hard and complex to calculate amount of money.	Escobar-Perez (1998), Bacon (1992), Walker and Hicks (2004)
Tangible benefit	It assesses the degree to which new technology will provide clearly defined cost savings.	Escobar-Perez (1998), Bacon (1992), Walker and Hicks (2004)

S3-10

Table 2 Criteria of AHP model and their definition (continued)

Criteria	Definition	References
Level 3 Low cost subcriteria		
Low conversion cost	They represent the amount paid to adapt the existing telephone system to the new one. This amount may be considered as the sum total of software and/or configuration and equipment expenses. A VoIP technology with low cost is a better alternative.	Jones and Beatty (1998), Irani (2002), Mirani and Lederer (1998), Banerjee and Golhar (1994), Iacovou et al. (1995)
Low on-going operating and maintenance cost	They represent the amount paid for permanent maintenance, materials and the necessary communication system infrastructure. A VoIP technology with low cost is a better alternative.	O'Callaghan et al. (1992), Walker and Hicks (2004), Gareiss (2005)
Level 3 Technical feasibility subcriteria		
Ease of implementation /management /maintenance	It assesses the degree to which new technology is easy to implementation, management and maintenance. If management of the IP telephony solution is not straightforward and intuitive, it will take a long time to operate the system.	Jones and Beatty (1998), Catchpole, Middleton & Nelson (2001), Pierce (2007),
Ease of use/ Friendliness	It assesses the degree to which new technology is easy to use. The IP phones and call control software should be intuitive and easier to use than the analog phones being replaced. Features like on-the-fly conference calling, drag-and-drop call transferring, and the forwarding of voice mail messages via e-mail should be simple for employees. The commands should be understandable and non-ambiguous commands: syntax clarity and semantic concision of commands accessible to users.	Walker and Hicks (2004), Hoover (2006)
Easy scalability	It assesses the degree to which new technology has capability to scale the system for specific needs of EGAT such ng and shrinking number of users during different times of the yea or in some other cyclical manner.	

S3-11

Table 2 Criteria of AHP model and their definition (continued)

Criteria	Definition	References
Multi-vendor interoperability	It assesses the degree to which new technology has capability to interoperate with the existing system and also other vendors.	Jones and Beatty (1998),
Equivalent voice quality to TDM	It assesses the degree to which new technology has the same quality as the traditional or TDM system.	Catchpole, Middleton & Nelson (2001), Pierce (2007),
High system reliability /availability /security	It assesses the degree to which new technology include mechanism supporting reliability /availability /security of telephone system such as redundant components in the case of a failure and the ways to reroute calls around a failed switch.	Walker and Hicks (2004), Hoover (2006)
Full suite of communications features & business-enabling applications	It assesses the degree to which new technology has value-added services that meet the majority of EGAT requirements.	Escobar-Perez (1998), Bacon (1992)
Level 3 Low risk subcriteria		
Enough appropriated skills	A skill set of new technology will be required for successful integration.	Irani (2002), Iacovou et al. (1995)
Low functional risk	The possibility that the VoIP does not fulfill the project's requirements. A VoIP technology with low risk is a better alternative.	Catchpole, Middleton & Nelson (2001), Pierce (2007),
Low risk of technological changes	The possibility that the use of the technological pattern adopted is discontinued in a near future. A VoIP technology with low risk is the a alternative.	Walker and Hicks (2004), Hoover (2006)
Low support risk	The possibility of interrupting product support. A VoIP technology with low risk is the a alternative.	Catchpole, Middleton, & Nelson (2001), Pierce (2007),
Low technical infrastructure Risk	This assesses the degree to which extra investment, outside the specific project, may be necessary to undertake the project. A VoIP technology with low risk is a better alternative.	Walker and Hicks (2004), Hoover (2006)
Low trade-off risk	The possibility that the adoption of a given VoIP solution might block or

S3-13

Table 2 Criteria of AHP model and their definition (continued)

Criteria	Definition	References
Level 4 Benefit/tangible tertiary subcriteria		
Moves/Adds/Changes (MAC) cost savings	Moving an IP telephone station temporarily or permanently or adding a new user usually simply entails carrying out a quick and simple GUI-based command. Companies save on MAC activities, depending on the company size and number of MACs per year.	Jones and Beatty (1998), Irani (2002),
Reduce travel cost to remote sites	Employee can use viedeo conference to have a meeting instead of travel to any remote site. They can save a lot of time. Company can save a lot of allowance for traveling, house, food, and others.	Mirani and Lederer (1998), Banerjee and Golhar (1994), Iacovou et al. (1995), O'Callaghan et al. (1992),
Fewer support staff required	With VoIP, management savings are usually immediate since the information technology team can support the voice network as well as the data network because they're now one in the same. There is no longer a need to have two teams of technical professionals to handle each entity which adds up to tremendous savings.	Walker & Hicks (2004), Gareiss, R. (2005)

Synthesizing the Results

The experts were asked to compare each pair of alternative with respect to each of the main criteria in Level 2, each sub-criterion in Level 3, each secondary sub-criterion in Level 4 and each secondary sub criterion in Level 5.

In this study, the so-called "ideal mode" would be the way to synthesize the results since the decision is to find the one best alternative. After deriving the local priorities for the criteria and the alternatives through pairwise comparisons, the priorities of the criteria are synthesized to calculate the overall priorities for the decision alternatives. *Pure IP-PBX* turns out to be the most preferred supplier among the three alternatives, with an overall priority score of 0.411.

Sensitivity Analysis

One of the advantages of the AHP process is that one could test the sensitivity of the final choice to retrospective changes in the assessment of a criterion or parts of the model. A series of sensitivity analyses were conducted to investigate the impact of changing the priority of the criteria on the VoIP technologies' rank. *Performance* sensitivity analysis of *Expert Choice* was performed. *The Performance graph* displays how the alternatives perform with respect to all objectives as well as overall.

The sensitivity analysis of four main criteria is shown in Figure 2. In terms of the *benefit, low cost,* and *technical feasibility* criteria, the overall results indicate that *pure IP-PBX* appears superior to the other alternatives whereas *hybrid IP-PBX* appears superior to *open source IP-PBX*. The results of the sensitivity analyses indicated that when the importance of the *benefit, low cost,* and *technical feasibility* criteria were changed, the VoIP technologies' ranking do not change for all priorities. As shown in Figure 3, however, the decision will change when the importance of the *low risk* criterion was increased more than 0.58, then the *hybrid IP-PBX* will be superior to *pure IP-PBX.*

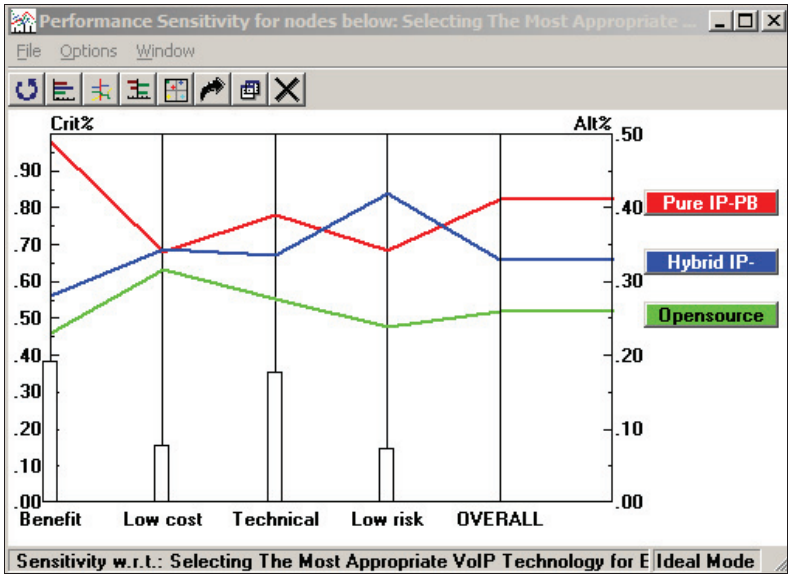

Figure 2 Performance sensitivity graph shows the priorities of the alternatives of VoIP technology for m
ain criteria as well as overall with respect to goal.

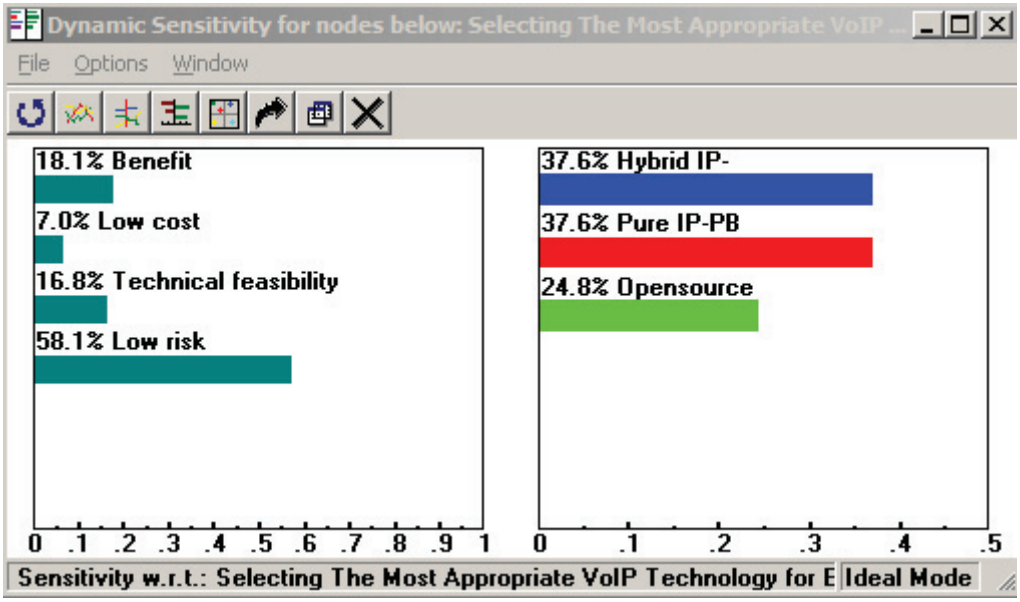

Figure 3 Dynamic sensitivity graph shows the priorities of the alternatives of VoIP technology for 58.1% priority of *low risk criterion* with respect to *goal* at a time.

DISCUSSION AND CONCLUSION

When EGAT is confronted with choosing the best technology to deliver a good or service, the decision can often be very complex. Technology selection problems are multi-objective problems which have many qualitative and quantitative concerns. Decision-makers needed a methodology well supported with a well developed-software conducive to real life applications that is easily understandable by the managers.

The methodology of this research applied decision process of Simon (1977) to obtain the most appropriate VoIP technology for EGAT. First, in-depth interviews were conducted to discuss about problem identification, evaluation criteria and alternatives. Second, the validated list of criteria from literature review and alternatives were revised. Third, the revised criteria and alternatives were used to establish AHP model.

The goal of AHP model was *"Selecting the most appropriate VoIP technology"*. The main criteria were *"benefit"*, *"low cost"*, *"technical feasibility"* and *"low risk"*. Those main criteria were decomposed into 26 subcriteria. Seven experts then performed pairwise comparison of AHP model via questionnaires. The individual results of pairwise comparison were checked for consistency. If the results were inconsistent, then experts would have asked to revise the comparison again. Actual process of conducting this analysis helped the decision making team prioritize the criteria in a manner that otherwise might not be possible. The team was far more confident with their decision since this study showed them even if the importance of certain criteria changes overall ranking does not change though the degree of preference rating is strengthened or weakened. Bounded rationality and limited cognitive

processes make it really impossible for the decision maker to adequately consider all of the factors involved in a complex screening decision. Without decision support methodologies like AHP, managers might base their decisions on only a subset of important criteria while not understanding their relative importance and interactions. After that, the results of every expert were combined and also checked for inconsistency.

With its commercial software, AHP enables sensitivity analysis of the results which is very useful in practical decision making. This study performed sensitivity analysis to see how robust the final outcome was. It was found that no matter how much we increase or decrease the priorities of three main criteria (*benefit, low cost* and *technical feasibility*) and their subcriteria, the overall rank of the outcome was preserved although these experiments changed the magnitudes of the superiority of the best alternative. However, sensitivity analysis indicated that outcome is sensitive to the changes in the importance of *"low risk"* criterion. The highest rank of the alternatives was going to change from *pure IP-PBX* to *hybrid IP-PBX* when the importance rating of *"low risk"* changed from .137 to .581.

It can be concluded that *pure IP-PBX* is the most appropriate VoIP technology for EGAT with respect to overall priority of four main criteria. This result was rather insensitive to the changes in the importance of each main criterion.

In the actual situation of EGAT, the management team considered mainly tangible and financial factors including return of investment. They were confident to make decision based on those factors. They simply select the most appropriate alternatives by comparing capital cost and operation cost of each solution. The results of this study also support this judgment. Table 4 shows that *hybrid* IP-PBX receives the highest priority with respect to *low cost* criteria. However, this study considers not only tangible factors but also intangible factors such as intangible benefit, risk, ease of maintenance, ease of use and etc. It uses AHP as a decision tool to combine both tangible and intangible factors. The highest rank of VoIP alternatives was changed from *hybrid* IP-PBX to *pure* IP-PBX.

With VoIP technology selection problem, EGAT has to confront with several alternatives and various decision factors. Without the decision tool, management team can only decide based on tangible factors. This decision may have negative impact to maintenance team and EGAT users. If the selected choice is difficult to maintain and use, the operational cost will unexpectedly increase. Technology acceptance of maintenance team and users were low. This perhaps led to low productivity of EGAT. AHP can help EGAT to select the most appropriate choice. The decision team of EGAT can consider both tangible and intangible factors by merging the result of each pairwise comparison into AHP software. AHP can be used as a decision tool to combine every significant factor. A group of selected experts were then invited to make pairwise comparisons on alternatives with respect to criteria and sub-criteria. AHP software will combine the judgment of each expert automatically and then compute the priority and rank of every alternative. Then, the best alternative with highest priority was selected.

Although AHP methodology is quite complex and requires much effort to create questionnaires, it provides the sensitivity analysis which is very important for practical decision making, sometimes even as important as finding out the best solution. It must be stressed that any decision making technology serves as an enhancement to human judgement

by, among other things, conflicting criteria and the subjectivity of the individual decision makers towards an acceptable consensus decision. Moreover, the functions and features of each VoIP alternative are changing annually. These changes influence decisions of the experts. AHP would be refined with new information, experience, increasing the accuracy of and the time taken to make the most appropriate choice of VoIP technologies. Therefore, it is suggested that an AHP decision making template be developed for the selection of VoIP technologies that would be regularly updated and improved. To implement AHP in EGAT seamlessly, management team should push AHP into policy and encourage decision makers to apply it in a real scenario.

THE TACIT SIGNAL E-HRM METHOD AT ORGANIZATION PERFORMANCE DEVELOPMENT

Marko Kesti and Antti Syväjärvi University of Lapland, Finland
marko.kesti@mcompetence.com, antti.syvajarvi@ulapland.fi

ABSTRACT

Article describes new tacit signal measurement as a function of employee performance and productivity development. Tacit signals are personal, circumstances and item connected guiding beliefs that arise from emotional and tacit knowledge which are usually difficult to express by words. Tacit signal competence measurement gives new information about organization development. Article describes also new mental model of five interrelated competences for understanding organization development pluralistic nature.

By measuring and analyzing tacit signals in real time the optimal improvement actions can be started in short notice. Systematic and effective work practices development increase organization productivity which is showed by large business company case study in three years empirically grounded research. Systematic employee performance development using tacit signal method has shown to be effective in improving organization productivity.

Tacit signals together with systematic development services enable whole organization development. This is important since the majority of the groups need tools and expertise to succeed in their work practices improvement. Weakest performing groups produce the majority and are therefore the most potential in profitability improvement. It seems that with effective e-HRM tools and practical development the organization can successfully implement profitable growth strategy.

Keywords: innovation management, performance management, competence management, organization development, productivity, e-HRM.

INTRODUCTION

The internal and external environment of organizations is changing continuously, which causes challenges for the human competence development and management. Most of the quality costs forms from poor work practices causing lost labor (Andersson et al., 2004). Hence continuous development is crucial for maintaining competitive advantages. However many managers don't understand the nature and potential of work organization development (Alasoini et al., 1997). Improving organization operations is complicated because development should be based on tacit knowledge of humans in social environments. Organizations need conceptual understanding and practical tools to analyse, plan and implement the change process (Alasoini et al., 1997). Hence, an obvious need for developing the organizational information systems (e.g. Beynon-Davies, 2002) exists especially in the area of human resources.

In the case of humans and competitive advantages, the organizations want to improve their human competence recognition and management. Usually, the human competence is found so difficult and complex that the recognition or development cannot be easily done. In addition, the traditional methods are repeatedly too expensive, slow or otherwise complicated for

achieving continuous performance improvement. This article will demonstrate tacit signal method as an effective e-HRM system for utilizing tacit knowledge in organizations. The tacit signals refer to personal beliefs concerning the improvement needs of human competencies (rf. Stone, 2002; Kesti, 2005), but also to a fundamental element of effective leadership.

New tacit signal based e-HRM system is introduced as a human resource information system (HRIS) (Kesti et al., 2008). An information system itself can be seen as physical process that supports organization by providing critical information to achieve goals (Syväjärvi & Stenvall, 2006). The current e-HRM serves as a fluent, accurate and fast responding human resource information system. The current human resource information system is seen as a support for effective leadership and performance management. This allows leaders to accomplish productivity improvement actions across the working community based on the collective tacit knowledge. By tacit signal e-HRM it is possible to relate the human competence success factors with a positive spiral and thus to minimize the risk of low human competence utilization. New tacit signal e-HRM method seems to recognize and develop the intangible assets quite optimally and fast. It seems that measured tacit signal competence correlates with the working society performance and therefore supports organization performance management and productivity improvement.

Jack Welch has divided employees to three categories in terms of performance: top 20 %, middle 70 % and bottom 10 % (Welch & Welch, 2005). Our observation is that that there seems to be two general obstacles preventing organization performance improvement. Normally only 20 % of organization groups succeed in developing their work practices and 80 % are not able to develop by themselves. Furthermore the limited development time is misused so that 80 % of that time is used at not constructive defensive mechanisms and only 20 % to solving problems. When both these rules apply, the organization can not improve productivity. This phenomen is extremely crucial for labour-intensive organizations in private and public sector. Effective development methods with proper e-HRM tools should enable to convert these obstacles to great possibilities to improve organization performance and productivity.

BACKGROUND

In modern society the economical meaning of knowledge base and intangible assets has exceeded the material capital, natural resources and work force (Drucker, 1993). To succeed the organisation should have process where each person and group can reflect knowledge and experiences and so improve the contribution to the organization objectives (Argyris & Schon, 1978). Several research studies show that organisations which are committed to the employees and let the tacit knowledge base increase are the most successful in longer term (Arie de Geus, 1997; Ylöstalo, 2005; Collins & Porras, 1994). Some business areas the intangible assets managing is the most important issue in creating the competitive advantage (Porter, 1985). Therefore the human intangible assets should be one of the most important development items in the organisation. These human success factors or competences are intangible drivers of performance which are the most difficult to identify and develop.

The management has important role in identifying the performance drivers and investing in the development. The most crucial thing is the top management ability to build visionary and

inspiring mission for the organisation, so that everybody are struggling along to the same direction (Collins & Porras, 1994). Top management, leaders and workforce all have crucial elements for the organisation performance and success. As in a car you can't say which part is the most important thing the steering wheel, the tires or the motor.

Human being is naturally social and in the interdependency the learning is the most effective and natural phenomenon (Vygotsky, 1978). In the organisation the knowledge forms from collective learning and sharing of information (Prahalad & Hamel, 1990). Knowledge can be divided to explicit and tacit knowledge. Explicit knowledge is rational and can be described and visualised by documents and pictures (Nonaka & Takeuchi, 1995). Tacit knowledge is experience based knowledge that is difficult or impossible to document or describe by words (Nonaka & Takeuchi, 1995). Tacit knowledge is highly personal emotion and feeling based and therefore difficult to express. Nonaka and Takeuchi (1995) describe the new knowledge creation with interactive social process between explicit and tacit knowledge. Tacit knowledge has to be formulated to words or documents so that it can be further converted to explicit knowledge which creates again new tacit knowledge. Social intercommunication like dialogue, discussion and observation speeds up the knowledge creation process and activates organisation learning.

It has been shown that the best performance or optimal cognitive efficiency is achieved at optimum stress level (Goleman, 2006). Certain creative stress or tension is needed to get things done. When the optimal stress level is exceeded the performance will drop down as the harmful stress level increases (Abercrombie et al., 2003). This tension-performance phenomen is called inverted U-curve and was introduced by Yerkes and Dodson (Yerkes & Dodson, 1908) and is known by Yerkes-Dodson law. Goleman (2006) points out that stressed people become defensive and too high stress hormone levels causes mistakes and disables learning new things. A sense of safety creates good base for learning and some tension is needed to keep on the motivation (Goleman et al., 2002).

It seems that there are certain performance drivers which can be recognised as organization competences. As employees are best experts of their own work and working society, they have tacit knowledge based feelings about the development needs. If these personal feelings could be measured for each crucial competence using inverted U-curve principle, it could be possible to do the right corrective actions to improve the competence. As inverted U-curve correlates with the performance the measurement should have the same feature. Tacit signal method appears to have these qualities.

If organization can keep competences at good condition when facing new challenges, it can also maintain good business performance. This balance between creative tension and competence development is important for organization continuous improvement. Senge (2006) points out that goal setting and balancing feedback must go together in balance to perform goal oriented operation (Senge, 2006). If balancing feedback is blocked it will complicate strategy implementation. Tacit signals e-HRM system support managers and leaders to make right decisions to improve the performance driver back to optimal balance.

THE TACIT SIGNAL PRINCIPLE

Tacit signals are personal beliefs and ideas relating to improvement needs of human competencies. When the organisation is influencing those beliefs the competence factor can be developed more consistent with the goals of the organization. Tacit signals are personal, circumstances and item connected guiding beliefs that arise from emotional and tacit knowledge which are usually difficult to express by words. Measuring and analyzing tacit signals in real time the optimal improvement actions can be started proactively.

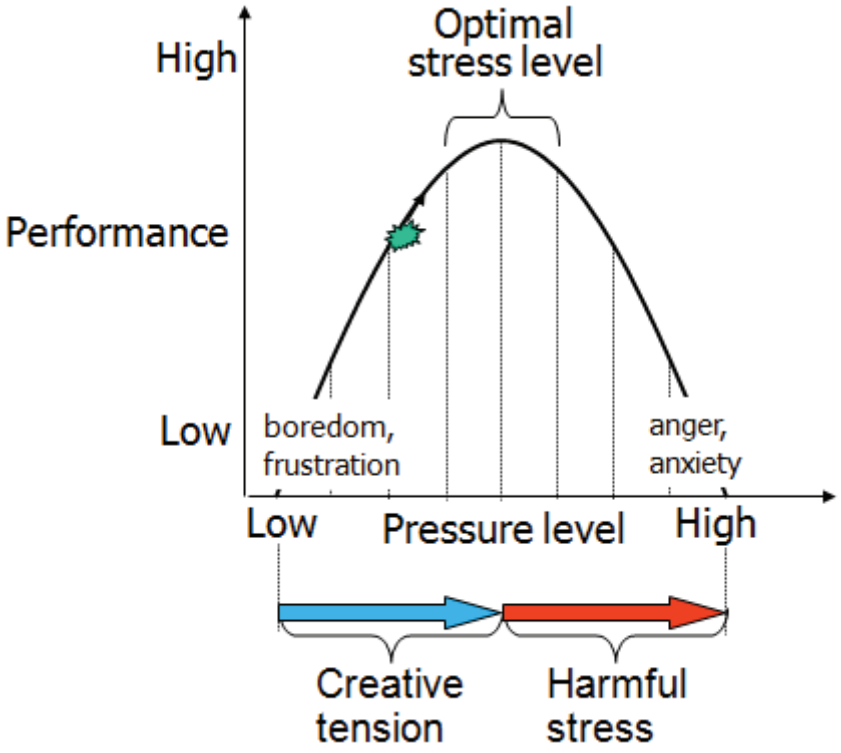

Figure 1. Tacit signal principle in performance stress curve (inverted U-curve).

Tacit signal method fits well to the phenomen of inverted U-curve. Figure 1 shows the principle of how tacit signal shows if there is balance or unbalance at the chosen performance driver or competence. Measured competence can be linked to the scorecards like internal and external quality costs, work absence, disembarkation rate and profitability. Therefore measuring tacit signals fits well for the Balanced Scorecard measures for the learning and growth perspective (Kaplan & Norton, 1996).
The main idea in measuring the tacit signals is to increase the innovativeness and profitability through better management and the development of the whole organization. It improves the organization's ability to prioritize the development actions of competencies and do improvements effectively.

TACIT SIGNAL MEASUREMENT

The principle of interrelated and opposing factors affecting at organization is raised in the Nonaka and Takeuchi book The Knowledge Creating Company. They have observed that there are multitude dichotomies – such as tacit vs. explicit, mind vs. body (or matter), self vs.

others – are affecting on organization knowledge creation. These dichotomies are not different coins but rather the opposite sides of the coin being mutually complementary (Nonaka & Takeuchi, 1995). At our research from several organizations we have noticed that optimal condition for organization development exists when two affecting complementary sides are in harmony. Furthermore the development need is determined based on the side the unbalance occurs. This approach of two opposing interrelated forces guiding to correct the organism back to harmony is also visible at oriental philosophy of yin and yang (Xinnong, 1999). Same phenomen is visible at the Yerkes-Dodson law of tension-performance relation, which is important basis of human performance and emotional intelligence development (inverted U-curve) (Yerkes & Dodson, 1908).
Kaplan and Norton has pointed out that the balanced scorecard has been lacking good company specific measures for the learning and growth perspective. They note that absence of specific measures indicates that the company is not linking its strategic objectives to activities for re-skilling employees, supplying information, and aligning individuals, teams and organizational units to the company's strategy and objectives (Kaplan & Norton, 1996). Tacit Signals e-HRM system makes possible to measure and analyze tacit signals in real time. Measuring is based on a dichotomy scale self-assessment and the analyzing is done using competence potential vectors.

Specified Tacit signals measuring tool consist of following measuring principles:
The specified human competence measurement has several competence attributes which are evaluated by dichotomy scale of guiding forces to help improvement decision making. Tacit signals are inquired systematically for specified human driver of performance (competence). Tacit signal opinion includes the guiding factor and possible informal comments for each question. Employee individual answers are under the influence of their personal tacit knowledge which are highly respected by privacy in Tacit signals e-HRM-system. The guiding forces are to be chosen so that it meets the dichotomy principle of two interrelated and opposite forces like rational vs. emotional or quantitative vs. qualitative. One force is guiding to more straightforward actions and the other is more related to emotions needing usually a dialog between the parties and individuals to be improved. Dichotomy improvement semicircle (see figure) adapts to the size of the group so that every individual tacit signal vector can be summed, showing the collective development need and competence (Kesti, Stenvall & Syväjärvi, 2008).

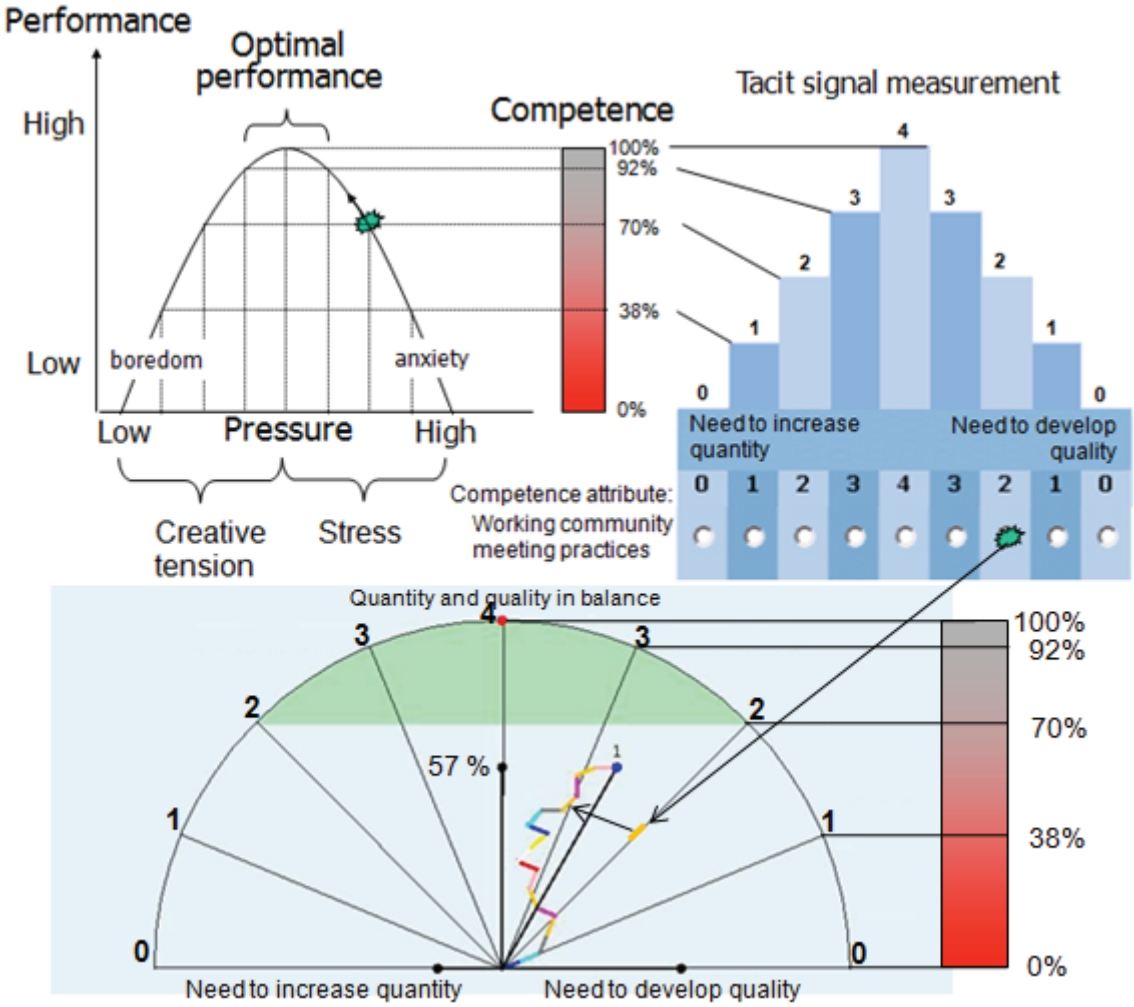

Figure 2. Tacit signal dichotomy scale relation to the inverted U-curve.

Tacit signal measures the development need with the direction to improve the competence. The development is needed if the two interrelated guiding forces are not in balance. The measured improvement focus is on the side where the unbalance is. In the figure 2 the group's (17 persons) collective competence is 57 % against the measured competence attribute: working community meeting practices and the development need is on quality side.

TACIT SIGNAL CONNECTION TO ORGANIZATION COMPETENCES

Nokaka and Takeuchi (1995) points out that each employee is knowledge worker having important tacit knowledge about the organization operations and own work. Individual has skills, knowledge and energy that we try benefit in achieving our aims. Human drivers of performance are the known competence factors contributing the organization to improve productivity and achieving the target.

Each human driver of performance is build from participating individual competence potential. Competence potential has a direction which shows how much of the competence potential is utilized. In this specification the potential can be shown as a vector where the part leading towards the target is the competence (see figure 3).

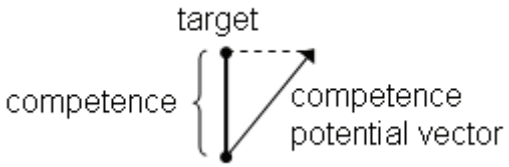

Figure 3. Competence vector principle.

Organization is complex human intelligence system where different competences are interrelated to each other. We have studied organization system intelligence by using the ancient mental model of interrelated five elements. In system intelligence model the five elements are the main competences which seem to be the most important intangible drivers of performance.

One general management definition by Henry Fayol specifies five management areas which are planning, organizing, directing, coordinating and controlling (Fayol, 1949). Drucker (1977) points out successful management areas so that among target setting management requires organizing, motivating, communication, measuring and employee development (Drucker, 1977). Bartlett and Ghoshal (1995) point out that top management first activity is to create attractive meaning for the organization. Mission clarifies the organization direction for development and so it makes easier for the middle managers or leaders to agree and execute the concrete operative actions.

Schein (1985) says that one of the management most important tasks is to strengthen the organization culture. Manager must ensure that the work community can develop and positively adapt to the continuous change of business circumstances. Good manager and leader observe the weak signals and when needed starts collective discussion and co-operation to develop the organization knowledge base, products, processes and tools. The strategically relevant competence is never certain, but rather exists in the form of beliefs which are inconsistent or even contradictory (Sanches & Heene, 1997).

Competences are situation sensitive and therefore constantly changing as organization internal and outside environment changes. Study has shown that for example high employee turnover rate decrease the collective competences (leadership and group culture). This is logical as the competence needs to be updated to meet the new challenges. Therefore competence development is needed to stabilize organization performance to new level. This is referring to the balancing feedback (Senge, 2006) that is needed for organization development. However the organization development is not so straight forward since competences seems to affect each other. For example individual skills are important but do not guarantee organizational learning (Senge, 20006). Group culture affects to the motivation in sharing and adapting information. To make organization learning possible the competences relation to each other must be recognized.

Organization system intelligence model can be built from five important competences: management, leadership, group culture, personal skills and processes (Kesti, 2007). Each competence has several attributes that illustrates the human success factors which should be in good condition for optimal organization development which forms positive spiral (see figure 4). Leadership and culture are collective competences that consists similar competence attributes for each working society. It seems possible to measure these attributes by tacit signal method.

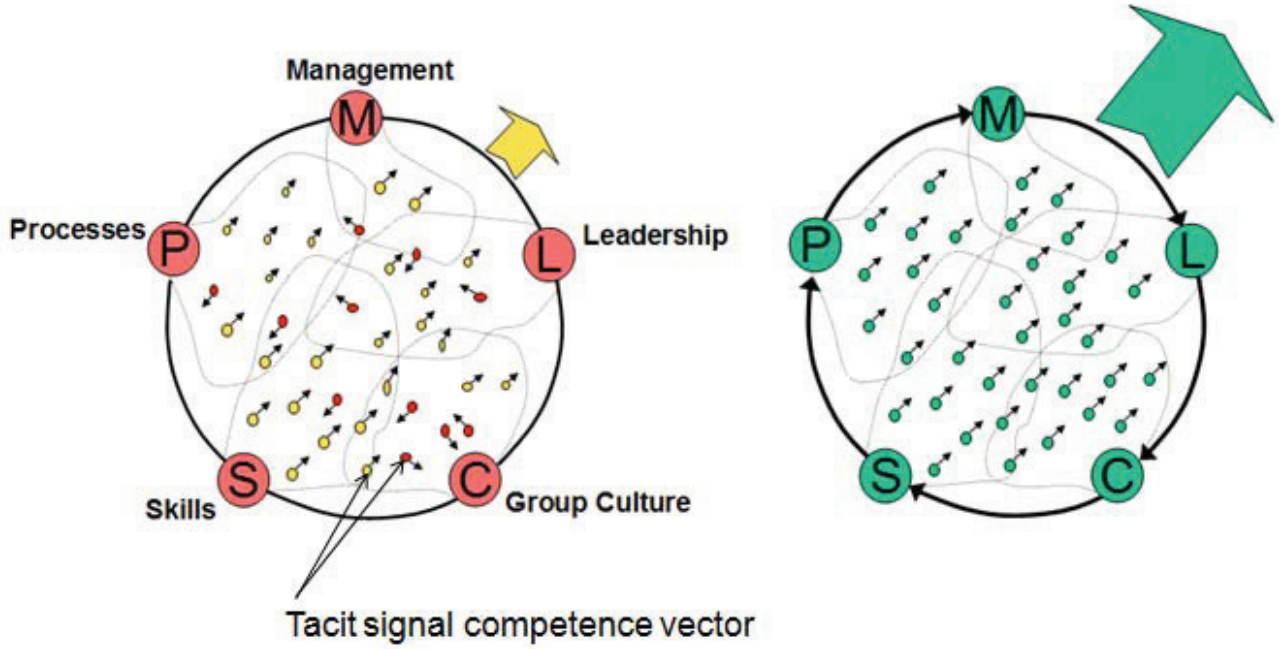

Figure 4. Organization system intelligence consisting five competence areas affecting to each other. (Kesti, 2007)

Tacit signal balance shows if the attribute needs reinforcement or development. Unbalance in reinforcement side means that the attribute is not strong enough to form a positive spiral and therefore needs more activating. Unbalance at quality development side means that the attribute affects negatively to the system. This needs changing the harmful habits and therefore quality side development is more difficult and critical for the organization future. For the organization development as a system it is important to solve the problems but also to strengthen the competence attributes that has positive influence and so contributes the positive spiral. Seeing and analyzing the organization as a system with interrelated competences the organization can be developed optimally and with increased profit earning capacity.

The specified tacit signals e-HRM system consists of following measuring principles:

1. The specified human competence measurement has several competence attributes which are evaluated by dichotomy scale of guiding forces to help competence improvement decision making.
2. Tacit signals are inquired systematically from each working community for specified competences (performance drivers, intangible assets). Opinion includes the guiding factor and possible informal comments for each competence attribute.

The guiding forces are to be chosen so that it meets the dichotomy principle of two interrelated and opposite forces like increase quantity vs. develop quality. One force is guiding to more straightforward actions and the other is more related to emotions needing usually a dialog between the parties and individuals to be improved and understood.

Managers and leaders participation to the development process planning is essential prior to the tacit signal method implementation. Knowledge creation process includes always that the results are gone through at each group after the management review. At the management

review the whole organization is analyzed at strategic point of view by using the system intelligence model. After that each working community goes through their own results with discussions and prioritizing the corrective actions.
Our empirically grounded research has shown the effectiveness of tacit signal method in organization knowledge creation process. The group is able to share the knowledge and agree optimal improvement actions within couple of weeks. In this development process each employee spends about half an hour answering to tacit signal query and 2 to 3 hours at the group meeting. It seems that the tacit signal e-HRM system speeds up the knowledge creation process significantly. The group can agree the corrective and optimal actions with the leader in productive way.

It seems that tacit signal query activates to give written comments and those comments are usually constructive. Our empirically grounded research shows that group is committed to the actions when they are participating to the action idea generation group meeting. Meeting is highly effective because measurement results leads to constructive discussion and concrete development. This beneficial brainstorming increases the group collaboration and self-esteem. Group can innovate corrective actions and prioritize the most important. Agreed actions are followed by electronic group diary and supported by group meetings later on.

RESULTS IN ORGANIZATION PRODUCTIVITY IMPROVEMENT

Case results are based on empirically grounded research at large company (1000 employees) for three years period. Leadership and group culture competences were measured once a year at each 20 business units. Competence development process was done systematically at every unit. As a result of this development the work practices were improved by practical innovations based on group's tacit knowledge (e.g. meeting practices). Business unit's employee productivity was calculated by summing up the HCROI and personnel increase percentages.

Our studies in this large company indicate that in three years period the tacit signal development process has improved company productivity significantly. Measured leadership and culture competences correlation with organization employee productivity was slightly over 25 % (see figure 5). This is understandable since there are also plenty of other important factors like strategy and market situation which are affecting to organization business performance. HCROI (Human Capital Return On Investment) is index that comes from sales margin divided by staff costs (Fitz-enz, 2000). Employing new staff is investment that at least in short term reduces profitability and therefore profitable growth factor is calculated from HCROI and personnel increase percentage.

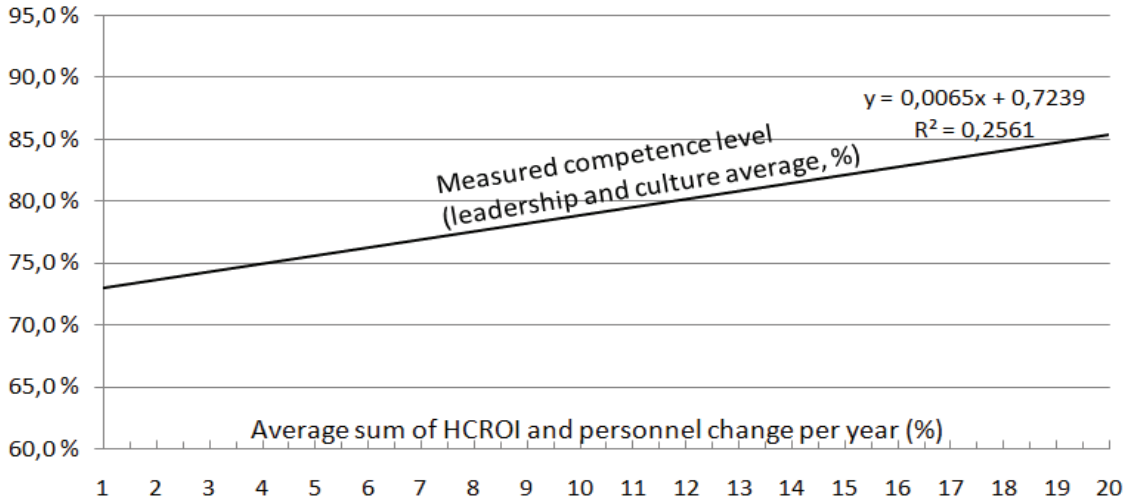

Figure 5. Trend line from competences (leadership and group culture) correlation to employee productivity (average of HCROI increase percentage and personnel increase percentage). Trend line correlation factor is 0,256.

It seems that average competence improvement is not only aim, but also increasing the weakest performing group's performances. These weakest performing groups are the majority and therefore producing the most value in organization productivity. This phenomen that was found at the case study is important to understand. For example the climate survey results are usually compared to average business branch values, which in respect of this new information is not enough. The competence variation seems to be as important, giving essential information about organization business performance. In this case study the average competence remained in good level but the variation was reduced significantly (see figure 6). At 2005 there were 20 % of units below 70 % competence and three years later every unit was over 70 % in measured competences (leadership and group culture). In this study the units are arranged in order of competences magnitude.

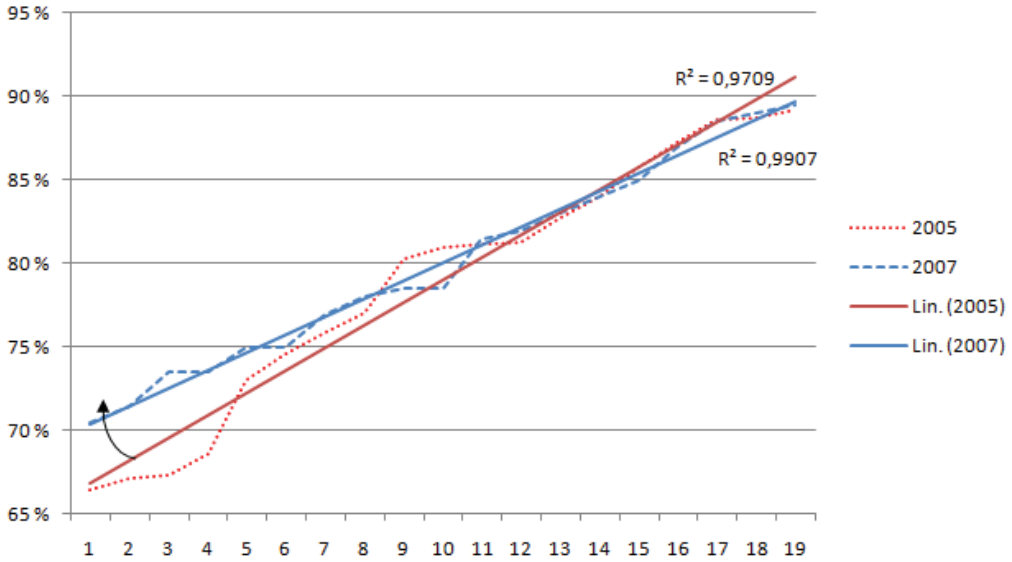

Figure 6. Figure shows the competence distribution in the beginning and after the organization change.

Same phenomen is visible at one year development where each unit is measured and arranged based on extent of unit's employee productivity (see figure 7). It seems that employee productivity goes together with competences. Also weakest performing unit's competences are improved most. Competence trend line break even in development is little over 80 %. It may so be that when groups self esteem gets better the group is motivated to take new challenges which stabilizes the competence and may even decrease it. Correlation to trend line is visible at figure 7 but not very strong indicating that there are lots of things affecting to each units competences.

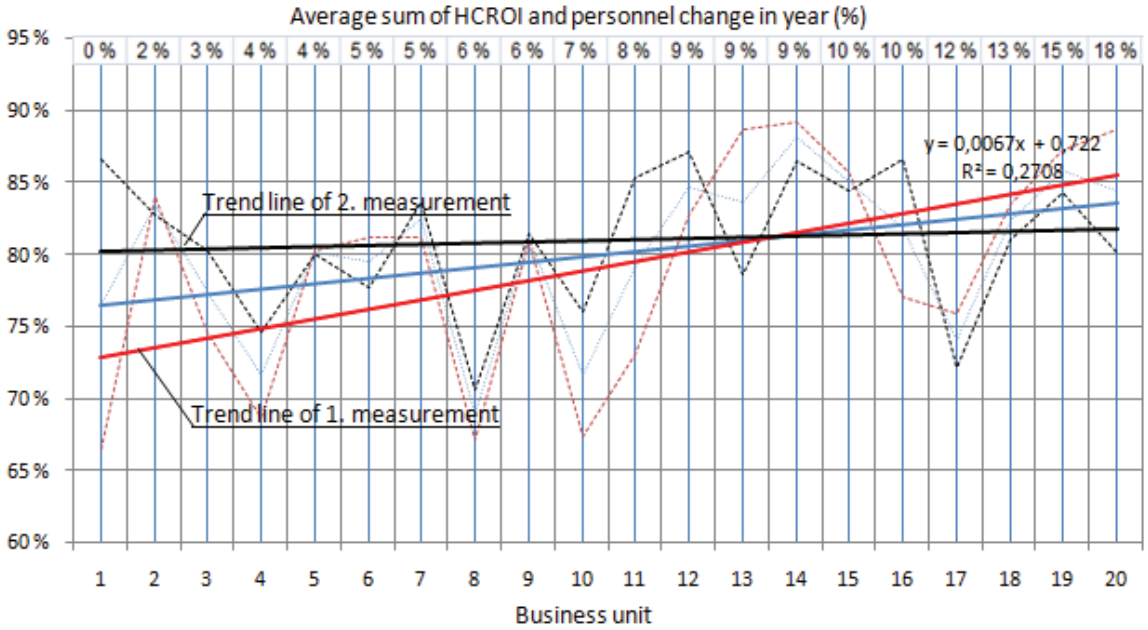

Figure 7. Business unit's competence development related to employee performance.

In this practical case the competences were developed systematically. However company average competence did not improve much but stayed at good level. We noticed that when the staff remained the same the competence improvement was more than in case where growth, transfer or reorganization changed the group arrangement. Figure 8 illustrates that groups are not improving competences so easily if group staff change is more than 15 % in year. The correlation in this phenomen was little over 20 %.

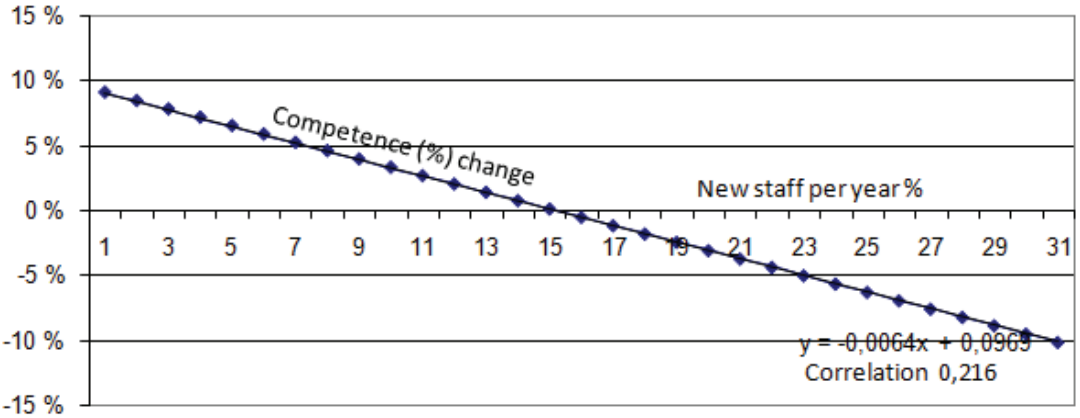

Figure 8. Measured competence change in correlation with new staff per year. Correlation factor is 0,216.

Systematic employee performance development using tacit signal method has shown to be effective in improving organization productivity. Following figure 9 shows that systematic whole organization development has improved the business performance significantly compared to average business branch. Productivity growth is a factor that comes from revenue multiplied with HCROI.

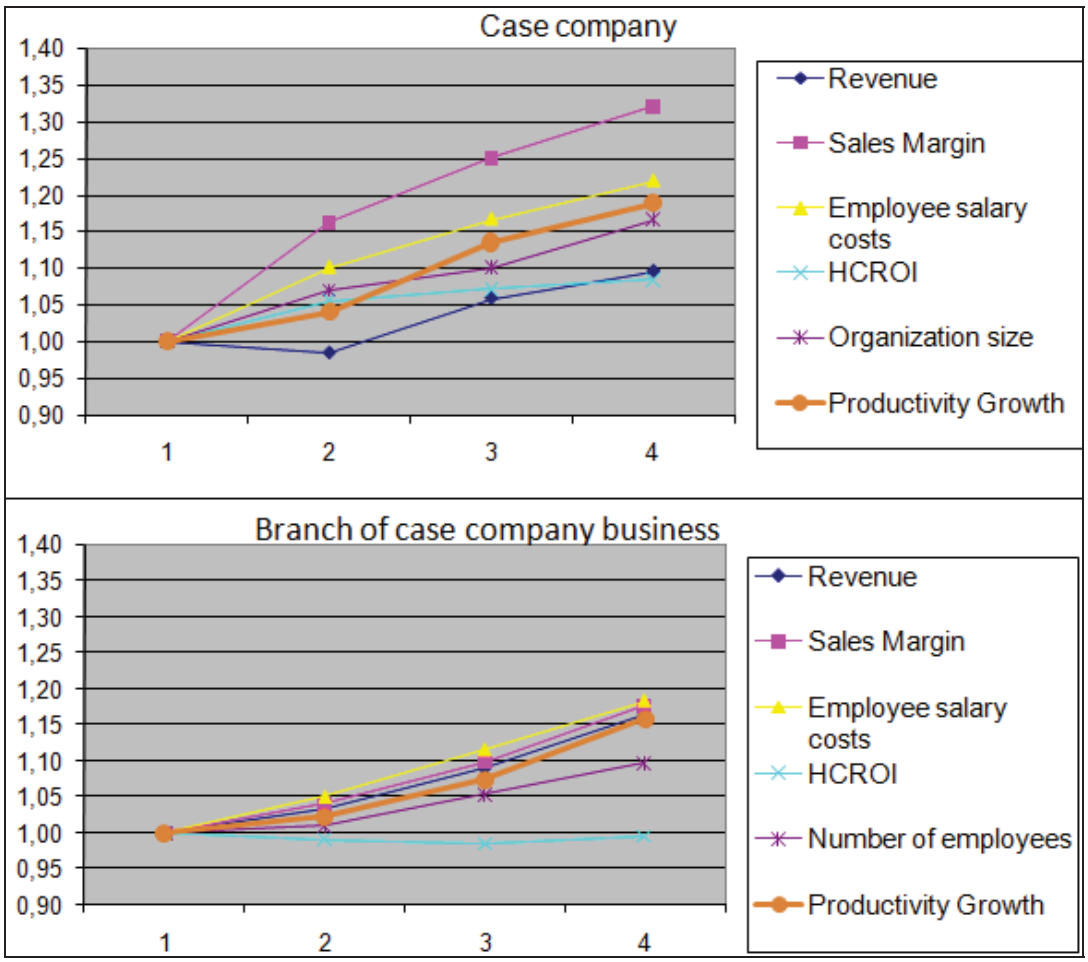

Figure 9. Case organization business scorecards compared to business branch at three years development period.

FUTURE TRENDS

Our investigation from several business and municipal companies in Finland indicates that when the organization size is more than 50 employees the main intangible drivers of performance are close to the same for all organization types. Syväjärvi (2005) has made the same observation in his academic dissertation. Empirically grounded approach to the organization development can be crystallized to the general system-theoretical approach to the organization development. We have noticed that competence levels are not stable but constantly changing. Organization structural changes, laying-offs and substantial growth decrease measured competences. Most probable there are several other reasons which cause decline in the competences. In constantly changing word it is the most advantageous competitive advantage if organization can improve weakest performing group's competences and so maintain constantly good level in business performance. We strongly believe that high

competence levels indicate also high innovativeness which helps organization to benefit business possibilities.

We believe that in the future the eHRM systems include intelligence in directing the organization to operate proactive and effectively in utilizing the human drivers of performance. Organization as a system is so complicated that managers and leaders are not able to do optimal decisions without the help of intelligent eHRM system. Our further study will connect the tacit signal eHRM measurement tool to our latest research of organizations performance as a system so that the managers can use the tool in fast decision making in managing and optimizing organization performance in long term.

CONCLUSION

Tacit signal method seems to get reliable information for effective organization development. Organization change and management needs understanding of humans in social relationship. Mental models describing this complexity can be useful when analyzing the situation and possible defects which disable competence development. Proper e-HRM systems should allow the organizational leaders to be more aware about human organizational behavior (e.g. Gibson et al., 2003). In improving organization productivity it seems that collective tacit knowledge is reliable in effective work practice development. Tacit signals together with systematic development services enable whole organization development. This is important since the majority of the groups need tools and expertise to succeed in their work practices improvement. Weakest performing groups produce the majority and are therefore the most potential in profitability improvement.
Agreed competences measurement and development are effective way to implement profitable growth strategy. By benefiting better the unidentified human assets, the public and private organizations can become aware how the human factors can create positive impact. When tacit signals are measured in real time and analyzing is guiding to the improvements, it is possible to start optimal development steps immediately. This has a motivation effect to all participants. It seems that tacit signals visualize collective competence in compliance with Yerkes-Dodson law (inverted U-curve).

The knowledge creation process requires that the measurement results are gone through with each working society. It is also recommendable that the management review is held before group development meetings. In this review the organization competence system model can be used. This guarantees that the complexity is understood and possible development obstacles are detected. After management review each group goes through their own results by constructive discussions. Groups also recognize the corrective actions and determine the most important. This group innovation forms effective foundation for knowledge creation corresponding the Nonaka and Nobory (1998) theory of ‘Ba’.

Our findings supports Argyris and Schon (1978) research, that to succeed the organization should have process where each person and group can reflect knowledge and experiences and so improve the contribution to the organization objectives. The tacit signal e-HRM tool produces valid data for decision making, strategic planning and more flexible working practices. These improvements can be linked to organization knowledge sharing, human wellbeing and productivity and thus supporting the organization performance management.

By measured tacit signals the group can improve the human competences which are linked to the business targets. For example leadership and proactive working culture are very important competences for collective efficiency. Proper HRIS is thus an extra way to develop effective leadership (e.g. Kets de Vries, 2006). We have experienced in many cases that in steady growing business environment the competences can be improved several percentages in one year. Our experience also indicates that the competence development relates with the improvement of human productivity measured by the metrics like HCROI (Human Capital Return on Investment). On the basis of several example cases, the current tacit signal e-HRM system is found to be useful for development purposes in public and private organizations.

TERMS AND DEFINITIONS

Tacit signals: Human opinions and feelings that are guiding to the improvement of known human competence. Competences can be measured by tacit signals.

Competence attribute: A human property or characteristic in organizational environment that has value. It is one kind of data about the nature of the human-organization environment.

HCROI: Human Capital Return of Investment calculated from revenue less operating expenses (excluding personal costs) divided by the personal costs.
Employee productivity: Average of HCROI increase percentage and personnel increase percentage

Productivity growth: Factor that comes from revenue multiplied with HCROI.
Human competence: A human property or characteristic according to which one has knowledge, capability and skills in certain task to perform or behave. It is the organization's capability to benefit the known intangible drivers of performance for reaching its goals.

HRIS: Use of information technology to systemically generate relevant and timely information for the making of human resource management decisions. (rf. Stone, 2002)

Information system: An information system is a system of communication between people and it involves the gathering, processing and use of information.

Intangible assets: Human capital, database or information system, responsive process, customer relationship, innovation capability and culture of an organization that all are needed for distinctive and sustainable value.

ABSTRACT

To reduce the dependency on foreign crude oil, many countries are promoting and regulating the use of alternative energy such as biofuels, hydrogen, solar energy and nuclear energy. Many researchers have studied alternative energy issues from a policy or industry viewpoint, but few have explored the consumer's beliefs and opinions. Since most applications of alternative energy are being developed for the consumer market, the consumer's acceptance and adoption of these new fuels and alternative energy vehicles are key factors to consider. This research studies the consumer's attitude toward vehicles using biofuel or hydrogen and evaluates the factors which influence the consumer's purchase decisions these cars.

Rogers' (1995) diffusion of innovation (DOI) and Bauer's (1960) perceived risk theory are used to design a national U.S. telephone survey (554 responses for the biofuels dataset and 443 responses for the hydrogen dataset). Ordinal logistic regression is used to analyze the factors which influence consumer's adoption of alternative energy vehicles. The results show that higher relative advantage, compatibility, observability and trialability leads to a higher probability of adopting a biofuel car. However, complexity is negatively related to the adoption of biofuel cars. While relative advantage, observability and trialability have a significantly positive relationships with the consumer's willingness to buy a hydrogen powered car, perceived risk significantly reduces the consumer's buying intention. Since these factors affect the consumer's purchase decisions, the results serve as a reference for marketers developing sales strategies for alternative energy cars.

Keyword: Adoption of innovation, Alternative energy, Biofuels, Hydrogen, Consumer behavior.

INTRODUCTION

The decision for consumers to adopt new forms of energy is an important issue for the global energy industry. New forms of energy for the marketplace, such as biofuels or hydrogen, require further research and development to match consumer lifestyles, channels of distribution, and product applications. Drastic oil price fluctuations during the year 2008 led the consumer

to new levels of energy awareness and searches for alternatives. For example, most consumers (European Commission, 2007) acknowledge that automobiles powered by gasoline emit CO_2 which in turn causes global warming. Since the US consumes up to 840 million gallons of petroleum per day and over 390 million gallons of gasoline were used for driving vehicles in 2008 (EIA, 2008), the US's transportation system is heavily reliant on oil. About 60 percent of the oil is imported into the United States (EIA 2008) which increases dependence on foreign sources of energy, a fact that is causing policy reviews and legislative debates at the highest levels of government. With a renewed focus on fuel conservation, the US is developing alternative fuels and encouraging drivers to consume non-gasoline fuels. The US government enacted the Energy Policy Act of 2005 to permit the partial tax reduction for the automobiles with alternative fuels and hopes to reduce gasoline consumption by 20% by the year 2017 (White House, 2007).

Other countries are also promoting and regulating the use of alternative fuels to resolve the crisis of global warming. In United Kingdom, greenhouse gas from transportation vehicles contributes to over a quarter of the total emissions. In order to reduce greenhouse gas emissions, the UK government stipulates that gasoline and diesel sold in retail stations should contain 2.5% biofuels and this ratio should increase to 5% by 2010 and 10% by 2015 (Perry and Rosillo-Calle, 2008). Brazil, as an alternative fuel leader, has endeavored to develop biofuels for 30 years (Pousa, Santos and Suarez, 2007). Mexico and Brazil promote ethanol fuels made from sugar cane and other countries, such as Germany, Hungary, Canada and Taiwan are promoting the increased use of biofuels and hold many related patents (Pintoa et al., 2005).

Many environmental experts believe that biofuels can reduce greenhouse gas and are a key solution to global warming (Fargione, Hill, Tilman, Polasky, and Hawthorne, 2008). However, other environmental groups warn that since biofuels are derived from corn, palm oil, soybean, and other agriculture products, their increased use for fuels may drive up prices and create a food crisis (Brown, 2006; Mitchell, 2008; Tenenbaum, 2008). The U.N. Food and Agriculture Organization's global food price index rose 40 percent in 2007 (von Braun, 2008) and biofuels have forced global food prices up by 75% (Chakrabortty, 2008). The countries cultivating products for alternative fuels are replacing the production of food for people; therefore, people in developing countries are facing greater food shortages. However, the creation of alternative energies is also necessary for developing and developed economics (Popp, 2001). This research study explores the consumer's attitude toward vehicles driven by new forms of energy, such as biofuels or hydrogen, and evaluates the factors which influence the consumer's purchasing decisions for alternative fuel cars.

There is the wide variety of alternative energy such as biofuels, hydrogen, solar energy and nuclear energy. This research focuses on biofuels and hydrogen. Biofuels are an important potential energy source for the United States because bioenergy crops used to produce energy can be cultivated on dormant farmland. Using biomass for energy production helps the US decrease the reliance on foreign energy and reduce emissions (Greene et al., 2004). Hydrogen

is a clean energy source with no CO_2 emissions and no air pollutants. The emission-free character of hydrogen has brought this alternative to the forefront policy initiatives (Ball and Wietschel, 2008). However, the public has limited knowledge about hydrogen fuel technology and are frequently concerned about the safety issues after remembering the Hindenberg of rigid airships disaster of 1937. However, as the technology has developed, the safety of hydrogen as an alternative fuel has greatly improved. Hydrogen is a reliable energy source but a new delivery infrastructure is needed before the fuel can be safely transferred into vehicles. Consumer's attitudes toward hydrogen likely influence their adoption of the technology of hydrogen-related product. Thus, before investing in an expensive hydrogen delivery infrastructure, more knowledge concerning the consumer's perceptions of the safety and utility of hydrogen is needed.

The research framework for this study is based on the Rogers' (1995) diffusion of innovation (DOI) and Bauer's (1960) perceived risk theory. There are five innovation characteristics of the DOI and these characteristics include relative advantage, compatibility, complexity, trialability, and observability. Roger's factors influence people's adoption process for an innovation technology or a new concept. The study also applies the concept of perceived risk proposed by Bauer (1960) to discuss consumers' adoption process for alternative energy automobiles. In order to understand the characteristics of potential buyers, several socio-demographic variables are also included in the research framework.

Section 1 of this paper provides an introduction and Section 2 discusses the Rogers' (1995) diffusion of innovation (DOI) and Bauer's (1960) perceived risk theory. Following the proposed hypotheses of this study, Section 3 describes the methodology and Section 4 presents the data analysis and analytical results. The last section provides a summary and conclusion as well as the discussion of the study.

LITERATURE AND RESEARCH HYPOTHESES

Alternative energy cars can be views as an innovation. Therefore, Rogers' diffusion of innovation is applied to explore the consumer's attitude and purchasing decision for an alternative energy car. Besides, Bauer's perceive risk is included in this study to compare and contrast the fuel alternatives. This section introduces the diffusion of innovations and perceived risk and proposes the hypotheses based on these theories.

Diffusion of innovations

Diffusion of innovation theory (DOI) was proposed in 1962 by Rogers who defined the word "innovation" as an idea, habit, or object perceived to be new by people or adopters. Thus, if an idea is a new concept to a person, then the concept is an innovation. Rogers defines diffusion as "the process by which an innovation is communicated through certain channels over time among the members of a social society." There are three characteristics of diffusion. Diffusion happens overtime and as people wait to adopt an innovation they undergo the stages of the adoption process. The attributes of innovation, the organizations, and the people involved also

influence the rate of adoption. Therefore, DOI illustrates who adopts what products, what technologies, what methods, and what ideas, and when, where, how, and why the adoption occurs (Rogers, 1983, 1995).

Rogers proposed a revised model for the consumers' adoption process called the "Innovation Decision Process." Consumers form attitudes toward an innovation after perceiving the innovation and then they decide whether to adopt the innovation or not. Once they adopt, they execute the decision and then reevaluate the decision. There are five stages underlying the process. The first stage is the knowledge stage where consumers learn of an innovation. The second stage is called the persuasion stage and consumers express their attitudes (likes or dislikes) toward the innovation and pursue the information related to the innovation. In the third stage, the decision stage, consumers either decide to adopt or refuse the innovation. In the fourth stage, implementation, consumers face a choice whether they should use the innovation or not. Note that consciously adopting the innovation is different from the practical implementation the innovation. During the confirmation stage, consumers may change their decision after gathering conflicting information.

Rogers outlines five attributes of innovation from the literature. These attributes affect the consumers' adoption of innovation (AOI) and include relative advantage, compatibility, complexity, trialability, and observability. Relative advantage means that the new innovation is considered better than the consumers' current product. Economic benefit, social status, convenience, or satisfaction can be used to determine whether the innovation has a relative advantage or not. The relative advantage is positively related to the AOI, so if the consumers perceive advantage is high, then they will likely adopt the innovation. Alternative energy vehicles with environmentally friendly features such as reduced or less toxic exhaust emissions make these vehicles more attractive to environmental conscious consumers and are increasingly providing economic advantage over conventional automobiles. Thus, it is expected that consumers who perceive alternative energy vehicles as advantageous will be more likely to adopt the innovation. Compatibility describes the degree to which an innovation is compatible with current values, former experiences, and needs. Higher compatibility determines higher probability of innovation acceptance. Researchers found that an innovation is more likely to be adopted when it is compatible with the consumers' value. Therefore, it is expected that consumers will be more likely to adopt alternative energy vehicles when they perceive the vehicle as compatible with their lifestyles. Complexity describes the degree to which an innovation is difficult to understand or use and is negatively related to the AOI. As the model of alternative energy car is different from traditional gasoline car, it is likely that potential customers may feel that alternative energy car are complex to use, and hence would be not likely to use these types of cars. Trialability measures the degree that an innovation can be tried or experienced and is positively related to the AOI. If consumers can try an innovation they are more likely to adopt. Thus, if consumers express more willingness to try an alternative energy car, they are more likely to adopt. Finally, observability measures the visibility of the innovation to others and is positively related to the AOI. The more consumers observe the

usage and function of the technology, the more likely they will adopt. So, if consumers observe the function of an alternative energy car, they are more likely to adopt.

Taylor and Todd (1995a) studied how consumers are affected by the attributes of innovation when they adopt a new product. The results showed that greater the relative advantage of the product relative to what was used before, the higher possibility of adopting the innovation. An important contribution of the study shows that consumers are willing to adopt an innovation when it is not complicated. Taylor and Todd (1995b) used the attributes of innovation to analyze the behavior of students in an information center. The results showed that students that acknowledged the relative advantage of the center hold a more positive attitude toward the center. Many researches have applied the AOI attributes to measure the adoption of new products or technologies and have found a significant relationship between the attributes and the adoption behavior (Al-Gahtani, 2003; Gatignon and Robertson, 1985; LaBay and Kinnear, 1981; Moore and Benbasat, 1991; Tan and Teo, 2000). Therefore, the attributes of innovation are useful measures for the adoption of an innovation and serve as a reliable means to forecast public acceptance. Based on the literature above mentioned, five hypotheses are proposed in the study:

H1: The greater the perceived relative advantage of using an alternative energy vehicle, the more likely that alternative energy vehicle will be adopted.

H2: The greater the perceived compatibility of an alternative energy vehicle with one's values, the more likely that alternative energy vehicle will be adopted.

H3: The lower the perceived complexity of using an alternative energy vehicle, the more likely that alternative energy vehicle will be adopted.

H4: The greater the trialability of an alternative energy vehicle, the more likely that alternative energy vehicle will be adopted.

H5: The greater the observability of an alternative energy vehicle, the more likely that alternative energy vehicle will be adopted.

Perceived Risk

Perceived risk was defined by Bauer in 1960. The basic concept of perceived risk is that if consumers are aware of the risks of their behavior, then they will try to reduce these risks. Bauer (1960) states that if consumers cannot determine the benefits prior to purchasing a product, then they are engaging in risk taking behavior. Perceived risk is determined by the expected results of the purchasing decision and the degree of the uncertainty. If the expected result is more important or the uncertainty is higher, then perceived risk to the consumer is higher.

Cox (1967) notes that if consumers are goal orientated, then they set a target for their purchasing action. If consumers cannot decide which purchasing decision can fit their target or if the decision cannot meet their expectations, consumers may feel they have made a wrong decision. Therefore, if consumers assume this regret will occur, then they will experience

perceived risk. Dowling and Staelin (1994) define perceived risk as the disadvantage or uncertainty that occurs when purchasing.

Researchers agree that there are many dimensions of perceived risk. Jacoby and Kaplan (1972) outline five dimensions for perceived risk: financial risk, performance risk, physical risk, social risk, and psychological risk. Financial risk describes that consumers may experience financial loss when the products or services fail to represent their value or display their expected function. Performance risk means consumers need to spend time to repair or adjust the products or services when they malfunction and do not operate normally. Physical risk implies that the products or services may harm consumers' health. Social risk indicates that the consumer may be assessed negatively by others after using the products or services. Psychological risk means consumers may feel guilty or regret after purchasing the products or services that do not satisfy consumers' expectations. Roselius (1971) lists four losses consumers may experience when purchasing. Time loss refers to the losses that occur when a product cannot function normally and consumers need to spend time repairing, adjusting, or exchanging the product. Hazard loss implies a product may endanger a consumers' health or security. Ego loss describes that consumers may lose their self confidence since they bought a defective product and other people treat the purchase as a foolish decision. Monetary loss means the expenditure comes from repairing or exchanging a defective product. Therefore, if consumers experience perceived risk toward a product or service, they may not make a purchase. Similarly, if an innovation is considered risky, then there is less chance that it will be adopted.

Ostlund (1974) used perceived risk as an additional variable to measure adoption of innovation (AOI). It is expected that only consumers who perceive using alternative energy car as a low risk behavior will likely adopt it. This leads to the hypothesis:

H6: The lower the perceived risk of using an alternative energy vehicle, the more likely that alternative energy vehicle will be adopted.

Social demographic characteristics

Social demographic characteristics, such as gender, education, age and income are also included in the research. The literature shows that the demographic variables may or may not influence consumer's adoption of innovation. However, some research indicates that demographic variable significantly affected the adoption of an innovation, and Gatingnon and Robertson (1985) concluded that higher income, better educated, and younger consumers are more likely to accept an innovation. Foxell (1995) found that demographic variables are positively related to new innovation adoption of computer software but not in the adoption of food innovations. Kolodinsky, Hogarth, and Hilgert (2004) concluded that some demographic variables, such as income and age are significantly related to the adoption of E-banking, while gender, marital status, race, and region are not. Taylor and Todd (1995b) could not establish a relationship between demographic variables and student's adoption of an information center. The study of Ostlund (1974) shows that the effect of demographic variables on AOI is weak.

Since there are no empirical results about the effect of demographic variables on the adoption of alternative energy cars, these variables are included in the research framework. Furthermore, the demographic variables are also used to analyze the potential consumers of alternative energy vehicles.

METHODOLOGY

This study assumes that if consumers wish to buy alternative energy powered vehicles then they are adopting an innovation. Rogers's five attributes of adopting an innovation (AOI), relative advantage, compatibility, complexity, trialability, and observability, affect consumer's decision of adopting the innovation. Perceived risk is often introduced in experiments by researchers studying the adoption of an innovation (Bauer, 1960; Ostlund, 1974). Thus, this study assumes that there are six variables that influence consumer's adoption of alternative energy vehicles. Since biofuels and hydrogen can reduce emissions and are clean energy, many countries promote these two energy as substantial energy resources. Therefore, this study emphasizes on the use of biofuels and hydrogen and discusses the factors that influence consumer's purchasing decision towards biofuels and hydrogen powered cars.

A questionnaire is designed to evaluate consumer's perception toward biofuels or hydrogen powered cars. The corresponding questions for biofuels are listed in Table 1 and similar questions are asked for hydrogen (Appendix 1). Answers ranged from 1 (very low degree on the AOI attributes) to 5 (very high degree on the attributes), and -8 (respondents don't know the topic) and -9 (respondents refuse to answer the question). Demographic variables are included in the questionnaire to analyze respondents' characteristics.

Table 1. Description of questions about biofuels and the corresponding dimensions

	Questions in the survey	Corresponding dimensions
1	To what extent do you think that biofuels, like ethanol, have advantages over gasoline?	Relative Advantage
2	To what extent is the use of biofuels compatible with your values?	Compatibility
3	To what extent is use of biofuels a complex issue?	Complexity
4	How risky is the use of biofuels?	Perceived risk
5	How likely is it that you will know if your friends are using biofuels in their cars?	Observability
6	How likely would you be to try biofuels when they are available at your filling station?	Trialability

The data was collected using telephone interviews conducted by the University of Florida Survey Center. The samples were created by randomly generating and calling US telephone numbers. Dialing was conducted from 9:00 AM to 9:00 PM local time from Monday through Friday. Weekend dialing was conducted from 12:00 PM - 9:00 PM local time, and Sunday dialing started at 2:00 PM - 9:00 PM. Call outs were made to the Eastern, Central, Mountain

and Pacific Time zones. One thousand and forty nine samples were collected. After deleting data with missing values, 554 samples were collected for the biofuels dataset and 443 samples for the hydrogen dataset.

To analyze the potential adopters of alternative energy cars, the samples are categorized into high alternative energy cars buying intention respondents and low buying intention respondents. High buying intention respondents are those who say they are very likely or somewhat likely to buy a car that runs on biofuels or hydrogen when the car is available and are ranked as low buying intention respondents otherwise. A T-test is applied to see the difference between high and low buying intention groups. Ordinal logistic regression is used to test the research hypotheses since the dependent variables are ordinal data, including level of willingness to buy a biofuels or hydrogen car (Cooper and Zmud, 1990).

DATA ANALYSIS AND RESULTS

The demographic characteristics for gender, education, age and total annual household income are presented in Table 2 and Table 3. The sample characteristics for biofuels and hydrogen are similar. Sixty percent of the respondents were male, half had college degrees, 30% had a total annual household income between $30,000 to $60,000, and over 60% of the respondents are middle age (35-65). Furthermore, we compare high alternative fuel powered car buying intention respondents and with low buying intention respondents. As shown in Table 2, female respondents tend to have a lower propensity to buy biofuels cars. Higher educated respondents (248) express a desire to buy biofuels cars and Table 3 displays the buying intention for hydrogen cars. 70% of the male respondents indicate a willingness to buy a hydrogen car, and respondents 51 to 66 years old (115) are more likely to buy a hydrogen car. Further, those whose annual household income between $30,000 to $90,000 (147) express a higher propensity to buy a hydrogen car.

Table 4 and Table 5 show the mean and the standard deviation of the demographic variables and the six dimensions of adoption of innovation (AOI) and the high and low propensity grouping. A T-test is applied to see if there is a significant difference between high and low buying propensity across the demographic variables. In this study, we found that the demographic variables play different roles in the biofuels and hydrogen dataset. In the biofuels dataset, there is no difference between high and low propensity across the demographic variables. However, in hydrogen dataset, gender, education, income and age are all significantly different between buyers with high and low propensity. In addition, higher income, better educated, younger consumers have a higher propensity to buy hydrogen powered cars. This result is similar to that of Gatignon and Robertson (1985) where they proposed consumers with these characteristics are more likely to adopt an innovation. Table 4 addresses the results for group differences between high and low propensity buyers of biofuels powered cars and Table 5 addresses the results for hydrogen powered cars. The results of the t-test reveal that all six dimensions of AOI, expect for complexity, are statistically different between high and low propensity groups for both biofuels and hydrogen datasets. Complexity

cannot be shown to influence the consumer's purchasing decision on buying a biofuels or hydrogen powered car. The results also show that relative advantage, compatibility, observability and trialability are positively relative to the consumers' intention to buy a biofuels or hydrogen powered car. Furthermore, perceived risk is negatively related to the buying intention of biofuels or hydrogen powered cars. The three most important attributes that influence consumer's alternative energy car buying decision for the high buying propensity group are trialability, compatibility, and relative advantage.

Using multivariate analysis, all variables are included in the model to analyze the factors that influence consumer's decision on purchasing an alternative energy car. As shown in Table 6 and Table 7, model 1 is for the demographic variables only and model 2 contains the demographic variables plus the six AOI dimensions. In Table 6, the demographic variables are not statistically significant for consumers purchasing a biofuel car. In model 2, when adding the AOI dimensions, the results are also not significant. As for the regression results of AOI dimensions in Table 6, the complexity and perceived risk are negatively related to the adoption of the biofuels car, but the perceived risk is not significant. The remaining four dimensions positively affect the adoption of the biofuels car, which means higher relative advantage, compatibility, observability and trialability leads to higher probability of biofuels car adoption. Therefore, hypotheses H1 through H5 for biofuels powered cars are significant and are supported.

Table 7 shows the ordinal regression results for hydrogen powered cars. For model 1, gender is a statistically significant variable which affects the consumer's decision to purchase a hydrogen powered car. Moreover, male consumers are more likely to buy a car that runs on hydrogen. The remaining demographic variables of education, income and age, excluding the dummy variable for ages 51-65 in model 1, are not statistically significant. Overall, the results are similar to the biofuels dataset and show that the consumer's education, income and age significantly influence their decision to adopt a hydrogen powered car. For the six dimensions of AOI in model 2 (Table 7), the relative advantage, observability and trialability have significantly positive relationships with the consumer's willingness to buy a hydrogen powered car. The results are different from the biofuels dataset. For the hydrogen dataset, there was no significant effect for compatibility or complexity on the buying intention for a hydrogen powered car. However, perceived risk is significant and negative for the buying intention of a hydrogen car. Therefore, the hypotheses H1, H4, H5, and H6 are supported for hydrogen powered cars, while H2 and H3 are not.

Table 2. Sample characteristics of biofuels cars

Variables	Total sample		High propensity		Low propensity

CONCLUSION

When discussing alternative energy adoption, most studies apply the viewpoint of industry and provide little research about the adoption from the consumer's point of view (Faiers and Neame, 2006; Kilinc, Stanisstreet, and Boyes, 2008). Therefore, this study focuses on exploring the factors that influence the consumer's adoption of alternative energy cars that run on biofuels and hydrogen.

The results of biofuels dataset shows that four dimensions of AOI, relative advantage, compatibility, observability and trialability, have positive relationships with the consumer's decision on purchasing a biofuel powered car. The other dimension of AOI, complexity, is significantly related to the consumer's biofuels powered car purchase decision. Rogers' five attributes of AOI are all related to the adoption of biofuels powered car, which means Rogers' theory fits this sample for explaining and predicting the adoption of biofuels cars. Although there are a number of ways to ask consumers why they adopt an innovation, Rogers' theory requires fewer questions and is particularly well suited to a phone survey. On the other hand, Bauer's perceived risk factor is not significantly related to the willingness to buy a biofuel powered car, which means the risk of using biofuels does not affect the consumer's purchase intentions. However, for the hydrogen dataset, perceived risk is significantly associated with the willingness to buy a hydrogen powered car. This indicates that consumers do not trust the safety of hydrogen as a fuel and consider buying a hydrogen powered car as a risk-taking decision. Sherif, Barbir, and Veziroglu (2005) mentioned the safety of hydrogen in their research. Since hydrogen is a diatomic gas with high flammability, that is easy to leak and can readily cause fires as well as explosions. These characteristics underlie the consumers worry about the risk of using the energy. Besides, gender, relative advantage, observability and trialability have a significantly positive relationship with the consumer's decision to buy a hydrogen powered car.

Trialability, observability, and relative advantage are the three factors that significantly affect the consumer's decision to purchase a biofuels or hydrogen powered car. Since trialability plays an important role for a new innovation product for early adopters (Gunderman and Meesa, 2008), manufacturers should encourage car trials for consumers in an attempt to increase their willingness to purchase the car.

Consumers will not adopt an innovation unless they are aware of it, observe it, and learn about it from others. Therefore, the alternative energy car manufacturers should design the alternative energy car differently from the traditional gasoline powered cars. The difference should be visible and when the alternative energy cars are driven on the road, so consumers can tell the difference. The observed difference will likely increase the consumer's

willingness to buy an alternative energy powered car. For example, Toyota alters the appearance of the Prius hybrid car so that it has a flat shape and a highly noticeable hybrid decal.

Relative advantage is significant factor underlying the consumer's decisions to adopt an alternative energy vehicle. Thus, if manufacturers promote the relative advantage of the biofuels or hydrogen powered cars (e.g., lower the price), the willingness to adopt biofuels powered cars will highly increase. Another important relative advantage for alternative energy cars is fuel efficiency. Therefore, manufacturers should emphasize the fuel savings advantages to attract consumer's attention. The demographic variables do not play a significant role in influencing the consumer's car buying decision. Only gender is significant with male consumers more willing to purchase hydrogen powered cars. However, in the univariate analysis, younger, higher income and better educated consumers have a higher propensity to buy the alternative energy cars indicating a potential target groups for manufacturers.

Fuel efficient vehicles will be the next generation vehicles and many manufacturers are currently in the process of testing and developing new vehicles. However, the popularity of alternative energy cars will be influenced by the consumer's adoption attitudes toward the innovations. This study outlines the factors that affect consumer's decision on purchasing alternative energy cars and serves as a reference for marketers in developing sales strategies.

Appendix 1. Description of the questions in the survey about hydrogen and the corresponding dimensions

	Questions in the survey	Corresponding dimensions
1	To what extent do you think that hydrogen fuel has advantages over gasoline?	Relative Advantage
2	To what extent is the use of hydrogen fuel compatible with your values?	Compatibility
3	To what extent is use of hydrogen fuel a complex issue?	Complexity
4	How risky is the use of hydrogen fuel?	Perceived risk
5	How likely is it that you will know if your friends are using hydrogen fuel in their cars?	Observability
6	How likely would you be to try hydrogen fuel when it is available at your filling station?	Trialability

ABSTRACT

Due to rapid advances in technology, computers have enabled substantial benefits to all fields of education. Instructors teaching spreadsheet applications such as Excel are faced with a variety of assessment and teaching methods to assign and grade homework projects that guide students in mastering the essentials of spreadsheet operations. Several grading software packages are available in the market to increase the efficiency and effectiveness of teaching an Excel course. This study discusses a system designed to create and grading Excel assignments. The system advantages and drawbacks are discussed and compared to those packages available in the market.

Keywords: Teaching Innovation, Software applications, Grading Systems, Excel Spreadsheet

INTRODUCTION

We can now look back to the beginning of the digital era and say that both the technological advancements and the human-computer interface have brought the education field new opportunities in the development of computer-based teaching and tutoring systems (Raineri, Mehrtens, Hubler, 1997). In modern education, computer applications are capable of enhancing the quality of teaching and learning. The technological revolution provides much faster facilities to access source of information and allows educators to provide instant feedbacks to students. In order to maintain such standards with the ever changing environment, it has become necessary for educators to revise their traditional methods of teaching and take advantage of the technological tools available so that a more productive and interactive course can be offered to students (McDermott, 1990, 1993). New curricula must be developed in order to adapt and better challenge students with various backgrounds and implicitly different means of learning (Raineri, Mehrtens, Hubler, 1997).

Aside from teaching, assigning homework and the grading process are significant tasks for most, if not all, educators. Going through assignments, tests, and other evaluations is time consuming, especially with large classes with more than 100 students (Friedler, Tan, Peer, Shneiderman, 2008). Nevertheless, grading thoroughly and constructively is important to the learning process. Students perceive grading as an effective assessment and thus it is viewed as an integral part of teaching and learning rather than being apart from a curriculum (Garfield, 1994). As the course progresses, instructors are required to pinpoint program weak points so that students who have difficulties in a particular area can be identified and help can be provided (Friedler, Tan, Peer, Shneiderman, 2008). Any tool or technique that can make grading easier helps educators identify and understand students' struggles and successes so

that above average students can be challenged and below average students can be helped (Friedler, Tan, Peer & Shneiderman, 2008). Hence the recognition to which an effective grading system can serve as a crucial tool to improve teaching and educational methods.

Although many educators have used automated grading to assess and provide quick feedback for a large number of students, there are few studies on automated grading and specifically for Microsoft Excel. This paper aims to introduce an alternative automated grading program for Excel in comparison to other known automated grading programs. Descriptions of these existing programs are provided, and a further detailed explanation of what they specifically target is discussed.

This article introduces a system which has been actively used in business computer classes at Texas A&M University - Corpus Christi. Students are required to submit an assignment every week. The use of the program reduces substantially the amount of time in grading the assignments, gives instant feedback, and provides enough flexibility to ensure the most accurate assessment.

BACKGROUND OVERVIEW

Prior to the use of computers, grading was a time-consuming and labor intensive process. Most educators spent between one-third and one-half of their time on grading students' assignments (Stiggins, 1999). Assessment was done entirely by hand or with the assistance of a calculator (Migiorino, 2002). Although the approach to grading by hand can vary if comparing the grading process of a program assignment versus an essay assignment, there is still a consistent element towards the human factor that fails to support such traditional systems. Within program assignments the human factor is considered inconsistent, dependent on the humor and vigilance of the grader. An exact same program when graded by different human graders most generally results in different grades (Cheang, Kurnia, Lim, Oon, 2003). To this extent, even when essays are recognized as being the one of best means to evaluate the performance of students, the subjectivity of the grading process raises difficulties in the attempt to produce consistent grades among different human evaluators (Valenti, Neri, Cucchiarelli, 2003).

Microsoft applications are being used widely in broader purposes, including grading systems. Among the automated grading programs developed to help instructors in Microsoft Excel and Microsoft Office Application are SAM – skill assessment training manager - (Thomson Learning/Course Technology) and MEAGER - Microsoft Excel Automated Grader (Hill, 2003). The overview of these systems will be provided in the next section.

Automated Grading Programs

Automated grading programs can be defined as a part of computer aided assessment (Tshibalo, 2005). The popularity of the computer aided assessment technologies rises significantly as the number of student increases. Previous research suggested that automated grading provides consistency, thoroughness, and efficiency (Isong, 2001). For example, among programming courses this benefit allows the assignment of more programming exercises for students since the automatic grading avoids any possible errors that can occur with human grading (Cheang, Kurnia, Lim, Oon, 2003). One of the major advantages of automated grading is that students receive timely feedback on their performance (Shah,

2003). Wang et al. (2006) suggests that benefits of automated grading are giving marks objectively, improving students' learning experience, and reducing the workload for instructors.

The early research of computer aided grading programs evolved in computer science classes. The early automatic grading prorams were used to evaluate student's problem solving skills in computer science (Wang et al., 2006). Many grading programs in this field include ASSYST system (Jackson & Usher, 1997), PGSE (Jones, 2001), Virginia Tech's Curator System (Edwards, 2003), GUI_Grader (McAllister & Feng, 2005) and Marmoset (Spacco, 2006).

Some programs are designed especially for essay assessments. Many studies have been conducted to validate the viability of using computer technology to grade short essay of English prose (Landauer, Laham & Foltz, 1998, Shermis et al., 2002; Yang et al., 2005; Dikli, 2006). Brent (2004) introduced Qualrus to automatically grade essay of students in an introductory sociology class (Brent, 2004). In addition, automated grading is also popular in other areas. For example, Beevers & Jackson (2001) suggested Mathwist to assess mathematics skills in engineering courses.

Microsoft Excel Automated Grader

Among the grading systems for office applications is SAM (Thomson Learning/Course Technology). SAM is a system of evaluation for Microsoft Office which requires students, on a time controlled basis, to conduct a series of tasks on a computer using the pertinent software. It evaluates a student's skill by asking him/her to perform specific activities and then measures his/her performance in that application (Whittle, 2005). A student conducts his or her assigned requirements on the computer. Then by recording the students' movement used with the mouse and keyboard in response to the tasks assigned, the system grades the students' performance in an Office XP environment (Whittle, 2005). When these are compared against the instructors' correct proceedings, grades are given based on the results (Hill, 2003).

MEAGER is another program used for skill assessment that, unlike SAM, more specifically evaluates students' skill on Microsoft Excel through statistical analysis on Microsoft Excel spreadsheet. The focus of the tool is on the end results that arise after the student's workbook is turned in, not on the steps he/she conducted to perform the assigned tasks. Since MEAGER is designed to grade assignments accurately in every detail, the program compares students' work with the instructor's correct version (Hill, 2003). It requires students to input the same exact format as the instructor provides in each cell (Hill, 2003). As a result, the program is not flexible, although it enables the instructor to see the score as soon as the assessment is completed (Hill, 2003).

Generally, for Excel-based courses instructors assign students to perform a number of tasks in a given workbook. When such workbooks are compared to the instructor's correct version, the differences are what define the errors and therefore the grade. MEAGER conducts this same comparison automatically grading from text labels, formulas, number formats, to cell orientation and even cell fill color among other characteristics. However, it has limitations for grading charts, embedded objects, drawing objects and controls (Hill, 2003). The assignment of the grade is derived by the taking the characteristics from both the instructors' correct

workbook and the student's workbook into MEAGER's system tables identified as Cell, Format, Border, Formula, Row, Col, and Worksheet (Hill, 2003). With the comparison of these characteristics, the system detects any errors and records them in an errors table (Hill, 2003). At the bottom of the worksheet, the number of errors encountered and the numbers of points reduced are shown in a grade summary.

The particular benefit of this assessment tool is a much more explicit evaluation than given by a human grader since the program emphasizes grading characteristics that may be missed by the human eye. Details such as alignments, column widths, row heights, number formats among others are many that MEAGER evaluates with greater detail (Hill, 2003). Further more comprehensive criteria can also be graded making it possible for instructors to fully cover various areas of the course that previously were difficult to evaluate given the tedious and time consuming task that it presented for the instructor. Without a doubt the use of MEAGER is timesaving, leaving the instructor only to define the seriousness of the errors listed.

Further benefits of MEAGER are the reports it generates after comparing a group of students files with that of the instructor. MEAGER can generate three reports: Grade Report, the Errors List, and the Common Errors report. The first contains the grade of each individual Excel file evaluated. The second provides an insight into all the errors detected among the group evaluated. The third report lists the common errors among the students evaluated by examining two student files at once, further helping the instructor in visualizing the key areas in which greater practice is required. This also provides the capability to the instructor to detect plagiarism among students since common equal errors listed among two student files may be a sign of possible plagiarism.

Despite all its benefits, no system is without weaknesses. Among the weaknesses of MEAGER is that it requires all student files be gathered at one time into one folder (Hill, 2003). This is not always possible, since some students may submit their work via email attachments or other electronic means making the gathering process slightly inconvenient for the instructor in order to initiate the grading process. Another recognized weakness is the abundant markings of its grading process (Hill, 2003). Given that the instructors' file serves as the control file for the correct base grading, any markings other than those included in the instructor's file is considered erroneous. Examples of this type of excess markings are a student including extra spaces in a label or if a student has even small differences among column height or width (Hill, 2003). Furthermore since MEAGER is in a beta release, if it finds an error in a file it will automatically continue grading the next file and leave the previous file with a grade of -1. This obligates the instructor to interpret the error of the file and go into the file to further grade it by hand (Hill, 2003).

eMarkbook Excel Template

Another assessment tool is known as the eMarkbook Excel Template. The approach of this timesaving tool is entirely different in comparison to MEAGER or SAM. Its primary function is to help instructors better manage student scores. Although developed on a Microsoft Excel based template, it does not offer the automatic grading of students' assignments in comparison to that of the instructor. It only manages student grade data and therefore offers instant updates of the students' grades individually as well as multiple classes of any given course (Watson, 2008).

The data is entered using a main sheet known as Class Marks (Watson, 2008). As the instructor inputs the grades of an assignment or exam the system automatically updates the grades, percentages and averages among students evaluated in the given group (Watson, 2008). Instructors are given specific cells within the sheet where they can introduce the data. The rest of the cells are blocked to avoid errors that may disrupt the formulas they contain, therefore updating instantly (Watson, 2008).

The system offers many functions including Rank/Print, that allows instructors to sort students into groups or rank students in individual classes and later generates a summary of their respective marks (Watson, 2008). Other functions include separating and delete the scaling of groups of marks, functions for printing, and emailing among others (Watson, 2008).

Although there are many alternatives from which to choose for grading and giving back a written online assignment, each modality has its benefits and pitfalls and it depends on the inclination of the grader as to which one to select (Jennings and McCuller, 2004). However, with the availability of a number of software applications, educators can reduce considerably the amount of time required to grade all students (Migiorino, 2002). In addition to the time saving factor, such support can allow instructors to offer students an enhanced learning experience with more objective evaluations and immediate responses (Tiantian, Xiaohong, Yuying, Peijun, 2006).

The system developed in this study has been actively used in business computer classes at Texas A&M University - Corpus Christi. Students are required to submit an assignment every week. The use of the program reduces substantially the amount of time in grading the assignments, giving instant feedback and provides enough flexibility to ensure the most accurate assessment.

EXCEL COURSE MANAGER (ECM)

The Excel Course manager (ECM) is developed as an Excel application. The application is placed inside a folder named “XCL”. This folder contains a “CourseManager” subfolder and other subfolders for each class section. For instance, if the class has two sections, two subfolders will be generated and named “CourseExcel001” and “CourseExcel002”.

For each section subfolder, two subfolders are created to contain a Project (Assignment) Template and Key for each Project. These subfolders are named as “ProjTemplates” and “ProjKeys”.

Project Template Folder

This folder contains Excel files for projects/assignments. Each file is named as Template + class number + section number + project number. For example, the file for project 1 for the class Excel, course/section 001 is named as “TemplateCourseExcel001Proj1.xlsx”

The template file contains several worksheets with instructions for a student to complete the assignment. Figures 1 and 2 below show examples of the first and the second worksheets for Project 1:

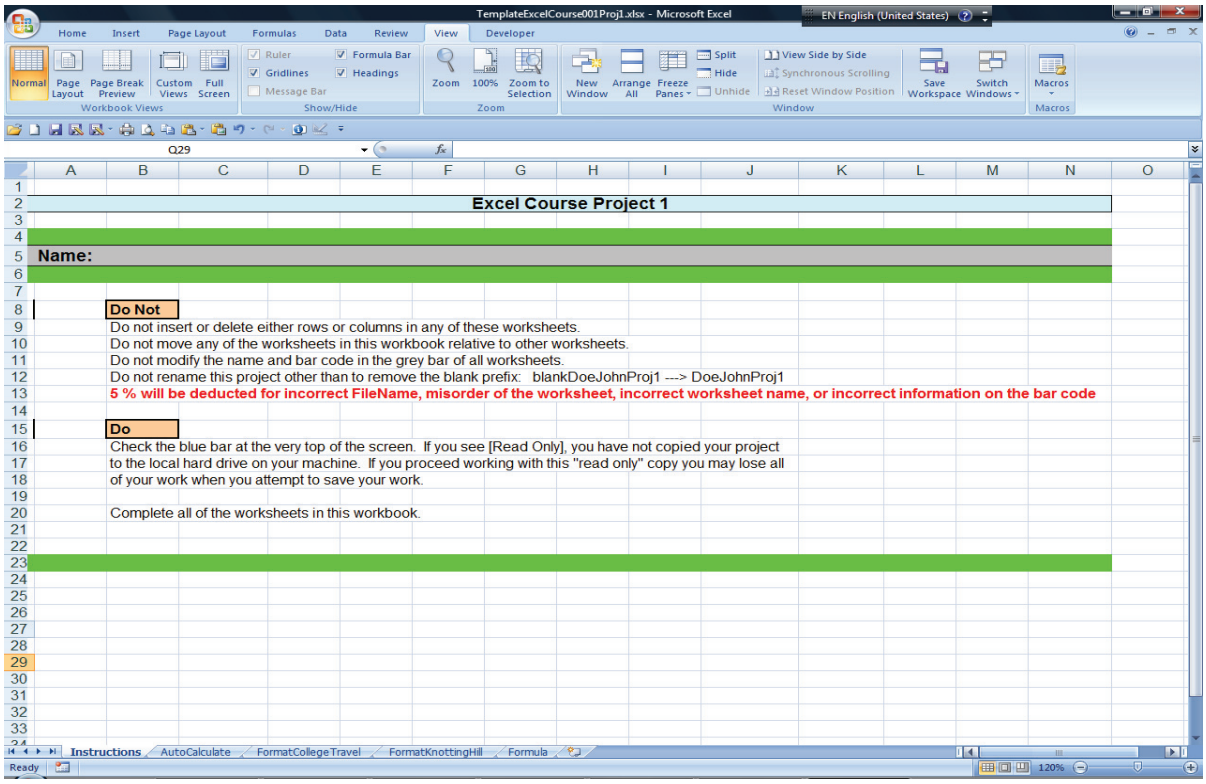

Figure 1: Template Instruction for Project 1 (First Worksheet)

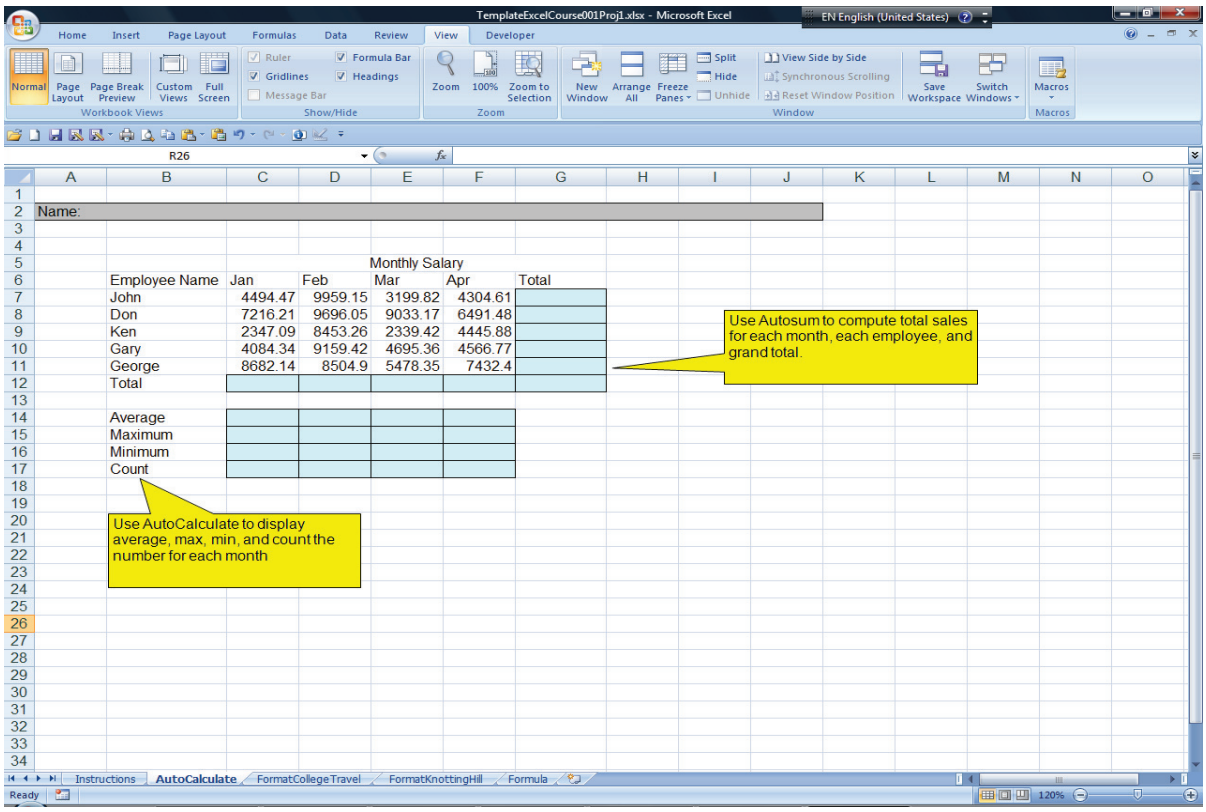

Figure 2: Template Instruction for Project 1 (Second Worksheet)

Project Key Folder

This folder contains Excel files solutions for projects/assignments. Each file is named with Key + class number + section number + project number. For example, the file for project 1 for the class Excel, course/section 001 should be named as "KeyCourseExcel001Proj1.xlsx" The Project Key files contain worksheets matching the Templates with all work completed. These keys are Excel workbooks which contain all data and all computations that students need to do to complete the project. These keys can easily be modified to suit the requirements of any particular Excel class. Projects can be customized by adding or deleting worksheets, or changing the work to be done within an existing worksheet. Figure 3 below show examples of the key for the second worksheets for Project 1:

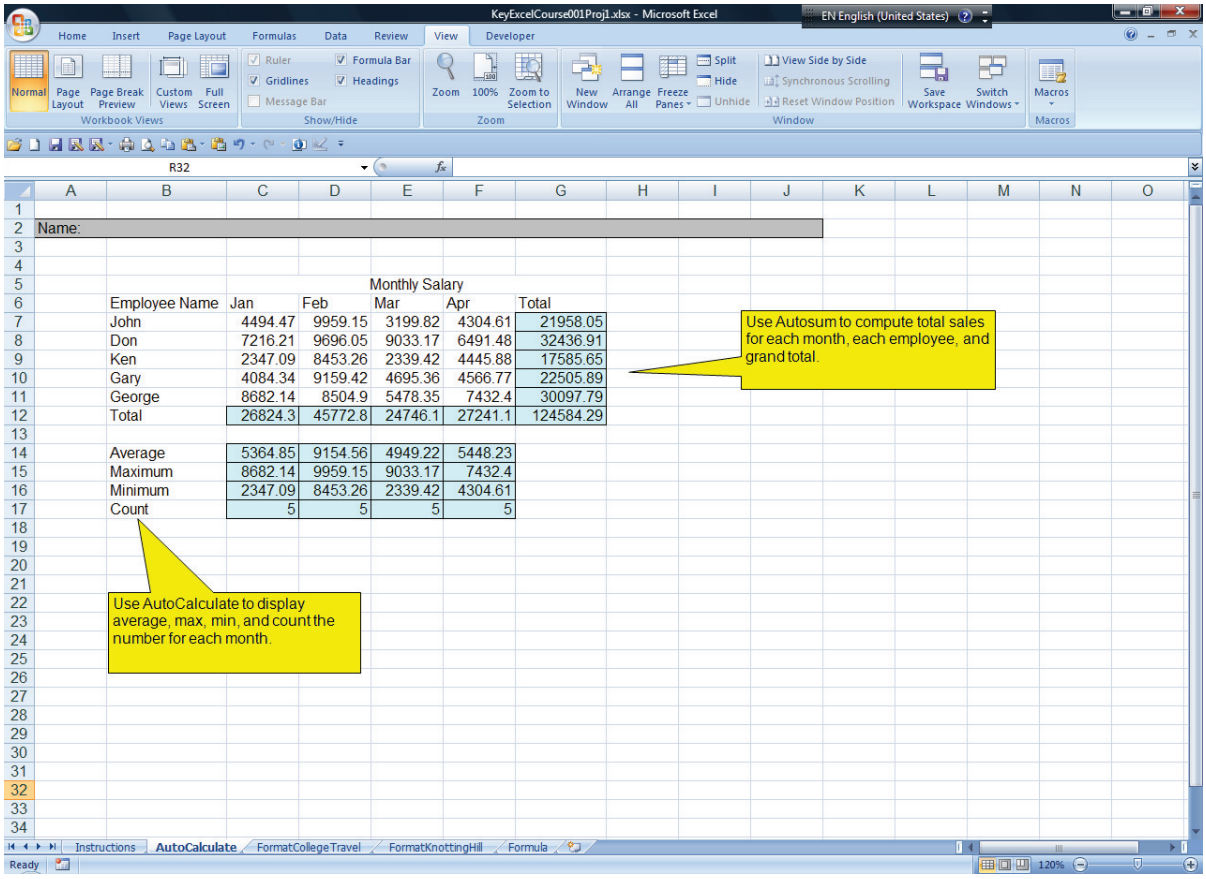

Figure 3: Key for Project 1 (Second Worksheet)

At this point, you may notice the name grey bar on the top of each worksheet. The purpose of this grey bar will be explained in a later section.

Course Manager Folder

This folder contains an Excel Macro-Enable file named "CourseManger.xlsm". The Course Manager file consists of the "Course Manager Console" and course worksheets (Usually name with course and section name, e.g., CourseExcel001 and CourseExcel002). The course

worksheet contains student roster and scores. Figures 4 and 5 below show the Course Manger Console worksheet and CourseExcel001 worksheet:

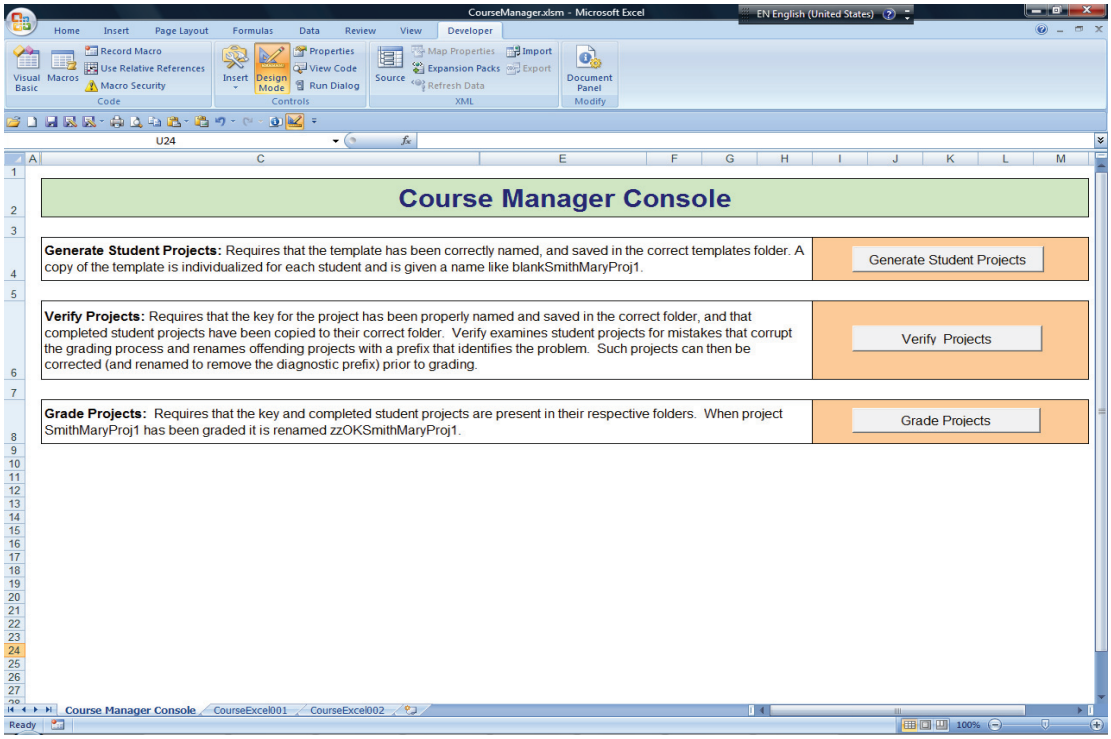

Figure 4: Course Manger Console

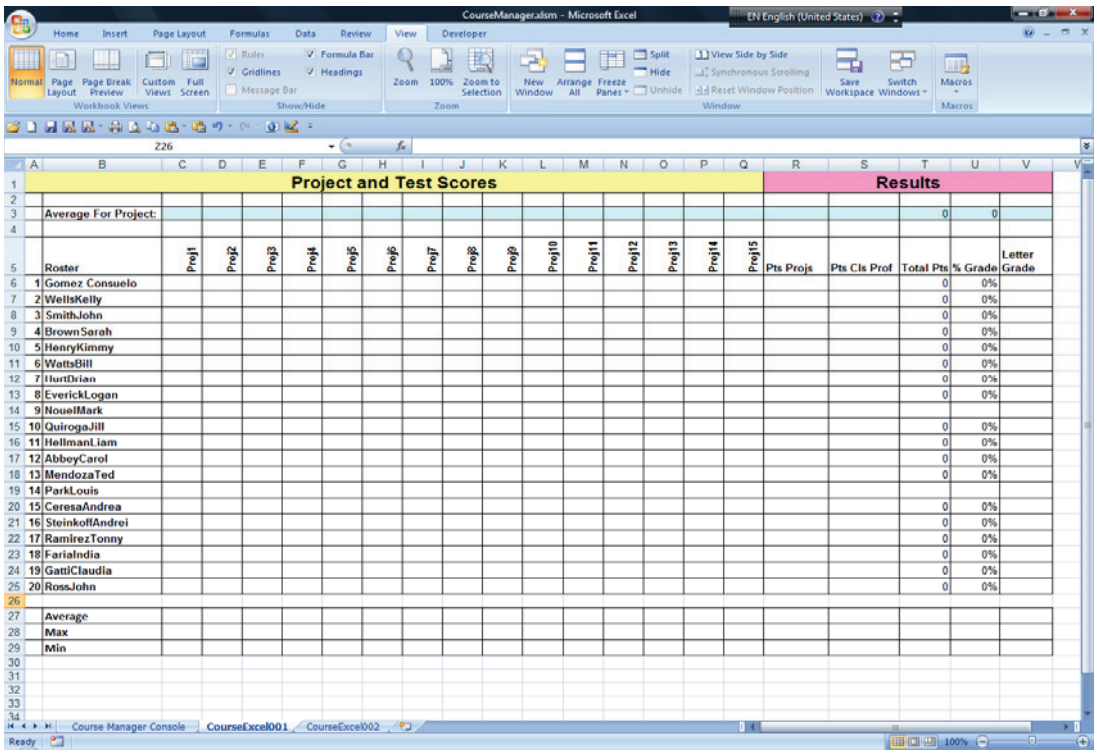

Figure 5: CourseExcel001 Worksheet

The Course Manger Console Worksheet contains three Control buttons: (1) Generate Student Project, (2) Verify Projects, and (3) Grade project.

(1) Generate Student Projects Control Button

Before generating a project, the instructor creates a subfolder within the course folder with using the project number as the name of the subfolder. For example, the name for project 1 subfolder should be named as "Proj1"

When the instructor chooses the control "Generate Student Projects" button, a "Generate Student Project" screen will be pop-up so that an instructor can choose which class and which project should be created (see Figures 6 and 7 below). An individualized copy of the chosen project is generated for each student listed in the roster for the chosen section. These files will be placed inside the "Proj1" folder. Each file is automatically given names like blankDoeJohnProj1.xlsx and the student's name is also placed at the top of each worksheet in the workbook along with a "bar code" to help curtail copying the work of others. The prefix "blank" is added to distinguish projects that have not yet been worked on. The instruction will be given to students to rename the file by removing prefix "blank" once they complete the project.

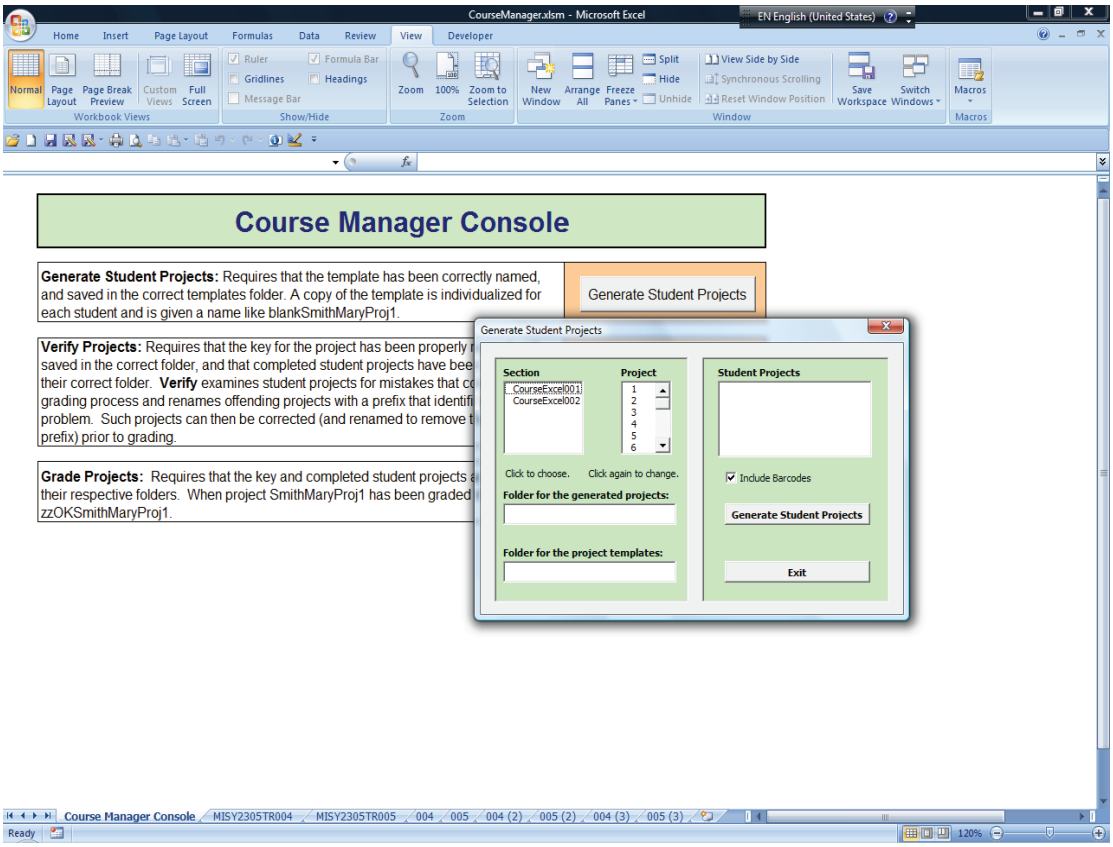

Figure 6: Generate Student Project Pop-up Screen 1 (before generate)

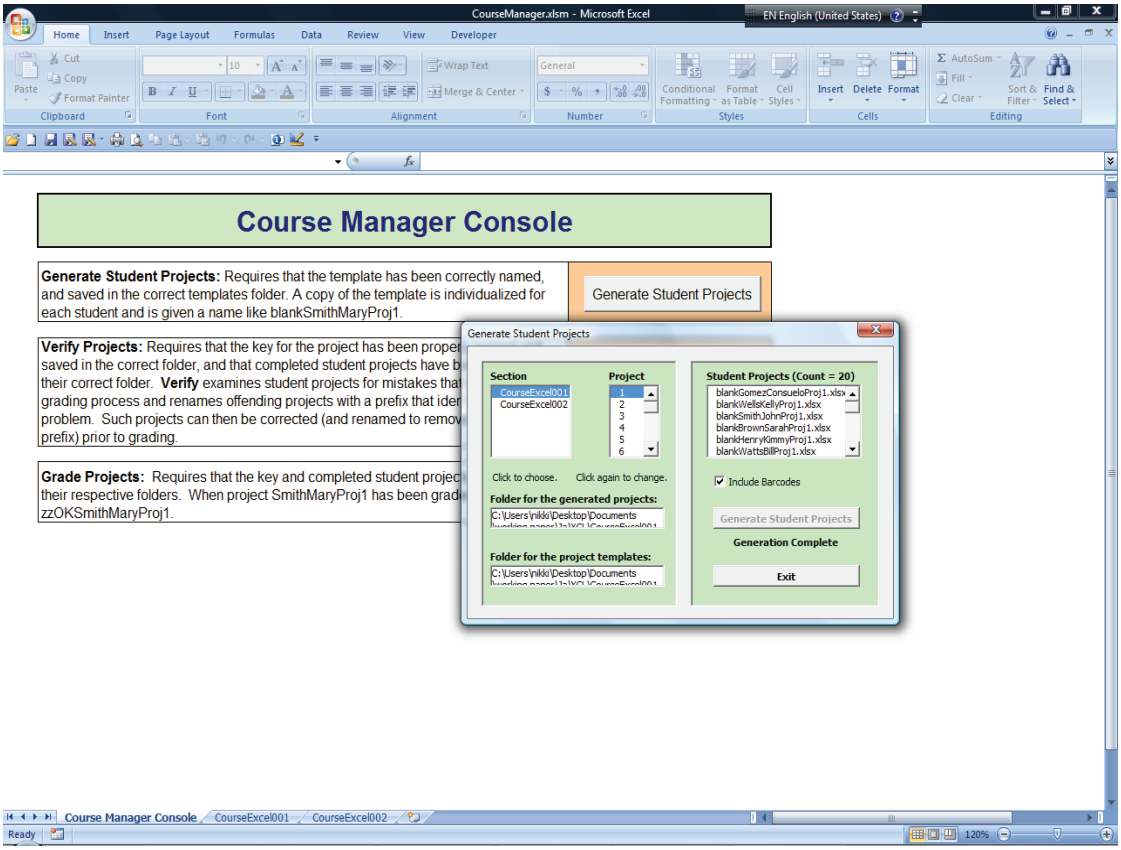

Figure 7: Generate Student Project Pop-up Screen (after generate)

(2) Verify Projects Control Button

Before projects are graded, it is helpful to trap irregularities. Pressing Verify Projects determines whether any of the following are present. (1) File name does not match a name in the roster. (2) Project number is incorrect or missing or "Proj" is not a part of the file name. (3) Student project cannot be opened because the workbook has somehow become corrupted. (4) Incorrect number of worksheets in the student workbook. (5) The order in which the worksheets appear in the student workbook is not the same as the order in the key. The verification process does not alter the student project except to rename the project with a diagnostic prefix. If, for example, John Doe changed the order of the worksheets within the project, the file name DoeJohnProj1.xls would be automatically changed to zz~TabOrderDoeJohnProj1.xls.

(3) Grade Projects Control Button

When an instructor chooses the control "Grade Projects" button, each student project will be graded against the project key. The grading system requires that the "ProjKeys" folder contains a file "KeyCourseExcel001Proj1" and that "Proj1" folder contains the student project to be graded, e.g., SmithMaryProj1".
When student projects are graded, the project key is opened in order to provide information for the grading process. To understand what follows, the term "selection" as it applies to a worksheet should be discussed. An instructor will select "Grading Cells" by clicking on specific cells. These selected cells will become the selection.

More than one cell can be selected either by holding down the left mouse key and dragging or continuous cells or by pressing the Control key while dragging for non-contiguous cells to become the selection. Each worksheet within the workbook can have its own selection of cells, and these will be saved when the workbook is saved.

The selection process allow an instructor to grade only cells that contain formulas or functions that he or she selects to test students' knowledge instead of grading the whole worksheet. For example, not all worksheets within a workbook will necessarily be graded; worksheets whose tab names are like Introduction or ScratchPaper would not be. Worksheets like this will not be graded when the selection saved with them contains just a single cell. If the selection contains more than a single cell, the corresponding worksheet in the student project is graded. When a multiple selection is present, just the individual cells within the selection are graded. This allows the instructor to choose representative cells within the worksheet to grade and avoids the redundancy and confusion of grading every cell within the worksheet.

If a cell to be graded in the key contains a formula, then the corresponding cell in the student project must also contain a formula (and the formula must compute the correct answer) for the student to earn points for that cell. Of course there will typically not be just one correct version of a formula. The issue here is whether or not the key has a formula at all in the cell to be graded. If the key does not have a formula in the cell to be graded, then the student project need not have a formula in the corresponding cell.

By default, the software assigns a point value of five for each correct cell in the student worksheet. If a particular worksheet contains cells which should have some other point value, the corresponding project key worksheet would contain "CellPoints = 3" as a label located somewhere in column A.

Also, by default the grading process assumes that formatting will not be graded on a particular worksheet. Otherwise, the corresponding worksheet in the project key contains "FormatPoints = 30" as a label located somewhere in column A. Each corresponding worksheet of the student project is automatically made visible to the instructor. The instructor visually assesses to what extent formatting is correct and then assigns a grade by clicking in a small window temporarily made visible for that purpose. Other aspects of the worksheet can be graded visually as well. If a particular worksheet contains an embedded graph, a macro button, or some other feature, the corresponding worksheet in the project key would have "OtherPoints = 20" located somewhere in column A. Once again, the grading process automatically makes such worksheets visible so that these features can be viewed or tested. As before, a small temporary window allows point values to be assigned. Printing can be graded this way as well. If a particular worksheet should have been configured for printing, putting a label like "Other Points = 30" will cause this worksheet to be visible. The instructor can then choose "Print Preview" to assess how the printed report would have looked. In a similar way a worksheet can be designated as extra credit by including a label like "ExtraCredit=20."

When all point values are assigned (either by the instructor or by the automated grading process), the total possible points and points earned by the student are computed. The percentage grade is automatically entered in the roster.

The graded student project is altered in the following ways. If the student has the correct answer in a graded cell, that cell is given a green background color; if the answer is wrong, the background color is set to red. In either case, the content of the cell is not changed. The grading process also records a page score on each page of the student project, as well as a cumulative project score on the Introduction page of the project.

When the student project is graded, it is renamed zzOKDoeJohnProj1. These naming prefixes allow blankDoeJohnProj1, DoeJohnProj1, and zzOKDoeJohnProj1 to be simultaneously stored in the same folder. The naming prefixes also prevent confusion among these three versions of the student project.

DISCUSSION

The ECM has been used for teaching Excel classes for over 15 years. The experience using the system has been very positive. The ECM minimizes the time an instructor needs for generating and grading assignments. The average time used for grading a project (for 40 students) is approximately 10 minutes. If the templates and keys are designed properly, the accuracy of grading is very high.

Compared to other Excel Grading Systems available in the market, the ECM contains several features that differ from others as follows:

- The ECM is independent of any particular textbook. Unlike other systems that provide an instructor with fixed templates and keys, the ECM allows an instructor to create his/her own files to test appropriate knowledge taught in the class. Several model templates come with the ECM system. Since these model templates can be modified as needed, it is not necessary for an instructor to create templates from scratch. Courses have been successfully taught with ECM using no textbook at all.

- An instructor can select any desired set of cells for grading, which avoids the redundancy of grading every cell.

- The ECM can grade not only cell contents such as numbers or formulas, but also allows for format, the operation of macros, or the correctness of printing to be graded visually. In addition any of the worksheets within the project workbook can be designated as extra credit.

- The ECM automatically individualizes projects by including students' name and a unique bar code at the top of each of the worksheets, thus preventing students from copying files from their classmates.

Although the ECM provides several benefits as mentioned above, it is also important to note its system limitations. In order to maintain the capability of grading a student project, students need to be careful while working on the project. For example, students cannot insert

or delete any rows or columns. (The projects have been designed in such a way that inserting or deleting is never necessary.) Students cannot reorder the worksheets within the workbook (by dragging the worksheet tabs to a different location) or give the worksheets a different name (by changing the name on the tab). Students cannot protect worksheets as this would disallow the changes made to their worksheets in the grading process. Otherwise all design capabilities within the spreadsheet environment are allowed.

Currently, the ECM has been developed to be independent of the Internet. The system works best in a classroom in which all students can log onto a network (either LAN or otherwise) so that the projects can both be submitted to the students, and received back from the students electronically. Future research can be conducted to develop the system to be Internet-based application.

CONCLUSION

With rapid advances in technology, it is obvious that potential employers will expect students to graduate with good computer skills. Since Excel is widely used in most organizations, it is very important that students are familiar with Excel applications. Typically, with hands-on class settings, the more students are required to practice with assignments, the better they learn and develop skills. Nevertheless, the impracticality of manually grading such a volume of assignments, especially when the class size is larger than 40, usually creates a tendency for the instructor to assign less homework than would be ideal for the learning goals of the class. The systems described here help minimize this problem by reducing the grading burden to minutes instead of disheartening hours. On an average, it takes approximately ten minutes to grade an assignment consisting of five worksheets for 45 students.

Currently, quite a few attempts, both from publishing companies and developers, have been conducted to develop systems accompanying Excel textbooks which allow for automatic grading of assignments and/or tests. These systems are aimed at reducing times and perhaps increasing the accuracy over an instructor manually grading Excel assignments. Since these systems have different capabilities and limitations, some will fit a particular way of assessing this work better than others. However, these systems are usually customized as they are designed to accompany a specific textbook. There is very little allowance, if any, for an instructor to change the design or develop his/her own worksheet templates. Different from these systems, the ECM was developed to allow for more customization. In fact, two instructors can assign completely different sets of assignments and/or tests using the ECM. An instructor has total flexibility in terms of the design of his/her own worksheet templates and the selection of which cells or knowledge they would like to select for grading.

ABSTRACT

The NFC (Near Field Communication) system has recently gained broad attention by the service industry. Service firms actively develop and expect NFC to have broad applications in the consumer market. The research applies the technology acceptance model (TAM) and innovation diffusion theory (ID Theory) to develop the conceptual framework and then discusses consumer attitudes and adoption behaviors concerning the NFC system applications. The discussion on factors in the research include perceived usefulness factor and perceived ease of use factor from the TAM model; and the compatibility, complexity, trialability, observability, and relative advantage, factors from innovation diffusion theory. Research results verify that specific factors of the TAM model and ID theory model could positively affect the NFC adoption attitude of consumers. Furthermore, when consumers have good adoption attitudes toward innovation technology, then consumers' adoption behavior concerning NFC systems will be effectively improved.

Keywords: TAM, innovation diffusion theory, Near Field Communication

INTRODUCTION

In Taiwan, due to the popularity of information applications (e.g. internet, computer and wireless applications), prevalence of cell phone, as well as the pursuing innovation in the life characteristics of Taiwanese people, there is a growing population of consumers who have higher high technology knowledge and expect innovation technology products, thus, the high technology and service firms in Taiwan are forced to improve constantly. The digitalization of cellular phone has brought an important influence to the Taiwan cellular phone industry. After applying NFC (Near Field Communication) security mechanism to the privately cellular phones, the security of mobile payment is highly enhanced, and the digital transactions become more convenient for the consumers.

Understanding factors that influence consumers' intentions to use or reject information and

communication technologies (ICT) is an interest topic. As new ICT continue to develop at a rapid pace, understanding these factors is important [39]. In the context of mobile commercial environment, numerous scholars have employed technology acceptance model (TAM) and innovation diffusion theory (IDT) as a base model, to investigate the use and acceptance of a mobile technology (e.g. [8]; [24]; [31]). TAM posits that behavioral intention determines actual systems use and behavioral intention is determined by both attitude and perceived usefulness. Perceived usefulness and perceived ease of use both affects on behavioral intention [37]. Further, innovation Diffusion Theory (IDT) (including the compatibility, trailability, observability, complexity, and relative advantage factors) has also been widely used for relevant IT and IS research ([20]; [13]).

By adopting an integrated perspective emphasizing the roles of TAM and ID theory, this paper addresses these key gaps by developing empirical NFC service development strategy explanations for related service innovation products application research in terms of a linear regression method. The objective of this study is to investigate and evaluate the TAM model and ID theory and to examine their importance in allowing service industries to design a development strategy of service innovation products (e.g. NFC system service) in the commercial marketplace. The findings have the potential to offer significant implications for theory and practice. In addition, it may also give some insights into related academic research in the future. The study includes developing a questionnaire that builds from the following conceptual framework (See Figure 1). The rest of the paper is organized as follows. Section 2 gives a review of the literature in the areas of TAM, ID theory, and use intention. Section 3 introduces the methodology used in the research. Section 4 presents the background of data sources and analysis and gives the research findings of the study. Finally, section 5 provides the discussion and conclusion.

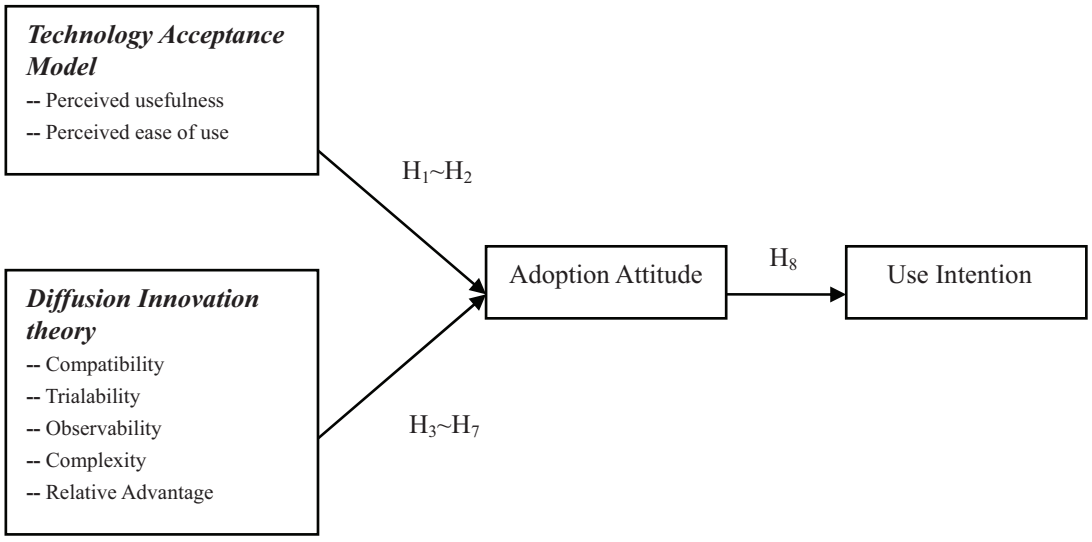

Figure 1. Conceptual framework

LITERATURE REVIEW

Previously, an NFC Service application in TAM and ID theory has not yet been explored. Therefore, this study aims to add to the limited literature on NFC Service, mainly in Taiwanese context. This section outlines literature reviews of former scholars and defines a theory base for this study.

Application of NFC System in Service Industry

NFC is a short range wireless technology that is quickly becoming the technology of choice by handset manufacturers, credit card companies and public transport operators around the world for contactless transactions including secure payment and ticketing [19]. NFC is an interconnection technology that enables secure short-range communication between electronic devices, such as mobile phones, PDA, computers and payments terminals via a fast and easy wireless connection [19]. According to a new research study from ABI Research, more than 419 million NFC chipsets will ship in 2012. NFC chipset shipments and revenue will continue to grow steadily over the next several years [15]. Several NFC applications are promising, including transit ticketing and payment. For example, in 2007, the initial UK contactless rollout in London proves a bellwether for the technology in Europe, NFC rollout is supported by the widespread adoption of contactless transportation and payment systems [16].

In Taiwan, the first NFC mobile co-branded transit card has been issued in cooperation with several companies, including ChungHwa Telecom, Master Card, and the Farglory Group. This corporation activity provides 6000 NFC mobile phones for the Farglory Group's architectural buildings. These NFC mobile phones have Easycard and Digitalhome equipment control functions. Furthermore, ChungHwa indicates that they will continue to develop NFC communication services, such as virtual shopping, E-guide, automatic download certificates, and other added service values in the near future. In academia, scholars have described the development of an NFC service instrument designed to measure user perceptions of adopting an information technology (IT) innovation [25]. While the decision to use IT service products and the key success factors behind IT products adoption and use intention have been the focus of a considerable number of studies worldwide, the examination of the use behavior of Taiwanese consumer has been limited. In addition, research in divergent socio-cultural settings, and different economic times yield conflicting results in relation to many of the factors hypothesized to impact on consumer adoption behavior of IT service products. Thus, an examination of the Taiwanese consumer for NFC mobile payment system is a worthwhile pursuit.

Application of Technology Acceptance Model on Innovation Service Products

According to the technology acceptance model an individual's behavioral intention to use a technology can be explained by their perception about the usefulness of the technology in question and their attitude towards technology use ([10]; [30]). TAM was adapted form the TRA [2] to understand the causal chain linking external variables to technology usage intention and actual use in a workplace [26]. The key purpose of TAM is to trace the impact of external variables on internal beliefs, attitudes, and intentions. The TAM suggests that two factors – perceived ease of use and perceived usefulness – are the two main factors in explaining system use [11]. According to the model, acceptance of technology depends upon user perceptions of the technology's usefulness and ease of use. These perceptions in turn affect user intentions to apply the technology at high levels and on a basis into the future [4].

In academia, scholars have applied TAM model to predict and suggest the application or promotion of new technoloogy. Many study findings indicate that these two constructs are useful and valid in evaluating consumers' intention to use information system (IS) (e.g., [3]; [8]; [9]; [28]). For example, Fang, Chan, Brzeinski and Xu (2005) suggested that under wireless PDA context, user intention to perform general tasks is influenced by perceived usefulness and perceived ease of use [12]. A study of consumers' adoption of a mobile system in Finland found that perceived usefulness among research factors played an important role in consumers' intention to use the mobile system ([17]; [31]). Further, Bhatti (2007) suggest that perceived usefulness, perceived ease of use and behavioral control are strong determinants of intention to adopt mobile commerce [6]. In the broad context of smartphone acceptance, mobile services can be available at any time and any place. Thus, perceived usefulness is defined as how well consumers believe mobile services can be integrated into their daily activities ([21]; [31]). In sum, from the above discussion about TAM factors on IT service products, the following relationships are hypothesized:

H_1: Perceived usefulness of the NFC mobile payment system has a positive effect on consumer's attitude of adoption for the NFC mobile payment system.
H_2: Perceived ease of use of the NFC mobile payment system has a positive effect on consumer's attitude of adoption for the NFC mobile payment system.

Application of Innovation Diffusion Theory on Innovation Service Products

The diffusion of innovation theory is as a theory of communication which has been studied extensively in the literature and with respect to different types of products and services ([5]; [7]; [25]; [36]). Innovation Diffusion Theory (IDT) is defined as 'the process by which an innovation is communicated through certain channels over time among the members of a social system [34]. It has been widely applied in disciplines such as anthropology, sociology,

education, communication, marketing, etc ([13]; [36]; [42]). The perceptions of adopting were initially based on the five characteristics of innovations derived by Rogers (2003) from the diffusion of innovations literature [36].

The factors in ID theory model include compatibility, observability, trialability, complexity and relative advantage. Comparability is related positively to its rate of adoption. The more an innovation is recognized as compatible with the system, the more it would be adopted [22]. Trialability would positively affect the user adoption. Rogers (2003) suggested that if a trial is permitted, adoption and implementation will be easy and quick [36]. Observability would positively influence the user adoption. When innovation is visible by users, it is more likely adopted [31]. Perceived complexity has been extensively studied by IT researchers. Several studies find significant relationships between perceived complexity and use intentions ([33]; [39]; [40]). Perceived relative advantage is 'the degree to which an innovation is perceived as being better than the idea it supersedes' [35], which include several dimensions to perceived relative advantage, increasing economic profitability, low initial cost, decreases in discomfort, and social prestige. Perceived relative advantage has received empirical support as having significant influence on use intentions ([32]; [33]; [38]; [39]).

The findings of Wu and Want (2005) indicated that all ID factors significantly affected users behavioral intent of mobile commerce [41]. Among them, the compatibility had the most significant influence. Diffusion theory is rooted in studies of mass media communications, and can be germane to field such as information systems and management [18]. From the above discussion about IDT factors, we assume hypotheses 3 to 7.

H_3: Perceived compatibility of the NFC mobile payment system has a positive effect on consumer's attitude of adoption for the NFC mobile payment system.
H_4: Perceived trialibility of the NFC mobile payment system has a positive effect on consumer's attitude of adoption for the NFC mobile payment system.
H_5: Perceived observability of the NFC mobile payment system has a positive effect on consumer's attitude of adoption for the NFC mobile payment system.
H_6: Perceived complexity of the NFC mobile payment system has a positive effect on consumer's attitude of adoption for the NFC mobile payment system.
H_7: Perceived relative advantage of the NFC mobile payment system has a positive effect on consumer's attitude of adoption for the NFC mobile payment system.

Effects of Consumer Adoption Attitude on Use Intention

In general, people perform behavior that is in accordance with their attitudes [14]. The TAM is a multiattribute model that predicts consumers' intentions to use a technology based on their perceptions of the user adoption attitude of the system [10]. Positive effects of attitude toward using an innovation technology on behavioral intention are proposed in the TAM [10], TRA (theory of reasoned action [14]), and TPB (theory of planned behavior [1]). Positive effects of attitude toward a behavior on behavioral intention are empirically shown in several studies ([1]; [10]; [14]; [28]; [29]). Therefore, hypothesis 8 can be formulated.

H_8: Perceived adoption attitude of NFC mobile payment system has a positive effect on consumer's use intention for the NFC mobile payment system.

RESEARCH METHODOLOGY

This study surveys consumer attitudes toward NFC mobile payment system chosen from Taiwan market. In addition, the questionnaire items are designed and then modified to make them appropriate for assessing attitudes toward NFC mobile payment system. Young consumers were chosen as survey targets. The data are collected over a period of two months (January to February, 2009). The research findings and suggestions are provided to examine the relationships among TAM, IDT and consumer adoption attitude and use intention for NFC mobile payment system. Data analysis methods used in this research include factor analysis, reliability analysis, and a linear regression method.

STUDY FINDINGS

This section discusses the data source and analysis results of the survey. Specific sites of Taipei County were chosen as survey sites. The population for this study mainly comprised young consumers. Over 240 questionnaires were issued, resulting in 220 responses. Of those received, 20 were removed because the responses were not valid. Thus, 200 responses were included in the final analysis. Based on the returned questionnaires, 42 percent of respondents are male, 58 percent of respondents are female. About 79 percent of the respondents are between 20 and 25 years old.

Factor Analysis and Reliability Analysis

To verify the relationships among the factors, the study performs factor analysis and reliability analysis using SPSS statistical package [27]. This entails a two stage process. Factor analysis is undertaken to identify underlying constructs from among sets of many

interrelated items. The principal - component method is used for factor extraction, with factor interpretation carried out by Variamax rotation.

Table 1 shows the factor analysis and reliability analysis for technology acceptance model. Two factors including perceived usefulness and perceived ease of use are produced using factor analysis. All factor loadings of variables exceed 0.8, while the α values of the item to total correlation exceed 0.8. Table 2 shows the factor analysis and reliability analysis for ID theory. Factors including compatibility, trialability, observability, complexity, and relative advantage are produced using factor analysis. With the exception of compatibility, trialability and observability, which have lower α values for the item to total correlation, all other factor loadings of variables exceed 0.7, while the α values for the item to total correlation exceed 0.6. Table 3 shows the factor analysis and reliability analysis for consumer adoption attitude and use intention. With the exception of use intention, which have lower factor loadings and lower α values for the item to total correlation, all factor loadings of variables exceed 0.7, while the α values for the item to total correlation exceed 0.7. The nine factors appear to be appropriate for next linear regression analysis.

Table 1. Factor and reliability analysis of technology acceptance model factors

	Factor Analysis		Reliability Analysis
	Eigenvalues	Factor loadings	α
Perceived usefulness			
Using the NFC mobile payment system can reduce the inconveniences of cash or credit card requirements of consumption.	2.19	0.87	0.81
Using the NFC mobile payment system allows rapid conduction of overall trade actions.		0.88	
It does not require a lot of time to learn how to use the NFC mobile payment system.		0.82	
Perceived ease of use			
I find the NFC mobile payment system is easy to use.	1.69	0.92	0.81
I consider the interaction design of the NFC mobile payment system is easy for me to understand.		0.92	

Table 2. Factor and reliability analysis of innovation diffusion theory factors

	Factor Analysis		Reliability Analysis
	Eigenvalues	Factor loadings	α
Compatibility			
Using the NFC mobile payment system fits well with my prior payment experiences.	1.66	0.71	0.59
Using NFC mobile payment system is a good complement to traditional methods.		0.77	
Use of the NFC mobile payment system still offers the original payment methods.		0.75	
Trialability			
Before deciding whether to use the NFC mobile payment system, I want to try its functions.	1.41	0.84	0.58
I want to spend time trying the NFC mobile payment system, in order to understand its functions.		0.84	
Observability			
I can talk about the NFC mobile payment system with my friends.	1.59	0.67	0.55
Benefits of the NFC mobile payment system are easy to understand.		0.74	
Under my circumstances, the services of the NFC mobile payment system are commonly used.		0.77	
Complexity			
The difficulty and complexity of use of the NFC mobile payment system is important to me.	1.83	0.72	0.68
Easy operating features of the NFC mobile payment system will attract me to use it.		0.80	
Using the NFC mobile payment system is very simple, which is an important consideration factor for me.		0.82	
Relative Advantage			
If the NFC mobile payment system can provide more complete and convenience services, as compared to current payment mechanisms, I will use it.	1.52	0.87	0.68
If the NFC mobile payment system can provide more value-added services, I will use it.		0.87	

Table 3. Factor and reliability Analysis of consumer adoption attitude and use intention

	Factor Analysis		Reliability Analysis
	Eigenvalues	Factor loadings	α
Adoption Attitude			
Using the NFC mobile payment system seems a very nice idea.	2.11	0.77	0.78
It seems a smart decision to use the NFC mobile payment system.		0.88	
The NFC mobile payment system seems valuable to use.		0.86	
Use Intention			
I will ask questions of consumer that have used the NFC mobile payment system.	1.46	0.55	0.43
I will recommend my friends use NFC mobile payment system.		0.87	
Using the NFC mobile payment system is very expensive; however, I am not concerned.		0.67	

One of the assumptions of regression analysis is that the residuals for consecutive observations are uncorrelated. If this is true, the expected value of the Durbin-Watson statistic is 2. Table 4 and Table 5 show that the values of the Durbin-Watson of the models are all near 2, which fit the requirement of the assumptions of regression analysis.

In Table 4, the results of regression model 1 and model 2 suggest that the perceived usefulness, perceived ease of use of consumer perception have positive effects on the consumers' adoption attitude concerning NFC mobile payment system. In regression models 3 to 7, significant results are obtained on the importance of ID theory: compatibility, trialability, observability, complexity, and relative advantages are important to consumer adoption attitudes concerning the NFC mobile payment system. Meanwhile, high usefulness, ease of use of NFC mobile payment system, and appropriate innovation diffusion methods: increasing compatibility, reducing complexity, high trial availability, ability to observe, marketing environment, and high relative advantages of new technology are helpful to the consumer's attitude concerning adoption of the NFC mobile payment system.

Table 5 compares the applications of TAM and IDT on consumer adoption attitudes. Model 8 shows that both perceived usefulness and perceived ease of use appear as significantly important to consumer's attitude of adoption of the NFC mobile payment system. Regarding the ID theory, among five factors, only relative advantages, and observability appear to significantly effect consumer's adoption attitudes. Both theory factors were considered in the regression, as shown in model 10, only perceived usefulness of the TAM and the observability of the ID theory appear to significantly effect consumer's adoption attitudes. Model 11 is the final model, which shows that if service firms and related IT firms could increase perceived usefulness and ability to observe the NFC mobile payment system, then the adoption attitude of consumers will be enhanced. Finally, model 12 indicates that adoption attitude appears to have significant effects on consumer's intention of use, therefore, if firms could apply the TAM and ID theories to increase consumer adoption attitudes, then the use intention of consumers could be effectively increased. In Taiwan, due to the familiarity of Easycard transit services, some respondents indicate that if Easycard transit services could be integrated into their mobile phone, convenience would be greatly increased. In this study, most young consumers, who are familiar with new technologies and expect new products, primarily consider the usefulness and ability to observe new technology products to be important when making purchase decisions. Therefore, perceived usefulness of the technology acceptance model and observability of the ID theory are most important factors of

market development strategies of the NFC mobile payment system for Taiwan young consumer.

DISCUSSION AND CONCLUSION

This study explores Near Field Communication system application in the Taiwan service industry. Consumers are surveyed and statistical methods used to verify key factors of a firm's innovation technology promotion strategy. The contribution of this research is to

incorporate TAM and ID theory key factors, as well as consumers' adoption attitude and use intention in order to construct a meta-dialogue for their relationships. Findings of the research provide support for the theoretical base that some TAM factors (e.g. [3]; [4]; [26]; [30]; [31]), and ID theory factors (e.g. [13]; [31]; [32]; [39]) do have a significant impact on consumers' adoption attitude and then lead to use intention concerning Near Field Communication system application.

Regarding the TAM model, the research findings indicate that increasing the perceived usefulness and perceived ease of use of the NFC mobile payment system will lead to higher degrees of consumer adoption attitudes. Therefore, if service firms could promote mobile payment systems, in terms of emphasizing the superior functions of NFC, such as real-time service, job utilities, and convenience, then the adoption attitudes of consumers will be effectively encouraged. Furthermore, the ease of use of the NFC system could decrease consumer psychological barriers and increase the intentions of consumer to use the NFC mobile payment system.

The analysis results of the ID theory show that perceived compatibility, trial availability, complexity, observability, and relative advantages of the NFC mobile payment system could effectively increase the adoption attitudes of consumers. In Taiwan, mobile payment service has not been broadly adopted by consumers. Therefore, the trial availability and ability to observe activities are required to plan and promote consumer trials to familiarize consumers with the new technology applications. Furthermore, low complexity is also important to consumers, while considering adopting the NFC mobile payment system. Compatibility of the NFC mobile payment system with original mobile phone systems are also important considerations for consumers. Finally, the infrastructure behind the NFC applications in service industry is complex and requires the cooperation on different levels to ensure interoperability and a thriving contactless scheme to be deployed [23]. The findings of this study suggest that consumer adoption attitudes will be increased if service firms could increase the relative advantages of the NFC mobile payment system, for example, through cooperation with omni bearing services, in terms of strategic business alliances, to provide more value-added mobile services, then, the attractiveness of the NFC mobile payment system will be increased in the consumer's mind.

NFC mobile payment systems are well developed throughout Europe and Japan, however, in Taiwan, the NFC system still has not been broadly adopted by consumers. Management implications and promotional strategies are suggested as follows: 1) Develop business operation models: Allow related firms to comprehend the advantages of the NFC mobile payment system, import, and integrate business operations and cooperative models to increase firms' participation intentions. When the perceived usefulness and relative

advantages and the NFC system, as compared to other general mobile or payment methods, appear, then the adoption attitudes of consumers will be enhanced. 2) Enlarging the service demands of consumers: mobile universal rates in Taiwan require strategies to increase consumer adoption attitudes, includes increasing compatibility (reducing adapted barriers) and decrease complexity (ease of use) of the NFC mobile payment systems. Design trial availability, and ability to observe marketing environments for consumers to experience the NFC system to enhance service demands. 3) Customization marketing: Designing various marketing activities from various channels or agencies, for example, acceptance degrees of young consumers concerning new technology applications are apparently higher than with the elderly consumers. Therefore, emphasizing the unique attributes and functions to young consumers is important, and emphasizing low complexity and relative advantages will interest elderly consumers.

The limitation of this research is that it is based on only 200 respondents. However, respondents who are involved in the adoption decision of NFC mobile payment system. Future research could extend the scope of samples, and add other discussion factors, such as age, risk attitudes, and various user types to expand the conceptual framework. A broader approach (e.g. multidimensional scale, structure equation model, etc.) would be valuable in analyzing the causal relationships among the factors.

INNOVATION INFLUENCE ON STRATEGIES OF ROMANIAN SERVICE FIRMS

Professor Cezar SCARLAT, PhD
cezarscarlat@yahoo.com
Lecturer Catalin ALEXE, PhD candidate
cataalexe@yahoo.com
University "Politehnica" of Bucharest, Romania

ABSTRACT

As the innovative potential of companies is increasingly becoming an engine of development, the literature deals with lots of related subjects – as innovation culture, innovation efficiency and investment in innovation, innovative technologies, innovation and strategy – to mention just a few of them.
In spite of its innovative potential, only 6.8% of Romanian entrepreneurs think that their firm brings on the market new or improved products and services; and the percentage of the innovators is lower than the one reported in the more developed countries.
Trying to identify the reasons, the paper presents some of the results of questionnaire-based research work, completed in 2005-2006, aiming at identifying links and correlations between innovation and innovative elements – on one hand – and the company strategy and decisions of the top management – on the other. Managers of 255 Romanian companies were subject of this survey – a significant number of them active in service industries as: consumer services; banking, investment, insurance; engineering, research and development; management consulting and business services; retail or wholesale trade; transportation and public utilities.
Conclusions are important for all business strategists and top managers of service companies.

Keywords: innovation, innovative technology, incremental vs. radical/disruptive innovation, innovation strategy, business strategy, service industry

INTRODUCTION: INNOVATION AND ORGANIZATION

Service firms can gain significant advantage by fostering innovation. Innovation is a powerful competitive advantage that is available to any firm that seeks and develops the necessary skills. Innovation depends more on the intention to innovate than it does upon corporate size and wealth.

In the global economy, to be innovative means to do something different and better than others (Ettile, 2006). To be innovative doesn't mean only to think creatively, but to turn creative ideas into something valuable for the organization and its customers, to bring extra-value. The success of the firms is intimately linked to the innovation (Peters, 1997).

Innovation is an active process. The companies which are not actively and continuously innovating are sentenced to failure, actually. The critical component of innovation focus is that it generates the learning capacity: "It is not so much the ability to operate at the global frontier which is important, but the capacity to continue to operate at a continuously expanding global frontier which counts" (Kaplinski, 2007: 82).

Innovation is beneficial to the firm if it leads to increased competitiveness. As Harrison reported (2002), the 1996 Global Manufacturing Futures Survey conducted in over ten countries and/or regions examined the correlation between investment in innovation activities and manufacturing performance improvements. It was observed that "those companies that are serious in implementing innovation management can identify significant operational improvements in performance" (Harrison, 2002).

Within organizations, it is not enough as one or more employees of an organization to be creative and have the intention to innovate so that we can talk about *innovative organization.* Organization creativity represents some average of the people's creativity within organization. Even if the creative potential of individuals is important, it does not mean that the organization's potential of innovation is high. The explanation: the people's creative potential in a firm can be ignored, underused or misused (Alexe, 2008).

It is not enough that managers deal with the rise in personnel creativity. In order to be innovative, entire organization as a whole has to offer an adequate framework for development and valorization. The rate of innovation in an organization depends on the management capability to create this context of updating the creativity throughout the organization. Therefore, good ideas are left disconnected and, often, they are lost. The solution is setting up an *innovation culture* (Scarlat, Alexe, 2008). Innovation culture and entrepreneurship are intimately correlated (Scarlat, Alexe, Simion, 2008).

The Innovation DNA Model[1] presents the innovation culture as one of the eight dimensions that are the basis of innovation within an organization:

1. Change, ideas, passion and trends. These are the innovation drivers. They provide the stimuli needed to start the innovation.
2. Challenge. The bigger the challenge and the passion behind it, the more energy the innovation efforts will have.
3. Customer focus. Innovation finally leads to create value for the customer. Interacting with and understanding the customers' needs are one of the best stimulators of new possibilities of innovation.
4. Creativity. The start point in innovation is the creativity and it follows up providing of potential useful ideas. Innovations means to bring successfully on the market a creative idea among many other possibilities.
5. Communication. Open communication of ideas, information and feelings is the lifeblood of innovation.
6. Collaboration. Innovation is a group process. It feeds on interaction, information and a shared vision.
7. Continuous learning. Learning from completed projects is favorable for the innovative projects that will come up.
8. *Innovation culture.* Creating an environment that honors ideas, supports ideas generation and communication, tolerates risk and may be the biggest challenge facing all organizations that want to be innovative.

Innovation is supported, more or less, by several types of organizational cultures – but an innovative culture is not achieved easily and requires strategic thinking (Angel, 2006). There is no guarantee that a breakthrough organizational culture will lead to innovation, but it certainly is a prerequisite.

The recent experience in Sub-Saharan Africa demonstrates that (excluding South Africa) the only significant manufactured export has been clothing while opportunities in service industries are neglected. Therefore, "the focus for development strategies targeting sustainable incomes needs to shift from industrialisation to innovation, and within that, to the endogenisation of learning capabilities in an appropriate comprehensive innovation strategy" (Kaplinsky, 2007).

The organization innovativeness is influenced by factors as external environment and organisational structure, and the firm's dynamic capabilities, which are relevant to managerial and organisation processes (Spanos and Prastacos, 2004). Based on survey data drawn from a sample of leading Greek firms, they have shown that the firm's dynamic capabilities, even though environmental and structural variables, seem to exert a significant influence on product innovation strategy.

Traditional organizations embrace their past, as a rule, they stick to a winning formula and seek for more efficient ways of achieving objectives and minimizing risks. Many times, we meet in these firms a culture of low risk, which leads to *incremental innovation*. Most of the innovative activity at the industrial enterprise level is incremental innovation. It focuses more on products and less on processes. Incremental innovation brings small changes every time; through accumulation, in time, it can lead to bigger changes, as it is received favorably by old producers on the market, because of lower investments and risks.

Radical innovation brings substantial changes associated to larger investments and risks, and offers opportunities to some new producers to enter the market. Once a radical innovation is brought in on the market, many and various incremental innovations spring around.

Based on a Norwegian case study, Hagen (2008) describes the new concept of environmental innovation and the way it is presented in the firm's strategic and identity documents. It could be either incremental or radical. The study suggests that the incremental innovation is stimulated by integration of industrial ecology into the corporate saga – while the radical environmental innovation is, however, hindered by such integration: radical innovation means discontinuity and confrontation with the dominating history of the company (Hagen, 2008).

The way from the incremental innovation to the radical one goes through broader and broader innovative activities which imply higher risks, but an increased degree of creativity. Incremental innovation assumes a series of processes which are more or less creative (even the attempts to copy the novelties occurred on the market due to the competition, imply time and again intense efforts of creative adjustment).

McFadzean's paradigm: Although innovation management is much more complex in case of radical innovation, the incremental innovation requires a larger volume of knowledge about the innovation management (McLaughlin, Bessant, Smart, 2000).

There are significant differences between organizations oriented towards incremental or radical innovation as far as organizational structure, procedures, human resources, methods of work, management systems and final results (Table 1).

Table 1. Differences between incremental and radical innovation

Incremental innovation		*Radical innovation*
▪ Formalized ▪ Centralized ▪ Systematic	*Procedures*	▪ Un-formalized ▪ Decentralized ▪ Loosely structured
▪ Functional ▪ Efficiency oriented	*Organizational structure*	▪ Facilitating knowledge gathering ▪ Supporting risk taking
▪ Homogeneous ▪ Older and experienced	*People*	▪ Heterogeneous ▪ Younger and entrepreneurial ▪ Ambitious ▪ Technical ▪ Questioning
▪ Mature ▪ High inertia ▪ Focus on efficiency ▪ Focus on team-working ▪ Continuous improvement ▪ Low investments ▪ Minor risk taking	*Characteristics of the organization*	▪ Entrepreneurial ▪ Emphasis on intrapreneurship ▪ Focus on discovery ▪ Individual co-operation ▪ High investments ▪ Major risk taking
▪ Cost reduction ▪ Feature addition ▪ Efficiency improvement	*Focus*	▪ Experimentation ▪ Creativity ▪ Foresights ▪ Psychology ▪ New methods and technologies ▪ New products
▪ Mostly existing	*Products/Technologies*	▪ Mostly new
▪ Linear ▪ Predictable	*Processes*	▪ Non-linear ▪ Explorative ▪ Experimental
▪ Between 6 - 24 months	*Periods for notable and practical achievements*	▪ Between 2 and 7 years
▪ Develop systems to make knowledge accessible across the organization	*Knowledge management*	▪ Knowledge is created and managed within the team
▪ Collaboration over various projects ▪ Long-term agreements	*Partnerships*	▪ Partners provide access to capabilities that the organization lacks
▪ Monitor current competitors and current eco-system	*External monitoring*	▪ Monitoring idea generation places-universities, labs, startups
▪ Exploitation	*Management*	▪ Exploration

Source: After McLaughlin, Bessant & Smart; Davila, Epstein & Shelton (2007)

Mature firms are less interested in radical innovation, as the mechanisms that allow them to be successful become inhibitors to innovation. Major risks involved by the radical innovations are more difficult to be accepted by larger firms.
Entrepreneurs with new and daring ideas are those who made breakthrough innovations within the framework of some small firms; their wish to put into practice their own ideas is much stronger than the assumed risks; economic and financial calculations are overtaken by their dreams.

Christensen (2003) has analyzed the innovative technologies, as *sustaining and disruptive technologies*. While the impact of sustaining technology is to improve the product's performances incrementally, disruptive technology represents discontinuous jump forward in product's performance. Based on the RPV framework[2], Christensen developed the model of strategic decisions in case of innovative technologies: *The strategic decisions are affected by these factors; success or failure of implementing the disruptive technologies do not depend on resources but processes and values.* When the capabilities (processes and values) required by the innovative technology do match with the current organization's capabilities, it is a matter of resources only – for a successful technology implementation.

The new technologies lead to process renewal. The "old and proven way of doing business" requires changes in the operational mode. However, in today's turbulent business environment, new technologies, continuous innovation and changes may cause chaos in the prevailing circumstances (Suikki, 2007). As the process renewal driven by disruptive technologies differs from management-driven process renewal, appropriate methods and deep understanding of the process should be used in each case. Suikki (2007) describes how the process renewal driven by disruptive technologies in the Nokia case unit was successfully managed, in the turbulent telecommunications business environment. The challenge was solved using a combination of adapted processes, focusing on the customer, and competence development.

Innovative technologies substantially diminish the personal interaction in service provision. Walker and Johnson (2004) discuss the implications of the diffusion of the technology-enabled service innovations.

INNOVATION AS NATIONAL STRATEGY

In many countries, innovation is part of the government policy. Just a few examples will follow.

- Since 1997, the Labour government in the UK has promoted policies of competitiveness and innovation, assuming the role of "enabler of a knowledge driven economy" – in order to stimulate competitiveness and define a third way between market-led economic policies and state intervention (Druker, 2003). However, the evidence "suggests that the rhetoric concerning the government's role as an enabler of innovation is stronger than the reality".

- Nigerian government is focused on information technology education and the National Information Technology Development Agency is a national initiative designed to dramatically improve the country's competitiveness in computer industries. Ariguzo et al. (2007) have investigated the effectiveness of public-private partnerships in IT and communication industries in Nigeria and provided recommendations for Nigerian Higher

Education Institutions and IT businesses in order to develop effective IT&C public-private partnerships.

- The Korean government has taken policy initiatives for the long-term planning of national innovation (as the promotion of basic research, the increase of national R&D investment, strengthening human resource development). Other important issues promoted: start-up of technological innovation ventures, international patents, scientific publications, and the private research institutes. According to the research conducted by Lee and Kwun (2003), the Korean government policies are characterised as government-initiated, target-oriented or plan-based, and input-focused – "which has caused its inability to tackle existing problematic practices ... as under-utilisation of research resources in universities, ... and created such unexpected problems as ... loss of entrepreneurship among venture businesses ..." Overall, the Korean public innovation policies "are undergoing the test of reshaping in their progress to a knowledge-based economy" (Lee and Kwun, 2003).

- Taiwan was very successful in using tax incentives, science-based industrial parks and public research institutions to promote and encourage R&D and innovation. The government has largely used new instruments (venture capital, innovation incubators, an open laboratory system, and e-commerce) but "the effectiveness of these policies cannot be assessed at this moment because they are too new" (Lee and Wang, 2003).

- In Thailand, Virasa (2007) has developed an analytical model to analyse the gap in government support for New Technology-Based Firms (NTBFs), which integrates the characteristics of NTBFs and various dimensions on entrepreneurial process and technology commercialisation. Benefits of this modelling process and a series of suggestions for public interventions on fostering entrepreneurship and innovation are presented.

The radically changing business environment opens new opportunities and forces the organizations to reshape their strategies. In their study on the service industries in Finland (electricity distribution, telecommunication industry in the beginning of the 1990s), Bergman et al. (2008) provide guidelines for future-oriented innovation management - for companies as well as for public authorities.

As cited by Kaplinsky (2007: 80-81), Lall and Teubal (1998) have provided a theoretical architecture and a three-level framework for developing innovation policies:

i. *Functional policies* – designed to improve market operations (as competition policy; trade tariffs).
ii. *Horizontal policies* – which cross sectors (as incentives to promote R&D training).
iii. *Selective policies* – designed to promote the advance of particular sectors (as preferential access to capital; sector-specific subsidies), particular regions or particular firms.

According to the same author (Kaplinsky, 2007), Broadman (2007) proposes an export-oriented innovation policy framework in Sub-Saharan Africa as comprising of a mix of Behind the Border (predominantly infrastructure), Beyond the Border (predominantly market access) and Between the Border (predominantly logistics) issues.

In 90s, the centralized totalitarian regimes have collapsed in Eastern Europe. The transitional changes have changed the economic and social landscape in the region. Kutlaca (2008) explores the main consequences of these transitional changes in the R&D sector in Serbia, which are partly oriented towards the creation of an innovation infrastructure.
The qualitative analysis of the effectiveness of the innovation infrastructure leads to the conclusion that public awareness and acceptance of innovation infrastructures are rising; political and financial support are larger and larger; the number of innovators is rapidly increasing; and the R&D sector has been integrated into the Science and Technology and Innovation system (Kutlaca, 2008).

In Romania, the National Strategy for Research, Development and Innovation (2009-2013) is currently in force – as result of a large consultation process, including the first national foresight exercise (2005-2007) led by the National Council of Scientific Research in Higher Education.

INNOVATION AND STRATEGY IN ROMANIAN SERVICE INDUSTRIES

In spite of its innovative potential, Romania does not document the same optimistic view on the business side: According to EUROSTAT Report (2006), only 6.8% of Romanian entrepreneurs think that their firm brings on the market new or improved products and services. The rest of the interviewees were satisfied to imitate the competition.

The percentage of the innovators is lower than the one reported in the developed countries – such as Luxemburg (25.8%) or Sweden (39.9%) – and neighboring emergent economies or ex-communist countries as Bulgaria (9.6%) and Czech Republic (19.6%).

Trying to identify the reasons, both secondary and primary researches were conducted. Secondary research completed in 2005-2006, among the professional associations led to the list of potential interviewees, Romanian companies with more that 5 years of activity. Managers of Romanian service companies were subject of this survey – companies active in service industries as follows:

- Consumer services (36.5%)
- Retail or wholesale trade (25.8%)
- Engineering, research and development (13.8%)
- Management consulting and business services (7.5%)
- Transportation and public utilities (5.7%)
- Banking, investment, insurance (4.4%).

Simultaneously, as result of several focus group analyses, a questionnaire was developed, aiming at identifying links and correlations between innovation and innovative elements – on one hand – and the company strategy and decisions of the top management – on the other. The innovation rate was defined as “the percent of the company’s revenue generated by products that did not exist three years earlier”. There were considered four “grand strategies”: stability, internal growth, external growth (by acquisitions), and retrenchment strategy.
The questionnaire was addressed to top-managers. 255 valid questionnaires were analyzed.

The data processing has revealed the following results:

- Almost one third are companies that reported innovation rate under 20% (17.2% companies under 10% innovation rate and 13.0% companies with innovation rate between 10%-19%).
- Almost half of the companies (47.1%) reported innovation rate between 20% and 50%.
- More than one fifth of the surveyed companies reported high and very high innovation rates: between 50-70% (11.8%) and over 70% (10.9%) respectively.
- Most of the companies declared stability (43.9%) and internal growth (33.5%) as their predominant strategy; 15.1% were in difficult situation as their strategy was retrenchment; only 7.5% of the companies have grown by acquisitions.
- Correlation analysis has suggested no strong correlation between innovation and grand strategy. However, two significant aspects should be mentioned:
  - All companies that grew up based on acquisitions have innovation rate superior to 10%; half of them reported innovation rates between 30%-50%;
  - Two thirds of the companies applying retrenchment strategies have innovation rates under 30%.

Other comments on the qualitative aspects:

- Lacking the financial resources to purchase licenses, patents and know-how, the modernization of the processes and products is achieved through imitations that have a bigger or smaller success depending on the organization's capacity of change, abilities, knowledge, and *personnel's creativity.*
- In the absence of their own innovation activities, many Romanian firms do have an imitation behavior: to transfer the successful innovations from the developed economies into Romanian economic context; consequently, the technology gap has deepened.
- For most imitators, the effort to imitate is significant; more significant when the firm is rather new, inexperienced, and less prepared technologically.
- There were cases of successful imitators who creatively adjusted the products and services, which has led to incremental innovation; imitators have had increased chances to succeed as they improved the original innovation model, becoming innovators themselves.

Conclusions are important for all business strategists and top managers of service companies.

CONCLUSIONS

In order to be competitive, firms have to innovate. The innovation culture is the ideal environment. As part of the innovation process, according to the intensity of the firm's strategic and structural change, incremental or radical innovation is possible. Incremental and radical innovations are associated with incremental and disruptive technologies, respectively. Incremental changes have the role of spreading base technology within the firm, while the radical innovations represent breakthroughs so important that they have to be sustained by an essential change of the organizational culture and firm's structure. As the incremental innovations may not involve major changes in the enterprise's strategy, they do not always cause the change of the enterprise's organizational culture and structure.

The growth of the Romanian service firms is based on incremental technological progress rather than radical, disruptive technologies.

In Romania, among the service companies, there is no strong correlation between innovation and grand strategies. However, it seems that less innovative firms are mostly firms in difficulty as two thirds of the companies applying retrenchment strategies have innovation rates under 30%.

The research suggested that innovation has a role in external growth of service companies: all companies that grew up based on acquisitions have innovation rate superior to 10%.
Half of the firms that aggressively grew up by acquisitions report relatively high innovation rates (30%-50%).

In the absence of their own innovation activities, many Romanian firms do have an imitation behavior: to transfer the successful innovations from the developed economies into Romanian economic context. Consequently, the successful imitators become innovators themselves but the technology gap is deepening, overall.

ABSTRACT

In this paper, we propose an intellectual capital view for understanding how successful software reuse really takes place in the software development companies. We present two different cases on how the reuse of the code is arranged, based on different management philosophies that again have their basis on different corporate situations: software reuse based on "ad-hoc" specialists and software reuse based on libraries and repositories. Our "ad hoc" case spreads human capital to organizational use through social capital, while our other case uses organizational-capital systems to spread the human capital and knowledge for software reuse. We suggest that these two systems would be in play in different types of companies; the ad-hoc social capital reuse system in small, young, or with simple products; organizational capital reuse systems more typically with more established, bigger, distributed, or with complex products. However, practical implementations seem to depend very much on the actual situation that can be a combination of the cases we suggest here, which could require combining human capital with either social or organizational capital or even with both; so, even code reuse, which would seem to be a very structurable activity, is clearly contingent.

INTRODUCTION

The success of software development companies depends on their ability to generate, assimilate, reuse and leverage their knowledge (Desouza, Awazu and Tiwana, 2006). This ability to leverage valuable existing knowledge internally is critical to building competitive advantage because of both the scarcity of valuable internal knowledge and the difficulty and expense of creating new knowledge (Szulanski, 1996). Software reuse is a software *process* innovation in that it shifts the focus from developing software artifacts for a single product to developing them for a future family of applications (Sherif and Menon, 2004). Developers reuse and recombine knowledge early in their involvement with the project, and then continue to work and contribute novel software code while refining the software product (Von Krogh, Hafliger and Spaeth, 2006). Software reuse already exists within most organizations, and is promoted by systems standards such as CMM and its derivatives. Nevertheless it's rarely discussed because it usually starts and ends in an informal way, with management having little understanding of how it started, why it persists and how they might proactively extract larger benefit from it (Lior and Jan, 2005).

Thus, we propose an intellectual capital view for understanding how successful software reuse really takes place in the software development companies. Three subcategories of intellectual capital may be considered (Subramaniam & Youndt, 2005): human capital, organizational capital and social capital. Given that the three parts of intellectual capital are interdependent, we want to analyze how they could interact for improving the innovation results of software reuse.

In this paper we present two different cases on how the reuse of the code is arranged, based on different management philosophies that again have their basis on different corporate situations: software reuse based on "ad-hoc" specialists and software reuse based on libraries and repositories. Although some people hold that knowledge repositories play a relatively unimportant role in knowledge reuse, arguing that face to face communication and good knowledge sharing processes are the keys to successful knowledge reuse, others are much more persistent about the potential for formal repositories especially in big software projects (Markus, 2001).

We thus propose that each of these different processes of knowledge reuse uses, as the main source of knowledge, different combinations of the elements of Intellectual Capital. The conclusion we make is that human capital processes are the key factor for software reuse, and investment in human capital is a good way to improve the code reuse processes. However, practical implementations seem to depend very much on the actual situation, which could require combining human capital with either social or organizational capital; so, even code reuse, which would seem to be a very structurable activity, is contingent.

Intellectual capital processes

With few exceptions, productivity in modern firms is based on the intellectual competence and system capabilities of the firm rather than on *hard assets* (Quinn, Anderson & Finkelstein, 2005; Boekestein, 2006). Managing the intellectual capital is a challenge especially for companies such as the software development companies, whose main resource base is their knowledge resource (Schoemaker and Jonker, 2005). Research focused on the analysis of this kind of companies provides interesting arguments clearly connected with the statements of the intellectual capital framework, even if the correlation between intellectual capital (as reported in intangible assets on the balance sheets) and company performance are not always visible (Boekestein 2006; however, Wang and Chang, 2005 and Lee, Lee and Lin, 2007, claim the opposite in their ICT and e-business studies). In theory, intellectual capital should be of greatest importance in innovative and knowledge-based fields (Cunningham, 2002; McElroy, 2002; McElroy, Jorna and van Engelen, 2006).

Three subcategories of intellectual capital may be considered (Subramaniam & Youndt, 2005): human capital, organizational capital and social capital. Sawyer and Guinan (1999) correspondingly highlight three perspectives in software development processes: the individual, the production, and the social perspective. In this paper, we illustrate with the connections of these subcategories of intellectual capital to software reuse within the software development process; we claim this may be the stage where human capital produces especially good return-on-investment.

Human capital, as a part of the intellectual capital, concerns the individual level and refers to knowledge and capabilities of employees who belong to the firm. Through selection and training processes managers may develop correct type of human capital to achieve the organizational aims. In many ways, human capital is comparable to the *individual perspective* of software development, which focuses on the unique contributions of individuals to the development team. Following Sawyer and Guinan (1999), issues from an individual perspective can include, for example, the degree of experience and skill that each software developer contributes.

For improvements in the human capital, or the human perspective of the development process, companies should design the selection and training processes that assure the level of

knowledge and capabilities of individuals that are needed for the company to run its main tasks. The sum of the employees' knowledge doesn't, however, guarantee that the knowledge of the firm (intellectual capital; Nahapiet & Ghoshal 1998) is a real competitive advantage (Bueno, Salvador and Rodriguez, 2004; Schoemaker and Jonker, 2005). Because of this, two other levels of knowledge must also be considered. Even when companies have exceptional individual talents, their contribution to their organization will not be significant unless their knowledge is networked, shared, and channelled through either institutionalized and formal mechanisms or interpersonal relationships (Subramaniam & Youndt, 2005). This would imply that companies that aim at reaching a competitive advantage through their knowledge resources should adequately manage the other two sides of intellectual capital, that is, organizational and social capital, which are also explored in this brief study.

Organizational capital corresponds to those aspects of explicit knowledge that may be documented and proceduralized. This can be particularly relevant for ICT companies as a way to preserve the knowledge generated within the firm. In these businesses, codification and documentation of the new software developed is essential if the companies do not want to risk that this knowledge only resides in the mind of the individuals involved, or if they want to make knowledge available for other individuals in the organization in a definite format. Organizational capital also implies the establishment of structured recurrent practices (Subramaniam and Youndt, 2005) and norms (McElroy, Jorna and van Engelen, 2006). This kind of knowledge is connected with the *production perspective*, which refers to how individuals should conduct the work, and it seeks to underscore the repetitive, predictable, and manufacturing-like aspects of software development. Reducing the variation in the development process, making the development process more routine, developing specific guidelines for how to best address common tasks, and making tools available to support these efforts, are seen as the central questions (Sawyer and Guinan, 1999). Organizational capital may become an important systematic source of knowledge for software reuse activity.

Social capital is the set of resources generated by interpersonal networks that are, therefore, embedded in and available within these networks (Nahapiet & Ghoshal, 1998). Collaboration and interaction among people are the bases for building social capital (Subramaniam & Youndt, 2005). For Sawyer and Guinan (1999), the *social perspective* focuses on how the software developers work *together* to produce software. This includes both informal communication and intra-group coordination activities such as discussing how activities will be performed, finding and taking the time to talk with other team members, resolving the conflicts that arise in the course of working together, and sharing of ideas and information (Sawyer and Guinan, 1999; Hoffman, Holscher and Sherif, 2005). Sometimes, software reuse may be based on social capital as an "ad-hoc" source of knowledge.

Software reuse: a specific form of organizational learning

There must be an organizational foundation in place for the software reuse to succeed, since many products are supposed to be built by the same building blocks made by domain-specific engineers ("product line approach"). The reuse process puts certain requirements on the code itself (e.g. robust open interfaces) but in order to build a system from existing assets, rather than building from scratch for each new application or customer, also some managerial requirements exist (Brownsword and Clements, 1996):

-definition of an organizational structure with the product line in mind, including core assets and the customer specific products with non-core functionality

-definition of the new product family members from the core assets with customer-specific requirements, and

-definition of a process for adding functionality to the core product line assets as required.

The idea of software reuse, thus, is based on knowing what pieces of functioning code that already exists, and then recognizing the need of one of these pieces and being able to find it easily; "collect, evaluate, and make available to software projects reusable software assets", "maintain the reusable assets by storing and providing an identification mechanism" and "incorporate reusable software assets into new or existing applications" (SEI 1996). The pieces of code that can be reused are, by the SEI definition, assets (=capital) of the organization. The most common reusable software entity types are processes, data and objects.

Depending on the level of abstraction of the software resources, the reuse process can be organized in different ways. For the most concrete resources, to a large extent the reuse of these assets can be gained by a mixture of organizational discipline and the use of some relatively mature technologies such as data dictionaries, database management systems, and version control software. Nevertheless, many researchers contend that larger savings can be obtained by the reuse of more abstract resources. This is because the cost of coding is generally only a small portion of the total development cost. At the most abstract level, experienced designers and programmers reuse internal "informal" software resources such as design and coding rationales learned from experience. The difficulty is gathering and representing this tacit, implicit knowledge so that others may benefit from it in their productive activity (Kim and Stohr, 1998). Thus, from our Intellectual Capital approach, the reuse of the most concrete software resources would be based mainly on the organizational capital, while the reuse of the most abstract software resources would be based mainly on social capital. We also assume the social capital solutions to be more effective in small units where everybody is in tight contact with the others, and the organizational capital solutions would become necessary for practical reasons when the unit size (and/or the complexity of the software) increases. Anyway, both of these methods must have their origin in the human capital system of the organization.

The software reuse through social capital is close to Schein's statements about learning. It seems (Schein 1997) that a great deal of the tacit cultural learning in an organization concerns persons' roles and past heroic deeds such as success in difficult tasks; mostly people know who has done something even if they do not know the details of what has been done. Since people use others as "external repositories" of information, they may provide answers to questions that are far beyond their own personal expertise. Thus a memory system of a group is larger than memories of its members. It develops over time and may be understood as a property of the group. The main stream of research on transactive memory is based to on the seminal work of Wegner (1986, 1995) who defines a transactive memory system as "a set of individual memory systems in combination with the communication that takes place between individuals." (Wegner, 1986), which represents a phenomenon close to the idea of social capital.

Some individuals may be recognized as experts in certain domains. In such a case they become responsible for encoding, storage and retrieval of any incoming information relevant to this domain. Other members of the group deliver new appropriate information (e.g. their own successful, innovative, pieces of code, or problems they themselves cannot solve) to them, thus storing this information externally in the experts. People may be recognized as experts on the basis of their personal expertise or as a result of circumstances in which they take responsibility for the information encountered by the group. Clearly, these processes

require that experts have been identified. In other words, this means people know who knows what. These "directories" are created and updated during the process of directory updating, but they cannot include the complete learned "sum" knowledge of the organization. Furthermore, all these processes require at least reasonably complete communication between members of the group.

Cohen & Levinthal (1990) and Helo & Kekäle (2006) claim that the work group-level learning is a path-dependent process. Cohen and Levinthal state that prior knowledge permits the assimilation and exploitation of new knowledge. This prior knowledge "should be closely related to the new knowledge to facilitate assimilation, and some fraction of the knowledge must be fairly diverse, although still related, to permit effective, creative utilization of the new knowledge" (1990:206). This idea is based on the preferred selection idea (Barabasi 2002) and the thoughts on transactive memory presented above: whenever a difficult task arises, any individual faces the options of either solving it by him/herself, or asking for help from somebody. In a system where the transactive memory of who knows what is effective and communication channels are well developed, the individuals tend to prefer asking for the person with the right kind of knowledge and skills for help, for the benefit of the project. If there are no mechanical code libraries or repositories, "lending" code from others very probably works in this way: the person who earlier has a working piece of code is recognized through either some kind of "expertise" list, either hard-copy or mental, or then through word-of-mouth on who has coded what in recent times.

However, only for the person who originally wrote the piece of code solves the problem based on his/her previous skills; the "reuser" typically gets only to work with the implementation problems. The learning of the original author of the piece of code becomes embedded in a way Cohen and Levinthal state (1990:136): he/she firstly learns by accumulating capacity to do the next similar task more effectively than the previous; but this accumulated capacity also makes him/her better suited to study intermediate or new but related technology advances, thus again accumulating his/her expertise in relation to that of the others. For the original problem stating person, the learning is of transactive memory character only. Similarly, persons who participate centrally in the definition of the product family ("domain analysers") identifying the platform model and identifying the allovable variations for each application will become the best (or often, the only) experts in product-line interfaces. This leads, over time, to centralization of knowledge about the most difficult tasks to few individuals in the organization in a power-law fashion. Thus, even in organizations where there is no computerized or paper-based code library, the members of the organizations start to use some of the more knowledgeable specialists as code repositories.

When the size of the organization increases, or the organization otherwise wants to improve the process e.g. against the CMM-i criteria, normally a systematic reuse process with a computerized library for the reusable software assets is built.

This leads us to analyze the software reuse through organizational capital, which represents the most explicit and systematic way to reuse the knowledge. It requires that the reuse is planned, that is, the organization develops explicit reuse processes and standards and, in particular, invests in the up-front development of reusable resources (Kim and Stohr, 1998). At this case, as these authors propose, software reuse can be seen as a clear process which includes several steps:

- Analyzing existing software resources to identify those that are suitable for reuse.
- Classifying and cataloging the identified reusable software reuse.

As result of these two steps, a library of software resources is developed. Furthermore, the following is needed:

- Specifying requirements for the new system.
- Retrieving appropriate reusable software from the software library.
- Understanding and assessing the functionality of the selected resources in order to use or modifying them.
- Modifying software resources, is necessary when the retrieved software resources do not exactly match the requirement specifications.
- Building new software resources is necessary when thera are no similar software resources in the software library for some requirements.
- Integrating the new and reusable software resources into the target software system

For Kim and Stohr (1998), there is a need to determine the most effective techniques in each of this phase of the reuse process and to develop an integrated and standardized approach that can be readily understood and adopted by a large community of software developers. Furthermore, the use of application generators in software reuse provides automated support for all the processes described. Thus, the idea of software reuse based on organizational capital is even clearer when the organization uses this kind of tools for software reuse.

The tools for making this process work include, except for the libraries/repositories, also tools to aid in the integration of the architecture, design and modifications, as well as configuration management tools to aid tracking the evolution of the product line (see e.g. www.scorpus.com, www.blacducksoftware.com, twitter.com/swreuse). Some pieces of software even can create new software by itself from the parameters the users choose (see Czarnecki and Eisenecker 2000).

In the case of such a computerized (or actually even a paper/file-based) code library, the library develops in quite the same way. Especially pieces of code that are used by common operations such as converting information between well-known formats, accessing external storages, interfacing with external programs, or general manipulations of information benefit from copying from a library that contains generic, well-tested pieces of software – but the library has to be acquired and configured, and the users must learn how to use the library, as well as what is in there. In order to make organizational capital by what has originally been individual human capital, the information must be stored in the libraries/repositories in "thick" (Geertz 1973:3-30) format, including usage details, change history and knowledge associated with the changes, context of applying the knowledge units along with the dependent software assets, as well as the knowledge units themselves. In ad-hoc repositories the specialist who has the code piece may reveal all these details when giving out the piece of code; in computerized libraries, he/she may not be available, or maybe not even alive.

To conclude, in both types, either ad-hoc (based on social capital) or systematic-processed (based on organizational capital) of software reuse, the human capital of the individuals is required. As Kim and Stohr (1998) state, even with a favourable climate and the best intentions, software reuse can be limited because it is difficult from a cognitive stand point. This applies to both the producers (who must understand the application domain) and consumers (who must understand the reusable resources before they can reuse them). Then, human information-processing capabilities are important deterrents to software reuse.

Figure 1 shows the two processes described.

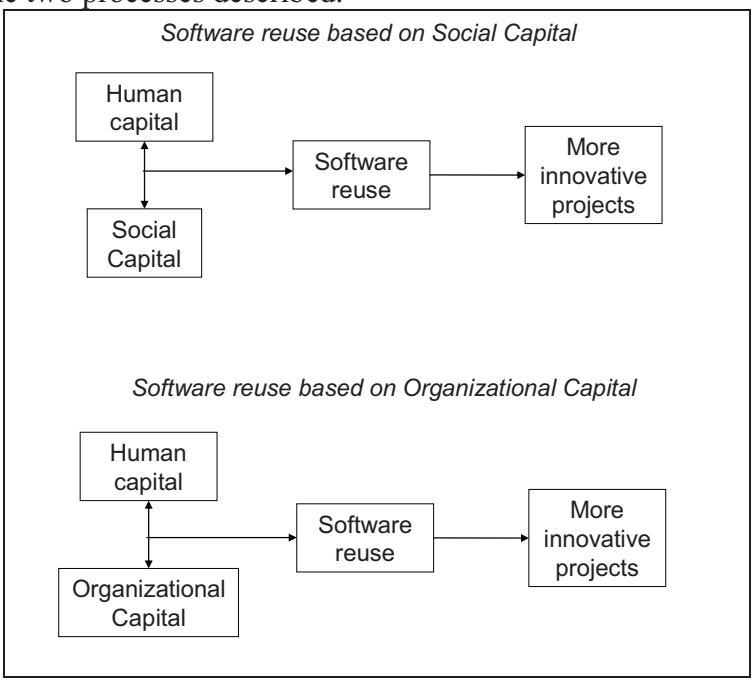

Figure 1. Software reuse based on Social Capital and software reuse based on Organizational Capital.

CASE 1: Ad-hoc "repository"

In a small software company "X" (that has since our intervention grown to a more than 100 persons through acquisitions, and also acquired software to aid code re-use) we noticed a very fine and typical ad-hoc knowledge reuse pattern when interviewing and modeling the activity in 2007. In small companies, especially when making relatively complex software to a multitude of customers, not everybody can be specialist of everything. Distributed knowledge in such a company typically refers to the situation when separate network actors bring different types of knowledge in the process (individual human capital), that allows the group as a group to accomplish difficult tasks in a flexible way. Further, people usually have through discussions, interaction etc. developed their own ideas of who knows what, that in other words can be called their cognitive perceptions of the knowledge networks of the company – or, by a more theoretical construction, social capital. These perceptions may be incomplete and/or inaccurate but they do exist, and should, according to theory, get more accurate over time when the common activity continues.

QuickTime™ and a
decompressor
are needed to see this picture.

Figure 2. Programmers asking for help from others to build code at "X" (the network is drawn here so that the "asking for help" goes from left to right, and the programmers who haven't asked, or haven't been asked, for help at east once a month have been left out; original N=40, but only 10 programmers were in the "frequent-contact network"). Legend: yellow line: about once-monthly request for help; red line: about once-weekly request; and black line, about daily request for help with the code.

The programmers who were working at X (40 engineers aged 20 and 34, all within the same physical premises in an open office floor partitioned by loose half-height cubicle walls) were asked to list the five colleagues that they most often asked for help in their tasks, and for each of these also to assess the number of times they requested coding help from these during a typical month. It turned out that asking for help was much less common occurrence than what was expected. Only a few persons "ever" had asked a colleague to help with difficulties in software programming (total N= 40, edge values relate to the number of times help was asked on average within a month; the 30 outsiders with edge value of 1 or less omitted in Figure 2). While this study was conducted without names, on request of the management at "X", we do not know for sure what kind of programmers asked whom for help; it might make sense that the persons requesting help might be the relative newcomers to the company and its product family at that given moment. However, in line with the previous theory, most of the events where programming help of some kind, such as ready-made modules or "earlier solution models" was needed included one of two "knowledge repository persons" at the company.

We then arranged for an interview with these two central persons in the expertise network. While the management again refused (for competitive reasons) to reveal the identities of the two, this interview was conducted by the secretary of the company according to our list of questions. Naturally, in such a setting, a complete thematic interview – that would have led us towards the "why" – was too difficult to arrange. However, even with this small-scale interview we managed to confirm that the solving of others' problems is a necessary source of increasing expertise. Individuals 5 and 7 stated that as much as between 10-20 % of their individual human capital (software coding skill) are solutions derived from solving others' problems, 40-50 % from their own previous coding, and the rest from their education (the answer alternatives for this question were for simplicity of analysis classified "none", "less than 10 %", 10 to 20 %" and so on).

Furthermore, another important finding in X was the unanimity of the other workers; it seems that a full 100 % of the "transactive memory", of the knowledge on who knows what and thus also the future preferences on where to find help (social capital), is due to the previous events where the experts have managed to help. No telephone books, knowledge catalogues, knowledge brokers or such were used in this smallish company. This would suggest that in an ad-hoc system, the organizational capital develops through the social stories, chats, legends and myths of organizational "heroes" precisely as culture is seen to be strengthened (Hatch 1993), and after that this informal organizational capital helps to strengthen the previous preferences on where to ask for help, which again at least to some extent leads to increased expertise among the preferred experts. Thus, in ad-hoc systems, the organizational capital seems to strengthen itself over time through the interaction of social capital and individual capital.

CASE 2: Systematic re-use process

Company Y was founded in 2000 for developing specialized software. Around that time interesting opportunities were emerging in the ICT sector in Spain, spurred by a new regulatory context that set the base for using the "electronic signature". With these new norms, there appeared to be an opportunity to promote also electronic public services that require a formal identification of the user.

Y was able to take advantage of this opportunity, and its founder and CEO created a very qualified team for developing this kind of software, mainly demanded by public institutions. Currently, Y has 50 employees. About thirty-five of them have a university degree, and the rest have some other type of computing qualification. The organizational structure is very flat and the culture rather informal. Under the CEO, there are just three levels: the project coordinators, the project managers, and the software teams.

The main niche for Ticsa is the electronic procedures connecting citizens with the government agencies, which require an electronic sign. Thus, most of the applications software developed by the company has many common elements. In this circumstances software reuse is a very valuable tool which allow to develop new applications very quickly, and to achieve an important advantage comparing to the competitors. Their systematic software reuse process assures that this potential become real benefits for the company. Nevertheless, the new applications obtained cannot be considered as high innovative, given they add new solutions to a basic structure common to all of them.

In this sense, the project coordinator interviewed highlighted the importance of the Applications Generator and the Software Repository. The success and productivity of building software is based on software reuse, and these tools make it possible. The accumulated experience on developing software in the company is stored in the Applications Generator (which is considered one of the most valuable resources in the company) and the Software Repository. As the project manager says, together they contain the main part of the collective knowledge of the company, which represents the organizational capital of Y. Along the next paragraphs, we describe the process of software reuse through the Application Generator.

Five years ago, two of the key employees (A and B) of Y originally built the Applications Generator. They are considered to be ones of the most qualified people in the company, and their high capability for developing new software is recognized by everybody in the company. So, as theory indicates, the origin of the knowledge is in the individual level. Programmers working in new applications can propose different kind of problems to be incorporated to the Applications Generator, and they constitute a list of proposals to be taken into account. Just the problems which could be present in the most of the applications developed by programmers should be incorporated to the Applications Generator, because it should include just the repetitive problems in the software development processes carried out by the company. Thus, some times, a certain discussion may take place among the programmers, through the Y's "Development Chat Line", about the advisability of including a new solutions in the Application Generator.

A and B finally implement the new solutions in the Application Generator, which provides a basic structure, useful for every new software which is being developed by some programmer. Furthermore, the Application Generator provides a methodology "to do things well", that is, it includes good practices to use the created solutions and to incorporate them in the software developed. The Application Generator has matured along its life. In the earlier time, a great number of proposals and an intensive informal process (collective discussion in the "development chat line") took place, in order to consider the advisability of including new solutions. Currently, the number of proposals and the level of informal discussion have diminished, because the Application Generator already include the most of repetitive

problems that may arise in the software development processes (the person interviewed told us that an average of one proposal at month is made by some programmer).

Parallel informal systems of software reuse are used in Y, similar to the described one for Company X. A free-flowing horizontal communication exists among the programmers proposing solutions to new problems which are not the kind of problems to be included in the "Application Generator". The Project Coordinator highlighted the willingness of the most of the programmers to share knowledge. Anyway, the key software reuse system for Y is based on its Application Generator, which represents a clear example of organizational capital.

We had defined organizational capital as the most explicit part of the knowledge, which to a certain degree can be expressed by codified documents. This knowledge expressed in several kinds of documents is very important for small IT companies, as Y is, in which very few people utilize very complex knowledge for developing new computing applications. Both for the colleagues (for whom this information can be very useful, in order to develop new applications) and the client institutions (which will be the users of the product), all the codified information about a new product is essential to reach the necessary knowledge. Specifically, for software reuse, Y follow a process much more systematic than company X and uses specific tools as application generators which provide automated support for this process.

Along the process of software development process in Y, is in the building phase where software reuse takes place. In this sense, the project manager interviewed highlighted the importance of the Applications Generator and the Software Repository. The success and productivity of building software is based on software reuse, and these tools make it possible. The accumulated experience on developing software in the company is stored in the Applications Generator (which is considered one of the most valuable resources in the company) and the Software Repository. As the project manager says, together they contain the main part of the collective knowledge of the company. At this point, the Application Generator in Y deserves attention as it reflects how the subcategories of intellectual capital interact.

One of the key individuals workers of Y originally built the Applications Generator. He is considered to be one of the most qualified people in the company, and his high capability for developing new software is recognized by everybody in the company. So, as theory indicates, the origin of the knowledge is in the individual level. Previous projects and solutions to different problems are incorporated constantly to the system, provided by individuals in the company. It is significant of the culture that people are willing to provide new solutions to be added to the system. At the same time, people also continuously demand solutions for new problems (Figure 3). Consequently, the communication and coordination among the people involved are also needed in order to optimize the advantages provided by the Applications Generator. Obviously the Applications Generator is a perfect sample of organizational capital, in which the knowledge generated within the firm is preserved, and structured recurrent practices are established.

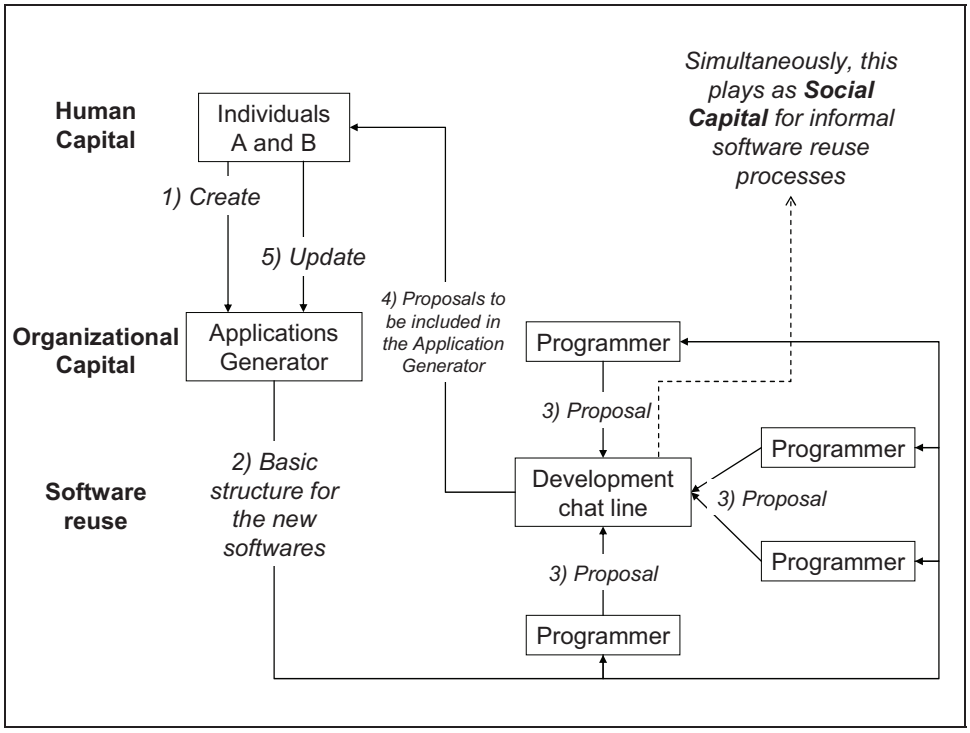

Figure 3. Software reuse through Application Generator at Y.

CONCLUSIONS

The two cases presented are quite similar to their sizes. The first company, X, however started by makng procts to anybody who was in need of embedded syetsms, while Y had a quite clear set of products in mind from the very beginning. Maybe this has been the reason why Y had a system in place while X did not. Our "ad hoc" case spreads human capital to organizational use through social capital, while our other case uses organizational-capital systems to spread the human capital and knowledge for software reuse. It may be difficult to state that companies always follow the path of developing reuse through ad-hoc social systems until at the size of about 50 persons (the size where also X went for code library systems); many other reasons should be tested in future studies. For example, the ad-hoc social capital reuse system could be suitable for small, young, one-location companies and software teams, or companies with very simple products; organizational capital reuse systems could again be more effective with more established, bigger, distributed, or with complex products.

To conclude, in both types, either ad-hoc (based on social capital) or systematic-processed (based on organizational capital) of software reuse, the human capital of the individuals is required. However, practical implementations seem to depend very much on the actual situation that can be a combination of the cases we suggest here, which could require combining human capital with either social or organizational capital or even with both; so, even code reuse, which would seem to be a very structurable activity, is clearly contingent.

FACTORS PREDICTING SMEs' SUCCESS

Dr. Jiraporn Tangkittipaporn, Ph.D. (Management) *
tangkitt@chiangmai.ac.th

ABSTRACT

Globalisation of the economy and the accession to WTO have put strong pressure on Chinese government to revise many laws and regulations and also accelerated changes in its economics system. These may create new opportunities for Chinese SMEs to improve their business related performance. The purpose of this paper was to survey the actual business management competencies and investigate which factors contributed to the Chinese SMEs' business success. The results obtained from a sample of 338 SMEs located in Kunming, Guangzhao, Hangzhao, and Shanghai, helped to confirm that, in a transitional economy, most of the Chinese SME entrepreneurs exhibited a high level of business success and paid more attention to the sophisticated western style of management practices. When considering the most significant predictors for business success, it was found that the education level, human resources and marketing management competencies, financial liquidity, and types of trading were the significant predictors for business success. The concluding argument suggests that even Chinese SME entrepreneurs' management practices have changed to a better direction. However, SME entrepreneurs are still required to be equipped with new perspective, knowledge and skills of human resources and marketing management competencies to get the optimal business outcomes. To facilitate this situation, there should be an encouragement for financial assistance, international business incentives, community education and training.

Keywords: SMEs, Business management practices, human resource management competency, marketing management competency, education, financial liquidity, trading, business success.

INTRODUCTION

Small and medium-sized enterprises (SMEs) are an essential element for the world economy. Their practical procedures can make a positive contribution towards improving the economy, reduce unemployment and avert individuals into becoming a victim of poverty. SME promotion is, therefore, an essential function for every country around the world.

China is one of the countries recognizing the significance of SMEs to its economic system. From the start of 1978 and there on, the Chinese government has implemented an economic reform as well as an open policy. In 1979, the Chinese government began the establishment and the promotion of private enterprises (Hu, & Smallbone, 2004). The number of SMEs increased from 90,000 in 1989 to over 10 million in 2003, thus accounting for 99% of the total number of enterprises (data from website: china.com.cn, June 3, 2004). However, the critical issue of Chinese SME development and success is unclear and remains the subject of considerable debate.

The optimists argue that, after accessing to the WTO, the Chinese government has revised many laws, regulations, policies, and have implemented numerous changes in its economic system. The government has provided various incentive schemes for upgrading the business management systems and operations to enable private enterprises in gaining access to the competitive marketing (Kanamori & Zhao, 2005). This may help to enhance private SMEs' competence and organizational performance.

Further, the transitional economy changed the social origin of the SME entrepreneurs. At the early stages of the transition, the Chinese people were pushed to work in private enterprises or face poverty or unemployment. The private enterprises were composed of lower class and uneducated individuals. By 1988, national investigation showed that 32% of the private entrepreneurs were lower-middle class and 21% were lower class. Since 1997, 85.7% of private entrepreneurs belong to the middle class and upper middle class, only 4.2% of the private entrepreneurs are farmers (Zhang, 1994 cited in Roberts & Zhou, 2002)

The changes in social origin and globalization, as well as government promotion policies, developed encouragement towards private entrepreneurs to uphold the Western characteristics of seeking opportunities and taking risks to gain global market prospects, focusing on the quality of the product/service, developing management and technological expertise, and committing to a quality workforce (Hu & Smallbone, 2004). With the private sector continuing to reform and expanding, the Chinese SME entrepreneurs would upgrade their business management practices and equip themselves with higher skills to gain an advantage in the competitive world.

On the other hand, the pessimists argue that though Chinese SMEs in the transitional economy have many good opportunities, they also encounter numerous problems. Chinese SMEs are under strong pressure to upgrade the present level of technology and competencies for the purpose of competing in the local and foreign markets. Chinese SME development is limited by a number of constraints (Chen & Sun, 2002). They range from a lack of access to modern financing, marketing, gaining information and mentoring, establishing business premises, acquiring business competencies, all the way to coping with a poor infrastructure (Astrachan & Kolenko, 1996). Most of the Chinese SMEs are family-owned business and the management practices of the enterprises' are lacking in qualifications and ineffective (Chen

& Sun, 2002). Therefore, the enterprises rely largely on traditional management, ie., bureaucratic controls, low formalization, low quality control (Menkhoff & Kay, 2000), to secure personal loyalty and trust rather than seeking to improve their business management competencies and strategies to gain optimum productivity and profit. A number of constraints have been cited as major reasons for the underdevelopment and the failure of the private SME sector. According to the above limitations, about 80 percent of SMEs fail within the first five years of operation (Wijewardena & Cooray, 1995), and about 10-15 per cent of SMEs fail per year (Keasey, Savery & Watson,1991 cited in Blackwood, & Mowl, 2000). This business failure is both frequent and potentially damaging to the efficient operation of the world market economy.

To test whether the optimists' or the pessimists' argument is true for the transition economy, the purpose of this paper is, therefore, to first investigate the actual practices of business related performance to confirm whether the Chinese SMEs have been highly engaged with the western sophisticated management competencies and have exhibited high level of business success and vice versa. The second part of this paper is to identify the most significant predictors for their business success. It is expected that the results of this study will help to stimulate both Chinese and foreign SME entrepreneurs' awareness of the need to improve their management practices to optimize business outcomes.

SIGNIFICANCE OF THE RESEARCH

The proposed research outcomes not only assist in making recommendations for those involved in supporting the business systems in China and Thailand as well as for other countries to provide more appropriate business support services at a local level to strengthen SMEs' business atmosphere and competencies. The outcomes of this study is also for making a contribution to the awareness of improving entrepreneurs' contemporary management competencies to facilitate firm performance while reducing business barriers to reach optimal business outcomes and success.

LITERATURE REVIEW AND HYPOTHESIS FORMULATION

1. A profile of Chinese SME entrepreneurs' management competencies and business success

As mentioned in the introduction, I accepted the optimists' argument in that the changes in social origin and globalization as well as government promotion policies would help encourage Chinese private entrepreneurs to upgrade their own management competencies and being equipped with higher skills to obtain better advantages in a competitive world. Therefore, it was hypothesized that:

HYPOTHESIS 1

> *"Chinese SMEs entrepreneurs in the transition economy would be occupied with more western sophisticated management competencies and, therefore, exhibited a high level of business success."*

2. Factors Predicting Chinese SMEs' Business Success

There were numerous approaches in trying to explain the factors which have influence business success. The most popular approach is the Resource-Based View of the firm (Barney and Wright, 1998 cited in Barjargal, 2000). This theory postulates that there are three basic types of resources crucial for the success of SMEs. (1) The human-based resources is defined as the personnel demographic characteristics (gender, age, education, race, marital status), competencies (knowledge, abilities, skill), psychological attributes (motivation, creativity, initiative, innovation, entrepreneurial orientation, autonomy, commitment) and social relationships. (2) The physical capital resources refer to the firm's plant, equipment, technologies and finances. (3) The organizational capital resources include the firm's structure and management process, e.g., planning, organizing, co-ordinating, and controlling. These resources are assumed to influence business success through a firm's marketing and resource allocation strategies (McGivern & Tvorik, 1997).

Pena identified three categories of factors that are thought to influence the likelihood of business success: human capital, firm internal and external capital. Human capital involves the accumulation of personal attributes, i.e., competencies, experience, motivation, personality, health (Pena, 2002). Firm internal capital includes the age, size, technologies, equipment, structure, marketing strategy, management process and cultural pattern. External capital is related to network opportunities, public policies, tax incentives, industry-specific regulations, stability of economy, and the market potential (Katsikeas & Deng, 1997). The last two factors may impact business success by providing industry-specific advantages to the enterprises.

A considerable number of studies ranging from single case studies to comprehensive surveys explicitly confirm that business success is the result of a web of factors (Wijewardena & Cooray, 1995; Lussier & Pfeifer, 200; Frese, 2000). These findings show that they are not identical attributes that are conducive to business success due to the differences in definitions and scope of the terms (i.e., business success and the antecedents) that the authors defined as well as the limitations of samples' national culture and constraints (Yusuf, 1995). However, previous evidence supported that human capital, in terms of management competencies, is the most prevalent factor found to be critical for business success. This includes human resource management (Berryman,1983 cited in Blackwood & Mowl, 2000; Chen & Sun, 2002; Luoma, 2000), marketing management (Conant, Mokwa, & Varadarajan, 1990; Acar, 1993; Paige & Littrell, 2002), financial management (McMahon, 2001), and production management (Acar, 1993).

When human capital is compared to the firm contextual capital, numerous studies have indicated that human capital influence firm performance to a greater extent than firm contextual capital. For instance, Hansen and Wernerfelt examined a sample of 60 Fortune 1000 firms and advocated that industry variables eg., market share and firm size, represented 18.5 per cent of variance in firm performance while goal and human resources emphasis contributed 38 per cent of performance variance (Hansen & Wernerfelt, 1989). Aaby and Slater's study also confirmed that firm contextual capital has only minor influence on SMEs' business success (Aaby & Stanley, 1989).

Given this general orientation, It was hypothesized that:

HYPOTHESIS 2

"Among human capital and contextual capital, human capital in terms of management competencies, is stronger than contextual capital in predicting SME business success."

METHOD

1. Unit of Analysis and Respondents

The expected SMEs was drawn through purposive sampling of the cities and industrial location (Kuming, Hangzhou, Guangzhou, and Shanghai), and then used accidental sampling to get the target subjects. One hundred twenty questionnaires were distributed to each city, with the expectation of 70 returned cases per each. Locations that had questionnaires returned with less than 70 cases were redistributed to ensure that 70 cases were obtained. The total returned questionnaires were 338, representing a response rate of 70.41 per cent.

2. Measures

The questionnaires were grouped into three main categories: personal and firm contexts (17 items), western sophisticated management competenices (40 items), business success (5 items). All the items had closed questions, with different options for answers depending on the nature of the question, yes/no and 4-point scales.

Before studying with the Chinese SMEs, the research instruments were developed for studying with the Thai SMEs. The full versions of the Thai scales were shortened by cutting down some of the unnecessary items to suit the Chinese SME atmosphere and the current research time frame. A final translated version of the questionnaire was revised by the Chinese-Thai translators and then examined for discriminative validity by a t-test. The Cronbach's alpha coefficient of inter-item correlation was calculated for a reliability test. A p-value was 0.05 or higher to be acceptable as having significant discriminative power, while Nunnally's prescribed Cronbach's alpha of .70 was used as a guide for judging internal consistency (Nunnally 1978; Abramson and Ai, 1999; Paige and Littrell, 2002). The results showed high discrimination (12.526-20.790, $p<0.001$) and internal consistency (Cronbach's alpha = 0.705-0.904).

RESULTS

1. Basic Characteristics of the Sample

Approximately 69.5 percent (n=232) of the Chinese SME respondents were male. Respondents' average age was 33, with a range of 18-62 years old. Almost one-half of the respondents held graduate degrees (42.8%). The majority (75.9%) of the respondents had no religion and 54.5% were married.

The responding firms represented a wide variety of trading including retail, wholesale, and hybrid types of trading. Of these, 69.5 percent were small firms (with the employees less than 50) and 47.1 percent located in industrialized areas (Guangzhou and Shanghai). The firms

ranged in age from 1 to 10 years, with a mean of 5 years. Average registered investment was 1,396,000 RMB and the average number of full-time employees was 28. Approximately 75.9 percent of the participating firms had borrowed funds. The commodity products selected were clothing, footwear, wood, leather, jade & jewelry, handicraft, food, and computer. Mostly or 90.1 percent of the commodity products were sold with in the country and only 9.9 percent were exported abroad.

Table 1 Descriptive statistics for Chinese SME entrepreneurs' Business Success

Business Success	*Descriptive Statistics*			
	Poor/low n (%)	*Moderate n(%)*	*High n (%)*	*Total n(%)*
Firm performance	12(3.6)	**163(48.4)**	162(48.0)	337(100)
Future growth	15(4.5)	**175(51.9)**	147(43.6)	337(100)
Firm expanding trend	50(14.8)	126(37.4)	**161(47.8)**	337(100)
Satisfaction with firm performance	86(25.6)	**199(59.2)**	51(15.2)	337(100)
Self esteem of firm image	44(13.1)	**239(70.9)**	54(16.0)	337(100)
Overall business success	14(4.2)	**166(49.4)**	156(46.4)	337(100)

2. Profile of Chinese SMEs' Business Success and Management Competencies

Table 1 shows that only 4.2% of the Chinese entrepreneurs exhibited low level of business success (overall success score is between 1% - 49%), 49.4% of the Chinese enterprises exhibited moderate level of business success (overall success score is between 50% - 75%), and 46.4% of the Chinese enterprises exhibited high level of business success (overall success score is between 76% -100%).

Regarding the rank order listing for entrepreneurial management competencies, budgeting management competency was rank as the highest competency occupied, followed by human resource, marketing, and trade operation management respectively (Table 2).

Table 2 Descriptive statistics for Chinese SME entrepreneurs' management competencies

Management competencies	*Descriptive Statistics*				
	Min.	*Max.*	*M (%)*	*Sd*	*order*
Trade operation management	9	18	15.20 (76.02%)	1.98	4
Human resource management	10	20	16.41 (82.05%)	2.74	2
Marketing management	10	20	15.52 (77.61%)	2.40	3
Budgeting management	10	20	17.10 (85.52%)	2.40	1
Total Management	**41**	**78**	**64.23 (82.28%)**	**7.24**	

3. Factors Predicting Business Success

The predictive models for business success presented in Table 3,4 are presented in two forms: the "full" model and the "reduced" model. The full model (model 1) contained all predictive variables while the reduced model contained only significant predictive variables.

As show in Table 3, when all of 10 personal factors (gender, age, education, religion, marital status, job tenure, trade operation management competency, human resource management

competency, marketing management competency, and budgeting management competency) were included in the model as predictive variables. The reduced model (model 2) shows that human resource management competency (β=0.214, t=3.435, p<0.001), marketing management competency (β=0.141, t=2.227, p<0.05), and education level (β=0.115, t=2.008, p<0.05) were significant predictors. The set of significant predictive factors accounted for 12.0%, with a standard error of 1.87.

Table 3 Personal Predictors for Business Success.

Personal Predictors *(Dependent Variable: Business Success)*	**Standard Equation (Model 1)**		**Stepwise Equation (Model 2)**	
	β	**t-test**	***β***	**t-test**
(Constant)		4.852***		7.314***
Human Capital				
Gender (male & female)	.005	.091

Borrowed funds (no & yes)	-.148	-2.564*	-.135	-2.375*
Types of trading (retail, wholesale & hybrid)	.093	1.500	.122	2.142*
Target market (within country & export)	.013	.212		
Business culture (Guanxi)	.048	.778		
Standard Equation: R = .241; R^2 = .053; Std. Error of the Estimate = 1.865; $F_{(9,295)}$ = 2.029, P=.036				
Stepwise Equation: R = .174; R^2 = .030; Std. Error of the Estimate = 1.871; $F_{(2,302)}$ = 4.717, P=.010				

β standardized coefficient; * probability <0.05;
Model 1 standard predictive equation, containing all contextual predictors;
Model 2 stepwise predictive equation, containing only significant contextual predictors.

Table 4 presents the models including only 9 contextual predictors (industrial location, firm size, firm label's language, types of ownership, registered investment, borrowed funds,

types of trading, target market, and business culture). The reduced model (model 4) shows that borrowed funds (β=-0.135, t=-2.375, $p<0.05$) and types of trading (β=0.122, t=2.142, $p<0.05$) were significant predictors. The set of significant predictive factors accounted for 3.0%, with a standard error of 1.87.

CONCLUSION AND DISCUSSION

The present findings help to confirm that there is a new profile of entrepreneurial competencies and success among Chinese SMEs in a transitional economy. Most of the Chinese SMEs exhibited high business success and paid more attention on western sophisticated management competencies. They ranked budgeting management activities as the highest frequent practices, followed by human resource, marketing, and trade operation.

Upon considering the significant predictors for business success, it was found that human resource management competency, marketing management competency, and the level of education were the most significant personal predictors, while financial liquidity (borrowed fund) and type of trading were the most significant contextual predictors for business success. It is interesting to know that the set of personal predictors has a stronger significance of influence on business success than the set of contextual predictors. Furthermore, even the Chinese SME entrepreneurs exhibited a high frequency of practice in budgeting management activities. However, it was not found to be a significant influencing factor for business success. Human resource and marketing management practices had stronger significant influence on business success. These findings are consistent with previous western modernized society's research findings. For instance, Lussier (1995) and Pfeifer (2001) found that human resource management or staffing, the education level, the use of professional advice, and planning had significant influence on small business success in both Central Eastern Europe and the United States of America. As for the set of contextual predictors, it was found that the financial liquidity and types of trading were the most significant contextual influencing factors for business success. This finding is also consistent with the foreign finding. For example, Yusef's (1995) study found that good management, the ability to access to financial resource, personal qualities, and adequate government support were the four most critical factors in successful small-business development in the South Pacific region (Melanesian Papua New Guinea and Vanuatu, Polynesian Western Samoa, the Micronesian Marshall Islands, and Fiji). Furthermore, Barjargal's study (2000) also supported that entrepreneurial versatility has a stronger and direct impact on Russian firm performance when it is in comparison to the general social (personal networks) and human capital resources (experience).

(1) The findings of these studies may help to confirm that the impacts of entrepreneurs' human resource & marketing management competencies, education and financial liquidity on business success have a universal value. However, in the reality of the business world, most of the SMEs are still encountered with the ignorance of the significant of human resource management practices. This experience may stem to the issue of the SMEs not having to deal with the labor unions (Marlow & Patton, 1993). Therefore, small and medium-sized firms have more freedom to manage their employees with little concern about human rights. This is confirmed by the study of Hsin, Kung, Chang, and Tam (1974). They found that Chinese small firms were production-oriented. In addition, the studies of Chen and Sun (2002) in China, Howe (1992) in Europe as well as Sim (2000) in Singapore also found that small firms are usually managed by entrepreneurs who are relatively inexperienced, as well as poorly

trained. Poor human resource management skills may result in poor personnel and asset allocation decisions, which may lead to job distress and malfunction. When the firms' entrepreneurs have less human resource management competencies, they will devote most of their attention to the liquidity of budget and the quantity of the products rather than to the quality of their employees. Yau (1994) advocated that the success of Chinese small firms is not solely influenced by marketing, but by doing favors for others. To be competitive, firms will require highly skilled, knowledgeable entrepreneurs and a relatively qualified and stable workforce. Firms achieve highly motivated and productive employees through effective human resource policy and practices which include recruitment, training, empowerment, motivation, utilization, and retention (Pfeffer, 1998). Various studies have suggested that inadequate and inefficient management of human resources has often resulted in low productivity, high dissatisfaction, and turnover among the employees (Mathis & Jackson, 1991). When the employees are poorly motivated, the employees' talent not only become wasted (Schuster, Morden, Baker, & McKay, 1997) but also decreases the firms' economic performance and limits business success (King, Solomon & Fernald, 2001).

(2) Marketing competencies in pricing, advertising, promotion, distribution, after-sale customer service, and sales force quality management is also recognized as the determinants of effectiveness of the firm's response to targeted market segments, as well as its access to alternative product/market positions (Conant, Mokwa, & Varadarajan, 1990; Acar, 1993). Marketing management competencies influencing business success through function as potential sources of increasing customers' satisfaction (Woodcock and Chen, 2000), sales growth and market share, which in turn increases shareholders' value by accelerating and enhancing cash flows, lowering the volatility and vulnerability of cash flows and increasing the residual value of cash flows (Srivastava, Shervani, and Fahey, 1998). According to Wijewardena and Cooray's study (1995), small business firms mostly failed within the first five years and the problem was mostly about the strategy and tactics of marketing (lack of a specific target market, site location, training of sales, distribution and advertising and merchandising or sales planning. Wu and Young (2002), Huang and Brown (1999 cited in Paige & Littrell 2002), Gilmore Carson, and Grant (2001) supported that small and medium sized enterprises (in China and other developing countries) have fewer marketing management competency and perceived marketing plan to be of little value in helping firm become successful. They do not comply with formal marketing strategies. Their marketing is likely to be haphazard, unplanned, loose, unstructured, and spontaneous. Several of these items have been previously proved as being important factors contributing to failure (Gaskill, Van Auken, Manning, 1993). To expand the Chinese economy, stimulate growth, and become successful enterprises in the 21st century, these Chinese enterprises have to be highly trained in marketing to carry out the capacity and be driven towards quality standard (Chen and Sun, 2002).

(3) The level of education for entrepreneurs' is one of the most cited personal demographic characteristic influencing business success (eg., Cooper, Dunkelberg and Woo, 1991; Judge, Cable, Boudreau, and Bretz, 1995; Pena, 2002). As noted by Useem and Karabel (1986 cited in Judge, Cable, Boudreau, and Bretz, 1995), the qualifications earned from formal tertiary education including scholastic capital (knowledge), social capital (personal contacts and network ties), and cultural capital (value and perspective) will enable the entrepreneurs to meet the demands of senior business executives. Higher education does not only help to stimulate entrepreneur undertaking formal business planning (Gibson, Brian, and Cassar, 2002) but also being exposed to key information and increasing their firms' aggressiveness in

marketing (Judge, Cable, Boudreau, and Bretz, 1995). In addition, formal education plays an important role with respect to entrepreneurial knowledge, ability and skill to access and adjust to external resources (Kennedy and Drennan, 1998) and to form the basis of analytical reasoning or rational response to problems. These education based characteristics are all important intangible assets for building successful firms through the development of entrepreneurial competences (Kiggundu, 2002).

(4) The role of financial liquidity (as measured by high or low use of outside borrowed funds) has been viewed as a critical element for the development of small and medium-sized enterprises (e.g., Isimbabi, 1990; Gaskill, Van Auken, and Manning, 1993; Gadenne, 1998). There are four reasons why sufficiency of financial leverage resulted in business success or failure. The first of these is management competencies. Firms with higher financial leverage or have lower use of outside borrowed funds may have the ability to enhance their management competencies which allow a business to be handled more appropriately and effectively (when the firm encounters problems, competencies help the entrepreneurs to select appropriate strategies to handle the situation). Lack of capital may inhibit the potential of entrepreneurs to hamper the growth of business and may finally cause failure (Isimbabi, 1990). Second, firms with higher financial leverage have higher investment capital for personnel development to gain competent personnel while firms with financial problems not only have no financial support for personnel development but also have no time for paying attention to personnel facilities. The entrepreneurs have to spend time in dealing with financial difficulties and find ways to solve the problems. Lower wages and facilities may induce to lower skills and performance. Third, firms with lower use of outside borrowed funds have higher purchasing power. Firms with higher investment capital can spend more money for purchasing stocks and products. These may result in an increasing of quality products but lowering the products' price (Dodge and Robbins, 1992). Fourth, firms with higher financial leverage can obtain advantages through better investment in marketing. Supplying products with higher quality and low prices can meet customer demand and satisfaction which finally generate profit for the firms. In contrast, firms that lack access to investment and working capital may prohibit the success of the business by choosing the dire alternative of acquiring poor supply of raw materials, lack of skilled labor, insufficient training, and having to cope with a poor infrastructure (Cook, 2001).

(5) Types of trading (retail, wholesale or hybrid trading) influence business success through financial resource, investment and marketing strategies. In comparison with hybrid and wholesale firms, retail firms are inferior with respect to both income and risk performance. Retail entrepreneurs often operate the firm at early stages of venture and start business with less capital and liabilities. Low capacity in assets and liabilities may induce the retail entrepreneurs to have a lower purchasing power to obtain lower invested prices. This also prevents them from building special relationships with financial resources to get a cheaper interest rate (Fink and Koller, 2002). On a desperate note, retail entrepreneurs sell the products in smaller quantities to individual customers (Alila, Odhiambo, Khayesi, and Pedersen, 2002). This may provide lower profit margins for the firms (Sim, 2000). Finally, low investment capacities may obstruct the retail entrepreneurs to develop internal resources and core competencies to meet marketing demands (Lawler, 1997). In contrast, higher capacities in financial resource, investment and marketing strategies may enable hybrid and wholesale entrepreneurs to have more influence on the competitive forces and gain more satisfaction with firm image and performance than those retail entrepreneurs having lower

experience and skills (Edwards and Royce, 2002) to sustain competitive advantages as well as facing credit rationing and higher financing cost.

IMPLICATIONS

The study may help to confirm that level of education, human resource and marketing management competencies are of utmost importance for SME business success. This evidences help to urge the Chinese and other countries' government to revise the education policy and pay more attention on improving SME entrepreneurial human resource and marketing management competencies and awareness to reach optimal business outcomes and success.

A better understanding of firm contextual constraints, specifically financial liquidity, will benefit policy makers, researchers, academicians and those involved in supporting business system to provide better financial assistance and a better learning process for improving SMEs' potential and international trade opportunity.

In addition, the government may need to provide some special tax withdrawal policy for the SMEs having human resource development. This may help to encourage micro, small, and medium-sized enterprise entrepreneurs to pay more attention to human resource's performance and quality of life.

Most importantly, the government and other related agencies may help the entrepreneurs to achieve their business success by developing business networking opportunities specifically for SMEs. This may help the SME entrepreneurs to gain both financial and information support to minimize "resource poverty" but increase "intellectual capital" to achieve business success.

At last, future research has to address the causality issues related to the constraints that limit SMEs' entrepreneurial competencies, financial liquidity, and international trade opportunity as well as ways for improvement to optimize the personnel's quality of work life and firm performance in both manufacturing and service providers.

ACKNOWLEDGEMENTS

The authors would like to express their sincere thanks to the Asian Scholarship Foundation (ASF) for funding the research.

BEHAVIORAL AGENT-BASED MODELING OF STOCK MARKET MICROSTRUCTURE

Dr Mariusz Kicia
Maria Curie-Sklodowska University, Lublin, Poland
The College of Enterprise and Administration in Lublin, Poland
mariusz.kicia@umcs.lublin.pl

ABSTRACT

The research combines three approaches of agent-based modeling, behavioral finance and market microstructure. The results of simulations for experimental fundamentals-driven single stock market are presented. That can provide understanding of how single decisions may lead to increased market volatility, security price discovery or its mispricing. It is highlighted in the end how investors' confidence fall during a financial and economic crisis makes fundamental pricing not able to discover fair values of the stocks.

Keywords: agent-based modeling, stock market microstructure, fundamental valuation.

INTRODUCTION

Economists were one of the early adopters of digital computing for numerical solving problems that were hard or impossible to solve analytically. One of the first common uses of computer technology in economics concerned business processes optimization. As operations researchers learned to solve wide classes of optimization problems computationally, through so-called mathematical programming methods, economists were early users of such techniques for practical and policy problems. In 1960s and 1970s, database technology, programming languages development and the first artificial intelligence systems made it possible to implement effectively numerical methods to estimate macroeconomic models and large amount of data processing (Axtell 2008).

The origin of multi-agent systems within computer science in the 1990s made an important, expected and permanent connection between distributed artificial intelligence, object-oriented programming and game theory to create a new powerful approach of agent-based simulation and complex systems modeling. In agent-based modeling (ABM), real-world systems are modeled as collections of autonomous decision-making entities, called agents. Each agent individually assesses its situation and makes decisions based upon its own set of rules. Model simulations are run hundreds or thousands times to generate distribution of behavior. That behavior may be confronted with real historical data to measure its calibration. In 1999, the NASDAQ stock market used BiosGroup software to simulate the impact of proposed regulatory changes on the financial market, especially in a tick size (minimal change in security price) from 1/8 USD through 1/16 USD to final decimalization (1/100 USD). Computer application created orders of thousands of individual investors, fund managers, day-traders and other market participants. Everyone made decisions of buying or selling securities on the basis of real market rules (Darley, Outkin 2007). ABM approach allowed to observe interactions between individuals and identification of phenomena that would never be explained by mathematical models. Using ABM methods, Macy's chain

designed shopping centers, Hewlett-Packard analyzed impact of employment strategy on organizational culture, and Société General made projection of operational risk in assets management process.

Agents modeled with ABM approach are not expected to be fully rational. There is an incredibly long list of phenomena which, while inexplicable with the standard tools and approaches of mainstream economics, have found a satisfactory explanation in behavioral approach. Behavioral finance rejects the vision of economic agents behavior based on the maximization of expected utility. Both, controlled experiments and real life situations prove that the assumption of rationality is too strong and unreal to explain some decisions and actions. Behavioral finance cannot be looked upon as coherent and uniform theory of human behavior, but still as a set of discoveries concerning simplistic ways of thinking (heuristics) and biases people have in their minds while making decisions. And since financial decisions are nothing more but a specific kind of decisions people make, investors are also exposed to heuristics and biases. Psychology of finance, originated as an answer to numerous anomalies of market effectiveness and now it is becoming a separate field of the capital market research. Its significance was appreciated by awarding Prof. Daniel Kahneman the 2002 Nobel Memorial Prize in Economic Sciences. Nowadays research on behavioral finance is being provided all over the world.

One of the interesting approaches is explaining market complexity by defining or simulating single market participants and interacting their decisions through the study of markets organization and function, or market microstructure. Most of the literature in this area focuses on the two central roles of markets - the transfer of ownership and price discovery. Research on the former role emphasizes the costs of trading (liquidity), while research on the latter emphasizes the process by which private information is incorporated into prices. Security market microstructure became the matter of interest in the late 1960's. One of the significant researchers of market microstructure, Prof. David K. Whitcomb (Professor of Finance Emeritus, Rutgers University, NJ; the founder and chairman of Automated Trading Desk, Inc., the first expert system for fully automated limit-order trading of common stocks) in 1981 analyzed relations between the bid-ask spread and the formulation of optimal investor trading strategies (Cohen, 1981). In another research dedicated to the problem of market liquidity analyzing relations between the bid-ask spread and the expected securities returns proved that reduction of the bid-ask spread leads to substantial increase in assets prices (Amihud 1996). The same authors, together with Beni Lauterbach examined the value effect of transferring stocks from a daily call auction system to a continuing trading mechanism (Amihud et al. 1997). Similar effect at Paris Bourse, existing after stock transfers, was shown by Chris Muscarella and Michael Piwowar (Muscarella 2001). Sang-Gyung Jun, Achla Marathe and Hany Shawky confirmed positive correlation of market liquidity and stock returns observing liquidity at 27 emerging markets from 1992 to 1999 (Jun, Marathe, Shawky, 2001).

The research presented in the article combines three above approaches of agent-based modeling, behavioral finance and market microstructure. First, a heuristic model of fundamental stock valuation is proposed. It is assumed that some of market participants are able to assess the fair value of the stock and start fundamental trends. Other market agents (quasi-rational behavioral investors, chartists and noise-traders) are involved in the fundamentals-driven experimental single stock market. All investors behavior rules (strategies) are explained. Findings in the field of stock market microstructure explain how investor's orders lead to transactions and price discovery, which makes them very close to the practice of investment. Including behavioral aspects in the market structure mainstream of the

research, especially behavior of quasi-rational investors, seems to be interesting. Agent-based modeling makes it possible to observe interactions between the investors both rational and irrational; individual and institutional; with short and long investment horizons. Computer technology allows to create model simulating real processes with growing number of variables, for example, a model of the security market that would be an effect of transactions of individually modeled but existing in the same exogenous conditions investors (agents). It is an interesting perspective to have the ability to compare how would the market react to the specific information depending on the market structure of investors.

The results of multiple simulations can provide better understanding of how single decisions may lead to increasing market volatility. Simulations in different market structures can show why patterns of reaction to the information are different in developed and developing markets. Behavioral agent-based modeling results is a realistic simulation of a system because it emulates the manner in which the world really operates. Even a simple model can exhibit complex behavior patterns and provide valuable information about the dynamics of the real world in the way other methods can never provide.

A HEURISTIC MODEL OF DCF VALUATION

Consider a single security market. Assume that the market consists of two sets of agents: fundamentalists and behaviorists. Agents with a fundamental invest attitude will buy a given security only if its market value is less that the fundamental value is not constant in time and depends on financial statement information that are available or expected by an agent. Suppose that a fundamental investor is able to assess a security value using the most commonly used valuation method of Discounted Cash Flows (DCF). Assume that all the fundamental agents are not fully informed on security issuer future financial condition and they only approximate a fundamental value at every moment using some simplification in calculations.

The practice of the financial market agents justifies such an approach. One of the most known Polish fundamental stock market investor, Zbigniew Jakubas, major shareholder of some Polish Warsaw Stock Exchange (WSE) companies, whose assets are estimated at 1 bln PLN (300 mln USD or 0,1% of Poland GDP in 2008; number 30. at the Most Wealthy Poles List), often glorifies benefits of his simple investment strategy. He considers buying a company only if the current capitalization to last year EBITDA ratio is no less than 2-3 and selling if it is higher than 6-7. The ratio mentioned in not the ultimate decision factor but the strategy is worth considering.

Let us define the DCF value of the company as the sum of discounted free cash flows (*FCF*) expected within next subsequent *n* periods and residual value (*TV*) which is the sum of the cash flows expected to be generated from *n+1* period to infinity. Let *g* denote a growth rate of the *FCF* in residual period and *WACC* denote waged average cost of capital used as a discount rate. The DCF value is given by the equation (1):

$$EV = DCF = \sum_{t=1}^{n} \frac{FCF_t}{(1+WACC)^t} + \frac{FCF_n \cdot (1+g)}{(1+WACC)^n \cdot (w-g)} \qquad (1)$$

Free cash flows generated by the issuer in a given period is a sum of an operational profit (*EBIT*) less adjusted taxes paid with *t* interest, increased by depreciation value (*DEP*) and decreased by capital expenditures (*CAPEX*) and working capital investment (ΔWC):

$$FCF_t = EBIT_t \cdot (1 - t) + DEP_t - CAPEX_t - \Delta WC \tag{2}$$

Suppose that agents have no detailed information on capital investment but they assume that the amount of the capital expenditures is equal to depreciation which means that in a long time a company will depreciate all the fixed assets it holds.

$$DEP_t = CAPEX_t \tag{3}$$

Simplifying assumption given by (3) allows to define *FCF* as:

$$FCF_t = EBIT_t \cdot (1 - t) - \Delta WC_t \tag{4}$$

Change in company working capital is a consequence of changes in inventories, short term receivables and short term liabilities:

$$\Delta WC_t = \Delta INV_t + \Delta REC_t - \Delta LIA_t \tag{5}$$

Suppose that agents are able to calculate realized lengths of inventories, receivables and liabilities restoration cycles (c_{INV}, c_{REC}, c_{LIA} respectively) and using sales expectations calculate the demand for working capital (5) with (6), (7) and (8), where SALES denote total revenues received by issuer and r is a sales and EBIT growth rate.

$$\Delta INV_t - INV_t - INV_{t-1} - c_{INV} \cdot \frac{SALES_t}{365} \cdot \frac{r}{1+r} \tag{6}$$

$$\Delta REC_t = REC_t - REC_{t-1} = c_{REC} \cdot \frac{SALES_t}{365} \cdot \frac{r}{1+r} \tag{7}$$

$$\Delta LIA_t = LIA_t - LIA_{t-1} = c_{LIA} \cdot \frac{SALES_t}{365} \cdot \frac{r}{1+r} \tag{8}$$

Suppose agents expect the operational cost structure of the company valued to be stable during the analyzed period. That makes EBIT to revenues margin to be constant and equal to ratio observed in the last financial statement (9).

$$m = \frac{EBIT_0}{SALES_0} \tag{9}$$

Completing (4) with (5), (6), (7), (8) and (9) gives:

$$FCF_t = EBIT_t \cdot \left[(1 \quad t) \quad c_{INV} + c_{REC} - c_{LIA} \cdot \frac{r}{1+r} \cdot \frac{1}{m}\right] \tag{10}$$

If we assume that α is equal to (11):

$$\alpha = (1 - t) - \frac{c_{INV} + c_{REC} - c_{LIA}}{365} \cdot \frac{r}{1+r} \cdot \frac{1}{m} \tag{11}$$

then (1) using (10) and (11) can be denoted as:

$$DCF = \alpha \cdot \sum_{i=1}^{n} \frac{EBIT_i}{(1 \mid WACC)^i} + \frac{FCF_n \cdot (1+g)}{(1 \mid WACC)^n \cdot (w \quad g)} \tag{12}$$

Assuming that revenues, EBIT and operational costs grow with the same constant rate r, we can define DCF enterprise value (EV) as:

$$EV = DCF = \alpha \cdot EBIT_0 \cdot \sum_{i=1}^{n} \frac{(1+r)^i}{(1+WACC)^i} + \frac{EBIT_0 \cdot \alpha \cdot (1+r)^n \cdot (1+g)}{(1+WACC)^n \cdot (WACC - g)} \tag{13}$$

Given (13) we finally define a ratio of enterprise value to last $EBIT$ as:

$$\frac{EV}{EBIT_0} = \alpha \cdot \left\{ \frac{1+r}{WACC - r} \cdot \left[1 - \left(\frac{1+r}{1+WACC} \right)^n \right] + \frac{(1+r)^n \cdot (1+g)}{(1+WACC)^n \cdot (WACC - g)} \right\} \tag{14}$$

The equation given in (14) is a quite simple to calculate parameter, using not only the past performance of the company, but also including the future expectations of the issuer fundamental parameters both microeconomic (r, m, g, c_{INV}, c_{REC}, c_{LIA}, $WACC$) and macroeconomic (risk-free rate and risk premium in $WACC$). The fundamental investment strategy proposed by Zbigniew Jakubas means buying when value of (14) is greater than V_{MIN} but smaller that V_{MAX} and selling below and above those limits.

It is interesting to check the performance of the multiplier at the real stock market. The given above procedure of heuristic DCF valuation ($HDCF$) was implemented to stocks listed at WSE. Below are example results for two companies: ALMA MARKET S.A. (ALM), a network of delicatessen and MIESZKO S.A. (MSO), a confectionery producer.

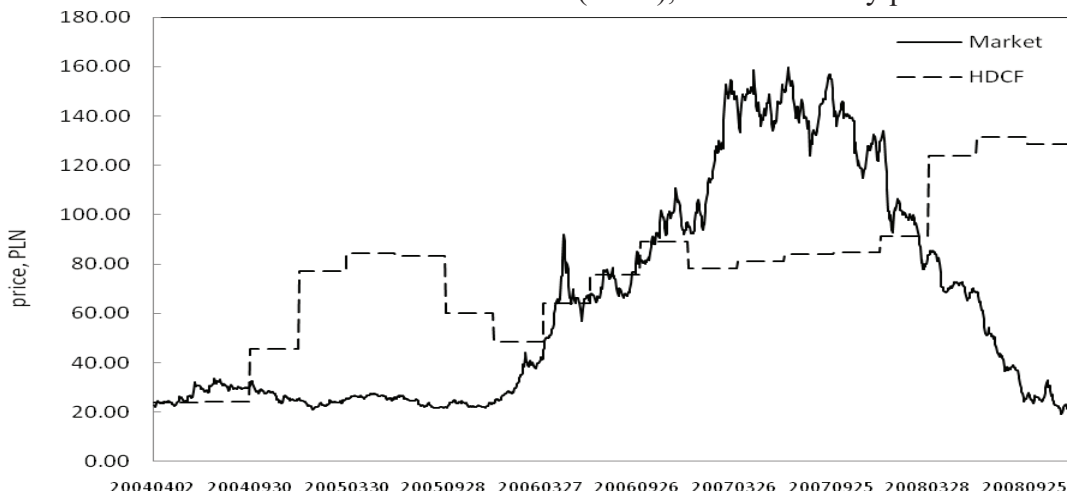

Fig 1. Market price and HDCF valuation price for ALM

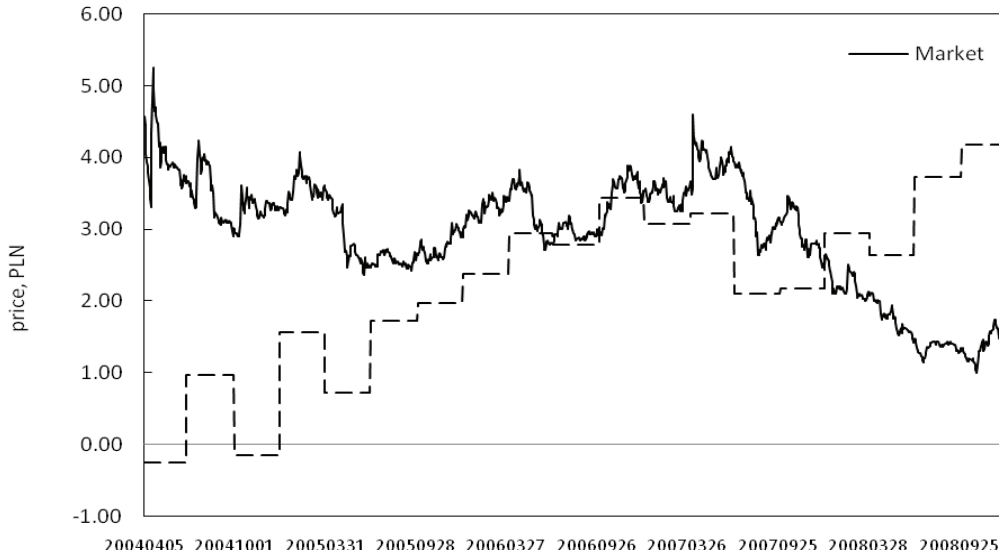

Fig 2. Market price and HDCF valuation price for MSO

The fundamental values for both companies were calculated with data provided in companies quarterly reports for 2004Q1 to 2008Q4. The *HDCF* values assumed that fundamental parameters observed in the last 4 published quarter financial statement would be constant within next 5 years (projection period). WACC were calculated upon current WIBOR3M (Warsaw Interbank Offer Rate) as a risk-free rate, 5% risk premium and beta equal to 1. Corporate Income Tax rate was constant at 19%. Fig. 1 and 2 present HDCF and actual market price of ALM and MSO during 2004Q1 to 2008Q4.

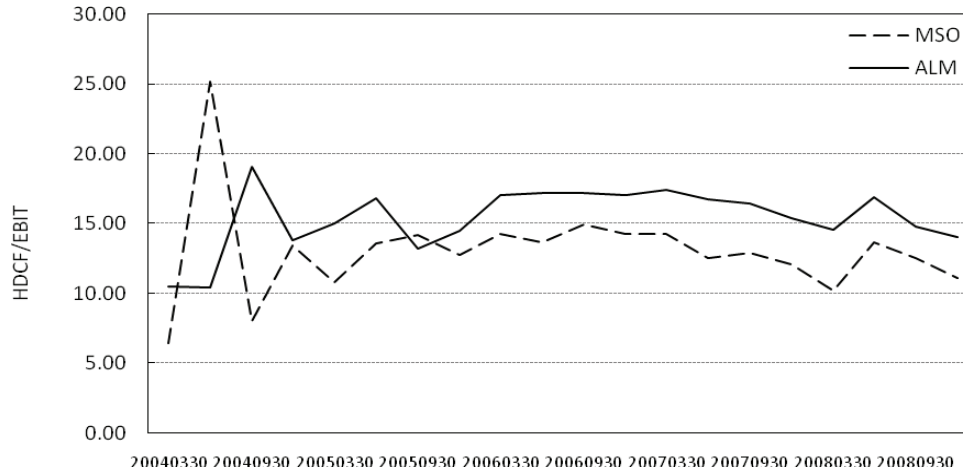

Fig. 3. HDCF/EBIT ratio for ALM and MSO

Fig. 3. presents changes in HDCF/EBIT ratio for analyzed securities. It shows that in both cases level of about 15 for the indicator can be observed when market prices of stocks reach their fundamental values. Benefits of the PRICE/EBIT ratio can be shown, when actual market price is taken to calculate it. The effects presented at fig. 4 and 5 justify Zbigniew Jakubas fundamental strategy.

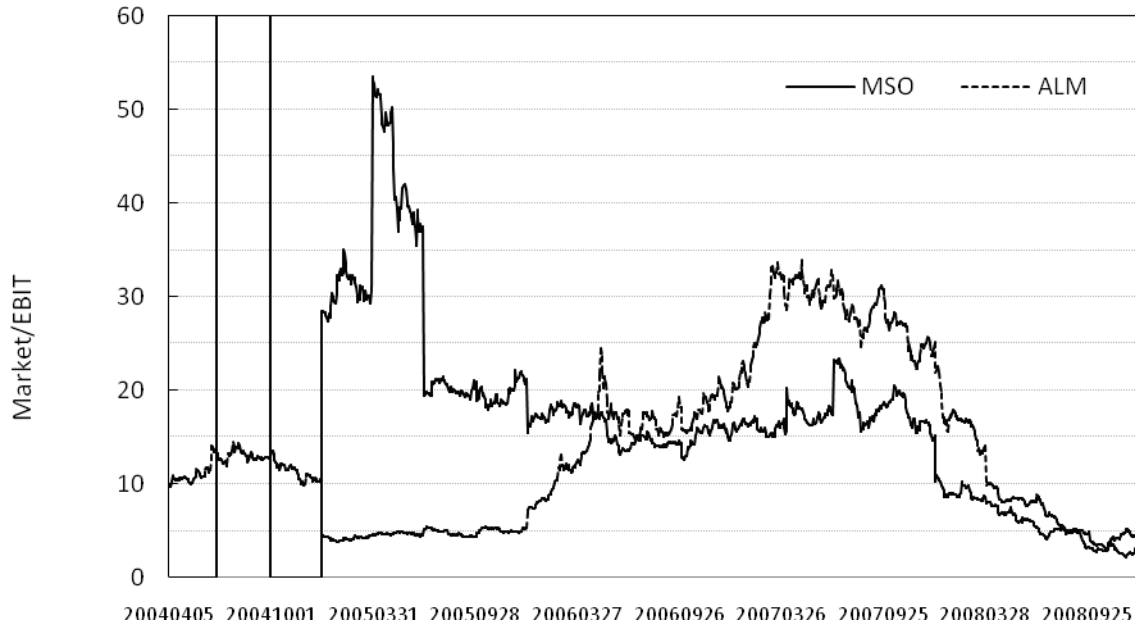

Fig. 4. Market/EBIT ratio for ALM and MSO

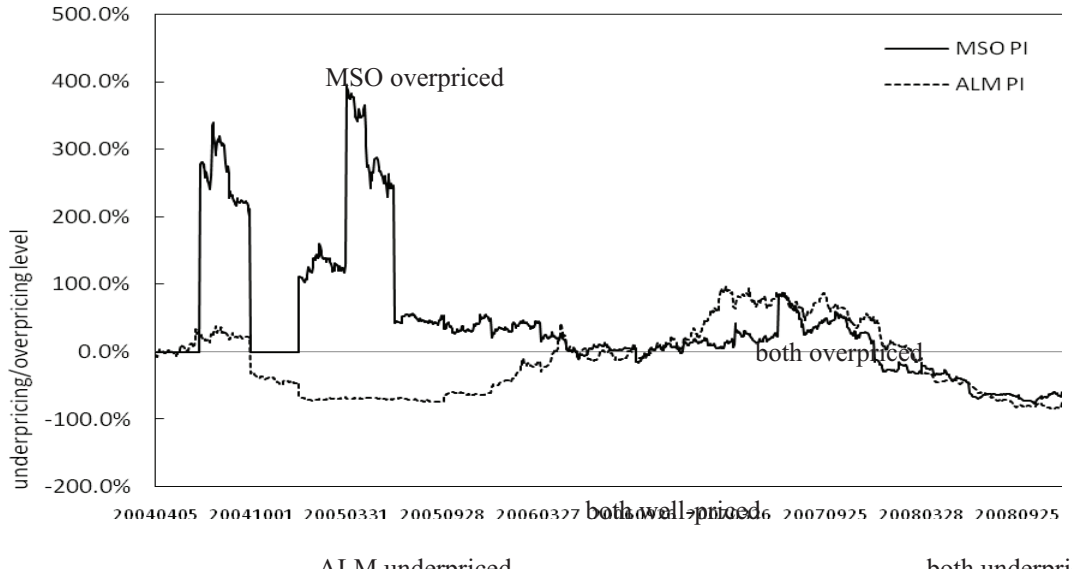

Fig 5. Underpricing/overpricing level for ALM and MSO as a difference between market and HDCF price

As we can see from above the level of fundamental mispricing observed is strongly connected to EV/EBIT ratio. The results show that 15-20 may be considered as the level comprising fundamental value for ALM and MSO shares. The initial research made by the author also shows that in most cases a level of 10-20 can be assumed for WSE listed companies. Fig. 6 shows the HDCF/EBIT sensitivity to *r* and *g*, at the commonly assumed in Poland 8% level of WACC.

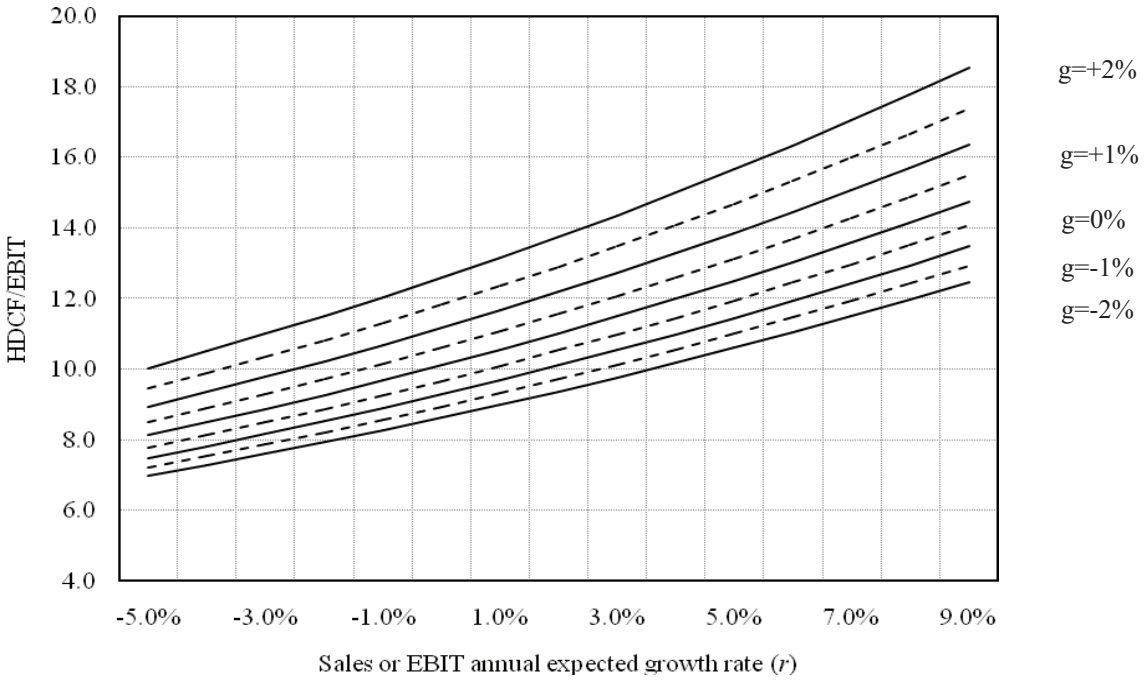

Fig. 6. HDCF/EBIT multipliers depending on EBIT expected growth rate (r) and residual growth rate (g) and 8% WACC level

Finally, let's assume that the fundamental agents operating at the experimental stock market decide to buy stocks if the market price is below HDCF and sell them if the price is above. Suppose beside the commonly observed parameters (EBIT margin, working capital cycles lengths, WACC), expected growth rates follow $g \sim N(g_0, \sigma_g)$ and $r \sim N(r_0, \sigma_r)$. As we observe, the fundamentals may explain only some rational changes in stock prices level but the market consists also of irrational or not informed agents.

EXPERIMENTAL MODEL OF FUNDAMENTALS-DRIVEN STOCK MARKET

There is only one virtual stock available at the market and the fundamental value of the stock can be assessed by HDCF model described above. All the information necessary for HDCF valuation can be easily collected (deterministic variables) or assumed (stochastic variables) by agents who follow a fundamental strategy in investing and are unknown or unnecessary for all other agents. Each virtual day of trading every agent can decide to buy, sell a share of stock, or do nothing depending on his strategy. Agents issue a orders with limit price. Every order is stored in a book until it is filled or cancelled if it is not filled within 5 virtual days of trading. During the single day transaction are settled until there are no more matching orders.

Suppose there are four categories of investors at the market: fundamentals, chartists, behavioral investors and noise traders. In case of low liquidity market makers also appear and issue buy or sell orders. Every category of investors except market makers is represented by equal number of market participants. It is assumed that there is one market maker that begins trading when demand and supply become unequal. Except for the market makers short-sale is

unavailable. Starting the simulation half of every group is equipped with a given number of stocks and the other half is only observing the market to buy stocks in the future.

Fundamentals. Fundamentals may issue buy order only if HDCF price is higher than the market price at the moment and may sell it otherwise. In every period not all but only some fundamental agents are randomly allowed to act at the market (Shimokawa, Suzuki, Misawa 2007). HDCF valuation changes when new financial statements are announced. Investors recalculate the fair value of stocks traded with parameters of r, m, g, c_{INV}, c_{REC}, c_{LIA}, $WACC$, risk-free rate and risk premium. Expected growth rates follow $g \sim N(g_0, \sigma_g)$ and $r \sim N(r_0, \sigma_r)$. Other parameters are commonly observed and the same for all the market participants.

Chartists. Chartists decide to issue buy or sell orders depending on Relative Strength Index value and 5-day return. Following strong growth period (more than 10%) part of the chartists are allowed to issue buy orders (trend-followers) while the other part is considered to be contrarians and issues sell orders. After the deep fall period (more than 10% in 5 days) trend-followers try to sell the stocks they hold and contrarians begin to issue buy orders in hope of mean-reversion.

Behavioral investors and noise-traders. Empirical researches of investors' activities at the stock market highlight some specific behaviors of individual investors that can affect their portfolios performance. Numerous researches show inclination to follow heuristic thinking and cognitive or emotional biases when investing. The main areas of irrational behavior concern stochastic of price changes, pricing securities, portfolio management strategies and transaction practice (De Bondt 1998). Most individual investors follow a trend. The research provided among American Association of Individual Investors members show that 1% growth of stock market index in a week increases the difference between investors expecting index to continue rising the following week and investors expecting index to fall. Moreover, investors sentiment depends on market performance in previous 100 days (De Bondt 1993) and trend or risk extrapolation for most of investors is only intuitive and naive (Andreassen 1988). Bull market makes investor more bullish, while bear market makes them more bearish. Similar intuitive processes are observed in capital assets pricing. Only a few individual investors uses formal pricing models, while a common practice is using informal information from other investors or financial advisors that may cause availability and anchoring heuristics. Individuals consider as the best investment stocks that recently grew sharply or are highlighted in media (Shiller 1990). They chose also overvalued companies with high price to book value ratio. Most of the individual investors do not use formal strategy rules and most of their decisions are random and often is not planned. Even if formal strategy exists it is being commonly broken (Shefrin i Statman 1997) and average individual investor portfolio is usually weakly diversified (Shefrin 2001, Benartzi and Thaler 2005).

Behavioral investors in the experimental market buy or sell stocks assuming the trend to last. For every single virtual day investors calculate expected stock prices at t+20 periods ahead depending on simple linear regression estimated with the last 20 closing prices which in practice means a intuitive graph extrapolation of the trend. If the expected price is lower than the market price stocks are sold if possible or nothing is done if investors holds no stocks. If stocks are traded below the expected price investor issues buy order. And finally, noise traders issue buy and sell orders with the random prices near best buy and offer orders in the book.

RESULTS AND DISCUSSION

The experimental market was simulated for hypothetical N=1200 days for ALM stocks. Fig. 7 presents two examples of market price changes process with normal parameters of HDCF valuation procedure and panic parameters caused by world financial and economic crisis strongly affecting market prices of WSE traded stocks starting from 3Q-4Q2007.

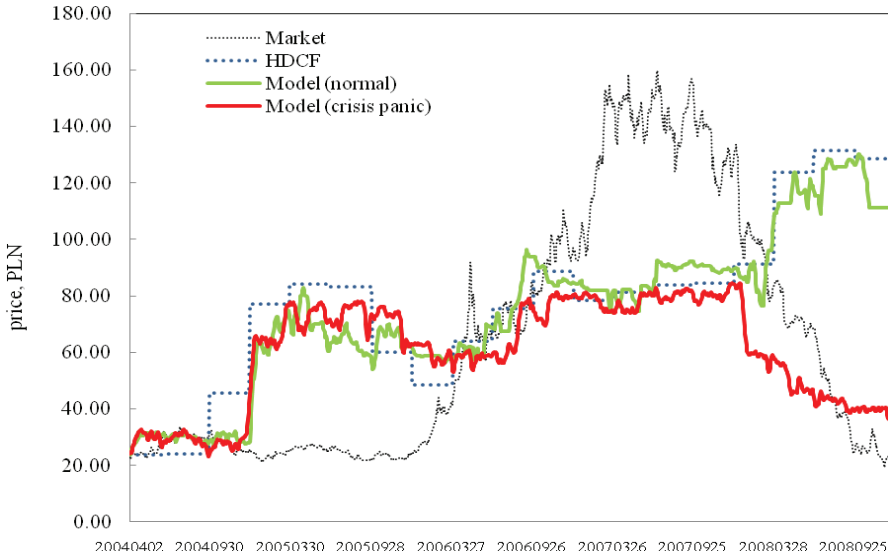

Fig. 7. Market, HDCF and examples of experimental ALM prices with normal conditions and financial crisis low sentiment

The experimental market behavior is an outcome of the rules by which agents make decisions, the principles by which agents issue their orders and the mechanism by which agents learn or evolve (Liu, Gregor and Young 2008). The most important power of simulated market was the fundamental value of the stock and behavior of fundamental investors. During the experiments with different market microstructures of investors categories is was confirmed that the necessary condition for the market mechanism to discover the fair value of the stock is that there will be large enough group of investors with fundamental strategy and ability to assess the fair value. If there was a relatively small group of fundamental agents active at the market with chartists or behavioral agents dominating the market trends were approaching the fair value of the stock only accidentally. It was also proved that for the market defined as above lack of noise-traders will provide higher liquidity risk and long periods without transactions especially when market makers were not active at the market.

The purpose of the experiments was also to confront behavioral aspects of investors' decisions by their influence on price settlement with actual market price of the stocks. It is confirmed that information on fundamental value of the stocks is not enough to explain market price behavior since it can be detached from the fair value. Although, at least in case of ALM stocks, fundamental valuation can be helpful in building a successful long term investment strategy.

Fundamental strategy effectiveness is unfortunately decreased during the periods of low market sentiment caused as from half of 2007 year by world financial and economic crisis. The HDCF valuation does not explain such a strong decrease in ALM stocks market value. Contrary, in normal conditions fair value of the stock should have been rising instead of continuing falling. Moreover, the same level of underpricing often without fundamental

reason concerns most of Polish stock exchange traded companies. The main WSE index, WIG20, lost almost 67% of its value from the middle of 2007 (about 3900 points) to beginning of 2008 (about 1300 points). Of course, if we consider ALM market and fair value, we can see a strong overvaluation during 2007, a year of strong economic growth for Polish GDP. Even in 2008, when USA and EU announced a pending recession, Polish economy ended with almost 5% dynamic of GDP. The fundamental parameters do not explain such a strong reverse. But if we consider that the effects of world crisis are widely discussed also for Polish economy and companies, consumer confidence and business activity fall and risk-aversion rises due to lack of free capital, fundamental pricing becomes more heuristic than before and explains market overreaction. ALM HDCF valuation based on data from the 4Q2008 and market parameters is about 94 PLN (26 USD). If we lower EBIT margin to -5% (from almost constant 4-5%), sales annual growth to -10% (from 7-9%), residual growth to -2% (from 1%) and rise WACC to 12% (from 7-8%) according to risk-aversion, ALM HDCF price falls to 26 PLN (7,25 USD). The market price at the end of March 2009 for ALM was about 18-20 PLN. The same assumptions for MSO stocks lowers its HDCF value to 3,90 PLN, small but still high above the market price of 1,20 PLN at the end of March 2009.

That is a part of the process that happened in reality. The wide panic stocks sale out by individual and institutional investors in Poland that took place in 2007 and 2008 made the falling trend stronger and was confirmed in simulation when "panic factor" was involved in the HDCF model and fundamentals decisions by changing parameters mentioned above. Not only fundamentals reverted their positions but also trend-followers, chartists, behavioral and noise-traders.

CONCLUSION

The research presented in the article combines agent-based modeling, behavioral finance and market microstructure approaches. First, a heuristic model of fundamental stock valuation was proposed (HDCF). Examples of HDCF valuation for Warsaw Stock Exchange companies were presented showing that in steady market conditions fundamental value may be a main but not the only force to change market prices. It is assumed that participants who are able to assess the fair value of the stock start fundamental trends and price correction in a long time. Including behavioral aspects in the market structure. The results of simulations for experimental fundamentals-driven single stock market were presented. The model can provide understanding of how single decisions and strategy choice may lead to all market volatility. It is highlighted in the end how investors' confidence fall during a financial and economic crisis makes fundamental pricing not able to discover stock fair value.

ABSTRACT

In today's ever-changing business environment, it is imperative for a firm to be able to dynamically adapt to the changes in order to maintain and/or enhance its competitive advantage. Therefore the evaluation and selection of the best business strategy, given the company's limited resources and capabilities, could be a vital task. Due to the uncertainty and dynamics of the business environment, previous research in strategic management has mainly focused on using qualitative research methodology to understand the process of forming business strategy. In this research, we propose a comprehensive quantitative model for business strategy evaluation. The study first reviews the literature in resource-based theory and value chain analysis to identify important factors in making business strategy. A fuzzy multiple criteria decision-making technique is implemented that combines both the empirical data of the firm and experts' subjective opinions to automatically rank and evaluate the degree of fitness of different business strategies. To demonstrate the applicability of our model, we apply it to analyze the fitness of the four business strategies in Miles and Snow typology. The model integrates factors related to both environmental uncertainty and industry attractiveness and facilitates firms to formulate the strategy through a more holistic and objective perspective.

Keywords: Miles and Snow typology, strategic management, fuzzy theory, strategy classification system

INTRODUCTION

Strategic management as an academic field is relatively young comparing with other fields of business. Research on strategic management and organizational theory has made significant progress during the last few decades. The early development of business strategy is primarily due to the work of Alfred Chandler and others at Harvard Business School. Chandler (1962) and Ansoff (1965) defined corporate-level strategy as a match between the organizational strengths and weaknesses within the universe of environmental opportunities and threats. Corporate-level strategy helps a company to determine what business it should be in. One problem with the applicability of their works is the lack of systematic procedures to help evaluating the fitness of the strategy. An important breakthrough in the field of strategy was developed by Porter (1980). He pointed out that the structures of an industry were determined by the conditions and competitions within the industry. The business-level strategy helps a company to find out how it should compete in a given line of business. Wernerfelt (1984)

extended Porter's model by considering the endogenous resource and capabilities of the companies. The resource-based approach built on combining the internal analysis of the firms and the external analysis of the industry, and was considered a powerful approach to help selecting suitable business strategies. The strategic management field has gone through a period of rapid growth during the subsequent two decades and since was considered a more matured discipline. Nag, Hambrick, & Chen (2007) recently performed a large-scale survey of strategic management scholars and derived an implicit consensual definition of the field. Their findings suggest that "*strategic management's success as a field emerges from an underlying consensus that enables it to attract multiple perspectives, while still maintaining its coherent uniqueness.*" It can be evidenced by more and more scholars with different background of training and expertise to join the field of business strategic management (Nerur, Rasheed, & Natarajan, 2008). Strategic management is a multi-disciplinary field that encompasses from economics to organizational theory, and is also closely related to the development of enterprise. There are increasing interests from both researchers and practitioners in the field of business strategies (Boulianne, 2007; Lin & Tseng, 2006). Firms are under the rising global competition and ever evolving business environment changes. It is vital for a firm to thoroughly understand the effects and interactions between uncertain business environment and organization capabilities in order to enhance the performance of the business strategy implemented. Superior performance often depends on the quality and consistency of the firm's strategic orientation, and a right business strategy would help in achieving the organization's goals and objectives (Casey, 2004). Therefore, one of the critical tasks faced by a firm today is to maintain sustainable competitiveness through utilizing effective techniques to help selecting the right business strategy.

The extant research in strategic management has mostly adopted qualitative research methodology that collected data to explore the relationship between strategy measurement and organizations' performance using questionnaires and/or in-depth interviews (e.g., Gaiardelli, Saccani, & Songini, 2007; Pinto & Curto, 2007). In this research, we propose a quantitative method based on fuzzy membership functions to evaluate and rank the appropriateness of the four basic strategy types of Miles and Snow. Both internal and external environment factors of the organization will be considered in the proposed model.

LITERATURE REVIEW

Business strategy is viewed as the integrative actions to achieve corporate goals that takes into consideration of both the influences of internal organizational capabilities and the external environment (Nonaka & Toyama, 2007; Hill & Jones, 2007). Therefore, the differences and diversifications in the scope of business strategies can be accounted for by the complexity and variety of the organizational structure. Miles & Snow (1978) typology of strategy focused on the product-market interrelationship and has received great attention in the management literature over the last two decades. DeSarbo, Di Benedetto, Jedidi, & Song (2006) argued that Miles and Snow typology has been the most enduring and scrutinized strategy classification systems (Kabanoff & Brown, 2008).

Miles and Snow typology classified firms into four archetypes, Defender, Prospector, Analyzer, and Reactor. Defenders are companies that focus on a narrow market in which they attempt to

seal off a part of the total market and to remain competitive through creating a stable set of products and customers. Prospectors are organizations that focus on constant innovations. They seek to exploit new product and market opportunities, and tend to be highly flexible and entrepreneurial. Analyzers occupy an intermediate position that combines certain characteristics of both Prospectors and Defenders. They compete on the Defender's strengths of efficiency, and act like Prospectors to search for innovations. Reactors are firms that exercises incoherent strategy therefore are usually fragile and hard to sustain in business (Ghoshal, 2003). In this research, we demonstrate the effectiveness of our proposed strategy evaluation model using Miles and Snow typology.

The process of formulating business strategies

Previous research in strategy has identified several factors that can affect the relationship between decision process and organizational outcomes. The process of formulating the generic strategies should reflect the interaction between an organization and its environment, hence environment related analysis should be viewed as the basis of the decision and can assist in accomplishing a firm's mission. (Elbanna & Child, 2007; Kabanoff & Brown, 2008). We review the relevant dimensions of the external and the internal environments in the following sections.

External Environment

The dimensions that the firms have to continuously monitor in the external environment in order to make better policy and to attain competitiveness are depicted in Figure 1 (Hill & Jones, 2004; Porter, 1980).

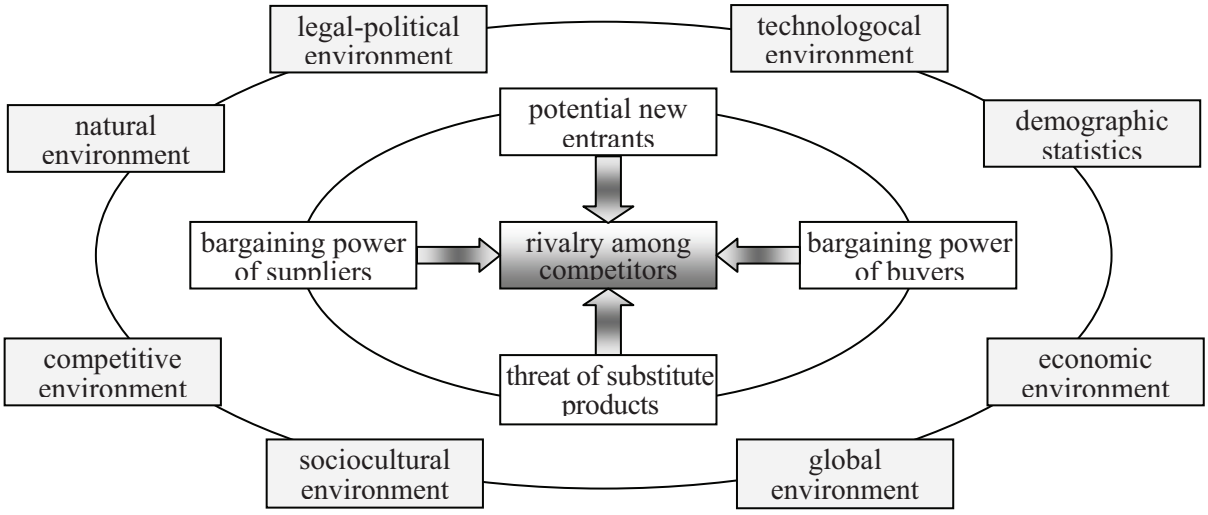

Figure 1 Dimensions of external environment (adapted from Hill & Jones 2004, Porter 1980)

The performance of strategy are influenced by environmental factors such as dynamism, munificence, and complexity (Harris, 2004;Goll & Rasheed, 2005). Dynamism is the degree and unpredictability of environmental changes; environmental munificence is the capability to make the surplus resource evolve; complexity of the environment reflects the heterogeneity in

the range of the organization's activities. The uncertainty which can be expressed by the degree of environmental turbulence makes it difficult for managers to continuously formulate the proper strategy to respond to the minor cues from external environment. There are both potential benefits and pitfalls to carry on business in an uncertain environment (Hutzschenreuter & Kleindienst, 2006; Elbanna & Child, 2007). Since the degree of uncertainty is hard to evaluate, Ansoff (1990) divided the environment into five levels of turbulence according to the difference on its intensity. Table 1 shows the corresponding strategic aggressiveness necessary for success at each turbulence level. For example, the organizations that experience repetitive external environment should maintain stable strategy unless forced by a threat to their survival. On the other hand, companies in expanding environment will succeed if they can be reactive and modify their strategy in response to competitors' actions. The level of turbulence arises, the need for innovation and technology increases. In this research, we adapted and quantified the factors presented in Table 1 in our proposed model to evaluate and rank the appropriateness of the four strategies.

Table 1 Matching of business strategy aggressiveness to the degree of environmental turbulence

Environmental turbulence	Repetitive	Expanding	Changing	Discontinuous	Surprising
Strategic aggressiveness	Stable	Reactive	Anticipatory	Entrepreneurial	Creative
Level	1	2	3	4	5

(source: Ansoff, 1990)

Internal Environment

Many tools and techniques have been introduced and implemented to assay the resources and capabilities of companies and recommend ways to enhance firms' competitiveness. One of the most widely adopted methods both by researchers and practitioners (e.g. Spence & Kale, 2008; Francis, Simons, & Bourlakis, 2008) is the value chain model developed by Porter (1985) as shown in Figure 2. It is implemented as the basis in diagnosing the future needs of resources and capabilities of firms in order to remain competitive.

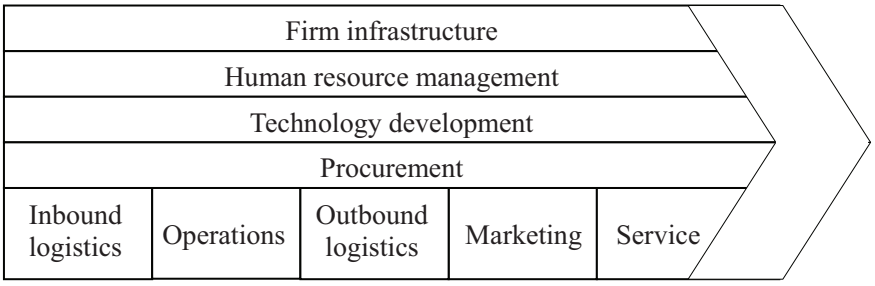

Figure 2 Porter's value chain model (source: Porter, 1985)

When evaluating the competitiveness of firms resources and capabilities in value chain, the VRIO framework (Valuable, Rare, Imitability, and Organization), a resource-based theory by (Barney & Hesterly, 2006), is usually applied. The framework identifies the organization's internal strengths and weaknesses by comparing the resources and capabilities of the firm with that of the competitors along the four dimensions (Sebestova & Wagnerova, 2007; Sebestova, Szkandera, & Bernatik, 2008).

In order to take into consideration of both external and internal environment factors and the uncertainty nature of the environment when evaluating the firms' strategy, we propose a multiple attributes decision support model based on fuzzy membership functions to capture the environment uncertainty. Unlike previous researches in strategic management that are mostly qualitative, this research suggests a quantitative model that allows managers to evaluate and select the right business strategy in a more systematic and scientific fashion.

Fuzzy multiple attributes decision support model

Fussy theory was first developed by Zadeh (1965) to quantify linguistic terms. Fuzzy multiple attribute decision making (FMADM) model combines the concepts of fuzzy theory and multiple attributes decision making theory to solve the problems of multiple attribute decision making that involves uncertainty (Chen, Fung, & Tang, 2006; Xu & Chen, 2007). In this research, we aggregate both external and internal environment attributes using FMADM that allows objective evaluation of all relevant factors together to measure the appropriateness of each strategy.

MODEL BUILDING PROCESS

We first identify all the relevant factors both from external and internal environments through the analysis of literature. Data need to be collected to determine the factor values and factor weights for each factor with corresponding fuzzy operation parameters in order to combine values and weights into fuzzy utility functions (Su, Shi, & Lai, 2008).

Model of external environment analysis

The factors proposed by Porter (1985) and Hax & Majluf (1996) are used to describe the relevant attributes from external environment as shown in Table 2.

Table 2 Summary of the external environment factors and notations

factors	Primary factors	Notations	Secondary factors	Notations
General environment	Technologocal environment	x_1^{OG}	Since general environment covers a wide range, only an integral sketch can be given of the factors herein.	No
	Competitive environment	x_2^{OG}		
	Sociocultural environment	x_3^{OG}		
	demographic statistics environment	x_4^{OG}		
	Global environment	x_5^{OG}		
	Economic environment	x_6^{OG}		
	Natural environment	x_7^{OG}		
	Legal-political environment	x_8^{OG}		
Industry environment	Potential new entrants	x_1^{OI}	Economies of scale	x_{11}^{OI}
			Product differentiation	x_{12}^{OI}
			Brand identification	x_{13}^{OI}
			Switching cost	x_{14}^{OI}

			Access to distribution channels	x_{15}^{OI}
			Capital requirements	x_{16}^{OI}
			Access to latest technology	x_{17}^{OI}
			Industry protection	x_{18}^{OI}
			Industry regulation	x_{19}^{OI}
			Consistency of policies	x_{110}^{OI}
			Capital movements among countries	x_{111}^{OI}
			Custom duties	x_{112}^{OI}
			Foreign exchange	x_{113}^{OI}
	threat of substitute products	x_2^{OI}	Availability of close substitutes	x_{21}^{OI}
			User's switching costs	x_{22}^{OI}
			Substitute price-value	x_{23}^{OI}
	bargaining power of buyers	x_3^{OI}	Number of important buyers	x_{31}^{OI}
			Buyers' threat of backward integration	x_{32}^{OI}
			Contribution to quality of buyers' products	x_{33}^{OI}
	bargaining power of suppliers	x_4^{OI}	Number of important suppliers	x_{41}^{OI}
			Suppliers' threat of forward integration	x_{42}^{OI}
			Contribution to quality of the industry product	x_{43}^{OI}
	rivalry among competitors	x_5^{OI}	Concentration and balance among competitors	x_{51}^{OI}
			Industry growth	x_{52}^{OI}
			Fixed cost	x_{53}^{OI}
			Product differentiation	x_{54}^{OI}
			Corporate strategic stakes	x_{55}^{OI}
			Asset specialization	x_{56}^{OI}
			One-time cost of exit	x_{57}^{OI}
			Strategic interrelationships with other businesses	x_{58}^{OI}
			Emotional barriers	x_{59}^{OI}
			Government and social restrictions	x_{510}^{OI}

The fuzzy membership functions are used to represent the uncertainty of the dynamism, munificence, and complexity of the general environment (Sirmon, Hitt, & Ireland, 2007; Rueda-Manzanares, Aragón-Correa, & Sharma, 2008) and industry attractiveness of the external environment. Table 3 summarizes the external environment characteristics and its corresponding membership functions. The following explains the notations adopted by our model:

f_n The membership functions of the general environment factors (n = 1,2,3,…,8)

y_{um} The membership functions of the industry environment factors ($m = \{13,3,3,3,10\}$) that belongs to each primary factor (u = 1,2,3,4,5)

a Constant of the model that can be determined by users

α The degree of the marginal decreasing effect

β The degree of the marginal increasing effect
k The upper limit of the membership function
x The variables of the model
i The primary factors of internal environment (i =1,2,3,…9)
γ The polar point of S-curve
c The weight of factors
w The weight of factors

The selection of membership functional form is based on the review of literature, and the relationships between performance and capability can be summarized as a nonlinear equation. For instance:

Let x_{Mn}^{OG} denotes the degree of environmental munificence, k_{Mn}^{OG} indicates the upper limit of the impact of the uncertainty, and a_{Mn}^{OG} be a constant that can be set by users according to problem situation. Munificence is one of the factors inducing uncertainty, and as a moderator of the relationship between decision making and organizational performance (Goll & Rasheed, 2005). The munificence of environment supports additional resources to the firm and the level of sustained growth complied with the environmental uncertainty (Chung & Beamish, 2005); moreover, Let f_{Mn}^{OG} indicates the relationship between environmental munificence and uncertainty which is the direct proportion of indefinite marginal effect, and the membership value is always between zero and one. Based on the above analysis, we can obtain the membership function of munificence as follows:

$$f_{Mn}^{OG} = \frac{k_{Mn}^{OG}}{\left(a_{Mn}^{OG}\right)^{\frac{1}{x_{Mn}^{OG}}}}$$

Following the same approach, we are able to derive the other three membership functions of external environment factors as shown in Table 3.

Table 3 Summary of the external environment factors and corresponding membership functions

Characteristics	Membership functions	Descriptions
Dynamism	$f_{Dn}^{OG} = \left(a_{Dn}^{OG}\right)^{\beta_{Dn}^{OG} x_{Dn}^{OG}} - 1$	Oreja-Rodriguez & Yanes-Estevez (2007) show that the relationship between dynamism and environmental uncertainty is direct proportion. Freel (2005) point out the more dynamic environment, the greater environmental uncertainty to bring.
Complexity	$f_{Cn}^{OG} = \left(a_{Cn}^{OG}\right)^{\beta_{Cn}^{OG} x_{Cn}^{OG}} - 1$	Oreja-Rodriguez & Yanes-Estevez (2007) show that the relationship between complexity and environmental uncertainty is direct proportion. A greater degree of complexity exacerbates uncertainty in the institutional environment. (Chung & Beamish, 2005)
Industry attractiveness	$y_{um}^{OI} = 1 - \left(a_{um}^{OI}\right)^{\alpha_{um}^{OI}\left(x_{um}^{OI}-1\right)}$	The increasing threats lead the gap in entering an industry to increase and the industry attractiveness decrease.

Internal environment analysis

The internal environment factors, corresponding factors, and notations are showed in Table 4.

Table 4 Summary of the internal environment factors and notations

Factors	Notations	Secondary factors	Notations	Proposed authors
Inbound logistics	x_1^I	Delivery reliability	x_{11}^I	Boyaci & Ray (2006), Schuh (2006)
		Forecasting accuracy	x_{12}^I	Gunasekaran & Kobu (2007)
operating	x_2^I	Capacity utilization	x_{21}^I	Gajanan & Malhotra (2007), Bansak, Morin, & Starr (2007)
		Defective rate	x_{22}^I	Roberts (2004), , Kwak & Anbari (2006)
Outbound logistics	x_3^I	Delivery reliability	x_{31}^I	Holweg & Miemczyk (2003)
		Damage rate	x_{32}^I	Forslund (2007)
Marketing	x_4^I	Market share	x_{41}^I	Hax & Majluf (1996), O'Sullivan & Abela (2007)
		Price sensitivity	x_{42}^I	
		Channel effect	x_{43}^I	
		Market acceptance	x_{44}^I	
Services	x_5^I	Response time	x_{51}^I	Alexander, Dayal, Dempsey, & Vander Ark (2002), Gaiardelli, et al. (2007)
		Customer satisfaction	x_{52}^I	van Birgelen, de Ruyter, de Jong, & Wetzels (2002)
firm infrastructure	x_6^I	Organizational culture	x_{61}^I	Henri (2006), Glomseth, Gottschalk, & Solli-Sæther (2007)

		Order Fulfillment	x_{92}^I	Burke, Carrillo, & Vakharia (2007)

After defining the notations of the internal environmental factors, we can identify the membership functions corresponding to each factor of internal environment as presented in Table 5.

Table 5 The membership functions of internal environment factors

factors	Membership functions	References and their descriptions
Delivery reliability	$y_{V11}^I = \frac{k_{V11}^I}{\left(a_{V11}^I\right)^{\frac{1}{x_{V11}^I}}}$	Sridharan & Li (2008) and Soepenberg, Land, & Gaalman (2008) point out that high delivery reliability is one of the critical criteria for winning performance.
Forecasting accuracy	$y_{V12}^I = \frac{k_{V12}^I}{\left(a_{V12}^I\right)^{\frac{1}{x_{V12}^I}}}$	The higher forecasting accuracy, the higher values of it. (Lawrence, O'Connor, & Edmundson, 2000; Gunasekaran & Kobu, 2007)
Capacity utilization	$y_{V21}^I = \left(a_{V21}^I\right)^{\beta_{V21}^I x_{V21}^I} - 1$	Bansak, et al. (2007) shows that the higher capacity utilization increased manufacturing capacity.Sun (2007) explores that the profits and value-added elements increased at higher capacity utilization levels.

Defective rate	$y_{V22}^{I}=1-\left(a_{V22}^{I}\right)^{\alpha_{V22}^{I}\left(x_{V22}^{I}-1\right)}$	Freimer, Thomas, & Tyworth (2006) discovered that there is a negative relation between the rate of defective goods produced and the organizational performance.
Delivery reliability	$y_{V31}^{I}=\frac{k_{V31}^{I}}{\left(a_{V31}^{I}\right)^{\frac{1}{x_{V31}^{I}}}}$	Sridharan & Li (2008) and Soepenberg, et al. (2008) point out that high delivery reliability is one of the critical criteria for winning performance.
Damage rate	$y_{V32}^{I}=1-\left(a_{V32}^{I}\right)^{\alpha_{V32}^{I}\left(x_{V32}^{I}-1\right)}$	Forslund (2007) emphasized the importance of a low damage rate for customers.
Market share	$y_{V41}^{I}=\frac{k_{V41}^{I}}{\left(a_{V41}^{I}\right)^{\frac{1}{x_{V41}^{I}}}}$	Vorhies & Morgan (2003) used market sharing to represent the products or service sales situation. Baker & Sinkula (2005) used change in market share as an indicator of firm performance, and figured out the performance is positively related in market share.
Price sensitivity	$y_{V42}^{I}=\frac{k_{V42}^{I}}{\left(a_{V42}^{I}\right)^{\frac{1}{x_{V42}^{I}}}}$	Price sensitivity in the grasp of dominate firms always bring the better performance. (Hsieh & Chang, 2004; Wakefield & Inman, 2003)
Channel effect	$y_{V43}^{I}=\frac{k_{V43}^{I}}{\left(a_{V43}^{I}\right)^{\frac{1}{x_{V43}^{I}}}}$	The effective channel minimized the total expected distribution cost. (Alptekinoğlu & Tang, 2005)
Market acceptance	$y_{V44}^{I}=\frac{k_{V44}^{I}}{\left(a_{V44}^{I}\right)^{\frac{1}{x_{V44}^{I}}}}$	The acceptance degree of brand information is getting higher, the customers will be willing to consume. (Hax & Majluf, 1996; O'Sullivan & Abela, 2007)
Response time	$y_{V51}^{I}=\frac{k_{V51}^{I}}{\left(a_{V51}^{I}\right)^{\frac{1}{x_{V51}^{I}}}}$	Mattila & Mount (2003) and Persse, Jarvis, Corpening, & Harris (2004) argued that a faster response has a positive influence on customer evaluations.
Customer satisfaction	$y_{V52}^{I}=\frac{k_{V52}^{I}}{\left(a_{V52}^{I}\right)^{\frac{1}{x_{V52}^{I}}}}$	The degree of solving customers' problem in one time visit is higher, the service performance is better. (Gaiardelli, et al., 2007; van Birgelen, et al., 2002)
Organizational culture	$y_{V61}^{I}=a_{V61}^{I}x_{V61}^{I}$	Organizational culture has a significant impact on the implementation of business activities. (Chan, Shaffer, & Snape, 2004; Stock, McFadden, & Gowen III, 2007)
Team performance	$y_{V62}^{I}=a_{V62}^{I}x_{V62}^{I}$	Garnett, Marlowe, & Pandey (2008) and Kim (2002) found that trusting and effective communication in teamwork is associated with better performance.
Human experiment	$y_{V71}^{I}=\left(a_{\mathrm{V}71}^{I}\right)^{\beta_{V71}^{I}x_{V71}^{I}}-1$	Stavrou, Charalambous, & Spiliotis (2007) explored human resource is a source of organizational performance. Human experiment is positively associated with firm performance. (Bae, Chen, & Wan, 2003)
Human skill	$y_{V72}^{I}=\left(a_{\mathrm{V}72}^{I}\right)^{\beta_{V72}^{I}x_{V72}^{I}}-1$	Human skill has a positive and significant impact on organizational performance. (Liu, Combs, Ketchen, & Ireland, 2007; Conner, 2006)
R&D intensity	$y_{V81}^{I}=\frac{k_{V81}^{I}}{1+e^{-\beta_{V81}^{I}\left(x_{V81}^{I}-\alpha_{V81}^{I}\right)\left(1-\gamma_{V81}^{I}\right)}}$	Kuzents (1930) applied the perspective of S-curve on deriving the technology change model.
Technology maturity	$y_{V82}^{I}=\frac{k_{V82}^{I}}{1+e^{-\beta_{V82}^{I}\left(x_{V82}^{I}-\alpha_{V82}^{I}\right)\left(1-\gamma_{V82}^{I}\right)}}$	Wonglimpiyarat & Yuberk (2005) and Boretos (2007) used the concept of S-curve to evaluate the process of technology development.
Supplier performance	$y_{V91}^{I}=1-\left(a_{V91}^{I}\right)^{-\alpha_{V91}^{I}x_{V91}^{I}}$	Hallikas, Puumalainen, Vesterinen, & Virolainen (2005) and Camuffo, Furlan, & Rettore (2007) found that the supplier performance is better, the purchasing risk will decrease, and the add value will increase.
Order Fulfillment	$y_{V92}^{I}=1-\left(a_{V92}^{I}\right)^{-\alpha_{V92}^{I}x_{V92}^{I}}$	Morgan & Dewhurst (2008) used the order fulfillment rate to evaluate the performance of purchase activities.

Finally, an aggregated viewpoint was taken to describe the membership functions of the VRIO framework, rareness, imitability, and organization, Table 6 shows the references, descriptions, and membership functions of those factors.

Table 6 The other membership functions of internal environment factors

Factors	Membership functions	References and their descriptions
Rareness	$y_{Ri}^{I} = \left(a_{Ri}^{I}\right)^{-\beta_{Ri}^{I} x_{Ri}^{I}}$	Barney & Hesterly (2006) argued that the resource rarity generally had a positive effect on firm's performance. Ainuddin, Beamish, Hulland, & Rouse (2007) proposed the rarity of resource had significant and positive influence on performance for the capabilities.
Imitability	$y_{Ii}^{I} = \left(a_{Ii}^{I}\right)^{-\beta_{Ii}^{I} x_{Ii}^{I}}$	For a capability, firm performance will be positively associated with its imitability. (Ainuddin, et al., 2007; Lavie , 2006)
Organization	$y_{Oi}^{I} = \frac{k_{Oi}^{I}}{\left(a_{Oi}^{I}\right)^{\frac{1}{x_{Oi}^{I}}}}$	Firms' resources become capabilities when they are integrated or organized in the performance of business activities. (Beard & Sumner, 2004; Barney & Hesterly, 2006)

Weight analysis

To determine the values of factor weights and the set of fuzzy numbers, expert opinion or survey questionnaire can be used to find out the importance of each factor. In this research, we used linguistic variables such as "very unimportant," "unimportant," "normal," "important," and "very important" to denote the factors' weight, and used the "core" member of the fuzzy number to represent a linguistic value in the MADM approach (Chen, et al., 2006; Xu & Chen, 2007). For example, the triangular fuzzy number (0.6, 0.8, 1) was used to approximate the linguistic variable "Important" (see Figure 3). Table 7 presents the fuzzy numbers and crisp scales (α-cut) of each linguistic variable.

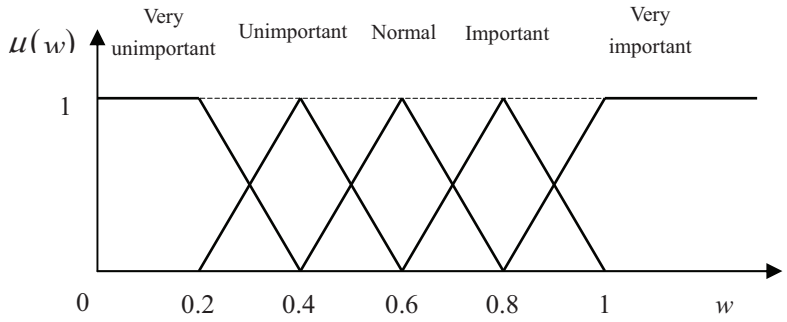

Figure 3 Fuzzy numbers for approximating linguistic weighting values

Table 7 Fuzzy numbers and α-cut of linguistic variables

Linguistic variables	Very important	Important	Normal	Unimportant	Very unimportant
Fuzzy numbers	$\begin{cases} 1 & 1 < w \\ 5w-4 & 0.8 < w \le 1 \\ 0 & \text{otherwise} \end{cases}$	$\begin{cases} 5-5w & 0.8 < w \le 1 \\ 5w-3 & 0.6 < w \le 0.8 \\ 0 & \text{otherwise} \end{cases}$	$\begin{cases} 4-5w & 0.6 < w \le 0.8 \\ 5w-2 & 0.4 < w \le 0.6 \\ 0 & \text{otherwise} \end{cases}$	$\begin{cases} 3-5w & 0.4 < w \le 0.6 \\ 5w-1 & 0.2 < w \le 0.4 \\ 0 & \text{otherwise} \end{cases}$	$\begin{cases} 2-5w & 0.2 < w \le 0.4 \\ 1 & 0 < w \le 0.2 \\ 0 & \text{otherwise} \end{cases}$
α-cut	$\left[\frac{\alpha+4}{5}, 1\right]$	$\left[\frac{\alpha+3}{5}, \frac{5-\alpha}{5}\right]$	$\left[\frac{\alpha+2}{5}, \frac{4-\alpha}{5}\right]$	$\left[\frac{\alpha+1}{5}, \frac{3-\alpha}{5}\right]$	$\left[0, \frac{2-\alpha}{5}\right]$

The aggregated function

The aggregation process includes the following four steps:

Step 1: Aggregate the membership function and the factor weight of each secondary factor.
Step 2: Integrate the membership function and the factor weight of each primary factor, which was composed by secondary factors.
Step 3: Combine the effects of the external and internal factors.
Step 4: Construct the strategy evaluation model

Step one

To aggregate the environmental factors using fuzzy weighted average operator, the results of the external and internal environmental factors are presented in Table 8 (partial results). The following is an example to formulate the membership function of a potential new entrant:

Let c_{1m}^{OI} be the weights of *m* secondary factors of potential new entrants, where m = 13 (see Table 2), and y_{A1}^{OI} denotes the membership function of potential new entrants which consists of thirteen factors. The weighted average is calculated to combine the impacts of all 13 secondary factors into one primary factor, potential new entrants.

By the same token, we can obtain the other integrated functions as shown in Table 8.

Table 8 The membership functions of environmental factors

Factors	Functions
Potential new entrants	$y_{A1}^{OI} = \frac{\sum_{m=1}^{m_1} c_{1m}^{OI}\left(1-\left(a_{1m}^{OI}\right)^{\alpha_{1m}^{OI}\left(x_{1m}^{OI}-1\right)}\right)}{\sum_{m=1}^{m_1=13} c_{1m}^{OI}}$
Inbound logistics	$y_{V1}^{I} = \frac{c_{V11}^{I}\left(\frac{k_{V11}^{I}}{\left(a_{V11}^{I}\right)^{\frac{1}{x_{V11}^{I}}}}\right)+c_{V12}^{I}\left(\frac{k_{V12}^{I}}{\left(a_{V12}^{I}\right)^{\frac{1}{x_{V12}^{I}}}}\right)}{c_{V11}^{I}+c_{V12}^{I}}$

Step two

To aggregate the weights of primary factor, we used the same fuzzy weighted average operator as step one and the results are summarized in Table 9 (partial results).

Table 9 The membership functions of the internal and external environmental factors

Factors	Functions
Environmental uncertainty	$f_{Un}^{OG} = \frac{w_{Dn}^{OG}\left[\left(a_{Dn}^{OG}\right)^{\beta_{Dn}^{OG} x_{Dn}^{OG}}-1\right]+w_{Mn}^{OG}\left[\frac{k_{Mn}^{OG}}{\left(a_{Mn}^{OG}\right)^{\frac{1}{x_{Mn}^{OG}}}}\right]+w_{Cn}^{OG}\left[\left(a_{Cn}^{O}\right)^{\beta_{Cn}^{OG} x_{Cn}^{OG}}-1\right]}{w_{Dn}^{OG}+w_{Mn}^{OG}+w_{Cn}^{OG}}$
Inbound logistics	$f_{1}^{I} = \frac{w_{V1}^{I}\left\{\frac{c_{V11}^{I}\left(\frac{k_{V11}^{I}}{\left(a_{V11}^{I}\right)^{\frac{1}{x_{V11}^{I}}}}\right)+c_{V12}^{I}\left(\frac{k_{V12}^{I}}{\left(a_{V12}^{I}\right)^{\frac{1}{x_{V12}^{I}}}}\right)}{c_{V11}^{I}+c_{V12}^{I}}\right\}+w_{R1}^{I}\left[\left(a_{R1}^{I}\right)^{-\alpha_{R1}^{I}x_{R1}^{I}}\right]+w_{I1}^{I}\left[\left(a_{I1}^{I}\right)^{-\alpha_{I1}^{I}x_{I1}^{I}}\right]+w_{O1}^{I}\left[\frac{k_{O1}^{I}}{\left(a_{O1}^{I}\right)^{\frac{1}{x_{O1}^{I}}}}\right]}{w_{V1}^{I}+w_{R1}^{I}+w_{I1}^{I}+w_{O1}^{I}}$

Step three

This process aggregates the membership functions of external environmental uncertainty and industry attractiveness, and the results are described in Table 10.

Table 10 Influential functions of external environmental uncertainty and industry attractiveness

	Environmental uncertainty	Industry attractiveness
Functions	$f_U^{OG} = \frac{\sum_{n=1}^{8} w_{Un}^{OG} f_{Un}^{OG}}{\sum_{n=1}^{8} w_{Un}^{OG}}$	$f_A^{OI} = \frac{\sum_{u=1}^{5} w_{Au}^{OI} \left[\frac{\sum_{m=1}^{m_u} c_{um}^{OI} \left(1-(a_{um}^{OI})^{\alpha_{um}^{OI}(x_{um}^{OI}-1)}\right)}{\sum_{m=1}^{m_u} c_{um}^{OI}} \right]}{\sum_{u=1}^{5} w_{Au}^{OI}}$

Step four

We construct the strategy evaluation model for Miles and Snow typology that considers both the importance of internal environment factors to strategies and the fitting of the characteristics of external environment factors to strategies. Table 11 summarizes the fit functions of external environment factors for Miles and Snow typology.

Table 11 Fit functions for Miles and Snow typology

Strategies	Fit functions	
Prospectors	$EGS_1 = 0.5^{\lvert \alpha=1 f_U^{OG} - 0.8 \rvert}$	$EIS_1 = 0.5^{\lvert \alpha=1 f_A^{OI} - 0.8 \rvert}$
Analyzers	$EGS_2 = 0.5^{\lvert \alpha=1 f_U^{OG} - 0.6 \rvert}$	$EIS_2 = 0.5^{\lvert \alpha=1 f_A^{OI} - 0.6 \rvert}$
Defenders	$EGS_3 = 0.5^{\lvert \alpha=1 f_U^{OG} - 0.4 \rvert}$	$EIS_3 = 0.5^{\lvert \alpha=1 f_A^{OI} - 0.4 \rvert}$
Reactors	$EGS_4 = 0.5^{\lvert \alpha=1 f_U^{OG} - 0.2 \rvert}$	$EIS_4 = 0.5^{\lvert \alpha=1 f_A^{OI} - 0.2 \rvert}$

EGS The fitting value of environmental uncertainty
EIS The fitting value of industry attractiveness

This research generalizes the studies of relationships between Miles and Snow typology and environmental factors' weights and the results are summarized in Table 12 (O'regan & Ghobadian, 2006; DeSarbo, Di Benedetto, Song, & Sinha, 2005; Brunk, 2003; Hambrick, 2003; Slater & Narver, 1993.)

Table 12 Summary of environmental factors' weights in Mile and Snow typology

Environment	In prospectors	In analyzers	In defenders	In reactors
Internal environment	important	important	very important	unimportant
External environment	very important	important	normal	unimportant
Inbound logistics	normal	important	important	normal
Operating	very important	important	important	important
Outbound logistics	normal	normal	important	normal
Marketing	very important	important	normal	unimportant
Services	important	normal	normal	normal

To combine the fitting results of external environment and the performance of internal environment, we can transform the linguistic terms in Table 12 into the fuzzy numbers in the strategy evaluation model as shown in Table 13.

Table 13 Competitive strategy evaluation model

Strategies	Evaluating model

Prospectors	$f_1=\dfrac{\left[\frac{\alpha+4}{5},1\right]\left(\frac{w_{U1}^{OG}EGS_1+w_{A1}^{OI}EIS_1}{w_{U1}^{OG}+w_{A1}^{OI}}\right)+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]\left(\frac{\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]f_{IL}^l+\left[\frac{\alpha+4}{5},1\right]f_P^l+\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]\cdot f_{OL}^l+\left[\frac{\alpha+4}{5},1\right]f_M^l+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]f_S^l}{\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]+\left[\frac{\alpha+4}{5},1\right]+\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]+\left[\frac{\alpha+4}{5},1\right]+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]}\right)}{\left[\frac{\alpha+4}{5},1\right]+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]}$
Analyzers	$f_2=\dfrac{\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]\left(\frac{w_{U2}^{OG}EGS_2+w_{A2}^{OI}EIS_2}{w_{U2}^{OG}+w_{A2}^{OI}}\right)+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]\left(\frac{\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]f_{IL}^l+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]f_P^l+\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]f_{OL}^l+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]f_M^l+\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]f_S^l}{\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]+\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]+\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]}\right)}{\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]}$
Defenders	$f_3=\dfrac{\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]\left(\frac{w_{U3}^{OG}EGS_3+w_{A3}^{OI}EIS_3}{w_{U3}^{OG}+w_{A3}^{OI}}\right)+\left[\frac{\alpha+4}{5},1\right]\left(\frac{\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]f_{IL}^l+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]f_P^l+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]f_{OL}^l+\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]f_M^l+\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]f_S^l}{\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]+\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]+\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]}\right)}{\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]+\left[\frac{\alpha+4}{5},1\right]}$
Reactors	$f_4=\dfrac{\left[\frac{\alpha+1}{5},\frac{3-\alpha}{5}\right]\left(\frac{w_{U4}^{OG}EGS_4+w_{A4}^{OI}EIS_4}{w_{U4}^{OG}+w_{A4}^{OI}}\right)+\left[\frac{\alpha+1}{5},\frac{3-\alpha}{5}\right]\left(\frac{\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]f_{IL}^l+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]f_P^l+\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]f_{OL}^l+\left[\frac{\alpha+1}{5},\frac{3-\alpha}{5}\right]f_M^l+\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]f_S^l}{\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]+\left[\frac{\alpha+3}{5},\frac{5-\alpha}{5}\right]+\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]+\left[\frac{\alpha+1}{5},\frac{3-\alpha}{5}\right]+\left[\frac{\alpha+2}{5},\frac{4-\alpha}{5}\right]}\right)}{\left[\frac{\alpha+1}{5},\frac{3-\alpha}{5}\right]+\left[\frac{\alpha+1}{5},\frac{3-\alpha}{5}\right]}$

CASE ANALYSIS

To validate the applicability of the proposed model, we implemented the model in a strategic planning project to help evaluating the fitness of each of the four strategies in Miles and Snow typology. The following are the detailed implementation tasks for each phase.

Variables and membership functions formulation

The membership function of each factor is a variable in the strategy evaluation model; therefore the parameter value can be adjusted or revised in accordance with characteristics of the industry and/or enterprise under analysis. It has greatly enhanced the applicability and flexibility of the model to allow proper reflection of the uniqueness of the underlying business environment. To simplify our calculation, we have selected parameter values that are mostly small integer numbers.

External environment

The graphs and ranges of membership functions were affected by the parameter settings, and the results are presented in Table 14.

Table 14 The membership functions of external environmental factors

Characteristics	Parameters	Graphs	Membership functions
Munificence	$k_{Mn}^{OG}=2$ $a_{Mn}^{OG}=2$		$f_{Mn}^{OG}=\dfrac{2}{2^{\frac{1}{x_{Mn}^{OG}}}}$
Industry attractiveness	$a_{um}^{OI}=2$ $\alpha_{um}^{OI}=3$		$y_{um}^{OI}=1-2^{3\left(x_{um}^{OI}-1\right)}$

The main objective of the case analysis is to demonstrate the marginal effect of the evaluation. According to our literature review, the external environment factors (Dynamism, Munificence, Industry attractiveness) each belongs to a different membership function therefore has different shape of graph.

Internal environment

Similar procedure is followed to set the parameter values for internal environmental factors. Table 15 shows partial results of the membership functions.

Table 15 The membership functions of internal environmental factors

Characteristics	Parameters	Graphs	Membership functions
Delivery reliability	$k^I_{V11}=2,\ a^I_{V11}=2$		$y^I_{V11}=\frac{2}{\frac{1}{2^{x^I_{V11}}}},\ 0\le x^I_{V11}\le 1$
Defective rate	$a^I_{V22}=2,\ \alpha^I_{V22}=3$		$y^I_{V22}=1-2^{3\left(x^I_{V22}-1\right)},\ 0\le x^I_{V22}\le 1$

Data collection and analysis

The values of the external environmental factors relating to the three external environmental characteristics, dynamism, munificence, and complexity were collected from expert of an aerospace company in Taiwan. Table 16 presents partial results of the weights and values of internal environmental factors.

Table 16 The weights and values of internal environmental factors

Factors	The weight of uncertainty	Dynamism		Munificence		Complexity	
		Weight	Value	Weight	Value	Weight	Value
Technological environment	important	normal	0.7	important	0.7	important	0.8
Competitive environment	important	normal	0.7	very important	0.5	important	0.9
Sociocultural environment	normal	normal	0.5	normal	0.5	unimportant	0.3
demographic statistics environment	normal	important	0.5	unimportant	0.3	unimportant	0.2
Global environment	important	important	0.8	normal	0.3	unimportant	0.3
Economic environment	important	important	0.5	normal	0.2	unimportant	0.3
Natural environment	unimportant	normal	0.3	unimportant	0.1	unimportant	0.3
Legal-political environment	important	important	0.5	normal	0.2	normal	0.5

We then plugged in the numbers to the proposed strategy evaluation model and derived the degree of fitness of each strategy as shown in Table 17.

Table 17 Summary of the strategy evaluation results

α	Prospectors	Analyzers	Defenders	Reactors
0.2	[0.277,1.719]	[0.217,2.062]	[0.157,1.817]	[0.110,3.012]
0.4	[0.322,1.227]	[0.279,1.441]	[0.214,1.273]	[0.168,1.822]
0.6	[0.379,0.909]	[0.357,1.047]	[0.287,0.918]	[0.248,1.167]

0.8	[0.456,0.702]	[0.460,0.782]	[0.381,0.676]	[0.363,0.776]
1	[0.561,0.561]	[0.592,0.592]	[0.504,0.504]	[0.529,0.529]

Result analysis

According to the fuzzy theory, the different α-value (shown in column 1) represents different level of confidence in controlling the environmental uncertainty. The higher the uncertainty is, the lower α value will be. The ranges of the intervals in the outcomes of our strategy evaluation model tend to be large when company has little information to handle the environmental uncertainty. On the other hand, when α is closer to 1, it represents the company has perfect information of the environment, the result range of interval should be very small. Regarding the aerospace company case, we can rank the fitness of the strategy from high to low as Analyzers (0.592), Prospectors (0.561), Reactors (0.529), and Defenders (0.504), the maximal evaluated value is 0.592 (Analyzers), the second one is 0.561 (Prospectors), when $\alpha = 1$. Therefore we can conclude that the company should adopt the Analyzers or Prospectors strategies or even consider the combination strategy.

CONCLUSION

The purpose of this research is to propose a strategy evaluation model that implements quantitative analysis techniques and fuzzy membership functions for business strategy selection. The model can assist firms in making more informed and objective decisions by analyzing the opportunities and threats in external environment together with the strengths and weaknesses in internal environment. It is a comprehensive model that encompasses factors identified from several classic researches in the field of strategy. Other contributions of this research include: the model provides a logical process for strategy analysis; the model applies the concept of fuzzy theory to quantify the factors and create membership functions by considering the influence of the characteristics of Miles and Snow typology; the membership degree of environmental factors can serve as an indicator for evaluating the performance of firm's strategy. With an increase of membership degree, the performance of firm's strategy increases. To reduce the subjective bias of the respondents, we transformed the linguistic terms into numbers and aggregated the weights and value of factors using fuzzy weighted average operator. One limitation of this research is we have only investigated the application of our strategy evaluation model to rank and evaluate the four strategies in Miles and Snow typology, one of the most popular strategy classification schemes. However, there are other strategy classification systems available. In the future we plan to investigate more classification schemes that may consider different sets of factors to broaden the scope and applicability of our model. Another possible future research direction is to automate the strategy evaluation model by implementing it using a Windows based business-programming language such as Visual Basic. The program will allow users to easily set parameter values through a user-friendly interface. It could also allow users to perform what-if analysis by altering some of the parameter settings.

ABSTRACT

Take a glace at the Taiwan virtual shopping environment. A growing number of branding manufacturers compete by decreasing product price, improving product quality or enhancing brand image. Numerous non-famous branding suppliers cooperate with famous TV shopping stores to reduce marketing costs and promotion risks, while increasing sales performance. Because consumers do not spend all their time online, they work, listen music, watch TV and read magazines, more and more TV shopping channels design marketing strategy or provide wholly customer post-purchase services, and increase the famous degrees and brand image of channels, to maintain consumer loyalty. Based above discussion, the research examines the marketing mix (e.g. price, advertising and selling international brands, etc) and channel branding issues (e.g. brand awareness, perceived quality, brand image, etc) for TV shopping stores. This paper provides the discussion of marketing strategy and channel brand equity for TV shopping retailers via consumer viewpoints.

By adopting an integrated perspective emphasizing the roles of marketing strategy and brand equity, this paper addresses these key gaps by developing empirical firm-marketing explanations of consumer purchase intentions and channel brand loyalty for related academic research in terms of linear regression method. The objective of this study is to investigate and evaluate the effect of business marketing strategy, brand equity on consumer purchase and brand loyalty and then examine their importance in allowing manufacturers and retailers to develop a competitive position in the commercial marketplace. The findings have the potential to offer significant implications for theory and practice.

Bring varied consumer-level notions of marketing management strategies toward TV shopping channels into the same plane as market-level measures of brand performance such as channel brand loyalty, customer purchase intention. Research findings indicate TV

shopping channels should (1) intensify emotional appeal, reduce rationalized appeal of advertising strategy, (2) sell international brand products in the context of a brand alliance strategy, and (3) develop channel brand equity helpful to the channel brand loyalty and purchase intention of consumers. The research results will help TV shopping retailers to formulate suitable marketing and branding strategies. In addition, the research results could be referenced by the manufacturers to decide their virtual channel marketing strategy. Further, the research findings contribute to the marketing theory and branding research in academia.

ABSTRACT

Purpose

The strategic thinking behind numerous M&As is: "bigger is more important than better". Such logic is also followed in the growth strategies of many players who believe that increasing scale via M&As will bring sustainable competitive advantage and generate above-average financial performance and value creation for their shareholders. But numerous failed M&As and the modest financial performance of many large players compared to smaller ones question the universality of this logic. The aim of this article is to emphasize strategic business process reengineering perspective to better understand the sources of value creation in acquisitions. Moreover, an integrated approach embraces conceptual viewpoint with resource based view, relational approach, and Porter's five forces are employed as a guideline for managers to formulate projects associated with business process reengineering.

Design/Methodology/Approach

The approach of this paper is to state a comprehensive strategy formulation process guided by three sections: case study to show the importance of operation fit between acquiring firm and acquired firm, business process reengineering initiative, and application of the strategic business process reengineering.

Findings

Scale does not necessarily bring competitive advantage, improve financial performance, or generate scale-related synergies per se. To develop sustainable competitive advantage, executives must understand the true nature and mechanisms which drive the operation fit process, value creation through M&As and the consequent reengineering projects of

enhancing company's competitive advantage.

Originality/Value

The article discloses key strategic elements to be considered when formulating effective corporate strategies in a complex business environment and a context of rapidly mature industries. The discussion also raises awareness regarding the importance of strategic logic, correct interpretation of integrated strategic concepts and guidelines to business practice.

Keywords: Business process reengineering, Merger and acquisition, Competitive advantage, Value creation, Operation fit

INTRODUCTION

Nowadays, a key word in any merger and acquisition (M&As) is "value creation". Value creation can be termed as synergy which delivers synergistic gains such as market power, economies of scale and scope, coinsurance, combination of complementary resources, and risk diversification (Eckbo, 1983; Stillman, 1983; Seth, 1990; Bradley et al., 1988; Malatesta, 1983; Shrieves and Pashley, 1984; Weston et al., 2004). Seth (1990) distinguished alternative sources of gain associated with different acquisition strategies based on capital asset pricing model and discounted cash flow approaches to estimate combined returns of the entity. Seth (1990) further indicated that the related acquisitions with relatively larger size of bidder tended to be associated with an increase in value creation due to operating efficiencies, which are measured by financial or economic ex-post predicator variables. But will this really happen? Why do so many M&As fail to deliver the above-average post-acquisition financial performance, sustain competitive advantages, and gain value creation for their customers, employees, and shareholders?

With failure rate around 50 percent, there was evidence that many mergers and acquisitions had unsatisfactory outcomes (Schoenberg; 2003). Most of the arguments derived from the organizational fit constraints or complexities stemming from the intangible knowledge assets surrounding the integration of people and business process which firms encounter on how to develop new business and products, and redeploying resources rapidly within their boundaries (Capron, 1998; Ranft, 2002; Chatterjee, 2007; Puranam, and Kannan, 2005). That is, there is evidence that ineffective business process integration appears to be a major reason that many acquisitions fail to create value, or from strategic management viewpoint, unable to achieve sustained competitive advantage (Harrison, et al. 1991; Jones and Miskell, 2007). Subsequently, the different value systems between firms can lead to different or opposite arguments with synergistic acquiring firms or acquired firms (Ernst and Vitt, 2000; Ranft and

Lord, 2002). For that reason, organizational value in M&A context, as well as business and technical BPR (Business Process Re-engineering) aligning with strategic fit needed to be taken into accounts. This work aims to show the importance of BRP in M&A through a best-practice company case.

To examine the effect of organizational fit, Daly et al. (2004) investigated M&A effectiveness by examining organizational espoused value. They examined the espoused value in two dimensions: concern for employees and concern for production. Espoused values are those values that are expressed on behalf of the organization or attributed to an organization by its senior managers in public statements such as in the firms' annual reports (Daly et al., 2004). Espoused values differ from what some have termed organizational values, (e.g., Rousseau, 1990), which are shared by all or a large proportion of an organization's members. Daly et al. (2004) found that organizational fit improve the performance of M&As. While Daly et al. (2004) employed statistical analysis of many M&As to show the effect of organizational fit, the current study employs case study to show the importance of operation fit between acquiring firm and acquired firm.

BUSINESS PROCESS RE-ENGINEERING

Business Process Re-engineering Initiatives

Organizations today seek to rationalize, innovate and adapt to changing environments and circumstances as part of business process reengineering (BPR) efforts (Kueng and Kaulek, 1997). As a consequence, many companies are engaged in intensive process redesign for their business processes. Different process models exist for use in analysis, design, and implementation phases (Georgakopoulos et al., 1995; Kueng et al., 1996; Mylopoulos et al., 1999; Ould, 1995; Gans et al., 2003; Gulledge and Deller, 2009). Irrespective of the process reengineering program selected and the IT-related technique used to model it, BPR brings with it the issues of organizational and process changes. Thus, BPR initiatives involve long-term strategic goal for an organization. An integrated strategy map represents a composite potential improvement path of an investigated enterprise, starting from and improvement of its organizational profile towards an improved realization of its business objectives, thus providing strategic map or strategic logic on important linkages between business process management and organizational fit.

Business Process Re-engineering and Strategic M&A Value

As mentioned in prior section, one of the sources of value creation in M&As is scarce complementary resources. Companies can acquire other firms such as a manufacturer of complementary product, or raw material suppliers, in order to control complementary

resources processes. However, the synergies promised to justify the transaction cost show up often as little more than goodwill on the balance sheet, without creating real value for shareholders. As a result, significant, unrealized value remains locked up in mergers. Reengineering is to unlock that value. The entire value chain, the costs of supporting multiple business models and architectures, and the technology road maps required to integrate businesses should be considered for integrating the acquired firm. Understanding the operation fit beyond strategic fit would greatly enhance the probability of successful merger.

Business Process Re-engineering and Integrated Strategy Map

Firms are constantly facing turbulent environmental changes. To remain completive, program, project, IT implementation for re-engineering should involve strategic thinking. Therefore, a conceptual framework encompassing both re-engineering and strategic thinking is required for developing a variety of service-oriented programs and projects across the organizations.

There are some conceptual differences of approaches to be addressed to accomplishing competitive advantage (CA). Three approaches: Porter's five forces (PFA), resources based approach (RBA), and relational approach (RA), pursue similar goals in somewhat different ways, we propose an integrated approach to strengthen the strategic management process in the golf club industry. Advances in understanding the strategic management process toward CA can be impeded if managers adopt the PFA, RBA, or RA one at a time.

Weakness of Non-integrated Strategic Management

During the 1980s, the PFA (Porter, 1980) helped managers understand how they could position their businesses for success in a competitive environment and how industry forces could affect their return on investment. Today, the new business world requires managers to recognize recent developments such as globalization, technological advances, and the Internet as new sources of CA. According to the PFA, firms achieve CA over their suppliers, customers, or competitors. However, this approach does not fully take into consideration advantages of collaborative relationships with suppliers and customers. CA can emerge from the ability of a firm to develop collaborative relationships with more volatile customers (e.g. brand-switching customers) and to manage far-reaching networks of partners for mutual advantage. Furthermore, firms try to form relationships with their competitors to add value to their business.

The RBA has focused on resources that are typically internally developed and that are specific to an organization (Barney, 1991; Wernerfelt, 1984). However, internally developed resources tend not to fully reflect the general needs of market constituents like customers and competitors. Therefore, we need to look at market-based resources such as the firm's market orientation, because those resources enable firms to overcome limitations of functional resources through the "commingling of the organization and the environment" (Srivastava et

al., 1998, p. 3). Market orientation is defined as firm activities/behaviors of offering unique products/services and creating customer value, based on a better understanding of customers' needs and competitors' actions or strategies (Kohli and Jaworski, 1990).

The RA tends to emphasize business-to-business relationships without giving a balanced treatment to business-to-customer relationships that also are important. The business-to-customer relationship is particularly critical in the service industry, because customers pursue ongoing relationships with service providers to reduce their perceived risk in evaluating services (Lovelock, 1983). Because of the intangibility and interpersonal focus of services, customers are likely to form relationships more with organizational members (i.e. employees) than with goods (Gwinner et al., 1998).

An Integrated Approach

Each approach has helped managers understand how CA could be achieved in different ways. However, these approaches have overlooked the fact that:

(1) firm resources are unique among firms within an industry and such unique resources can determine CA (i.e. PFA overlooked);
(2) market-based resources are a critical source of CA (i.e. RBA overlooked); and
(3) firm strategies should be aligned to firm resources (i.e. RA overlooked).

A firm's overall competitive position results from its internal and interfirm resources, both of which are greatly influenced by the firm's external environment (e.g. five industry forces). Because sources of CA tend to be interrelated to one another, an integrated approach will be necessary to obtain and sustain CA. Figure 1 shows how these three approaches are integrated for a comprehensive framework of strategic management. How each approach can contribute to achieving CA has been discussed in previous sections (i.e. A, B, and C in Figure 1).

The success of interfirm relationships can be affected by organizational resources such as organizational culture, decision-making processes, and information sharing among employees (Dyer and Singh, 1998). These organizational resources enable an organization to capture its value created through interfirm linkages. This is shown as "D" in Figure 1. Thus, the RA can be complementary to the RBA in that internal resources can affect the relationship between interfirm resources and firm performance.

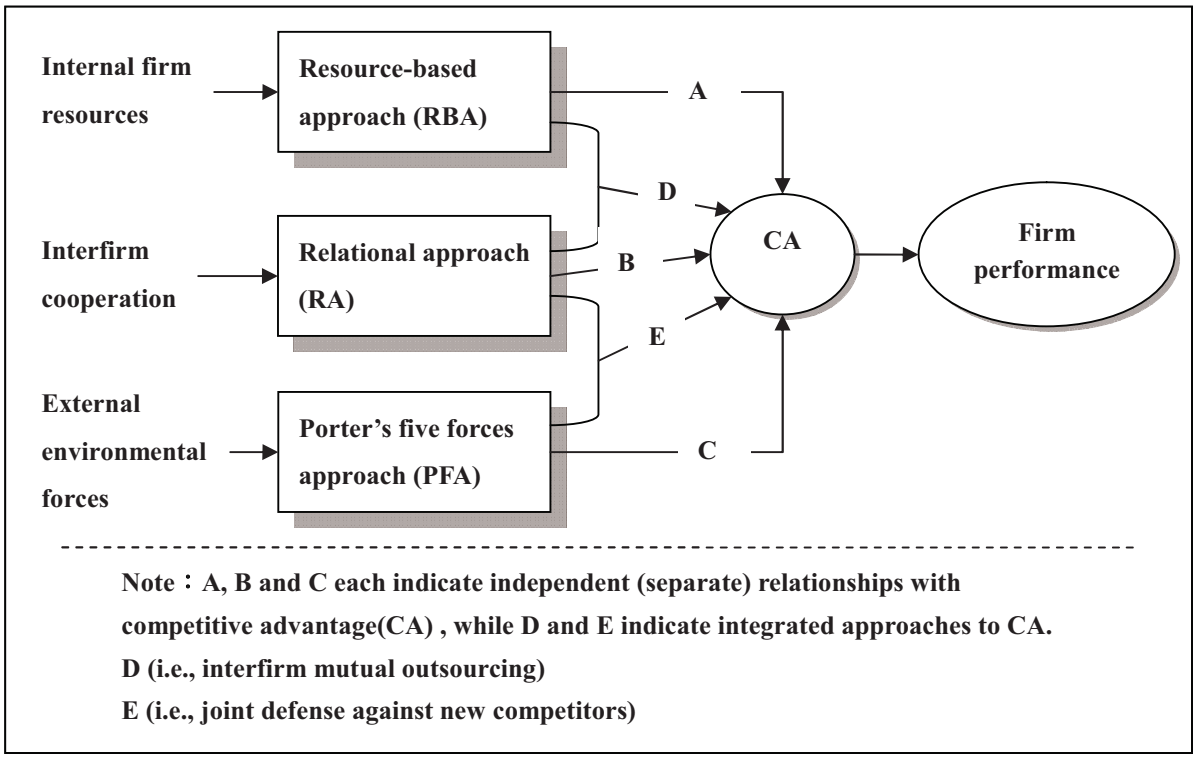

Figure 1. An integrated framework of the three approaches

An integrated approach is helpful in implementing firm strategies more effectively than otherwise. Increased competition encourages a firm to develop interfirm linkages. Competitive intensity described by Porter (1980) forces a firm to provide better products and services than its competitors'. Accordingly, firms should attempt to build close relationships with their suppliers. Cooperative buyer-supplier relationships in the business-to-business context help reduce costs and improve quality to the end buyer (i.e. customers). Reduced purchasing costs and improved product/service quality can enable firms to effectively implement their strategies such as product differentiation or cost leadership (Porter, 1980). Thus, sources of CA for achieving superior performance derived from mutually satisfying, sustainable relationships with suppliers. In addition, it is imperative for firms to build a close relationship with their customers to overcome heavy competition and stay profitable. These situations are described as "E" in Figure 1.

An integrated approach helps companies establish solid footholds for achieving long-term growth and profitability. To achieve long-term growth and profitability, firms should adapt themselves to the rapidly changing industry environment (i.e. PFA), continually develop new resources such as market-based resources (i.e. RBA), and build strong relationships with their customers as well as suppliers (i.e. RA). Because various sources of CA make it

hard for competitors to imitate the sources of CA (that is, value may be created by acquiring scarce complementary resources in M&As), companies can sustain their CA over the competitors.

In addition, an integrated approach would be beneficial to firms in developing an effective strategic plan. Strategic planning determines where a firm is headed in the next few years and how it is going to get there. Therefore, development of a strategic plan helps clarify the firm's future. The success of strategic planning depends on how effectively firm resources can be deployed along key priorities. Thus, identification of various sources of CA can help companies conduct strategic planning and implement the plan effectively.

APPLICATION

Background

With rapid emergency of China and other Southeastern countries, industry structure and markets in Taiwan change dramatically during a short period of time. Many firms shifted their production facilities to China or other Southeastern countries. For manufacturers in the traditional sectors, such as golf club makers, low cost may not be the deciding competitive factor. For example, golf club manufacturers in Taiwan have shortened the replacement cycles of their products and at the same time, they have been able to increase price. This has entailed focusing on golf club heads to make the swing even sweeter. That is a golfing term referring to the most desirable point of impact of the club face to the ball. Club-head components require the highest degree of know-how technical skills, such as CAD file producing, mold making, casting specialized titanium and steel alloys.

To meet the competition from manufacturers located in low cost areas and demands from their OEM customers, manufacturers in Taiwan may use M&As and reengineering to maintain and enhance their competitive advantages. This strategy has been successful so far. The number of golf club heads produced in 2008 by the four largest Taiwanese golf club producers— Advanced International Multitech Co. Ltd. (AIM), Fu Sheng Industrial Co. Ltd., O-TA Precision Industry Co. Ltd., and Dynamic Precision Industry Corp.--totaled about 22.5 million, or nearly 60 percent of total global production.

The Case Company

Advanced International Multitech, (AIM) established in 1987, is a publicly listed Taiwan based company engaged in the manufacturing of golf club heads, shafts, composite materials, carbon fiber components, and accessories for bicycles, such as forks, frames, and seat posts. Headquartered in Kaohsiung, Taiwan, the company employs about 10,500 people.

The golf club industry in Taiwan has been in existence for more than thirty five years. AIM

entered the industry in 1987. Within 20 years, the company has emerged as the largest golf club manufacturers in Taiwan. AIM suppressed other incumbents by focusing on this industry with value creation through acquisitions and integrated strategic business process re-engineering.

The Challenges

The fierce competition in this industry has caused many original equipment manufacturers (OEMs) to focus on their leading product and form partnerships, or purchase other specialized companies, to complete their product portfolio. Some examples from 2000 to 2003 are: Titleist buying Cobra for their low and midline product, Spalding buying Ben Hogan for their top line irons and then Callaway buying Spalding to gain market shares. To meet the demand from their customers, who are brand name owner and are facing intensive competitive pressure, manufacturers in Taiwan are investing enormously in R&D to capture the increased demand for personalized, value-added products, which is a growing portion of the 2.4 billion US$ market for all golf equipment (SRI International, 2002). Since 1990, the number of golfers grew about 5% to about 30 million golfers, hence supporting the demand for personalization. This has largely been explained by the advances in technology which provide customized high-end products highly valued by customers.

Supply Chain Management through Strategic Business Process Reengineering

Gulledge and Deller (2009) distinguished business process management (BPM) between technical IT perspective (Technical BPM) and business perspective associated with competitive advantage enhancement. Therefore, an integrated approach employed to deliver competitive advantage is proposed in this study.

The technical business process management (technical BPM) must be related to value-driven business strategy events to gain interface cost reduction and flexibility. For example, from relational approach perspective, AIM transformed from OEM to original design manufacturer (ODM). Intimate cooperation and coordination within supply chain partners as joint defense against new competitors is demanded, Co-Sports Chain e-project with IT implementation was proposed to reduce inventory cost, to gain competitive advantage in time to end user, time to volume, time to market, and time to technology performance.

Strategic Perspective to Create Business Process Reengineering Value

Companies who own strategic assets (internal firm resources) outperform competitors because they control valuable resources that are hard to replicate. To sustaining competitive advantage in the matured golf club industry (FPA issue encountered), a company should acquire or develop intangible assets such as employee know-how, reputation, and

organizational culture (Michalisin et al., 1997; 2000). To achieve the goal, AIM decomposed their major business operation process (here, operation fit is taken into account) with the following figure 2. which illustrated the process from customer request data input, CAD file producing, tooling, casting, forging, face producing, welding, painting, and shipping. Some of the processes are outsourced prior to M&A activities. Prior to M&As, AIM encountered difficulties in timely satisfying one-stop shopping service for customers. Because big customers quite often requested diversified models and products in one order, AIM had to outsource some of the products such as golf balls. However, golf ball manufacturers quite often couldn't meet the demand on time and the customized materials conforming to different models of shafts. By acquiring a top-tier golf ball manufacturer, AIM would be able to streamline the process and meet the demand of buyers on time as one-stop shopping.

Another merger that AIM did in the past was to purchase two mold manufacturers. Molds are critical technology for golf club manufacturing. Before the merger, the two mold manufacturers were in high demand and again quite often could not meet the deadline requested by AIM. Acquiring the two mold manufacturers involve strategic fit and operation fit. On the strategic facet (RBA issue encountered), due to the scarcity of excellent mold manufacturers, competitors had to look for the second best mold manufacturers, rather than the best.

To achieve effective integration between acquirer and target firm, the senior managers of AIM decided to establish strategic alliance relationship with potential target firms through intangible knowledge assets surrounding the integration of people and process prior the formal acquisition phase. The different value system between firms can lead to greater transfer of tacit knowledge due to increased interaction between individuals in acquired and acquiring firms (Ernst and Vitt, 2000; Ranft et al, 2002). Due to the close cooperation between the members of the two firms and the successful introduction of IT infrastructure, the acquisition started to create values for AIM relative early.

On the operation fit facet, time-lag minimization arises when waiting times between operations are imposed. Since the product design is integral, i.e., the design of most individual components is integral to other components, projects at this stage of the industry's development are best managed by tight integrated operation, which results in shorter delivery time for golf club head. The technology-facilitated forms of interaction or information communication technologies (ICT) also play an important role to strengthen the operation fit during M&A. For example, product knowledge management (PKM) platform facilitates knowledge sharing among various departments. PKM also ensures the quality of the product by enforcing the standard operation procedures. Facilitating the quick search of product information and offering online meetings, PKM shortens the new product development cycles. Thus, ICT strengths the operation fit for M&As.

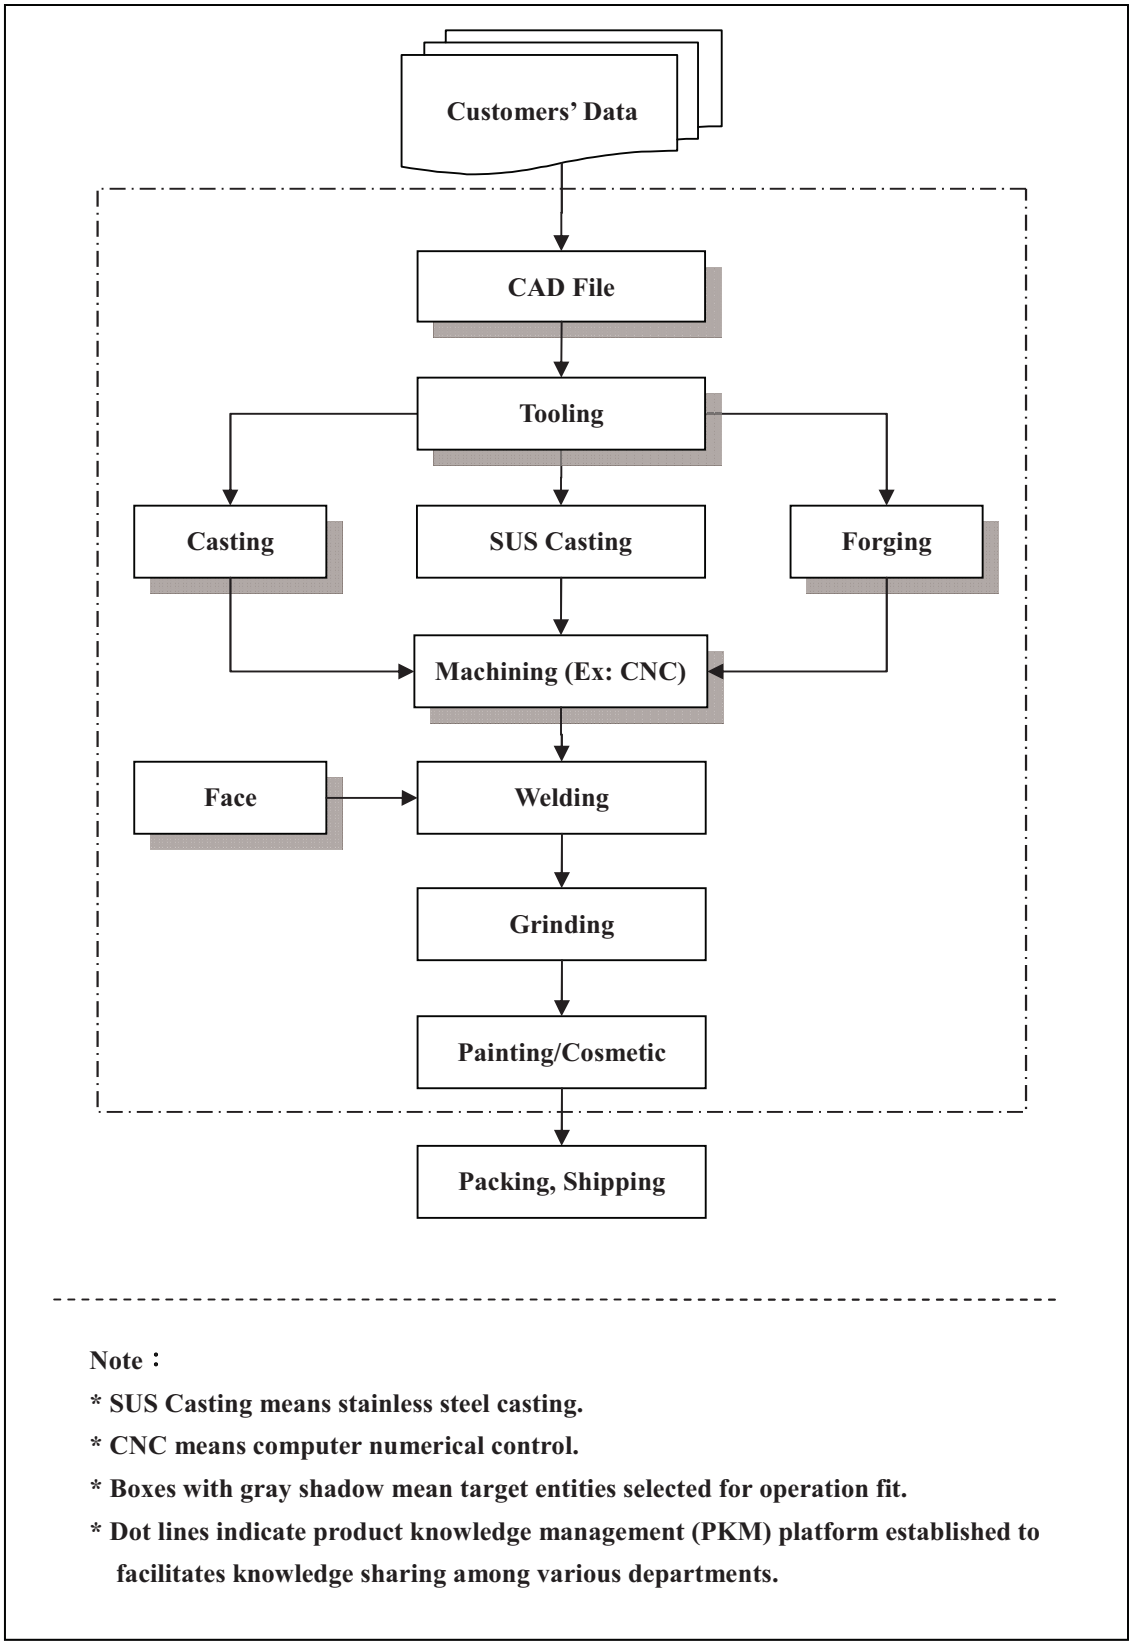

Figure 2. Decomposition of major business operation process in AIM

CONCLUSIONS

While sources of value creation in acquisitions was recognized as an important issue in B2B management literature, the selection of an ideal relationship with target firms would be a major advantage to acquiring firm and a way to achieve competitive advantage. This justifies the need for better understanding in operation fit through examination organizational value in M&A context, as well as business and technical BPR (Business Process Re-engineering) aligning with strategic fit.

Business process reengineering (BPR) involves relatively complex different business process types (Goldkuhl and Lind, 2008) and without the support of Information and Communication Technology (ICT), it would not be accomplished easily (Gulledge and Greg, 2009). This study proposed BPR associated e-project (ex. Co-sports OEM-ODM logistics e-project) stemming from the strategic integrated approach. The integrated approach includes resource base view point, relational approach, and Porter's five force approach to balance a portfolio of competitive advantage stemming from business process reengineering opportunities, that is , a strategic business process reengineering perspective. Successful merger & acquisition (M&A) practice, therefore, requires operation fit in consideration of composite strategic BPR perspective to create organizational value.

The major implication for academicians lies in that the particular connection of strategic logic and BPR implementation for commonly determining M&A for managers is unique in literature. Moreover, this study contributes not only in developing a well-defined integrated strategic process for BPR managers' requirement determination but also determining useful techniques to effectively implement it. In conclusion, a strategy-based analysis is important because firms are able to adopt various internal resources with interfirm cooperation to defend against new competitors.

MARKETING STRATEGY COMPARISON BETWEEN INTERNATIONAL BRAND AND THAI BRAND FOR PREMIUM COFFEE BUSINESS UNDER CUSTOMERS' PERSPECTIVE: CASE STUDY IN CHIANG MAI, THAILAND

Miss Chulaluck Pratip Na Thalang, School of Management, Mae Fah Luang University, Thailand
ohyoyo_8@hotmail.com

ABSTRACT

Coffee is a main drink for Thai people who love to drink for a long time and less of them are deny it. Because of coffee has it own tasty, sweet and richly scented for drinkers who admire. It makes the Thai and foreign investors are interested to investment due to they look at the chance that will be turn back a lot of benefit in this business. So, this business has more opportunities to grow up but market competitions have more increase. The entrepreneurs should be adapt the strategies both attraction and acceptation in order to follow up the market situations.

The purposes of this study are to compare the marketing strategies for coffee business between International brand and Thai brand under customers' perspective and provide the recommendations to interested investors for doing coffee business in Thailand. The results of the study found that, marketing strategy was not the same for international coffee brand and Thai coffee brand. Due to the most important marketing strategy for Thai coffee brand was product strategy while the most important marketing strategy for international coffee brand was promotion strategy.

The finding this study leads to recommend for impact in short term that have high price elasticity for products, find the outsourcing to reduce the cost of production, reducing the price to lower than competitors, and improve the service to become faster will help to increasing sales. Further more, quality of product, research and development of new technology, have various channels of distributions, decoration for more quality of the coffee shop, product tasting, and build up good relationship between consumers and the brands will be good thing in long term for this business.

Keywords: coffee business, Thai brand, international brand, marketing strategy

INTRODUCTION

Coffee is a main drink for Thai people who love to drink for a long time and less of them are deny it. Because of coffee has it own tasty, sweet and richly scented for drinkers who admire. Today, coffee is still more popular when coffee markets are remodel the product packages for responsible to customer's need in their daily life. Coffee ready-made, coffee can, and premium coffee shop that make the Thai and foreign investors are interested to investment due to they look at the chance that will be turn back a lot of benefit in this business. Until now, more producers are responsible and completely produce. The alternative of various tastes and unique for each brand that effect to the old producers who create the strategies reaching for market share.

Premium coffee shops are more completely, especially the distribution that most are open for modern trade: malls, hyper markets, and discount stores, which force the golden location. So the cost for each branches are high and entrepreneurs could adapt the strategies by

concentrate with vary and difference. To branch up for cover the customer target area by presentation about modern trade such as gas stations, theatres, electric trains, fairs, book stores, hospitals, fitness, electric train stations, and airports.

However the foreign investors in Thailand that shows this business has a lot of promise and carries the opportunities. Thai premium coffee shops are blend to foreign branches and Thai has just 3 premium coffee shops in Singapore, Malaysia, and Indonesia (Kasikorn Research Center, 2005).

The Bubble Economy, since 1997 that premium coffee shops were well-known for investors and consumers in this business type. The factor that supports for business grown up was increase cost together with consumer behavior. They prompted to pay more for quality. Other side, consumers who though about the inexpensive for real coffee with 80-100 baht for each one. Kasikorn Research Center (2005) expects the total value of market with this business is 3,500 million baht. Grown-up rate was still 20 percent per year. Consumers who use the product and service have more variety. Moreover, coffee shops in Thailand are more interested because of Thai consumers. So, the opportunities to run this business were high including with the consumer behavior that drinks for their daily life.

Premium coffee shops have 2 types; foreign premium coffee such as Star's Bucks, Au Bon Pain, Gloria Jeans, UCC and Thai premium coffee such as Black Canyon, Baan Rai Coffee, Coffee World, Modern Coffee. Market shares: inter brand is 60 percent and local brand is 40 percent (Siam Commercial Bank Library, 2003).

Conclusion, the coffee production is the interested business because of the growth up of Thai drinker who still in gain, less than 0.5 kilogram per person and per year or 130-150 cups per year. To expectation, Thai people will consume coffee only 30 percent of Thai population. So, this business has more opportunities to grow up but market competitions have more increase. The entrepreneurs should be adapt the strategies both attraction and acceptation in order to follow up the market situations. (Kasikorn Research Center, 2005).

The objectives of this study

The objectives of this study are to compare the marketing strategies for coffee business between International brand and Thai brand under customers' perspective and in order to provide the recommendations to interested investors for doing coffee business in Thailand.

LITERATURE REVIEW

Pao-Long Chang and Ming-Hua Chieng (2006) to study building consumer-brand relationship: a cross-cultural experiential view. This research aims to develop a framework of consumer-brand relationship by taking an experiential view. In this article, the authors report a cross-cultural comparative study that was conducted on a sample of real consumers at coffee chain stores in Shanghai, China, and Taipei, Taiwan. The findings reveal that individual as well as shared experiences work through brand association, brand personality, brand attitude, and brand image to shape a consumer-brand relationship.

Patrick De Pelsmacker, Wim Janssens, Ellen Sterckx, and Caroline Mielants (2005) to study consumer preferences for the marketing of ethically labelled coffee. The consumers attach greatest importance to the distribution strategy of ethically labeled coffee, followed by the

type of ethical label, and the issuer of the label. Ethically labeled coffee should be available in ordinary supermarkets and be presented along with non-ethical coffee brands. Fair trade labeled coffee is by far the most preferred over eco- and bio-labels. European government labels, or labels issued by non-governmental organizations, are preferred over national (Belgian) government endorsed labels. Consumers prefer extra information on the package, in addition to a label. Out-of-shop promotion of the label and the type of brand are of minor importance. The results are similar across different socio-demographic groups.

Laetitia Radder and Wei Huang (2008) to study high-involvement and low-involvement products: a comparison of brand awareness among students at a South African university. The results indicated a higher awareness of high-involvement product brands than of low-involvement product brands. Advertising played an important role in the awareness of sportswear clothing brands, but seemed unimportant in the case of coffee. The brand name was important for coffee, while the name and the logo played a role in students' awareness of sportswear brands. This study was limited to students of the Nelson Mandela Metropolitan University (NMMU) in Port Elizabeth, South Africa and to sportswear clothing and coffee product categories. Future studies could comprise larger samples, different contexts and other product or service categories. The findings suggest that marketers employ different strategies to create and increase brand awareness for high- and low-involvement products. Previous research found that brand awareness played an important role in low-involvement products; however, little is known about brand awareness differences between high- and low-involvement products, particularly with respect to the brand awareness of South African students.

Janet Adamy (2006) to study different brew: eyeing a billion tea drinkers, star bucks pours it on in China; its big challenge: creating a new taste for coffee, and charging top prices; wooing the 'Little Emperors'. The coffee giant is pursuing the second approach. It's trying to draw in Chinese customers with a new type of informal gathering place. Once captive, that's when consumers' coffee education begins. The chain stacks cream and sugar counters with brochures titled "Coffee Brewing Wisdom" and others that answer questions like "What is espresso?" Workers float through stores passing out small cups of pumpkin-spice latte and other drinks. Good-for-you messages about coffee are sometimes part of the pitch.

Competitors consider the coffee focus a weakness given traditional Chinese tastes. "They will enjoy tea more than coffee," says Garvin Lau, a general manager for Real Brewed Tea. Launched in Hong Kong, the chain of teahouses aims to be "the Starbucks of tea," Mr. Lau says. It has carefully studied the Seattle chain. Real Brewed Tea's 100 or so stylish locations have high ceilings, bright green chairs and menus that tell customers the chain are "determined to become a lifestyle." The stores sell basic tea drinks for about $1.75, slightly less than what Starbucks charges.

Executives didn't think the coffee part stood in their way. They hoped the appeal of the brand and experience of sitting inside Starbucks would be enough to draw Chinese fans. Many of Star buck’s espresso drinks are so heavily sweetened they don't taste like coffee, and some Frappuccinos don't contain any coffee. In 1999, Starbucks opened its first China store in Beijing's China World Trade Center.

Thampaphon Sirisophar (2005) to study attitude and behavior toward fresh coffee consumption star bucks store in Bangkok. The findings of products factors were that aroma scent of crush coffee seeds stirring with hot water and taste were the most important product

attributes. Coffee seeds were needed to grow locally, substituting imported seeds. Pricing was affordable. Service was accelerating. Distribution channels needed to be expanded to cover increasing demands for fresh coffee, or losing to substitute brands. Coupon was a necessary promotion tool which Starbucks neglected. Inferential statistics for data analysation were Pearson Correlation. Hypothesis toward value and benefits of product attributes was null. On the contrary, it was perceived as health hazards because of caffeine. Consumption in store was preferred.

Charles W. Lamb, Jr., Joseph F. Hair, Jr., and Carl McDaniel (2000: 44) say that the term marketing mix refers to a unique blend of product, distribution, promotion, and pricing strategies designed to produce mutually satisfying exchanges with a target market. Distribution is sometimes referred to as place, thus giving us the four Ps of the marketing mix: product, place, promotion, and price. The marketing manager can control each component of the marketing mix, but the strategies for all four components must be blended to achieve optimal results (O.C. Ferrell and Michael D. Hartline, 2005). Any marketing mix is only as good as its weakest component. The best promotion and the lowest price cannot save a poor product. Similarly, excellent product with poor distribution, pricing, or promotion will likely fail.

Variations in marketing mixes do not occur by chance. Astute marketing managers devise marketing strategies to gain advantages over competitors and best serve the needs and wants of a particular target market segment. By manipulating elements of the marketing mix, marketing managers can fine tune the customer offering and achieve competitive success.

Product strategies, a product is anything that is potentially valued by a target market for the benefits or satisfactions it provides, including objects, services, organizations, places, people, and ideas (David W. Cravens, 1997: 292). The product includes not only the physical unit but also its package, warranty, after sale service, brand name, company image, value, and many other factors (Charles W. Lamb, Jr., Joseph F. Hair, Jr., and Carl McDaniel, 2000: 44). It might arguably be said that the product or service that the organization offers for sale is the very reason for its existence. Without a product there is no company.

Distribution (Place) strategies, Ray Wright (1999: 132) say that place of purchase is where and how the product is made available for sale will also reflect on the image of the product and so should compliment all the other elements of the product. Premium priced, quality lingerie would create a negative customer reaction if sold from a stall in the market. Distribution strategies are concerned with making products available when and where customers want them. The goal of distribution is to make sure products arrive in usable condition at designated places when needed (Charles W. Lamb, Jr., Joseph F. Hair, Jr., and Carl McDaniel, 2000: 44). Decisions that are made include the type of channel organizations to use the extent of channel management performed by the firm, and the intensity of distribution appropriate for the product or service. The choice of distribution channels influences buyers' positioning of the brand (David W. Cravens, 1997: 19). Other meaning, distribution having the product available where target customers can busy it, is essential to success. Only in rare cases will customers go to much trouble to secure a particular brand (Del I. Hawkins, David L. Mothersbaugh, and Roger J. Best, 2007: 21).

Promotion strategies, Promotion includes personal selling, advertising, sale promotion, and public relations (Ray Wright, 1999: 144; David W. Cravens, 1997: 20). These activities make

up the promotion strategy, which performs an essential role in positioning products in the eyes and minds of buyers. Promotion's role in the marketing mix is to bring about mutually satisfying exchanges with target markets by informing, educating, persuading, and reminding them of the benefits of an organization or a product.

Pricing strategies, Price is the amount of money one must pay to obtain the right to use the product (Del I. Hawkins, David L. Mothersbaugh, and Roger J. Best, 2007: 21). It is often the most flexible of the four marketing mix elements the quickest element to change. Price is an important competitive weapon and very important to the organization because price multiplied by the number of units sold equals total revenue for the firm (Charles W. Lamb, Jr., Joseph F. Hair, Jr., and Carl McDaniel, 2000: 44). Price strategy involves choosing the role of price in the positioning strategy, including the desired positioning of the product or brand as well as the margins necessary to satisfy and motivate distribution channel participants.

EQUIPMENT AND METHODOLOGY

The questionnaire survey was asked to the consumers who buy coffee both of international brand and Thai brand in Muang Chiang Mai, Thailand 400 persons by random. Then analyzed the data by using SPSS program for windows and described about general information of consumer from frequency and percentage. Second, described about consumer behavior for decision making to buy coffee from frequency and percentage. Third, described about marketing strategies that effect for decision making of consumer from mean and standard deviation. For the third part, it was the rating scale by has ruled to give the counter to 5 levels where score of "5" mean "very important" while score of "1" means "very unimportant". Forth, hypothesis test analyze data with independent-sample t-test and one way anova.

CONCLUSION AND DISCUSSION

Summarize about general information of consumer found that consumers who prefer Thai coffee brand which accounted for 206 people and the consumers who prefer international coffee brand which accounted for 194 people. Most of the sample groups who prefer Thai brand are females accounted for 123 people or 59.7 percent and 76 people or 36.9 percent are between 36-45 years of age. Most of them are working as employees or freelance accounted for 67 people or 32.5 percent and 115 people or 55.8 percent has the income ranges below 10,000 THB per month. Consumers of local brands coffee have highest qualification at bachelor degree which accounted for 104 people or 50.5 percent.

Most of the sample group that choose to consume international brand are male which accounted for 99 people or 51 percent and 100 people or 51.6 percent aged between 16-25 years old. 92 people or 47.4 percent is high school /college students and have income below 10,000 THB per month at 75.3 percent. 98 people or 50.5 percent have highest education at bachelor degree.

For the result about consumer behavior for decision making to buy coffee found that Majority of the consumer of Thai brand drink coffee everyday which accounted for 105 people or 51 percent. 74 people of the people surveyed or 46.5 percent drink coffee in the morning. 57 people or 27.7 percent indicate that Black Canyon Coffee is their favorite brand and 128 people or 62.1 percent like cappuccinos and 82 people or 18.8 percent like the taste of coffee.

81 people or 39.3 percent state that the price of the coffee that they prefer to pay for is below 30 THB per unit. 95 people or 22 percent tend to buy coffee at tourist attractions. 131 people or 63.6 percent state that they prefer the coffee shop that has air condition and 146 people or 66.7 percent of people surveyed state that friends have influence on their decisions about the coffee shop they choose. 159 people or 71.3 percent state that the additional service that they want from the coffee shop is internet. Majority of the consumers (132 people or 43.1 percent) know the coffee shops from promotional activities at the selling points.

Additionally, most of the consumers of international brand drink coffee everyday 75 people or 38.7 percent. 70 people or 39.3 percent tend to drink coffee in the mornings. 24 people or 12.4 percents state that they tend to buy coffee from the brand Coffee World. 115 people or 59.3 percent like to drink cappuccinos. 70 people or 17.8 percent state that they tend to drink coffee because they like the taste of it. 75 people or 38.7 percent state that the price range that they would buy for coffee is 30-39 THB per unit. 92 people or 24.1 percent buy coffee at tourist attractions and 129 people or 66.5 percent like to buy coffee from the shop that has air conditions. 124 people or 62.6% state that friends have influence on their decisions of choosing the shop. 138 people or 75.8 percent say they would like the coffee shop to have internet provide for customers. Additionally, majority of the consumers know the coffee shop from promotional activities at the selling points that accounted for 103 people or 39.5 percent.

The result about marketing strategies that effect for decision making of consumer that summarize into 2 ways that are marketing strategy for Thai brand and marketing strategy for International brand. For Thai brand, they are put in order of the level of importance accordingly; product factors, aroma, this factor has a high level of importance with a total average of 3.79. Distribution channels have a medium importance with a total average of 3.28 which wide distribution of franchises is the highest ranked factor. Also, pricing factors have a medium importance with a total average of 3.22 and the factor that consumer gave most importance to is right pricing. Marketing promotions have a medium importance with a total average of 2.87 and the most important factor that consumers gave importance to is environmental concerns.

For international brands, they are put in order of the level of importance accordingly; marketing promotions have a medium importance with a total average of 2.72 and the most important factor that consumers gave importance to is environmental concerns. Pricing factors have a medium importance with a total average of 2.58 and the factor that consumer gave most importance to is right pricing. Distribution channels have a low importance with a total average of 2.45 which wide distribution of franchises is the highest ranked factor. Also, product factors have a low level of importance with a total average of 2.32 and the factor that consumer gave most importance to choice of own mix.

The results about hypothesis test for comparative marketing mixes that effect on the consumption found that the consumers give importance to the 4 factors namely; products, price, distribution channels and promotions. As for product factors, the consumer give importance to 10 factors namely; aroma, choice of various flavors, special in-house formula, variety of latte arts, brand popularity, container design, product cleanliness, choice of other food and drinks, choice of own mix and state of the art brewing machine and technique. For the factors on price, consumer give importance to 3 different factors namely; right pricing, variety of pricing, and the effect that pricing has on consumer behavior. For the factors on distribution channels, consumer give importance to 8 different factors namely; right location,

wide distribution of franchises, convenient parking space, comfortable seating, shop cleanliness, good interior design, proximity to workplace/ home and polite employees. Lastly, for the factors of promotions, consumers give importance to 4 different factors namely; advertisements, promotional programs, fast service and product tasting.

Other wise, hypothesis test for comparison the different between consumer behavior and personal factors found that consumer behavior related to sex can be classified into 5 issues which are preferred consumption time, preferred store, reason for consumption, price per cup and the concept or preferred shop layout. The factor that related to age can be classified in 5 issues namely; frequency of consumption, preferred store, preferred coffee flavor, price per cup, and preferred shop layout. The factors that related to occupation that make the difference consumption can be classified into 5 factors which are, frequency of consumption, preferred store, preferred coffee flavor, price per cup, and preferred shop layout. The factors that related to income that make the difference consumption can be classified into 5 factors which are, frequency of consumption, preferred store, preferred coffee flavor, preferred shop layout, and people who have influenced choice. The factors that related to education can be classified into 3 issues which are frequency of consumption, price per cup and preferred shop layout.

RECOMMENDATIONS

For use the outcomes of study about "Marketing Strategy Comparison between International Brand and Thai Brand for Premium Coffee Business Under Customers' Perspective: Case Study in Chiang Mai, Thailand" to make marketing strategies planning for efficiency and to be able respond the customer need to get the most satisfaction. In order to add ability for competition and for survive of business, a few recommendations for better and development of coffee business both of Thai brand and International brand are attempted:

Product strategy: The production methods have to concern more on quality of the products and the ingredients have to be clean and safe to consume to prevent any harm to consumers health and any side effects. The invention on new recipe and the practice of the making of latte arts are also important as to attract new customers. Also, research and development of new technology needs to be used to make the best of the products.

Price strategy: The entrepreneurs have to have high price elasticity for their products as to have the flexibility to adjust the price and make it consistence with the market price. Outsourcing is another way to reduce the cost of the production compared to other players in the market. Also, by reducing the price to lower than competitors helps increasing sales.

Place strategy: Because the consumers who choose Thai brands give the importance on number of branches that the coffee shop can provide, so the entrepreneurs should have various channel of distributions in order to get to more consumers, easy access for the consumers and also help increasing the selling number. Furthermore, the cleanliness of the coffee shops, comfortable seats for the consumers and the decoration of the coffee shop are the parts that Thai brands should improve the quality in order to attract more consumers and also help to create a fair competing with the international brands.

Promotion strategy: As the consumer of Thai brands rates the fast of services at medium state, so the entrepreneurs should improve their service to become faster in order to get larger number of consumers and also to increase the satisfaction of the consumers on Thai brands. For the consumers of international brands, the important of product tasting is at medium rate

therefore this type of service should be added to create an opportunity to show the value of our products, indirect advertisements and also build up good relationship between consumers and the brands which can lead frequent consumption of customers. Then the customer would change to be loyalty customers and they will then advice others to try the products. These are what the entrepreneurs should do for the survival of the business.

Moreover, the entrepreneurs both of Thai coffee brand and International coffee brand should study on the satisfactions of the consumer every 6 months in order to understand consumer needs because the consumer behavior can change all the time according to economic situation, social situations or politics. So the entrepreneurs should improve, adjust and carry on the policy in order to satisfy the consumer needs in every way. And also add more topics that were not included in this research or the comparison between others entrepreneurs within the same field in order to adjust the strategies for future management.

This research is completed by using the information from the surveys, which leads to limitations of this research. For better results in the next research both surveys and interviews should be used in order to create a better information interpretation and analysis, and the survey part should provided clear explanations and also people who complete the surveys can only give one answer to each question.

THE POWER OF EMPLOYER'S BRAND

Dagmara Lewicka, PhD, AGH University of Science and Technology
dagal@poczta.fm

ABSTRACT

The paper focuses on import ant issues connected with shaping employer brands. It lists factors decisive for attractiveness of a brand in the respondents' perception. It analyses factors which make employees loyal to their current employers. Research on which the paper is based is comparative and includes an analysis of preferences demonstrated by potential employees, students and employees of Polish enterprises.

Keywords: employer's brand, labor market, employment decisions, job satisfaction

INTRODUCTION

Even nowadays, contrary to popular belief, enterprises suffer from shortage of talented employees. Research has shown that the trend is going to intensify in time. The question how to enhance attractiveness of employment, attract and keep the best people is continuously growing in importance (Ewing et al.2002). At present, talented staff is as demanding as clients are. In consequence, companies have to fight and care for their staff as they do for their clients. Traditional human resources management was stressing the importance of the organisational culture, mission and value of a company as the main axes which supported the feeling of ownership as well as motivation of employees. As permanent employment contracts have become scarce, it is necessary to find new human capital management tools to ensure staff loyalty. According to the concept of personal marketing, employer's transaction with his employee has turned into an exchange, when in exchange for his initiative, ideas, creation of customer value and multiplication of company's profits, the employee receives an attractive package of working conditions and development opportunities (such as participation in interesting projects, participation in decision making process, working in teams of outstanding experts). Similarly, in the process of employer selection, a talented employee seeks to be hired by a company which offers the best package of opportunities. Among long-term solutions responding to these challenges, actions taken in order to create employer's brand should be mentioned. Activities in the area of building the employer's image have been growing in importance slowly as a field of HR departments' activities in Poland. It was not long ago that organisations with their own plans of building employer's brands, who worked towards their achievement, were in minority. Typically, these were the same organisations who took HR management seriously, as they consider employer branding a part of their selection strategy. It is common knowledge that clients cannot be attached to a brand on the basis of one-off, even very spectacular actions and campaigns. To achieve it, well-planned and long-term activities as well as some financial investment is required.

The strategy of building the image of a good employer requires yet another very import ant element which is cohesion of actions. The key part of the strategy focused on building a desired employer brand is the company's policy towards employees coherent with the assumptions underlying the image as well as activities oriented towards employee development and increase of their job satisfaction. Employees are one of the main carriers of information about a company as an employer. They represent a credible and important source of information for the company's surroundings. Messages conveyed in information

campaigns, which contradicts the status quo can even undermine the company's credibility and have an adverse effect on its image. We may even risk a statement that our culture has become the culture of brands. In particular, the statement applies to young people who tend to appreciate more the brand of a mobile than its technical parameters. Young and talented graduates know that a brand of a good employer in their CV is often a guarantee of their subsequent professional success. The above is confirmed by results of research carried out by the Polish Personnel Management Association and the Warsaw School of Economics (2008) on a sample of 342 large Polish enterprises which demonstrate that, according to 93% of respondents, the image of a company as a good employer is decisive for the efficiency of recruitment processes. 76% of analysed enterprises plan to prepare or revise their employer branding strategies in the coming year.

The paper focuses on employer branding aspects at the HRM level where it is particularly important to ensure employees' loyalty and attachment to employers as well as employee satisfaction from work and feeling of ownership in their organisations. The main contribution of this paper is determination of the importance that various aspects of brand attractiveness have for attractiveness of an employer on the basis of empirical research and analyses. The paper points to differences between factors in the perception of respondents: students and employees, also in terms of their demographic features, gender and years of employment. In addition, the research is an attempt to gain some additional knowledge on factors decisive for perception of an employer brand from the perspective of a member of an organisation. Loyalty understood as an inclination towards (conviction about) the choice of the employer made is analysed as well as taking or not taking own employer in consideration as a possible option upon subsequent choice of employer in relation to various factors shaping the perception of employer brand.

THE CONCEPT OF EMPLOYER'S BRAND

Employer brand in the meaning of building the employer's brand is one of possible answers to challenges of the ever-changing labour market, where the importance of employees' position is growing. As regards employer brand it is assumed that a brand of an organisation as an employer can be built in the same way as brands addressed to clients are built. The concept of employer's brand is a package of functional, economic and psychological benefits from employment, which are linked to a given organisation i.e. with an employer (Sullivan 2004). A sarong employer brand attracts better candidates (Collins and Stevens, 2002) and shapes their expectations towards their place of work (Lievens and Highhouse, 2003).

Research conducted by Chenerson Group has shown that more than 75% of respondents would prefer to work for a company which enjoys an excellent reputation rather than for an enterprise, which is hardly recognised, even if salary paid by the latter were higher. In addition, nearly 50% of all American employees indicate that the brand of their employer plays the key role in their employment decisions (Urbanek 2002). These results indicate high importance of employer's brand, which, in many cases, is a factor critical to employment (the external company's brand) or to retaining employees (the internal employer's brand).

Both personality-related factors and factors connected with the current status of the labour market affect employees' staying with or leaving an enterprise. However, research has shown that those who have the opportunity of ex pressing their lack of satisfaction are less inclined to leave than those who do not have such option (Spencer 1986). Decisions about leaving are

typically caused by the following: excessive stress at work, lack of satisfaction (Stel et al., 2002). A lot of research has pointed to the impact of employer brand on shaping satisfaction. Furthermore, it is material how employee satisfaction affects the way in which the brand is shaped. Research has show that employees who draw more satisfaction from their work as more effective in starting client relationship (Heskett et al., 1997).

POURPOSE OF THE RESEARCH

The purpose of the research was to identify factors affecting employer selection in the studied group as element affecting creation of employer's brand. By forming the profile of features that the most desirable employer should posses and its subsequent confrontation with images of companies on the Polish market and their popularity among potential employers, a list of the most powerful employer brands has been created. Next, factors affecting choice of employer brand were analysed. The final part of the research was focused on the group of employees and aimed at identifying factors affecting employee loyalty towards their employers.

RESEARCH METHODOLOGY

Brand power valuation is not supported by any uniform methodology. Unlike other areas, this area is susceptible to actions taken by individuals, which cannot be verified in other market conditions. In fact, the brand value evaluation is a relatively new phenomenon and, in spite of employing many well-proven tools, it has not succeeded yet in developing techniques of universal nature. For the purpose of the research, appropriately modified popular marketing models were used. In the research, a model of employer's brand power was tested, where the model was dependent on: company's properties, its presence in the media and opinion it enjoyed. When testing the process of measuring the power of employer's brand, a consumer decision-making model and the brand value pyramid were used as the basis (Keller 2001, Franca, Pahor 2007). It was assumed that the pyramid of employer's brand power had three levels. Recognition (employer's brand is recognised and its attributes and key messages are known), significance (the company is taken into consideration as a potential employer) and choice of employer (the employer is chosen by the employee). Respondents included students and potential or then-current employees. A list of 40 companies, leaders of national rankings, operating in the area of new technologies, economy and management was prepared. The name of the ranking was Top Employers 2008 and it was prepared by Hewitt Associates (http://was7.hewitt.com), a consulting and outsourcing company, which specialised in HR management solutions. To create the pyramid of employer's brand for an average company, on the basis of performance reported by analysed companies first the pyramid of employer's brand was created for each company separately. Next, by simple arithmetic, the results were extrapolated. The same procedure was followed when creating brand pyramids for an average international company and national company, selecting appropriate performance of international and national companies. Subsequently, factors affecting employer selection, employer attractiveness, etc. were analysed. Next, on the basis of the loyalty pyramid prepared specifically for this purpose, respondents were asked to answer the following question: If your place of work/employer were included in the list presented in part one, would you: make it your first choice, consider it as a possible option of employment, and not consider it as a possible employment option.

The research was conducted in the form of an electronic questionnaire. A network tool was created to collect results from respondents when ready and to visualise the results

automatically in an analysis-friendly format. Because of formal limitation of the size of the paper, selected results can be only presented.

PRESENTATION OF RESEARCH RESULTS
DESCRIPTION OF THE ANALYSED GROUP

471 respondents took part in the research, including students (253) and graduates of technical studies (predominantly from the area of new technologies) and business studies and employees (168) representing enterprises of various sizes and capital from various industries. Female and male participants of the research represented 49% and 51% of respondents, respectively. 31% of respondents aged below 25, 49% of respondents belonged to 25-35 age group, 15% of respondents belonged to the age group between 36 and 45 while 5% had between 46 and 55 years of age. The majority of respondents (41%) has been with their employer for a period shorter than 3 years, 40% for a period from 4 to 8 years, 14% for 9 to 13 years, and 5% for 14 to 18 years. The highest percentage of respondents has been employed by the state administration - 18% while 15% work in the industry sector and 12% in the service sector. Sectors of transport and logistics as well as the sales sectors had equal 10% representation. The highest percentage of respondents indicated their employment in state institutions (22%), 18% of respondents are employed in limited liability companies with the majority of shares held by Polish shareholders and 22% of respondents are employed in joint stock companies with the majority of shares held by Polish shareholders. Companies with foreign majority shareholders employ: 22% of respondents – joint stock companies and 8% of respondents – limited liability companies. These results demonstrate that the majority of respondents works for large enterprises (41%). A medium size employer was indicated by 30% of respondents, while 19% of respondents are employed by small enterprises.

RESULTS OF REARCH ON EMPLOYER BRANDING

When comparing brand pyramids of employers representing average international and national companies, one can see that their recognition in both cases in similar and reaches 80%. Still, when it comes to significance in the process of selecting potential employers, internationals are in favour with a difference of 10%.International employers take also priority in the process of choosing employers – an international employer is seven times more likely to be chosen over a national employer. A large international company would be the employer of choice for the majority of potential employees. Furthermore, nearly all respondents indicated sectors or industries of their preference on the labour market. Only 2% declared the issue to be of no importance.

In the students' ranking of the best employer Google came first (18%) followed by ABB (12%) and Delphi (9%).

Those currently employed had a slightly different approach to the issue. In this group, brand recognition is markedly lower – 60.02. The majority has a preference for large Polish enterprises. A 10% difference in favour of Polish companies is shown at the stage of considering prospective employers. Polish employers tend to be selected more often (eventually, respondents demonstrated equal preference for Polish and foreign enterprises) although the number of foreign employers on the list was 2.5 higher than the number of Polish enterprises. Employees believe that the best employers were the National Bank of Poland and a Polish insurance company PZU (each selected by 11.5% of respondents) as well as bank

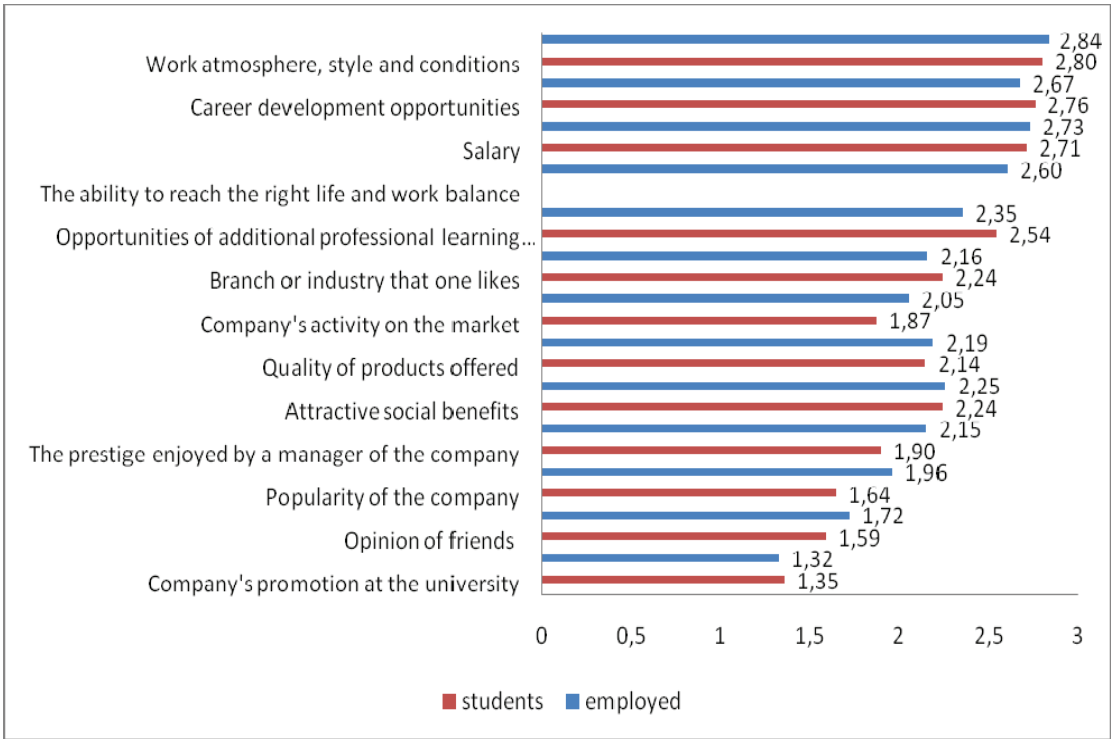
PKO B.P. selected by 9.6%. The result could be interpreter in the context of the global crises which also affects foreign companies operating on the Polish market. These companies often do not hesitate to take some drastic steps such as downsizing their operations and redundancies. Polish large enterprises are still considered relatively stable and safe employers. As little as 1.2% of respondents indicate that the sector is of no importance while more than 1/3 of respondents indicated finance and banking as their preferred sector.

FACTORS DECISIVE FOR SELECTING EMPLOYER

Work atmosphere, style and conditions topped ranking of the most desirable factors which attract potential employees. Professional development opportunities, salary and the opportunity to maintain the right life-work balance ranked equally high.

The graph below compares results in the groups of students and the employed.

Graph 1. Factors decisive when choosing employer.



Source: own study

Two factors characteristic for your generation were selected: the importance of professional career opportunities, which is one of the three crucial aspects when considering an ideal work/employment and the possibility of reaching a good life-work balance.

By using Mann-Whitney U test, material differences between responses given by female and male respondents were determined. Female student respondents expressed the highest appreciation of the following factors: the prestige of working for the company (p=0.02093), the popularity enjoyed by the company (p=0.02009), style of work and atmosphere at work (p=0.02835), attractive social benefits (p=0.035494) as well as opinion of friends (p=0.22037). Male respondents attached the highest importance to the salary and differences

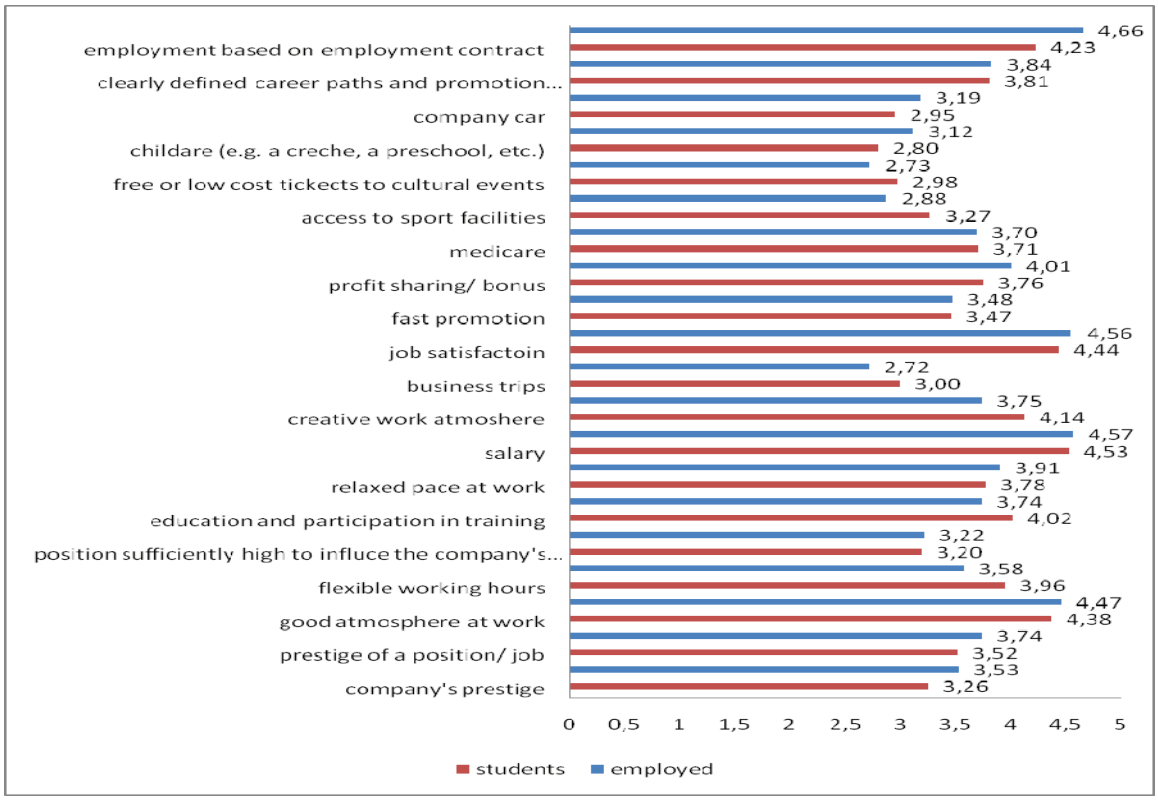
in this aspect are very clear (p=-.000014), development of professional career (p=0.006885) and sector/industry which they liked (p=0.002093). In the group of the employed, the test demonstrated some material differences between female and male respondents: female respondents expressed the highest appreciation of the opportunity of reaching a good life-work balance (p=0.070491) and attractive social benefits (p=0.0086930) and male respondents their preference of the sector/industry (p=0.028772).

By applying Kruskal Wallis' test we could see that together with the period of employment (some students had had the opportunity of traineeships, apprenticeships and part-time employment during the final years of their studies) their value more their salaries (p=0.0370), the opportunity to receive additional training and learning opportunities (p=0.0164), the opportunity to reach the right life-work balance (p=0.033), sector/industry of their liking (0.0005) and the company's activity on the market (p=0.0289). As regards the employed respondents, no material differences could be found. It may indicate that young employees learn about the realities, their own needs and importance of specific factors after one year of employment. No material changes could be seen here in subsequent years.

FACTORS DECISIVE FOR EMPLOYER'S ATTRACTIVENESS

Next, the impact of individual enterprise components on the pyramid of employer's brand was tested. On this basis, the profile of features of the most desirable employer was drawn. Respondents, both students and employees, could assign weights to factors dominant when assessing work in a company. Below, differences in responses given by both groups are presented.

Graph 2. Factors decisive for employer's attractiveness.



Source: own study

Factors connected with safe and long-term employment, job satisfaction, work atmosphere and development opportunities received the highest appreciation. It is interesting to mention that salary is no longer the one and main priority, as it used to be until very recently.

Levels of salary received the highest weight in the ranking of the most desirable factors which attract potential employees. Satisfaction from work and good atmosphere in the workplace were considered equally important. In addition, respondents highly appreciated the aspect connected with employment stability i.e. employment based on an employment contract.

By using Mann-Whitney U test, material differences between responses given by female and male respondents were determined. Female student respondents expressed the highest appreciation of the following factors: the company's prestige (p=005552), good atmosphere at work (p=0.033346), medical care (p=0.000334) and reduced price tickets to cultural events (p=0.001562). Among male respondents, salary (p=0.017311) and profit-sharing topped the ranking (p=0.000092). In the group of the employed, the test disclosed material differences between female and male respondents in terms of the following factors: the company's prestige again (p=0.025900), good atmosphere at work (p=Male7812) as well as flexible working hours (p=0.0010028), relaxed pace of work ((0.012877) and employment based on the employment contract (p=0.038205). Statistically, male respondents tended to point more often to a position giving influence on the company's strategy (0.016184) and business trips (p=0.010750).

With Kurskal Wallis test we could see that, with longer history of employment, employees tend to appreciate more factors such as job satisfaction (p=0.0363), profit-sharing and bonuses (p=0.0003), prestige of their position/job (p=0.0168), good atmosphere (p=0.0309) or access to sport facilities (p=0.0412).

The attractiveness of business trips decreases among the employed as the number of years of their employment grows (p=0.0470). Employees with history of employment up to 3 years appreciate very much employer's support in childcare (p=0.0279).

FACTOR AFFECTING THE LOYALTY PYRAMID

Below responses given by employees of analysed companies on factors affecting employee loyalty towards employers are presented.

Table 1 Factors affecting employee loyalty

Source: own study

Analysing the above-presented factors we can see that loyalty is predominantly affected by work satisfaction and, secondly, by pride from working in a company, the company's activities and own contribution and by fair treatment and in-company relations. It would be interesting to find the reason for respect for employees ranking last in the hierarchy of factors.

CONCLUSIONS

It is worthwhile to introduce selected practices applied by companies which occupy the tops of best employers' rankings. It will be certainly helpful to build an organisational culture that would make all employees feel welcome and appreciated and where they can become a true asset for their employer. Although it takes a lot of effort and internal determination of management to build a strong employer's brand, this effort may be beneficial and profitable in the end. A strong employer's brand enhances effectiveness of the recruitment process, has a significant impact on retention of key employees and talents, increases productivity, loyalty and commitment of staff and, eventually, improves the employer's financial performance.

The research confirms that factors such as work atmosphere, style of the organisation and work conditions have a material impact on the employer brand. Other factors appreciated by respondents, graduates in particular, include the opportunity of development in the company. Salary is also an important but not a priority factor. Work satisfaction is of major importance when it comes to employee loyalty. In addition, employee loyalty is affected largely by pride for working in the company, price in the company's activities, in-company relations and fair treatment. Company's credibility is also appreciated. There is no doubt that the strength of employer brand is a complex issue dependant on many factors. The research has shown one possible solution; nevertheless, the issue requires further and in-depth research.

ABSTRACT

This paper investigates the effect of the Taiwanese foreign direct investment on the operating efficiency in China. We applied data envelopment analysis (DEA) to operations data for 3,506 firms over the four year period (2004-2007). We found that companies located in the economic (technology) development zones benefit from lower tax rate privileges than their counterparts in the development and the industrial zones, and that their operating efficiencies are better with statistical significance. The high technology industry receives better tax incentives but requires more capital investment and the operating risks are higher. As the company size increases, the operating efficiencies worsen. The greater capital requirement and the difficulties in achieving economies of scale are the major reasons for the deterioration. The averaged invested year is shorter and the payback period is longer rather than others industries. The major production type of the high technology sector in China is original equipment manufacturer (OEM) with lower margin rate compared with the upstream value chain of the high technology sector. Finally, when the company has higher sales growth exhibits its better operating efficiency.

Keywords: Data envelopment analysis (DEA); Operating efficiency; Foreign direct investment (FDI); Economic (technology) development zones; Tax incentives.

INTRODUCTION

In order to attract foreign investment and enhance economic performance, a country needs to obtain at least one core efficiency-creating competency among the key inputs of wages, education, and infrastructure (Bunyaratavej et al., 2008). Governments often provide various tax incentives to attract investment in order that the businesses may satisfy various employment levels, locations, export requirements, and performance requirements (Davies and Ellis, 2007). Various studies have focused on the impact of foreign direct investment

(FDI) on the host country's productivity but have demonstrated inconsistent results (Buckley et al., 2007b). Buckley et al. (2007a) claimed that the nationality of the foreign investors has a significant impact upon the productivity, with the spillover effects being most forthcoming from the overseas Chinese (Hong Kong, Macau, and Taiwan; HMT) multinational enterprises, but not from the Western firms. China initiated the high and new technology industry development zones to promote its economic growth and social progress (Ma and Goo, 2005). Hu (2007) suggested that the FDI contributes to the productivity growth in the technology parks of China, while Havrylchyk and Poncet (2007) claimed that incoming foreign investment provides additional sources of capital to China.

Initiated by the 1978 market reforms, China's economic miracle and phenomenal growth have been considered critical and interesting issues (Wu, 1995, 2000; Wang and Yao, 2003; Henderson et al., 2007). China has attracted investment from 80% of the world's top 500 enterprises (Powers, 2001). In 1980, China's industrial sector consisted almost on state- and collective-owned enterprises. Until the mid-1990s, the most dramatic method of ownership reform in Chinese industry was the entry of new non-state firms, including the foreign investment from the investors in HMT, [1] and from foreign sources, primarily OECD and South-east Asian countries. Although many of these foreign sources and HMT firms had previously been state- or collective-owned enterprises that were converted into joint ventures as a vehicle for FDI, the restructuring of these firms represents an important form of new entry into China's industrial enterprise system (Jefferson and Su, 2006). Concerning the Chinese economic growth issue, researchers have concentrated on the productivity changes deriving from the various reform policies and these have been expansively reported in the literature (Wu, 1995, 2000; Wang and Yao, 2003; Henderson et al., 2007). Wu (1995) suggested that it is worthwhile to compare the different reform policies in terms of productivity and efficiency performance. Previous studies of productivity have focused almost on state- and collective-owned Chinese firms. The growing importance of foreign-invested firms is significant to investigate for both policymakers and FDI managers (Jefferson et al., 2000). Therefore for FDI, it is imperative to examine whether the invested firms can gain higher operating efficiency (Baek, 2004).

The meaning of higher efficiency is equivalent to being more competitive and profitable for business operation (Tsai et al., 2006). We apply data envelopment analysis (DEA) to measure business performance (Ma and Goo, 2005; Düzakin and Düzakin, 2007; Asmild et al., 2007)

1 Regarding the FDI in China, the investment was US $40.319 billion in 1999. This rose to US $74.768 billion in 2007. The majority resources of FDI in China are 41.35% from Hong Kong and Macau. Taiwan at around 5.66% is the fifth largest resource of FDI in China. According to the Taiwan's Investment Commission of the Ministry of Economic Affairs, the approved investment to China was US $1,252.78 million in 1999. The investment increased to US $9,970.55 million in 2007. Among the FDI investment areas, Kiangsu province accounted for 32.33% and the major industry was the electronic parts and components manufacturing for 15.97%.

and analyze the operating efficiency for Taiwanese FDI in China during the four year period 2004-2007 for a sample of 3,506 firms in China. An investigation of China's productivity performance provides valuable insight into the understanding of that country's spectacular growth over the last two decades (Wu, 2000). Our results indicate that China provided Taiwanese businesses invested in the economic technology development zones and the economic development zones with better operating efficiencies than Taiwanese investments in the other zones. The tax incentive programs lowered the tax expenses and improved the operating efficiencies. Furthermore, our study results reveal that Taiwanese investments in the high technology sector result in deteriorated operating efficiencies due to the higher capital requirements and greater operating risks. In addition, the averaged invested year is shorter and the payback period is longer rather than others industries. The major production type of the high technology sector is original equipment manufacturer (OEM) in China. Therefore, the margin is relative smaller than upstream value chain of the high technology sector.

Our study contributes to the literature in at least two ways. Firstly, our study provides evidence of the operating efficiency performance of the Taiwanese FDI in China. Evaluating how the tax incentives and industry characteristics affect efficiency in China provides insight for current and potential foreign direct investors seeking to improve operating performance, and for policymakers considering foreign direct investment. Secondly, our study provides additional empirical evidence on the impact of various factors on operating efficiency. Many governments have used a variety of tax and financial incentive programs to foster economic stimulation influencing business relocation and expansion. Despite the large amount of attention and resources that policy makers have devoted to these incentive programs, there is little systematic empirical evidence concerning the impact of business incentives (Lee, 2008). Chen et al. (2006) found that there is a lack in related empirical studies. Our research might fill the gap in the literature.

LITERATURE REVIEW

China's Tax Incentive Programs and Hypotheses Development

The Chinese government has offered a number of investment incentives, such as tax concessions, an abundant supply of cheap labor, and a large domestic market for FDI. The success of this policy is demonstrated by the large and increasing inflows of FDI (Chow and Fung, 1997). Prior to 2008, the highest corporate tax rate in China was 30%, plus a local 3% tax rate. The aggregate tax rate would thus be 33%, which is higher than the highest corporate tax rate of 25% in Taiwan. In China, there are different laws and regulations for foreign

companies to enjoy permanent local tax exemptions and China also provides various tax incentive programs in terms of different investment locations and industries. The approved productive FDI corporate tax rates promulgated by China's State Council for the economic technology development zones located in the coastal cities are 15%. For the productive FDI located in the old cities and coastal economic development zones, approved by cities, counties, and regions, these rates are 24%. Furthermore, productive FDI businesses operating more than ten years are exempted from corporate taxes in the first and second profitable years (the first five years' losses are deducted in calculating the first operating profit year). From the third to fifth years, the actual corporate taxes imposed are half the stipulated corporate taxes: this is the so-called "two (years) exemptions and three (years) half-tax deductions" incentive. The non-productive FDI businesses are not eligible for these tax privileges. For the productive FDI businesses with some non-productive operations, if the productive sales revenues are over 50% of the total sales revenues within the tax deduction period, the businesses are either exempted or the tax is reduced for the current year subject to the approval of the tax authorities. If the productive sales revenues are less than 50%, there shall be neither exemption nor tax reduction permissible even within the tax deductions period. Apart from the economic development zones and the economic technology development zones, the statutory regular higher tax rate is imposed on all other zones, such as the development zones and industry zones.

Although the economic reforms have been beneficial to all the regional economies in China, in general, those located along the coast of China have been able to grow much faster than those located in the interior provinces of the Central and Western parts of the country (Henderson et al., 2007). Klimberg and Ratick (2008) suggested that the location might affect the efficiency performance. They assumed that the optimal and most efficient location derived from the attributes of the local labor markets, the available infrastructure, and other necessary resources. The advantageous geographical location of the coastal provinces has enabled them to attract large inflows of FDI as well as of domestic capital (Zhang and Zhang, 2003). China initiated the high and new technology industry development zones to promote its economic growth and social progress (Ma and Goo, 2005).

The tax cost is part of the business operation cost. In order to attract foreign investment, China has established the state-level economic (technology) development zones. Besides the lower tax incentive programs to attract FDI, these zones offer superior infrastructures (such as discounts in terms of the land costs, construction expenses, utilities bills, transportation costs, and other communication expenses), better worker fringe benefits, and insurance welfare. Therefore, we propose the following hypothesis:

H_1: If the Taiwanese FDI business invested in the economic (technology) development zone for the tax incentive, the operating efficiency is higher.

Besides the investment location selection, the type of industry is a critical decision. In July 2000 China's State Council announced the "Software industry and integrated circuit (IC) industry development policy". In the IC industry, the Taiwanese investment is over RMB $8 billion and the integrated circuit line width is less than 0.25 μm (micrometer). The Taiwanese investors are eligible to apply for the "five exemptions and five half-tax deductions" tax privileges. A Taiwanese software company established in China would benefit from the corporate tax incentives. The new software company, once approved, would benefit from the policy of "two exemptions and three half-tax deductions" starting from the profit year. In order to encourage the domestic software development and in-house production, the statutory value-added tax rate of 17% is applicable before 2010. If the actual tax rate is over 3%, the excess tax is imposed and deducted instantaneously. This policy encourages the Taiwanese businesses to focus on R&D and reproduction expansion. The abovementioned industry incentive programs have attracted many global software and IC industries to China. Therefore, we propose the following hypothesis:

H_2: If the Taiwanese FDI business invested in high technology industry for the tax incentive, the operating efficiency is higher.

METHODOLOGY

Data Envelopment Analysis (DEA) and Test Statistics

Performance evaluation and benchmarking have become important continuous assessment and improvement tools for firms in a business environment facing global competition (Cook et al., 2004). Contrary to the incompleteness of a single performance evaluation measure, benchmarking models integrate multiple performance measures. One such model is DEA, a linear programming technique introduced by Charnes et al. (1978) and extended by Banker et al. (1984). DEA has been proven to be an effective method to evaluate the firm's relative performance (Banker et al., 1989; Mensah and Li, 1993; Sherman and Zhu, 2005; Düzakin and Düzakin, 2007; Tseng et al., 2009). Our study applies DEA for the measurement of a firm's operating efficiency.

We adopt an output-oriented efficiency measure by assuming that firms maximize output given the available inputs. This output-oriented approach measures how much output can be generated from a given level of inputs (Chang et al., 2004). The output-oriented efficiency

measure θ_j is estimated by the following DEA model:

$$\theta_j = Max\theta \tag{1.0}$$

$$\text{s.t. } X_{ij} \geq \sum_{j=1}^{N} \lambda_j X_{ij}, i = 1,...,I \tag{1.1}$$

$$\theta Y_{rj} \leq \sum_{j=1}^{N} \lambda_j Y_{rj}, r = 1,...,R \tag{1.2}$$

$$\sum_{j=1}^{N} \lambda_j = 1 \tag{1.3}$$

$$\lambda_j \geq 0 \tag{1.4}$$

where j is the firm being evaluated, θ_j is the estimated inefficiency for firm j, X_{ij} is input *i* for firm $_j$, Y_{rj} is output *r* for firm $_j$, and λ is the weight placed on each firm. Model (1) is constructed under the assumption of variable returns to scale and referred to as the BCC model of DEA (Banker et al., 1984). If a constant return to scale is maintained instead, equation (1.3) is removed and the resulting model is labeled as the CCR model of DEA (Charnes et al., 1978).

Prior research applied two conventional parametric based tests to examine efficiency differences between two groups of DMUs: Welch's mean test; and the Mann-Whitney test (Siegel and Castellan 1988). However, Banker and Chang (1995) documented that these two test statistics did not perform as well as those of the DEA-based tests. The inefficiency θ_j is a consistent estimator (Banker, 1993). We can employ two DEA-based test statistics[2] (Banker 1996; Banker and Chang 1995) to evaluate efficiency differences.

If θ_j is assumed to be exponentially distributed, then, to test the null hypothesis (that the two groups have no efficiency difference), we can use the following equation:

$$T_{EXP} \equiv \left[\sum_{j=G1}^{N1}\left(\theta_j - 1\right)/N1\right] / \left[\sum_{j=G2}^{N2}\left(\theta_j - 1\right)/N2\right] \tag{2}$$

which is evaluated with *F*-distribution with (2*N1*, 2*N2*) degrees of freedom. *N1* and *N2* are the number of two groups sample respectively.

2 See Banker (1996) for details on the construction of DEA-based tests for efficiency difference.

If the θ_j is assumed to be half-normally distributed for firms, then we can test the null hypothesis against the alternate hypothesis, described above, by employing the test statistic given by

$$T_{HN} \equiv \left[\sum_{j=G1}^{N1} \left(\theta_j - 1 \right)^2 / N1 \right] / \left[\sum_{j=G2}^{N2} \left(\theta_j - 1 \right)^2 / N2 \right] \quad (3)$$

which is evaluated by the F-distribution with (*N1*, *N2*) degrees of freedom.

Multivariate Analysis

In order to evaluate the influence of factors on operating efficiency for Taiwanese businesses in China, our research design, using the two-stage procedures represented in equation (4), is motivated by prior research. Banker and Natarajan (2008) have provided theoretical justification for the use of two-stage models in DEA to evaluate the contextual variables affecting DEA efficiency scores.

$$\ln\theta = \beta_0 + \beta_1 AREA + \beta_2 ELEC + \beta_3 SIZE + \beta_4 GROWTH + \beta_5 DYEAR5 + \beta_6 DYEAR6 + \beta_7 DYEAR7 + \varepsilon \quad (4)$$

where $\ln\theta$ is the natural logarithm of the operating inefficiency estimator θ obtained from equation (1). *AREA* is a dummy variable that takes the value of 1 to indicate the firms located in the economic development zones or economic technology development zones and businesses that receive more tax incentives. *ELEC* is a dummy variable that takes the value of 1 to indicate high technology industry. Company characteristics may contribute to operating efficiency. We choose two characteristics, firm size and production growth, as the control variables (Hamblin and Iyer, 1996). Dhawan (2001) examined the production of large and small US firms for the 1970-1989 period and found that the small firms are significantly more productive than their larger counterparts. Margono and Sharma (2006) also support the finding that size contributes to inefficiencies among the textile, chemical, and metal industries. We measure the natural logarithm of total asset (*SIZE*) to proxy for the firm size. Firm growth is an important precondition for the achievement of the other financial goals of business (Geus, 1997; Reynolds, 1993; Day, 1992; Phillips and Kirchhoff, 1989). Prior literature had found that firm growth contributed to performance and some studies controlled annual growth for research (Chang and Choi, 1988; Dunne and Hughes, 1994; Koh, 2002). We measure the growth rate of total sales growth (*GROWTH*) to proxy for firm growth. Based on the economics theory, there is incentive toward maximization of profit for business. Upon receipt of a customer's order, the business would evaluate whether there is marginal utility in this order. Under normal business operation, sales revenues and profit would increase continuously along with better sales growth and operating efficiency. Finally, we

include three years independent control variables *DYEAR5*, *DYEAR6* and *DYEAR7*.

Data

The sample of Taiwanese enterprises in China that is included in this study is derived from the *Top 1,000 Taiwanese Businesses in China* database by China Credit Information Service, Ltd. The database[3] contains data on the top 1,000 businesses each year ; however the data given only consists of the total revenue, total assets, net value of firm, after-tax income, capital, number of employees, and growth rate of total revenue for each business. Our study examines four annual periods from 2004 to 2007. We begin with an original total sample of 4,000 firms and eliminate those firms with incomplete data. The final sample consists of 3,506 Taiwanese businesses in China, comprising 861 firms in 2004, 714 firms in 2005, 951 firms in 2006, and 980 firms in 2007.

DEA is an approach for measuring the relative efficiency of peer decision making units (DMUs). Färe and Grosskopf (1996, 2000), Seiford and Zhu (1999), Zhu (2000), Chen and Zhu (2004), and Kao and Hwang (2008) used the two-stage DEA method[4] and identified revenue as an intermediate product. Therefore, we did not choose total revenue as an output variable. Based on prior literature (Düzakin and Düzakin, 2007; Mok et al., 2007; Zofio and Prieto, 2007; Lee et al., 2008; Goto et al., 2008; and Tseng et al., 2009) and data availability, we select one output and two inputs for production. The output variable is measured by after-tax income for each firm. The input variables are the number of total employees and the paid-in capital of the firm.

EMPIRICAL RESULTS

Descriptive Analyses

We investigated the production efficiency of Taiwanese businesses in China. Based on Table 1, Panel A, the paid-in capital mean of the four-year period for Taiwanese businesses is RMB $183,584.44, with the paid-in capital being highest in 2006. The mean for the number of the employees was 1,847.4, and that for the after-tax income was RMB $35,698.78. The numbers of the employees and the after-tax income increased incrementally each year.

With regards to the investment location, we combined the economic technology development zone and the economic development zone as (*EA*) and the other zones as (*NEA*)

3 The database is not disclosed to public and offers limited data to analyze.

4 DMUs have a two-stage structure in which all the outputs from the first stage are the only inputs to the second stage, in addition to the inputs to the first stage and the outputs from the second stage. The output from the first stage to the second stage is called intermediate product.

for location selection analysis. From Panel B, it can be seen that the economic technology development zone and the economic development zone took 15% or 24% lower tax rate privileges than the development zone, industry zone, and others. Therefore, the Taiwanese businesses have tax incentives to invest more capital at either the economic technology development zone or the economic development zone. The numbers of the employees are lesser inputs but generated higher after-tax income and paid-in capital.

Pertaining to the industry analysis, the top three highest paid-in capital industries are: the glass industry; the communications industry; and the rubber industry. The top three biggest employers are: the communications industry; the leather industry; and the optic industry. The top three best performing industries in terms of after-tax income are: the communications industry; the high technology industry; and the glass industry. If we compare the high technology industry (*EI*) with the others industries (*NEI*) (Panel C), generally speaking, a larger paid-in capital and a greater number of the employees in the high technology industry generates higher after-tax income compared with the other industries.

Before China's new 2008 corporate tax law inauguration, foreign companies (sole proprietorship or joint venture) had a greater number of tax privileges. These privileges included: a halved export tax; a tax credit for 40% of any re-investment; a halved tax rate for advanced technology businesses; an exemption from corporate tax for investment in the purchase of a Chinese domestic facility; and the treatment of a foreign company as an investment company with the profit (divided) derived from the invested company being exempted from corporate income tax. However, after the 2008 corporate tax law amendment, the tax privilege principles have focused on the industry privilege rather than on the previous regional privilege.

Operating Efficiencies Analyses

Based on Table 2, Panel A, the operating efficiency value analysis demonstrates that the mean of the four-year period efficiency value is 2.41. In 2004, the efficiency value reached its best value and deteriorated thereafter. The mean of operating efficiencies at the economic development zone is 2.38, which was better than the economic technology development zone, development zone, industry zone, and others. Based on Panel B, the mean of the operating efficiency (*EA*) is superior to the others (*NEA*).

From the industry operating efficiency analysis, the top three best industries are: the biotechnology industry; the cement industry; and the paper industry. As shown in Panel C, we use dichotomy for the high technology industry (*EI*) and others industries (*NEI*), and the mean of the high technology industry (*EI*) at 2.68 is worse than the mean of other industries

(*NEI*). The possible reason is that the high technology industry requires more land, capital, and employees compared to the others. Moreover, the high technology industry suffers from higher operating risks as well as being subject to more government restraints. Therefore, the operating efficiency of the high technology industry is worse than that of the other industries.

Univariate Mean Test

Table 3 exhibits the difference in efficiency test results for the combination of the economic technology development zone and the economic development zone, as *EA,* compared with the rest of the three zones, as *NEA* (the development zone, the industry zone, and others). The *EA* take the tax advantage of either 15% or 24% yet show a worse operating efficiency. Although this is inconsistent with the predictions of our research, it is the only statistics significant shown in the DEA test. Regarding the Taiwanese businesses invested in the high technology industries (*EI*), all the tests, comprising the parametric *t* test, the non-parametric Mann-Whitney test, and the DEA test, demonstrate this statistics significant. The high technology industry enjoys various tax privileges, but the huge invested paid-in capital, the vast number of employees, and the high operating risk compared with the traditional industries results in a worse operating efficiency than its counterparts (*NEI*).

Multivariate Regression Analyses

China introduced the state-level economic zone in order to attract foreign investment through lower tax rates. For foreign invested businesses approved by the China's State Council, either at the economic development zones or the economic technology development zones at the coast cities, the corporate tax has become 15%. The foreign invested production-style businesses approved by the city, county, or region at the old cities and in coast economic development zones still need to pay the 24% corporate tax. Table 4 of the multivariate regression analysis shows the coefficient of *AREA* (α_1) is significantly negative with operating efficiencies consistent with the prediction of our research hypotheses H_1. If the Taiwanese invested businesses are located in the economic (technology) development zones, they receive more tax privileges than in the other zones. In addition, their operating efficiencies are better with statistics significant. China provides the 15% or 24% low corporate tax rates to the FDI firms located in the economic (technology) development zones. When compared to the 25% statutory tax rate in Taiwan, the lower tax incentives trigger Taiwanese FDI approaches to these economic (technology) development zones. The lower tax cost promotes the operating efficiency.

China aims to promote high technology industries by providing more tax incentives. There

are the low 15% corporate tax rates for high technology and advanced facility industries as well the "two (years) exemptions and three (years) half-tax deductions" or "five (years) exemptions and five (years) half-tax deductions" tax incentives. Our empirical study results found that the coefficient of *ELEC* (β_2) is significantly positive with operating efficiencies for the Taiwanese invested high technology industries, whereas their actual operating efficiencies are worse, which is inconsistent with the predictions of our research, so we are unable to support the hypotheses H_2. We conclude that tax incentives might only be part of investment consideration but not the most important one for Taiwanese high technology industries businesses. The high technology industry is mainly impacted by economic fluctuations. We conducted further analysis and found that the average number of years that Taiwanese businesses had invested in the high technology industry in China is 8.76 years compared to the 10.72 years for the investments in the non-technology industries. Regardless of the invested locations being in the economic technology development zones, the economic development zones, or the industry zones, the high technology industries invested years are all less than the non-technology industries. In other words, the paid-in capitals of the high technology industry are substantial. The time involved from plant inception, through machinery purchase, installation, and trial run to mass production is longer than for other industries. For the high technology industry, the number of years to achieve profit return is longer, the operating risk is higher, and the required time for the promotion of operating efficiency is considerably longer than that for the non-high technology industries. The averaged invested year is shorter and the payback period is longer rather than others industries. The major production type of the high technology sector is original equipment manufacturer (OEM) in China. Therefore, the margin is relative smaller than upstream value chain of the high technology sector. Furthermore, the local Taiwanese government imposes more restraints on the Taiwanese high technology industries invested in China. Their operating risks are higher than the other industries. Therefore, their operating efficiencies are relatively worse.

For the control variables, like the characteristic impact of company size and sales growth on the company, test we found that as the company size becomes larger, their operating efficiencies worsen. This finding is consistent with works of Dhawan (2001) and Margono and Sharma (2006). The higher productivity or efficiency of smaller firms is the result of their leaner organizational structure that allows them to take strategic actions to exploit emerging market opportunities and to create a niche market position for themselves (Dhawan, 2001). Therefore, the operating efficiency is worse. However, as the company has higher sales growth exhibiting its operating efficiency is better as well as better efficiency performance. This finding is consistent with works of Margono and Sharma (2006).

Finally, we controlled the macro economy to assess its influence on the operating efficiency, with *DYEAR5*, *DYEAR6*, and *DYEAR7* as the control years, and investigated the macro environment factor impacts. Table 4 shows the operating efficiency for the year 2007 deteriorated relative to other years (2004, 2005, and 2006). During the sample periods, starting from 2004 to 2007, the operating efficiency was getting worse by the year.

CONCLUSION

Applying DEA to the operations data for 3,506 firms over the four year period 2004-2007, we find that the economic technology development zone and the economic development zone offer 15% or 24% low tax rate privileges surpassing that offered by the other zones. When the Taiwanese invested businesses are located either in the economic technology development zones or in the economic development zones, their production efficiencies are better. Taiwanese invested high technology industries showed worse operating efficiencies. Although, for the high technology industry, they may enjoy better tax incentives but these benefits are superseded by the greater amount of capital invested and the higher operating risks. Regarding the impact of the company characteristics on operating efficiency, we also find that as the company sizes become larger, their operating efficiencies worsen. The greater capital requirement and the difficulty in achieving economies of scale are the major reasons. However, when the company exhibits higher sales growth its operating efficiency is better as a consequence of its better performance.

Reform in China began in the late 1970s and China has embarked on a path of rapid economic growth (Xu et al., 2006). However, China's dynamic and rapid economic transformation and development, has led to an unbalanced economic structure, regional economic development disparity, and a burgeoning gap between rich and poor. The Chinese government has been trying to modify the industry structure and import/export goods structure. In order to solve the related economic problems, China has continuously ounced and implemented various new economic and trade policies since 2007. For FDI, the new corporate tax laws and policies were implemented on January 1, 2008[5]. This significant regulation change impacted all FDI businesses and increased the tax burdens regarding the business model, investment structure, site selection, and financing strategy.

5 The new corporate tax laws set all the domestic and foreign corporate taxes at 25%. However, for the small businesses and high-and-new technology enterprises 20% and 15% privilege tax rates are applied. The former tax privilege policy of "regional privilege" has turned to "industry privilege". To qualify for the 15% tax benefit, the Chinese government announced "High and New Technology Enterprise Accreditation Rules" on April 14, 2008. The products should be qualified in the "High and New Technology Expertise of National Focus Support". These technologies include: electronic information; biology and new medical engineering; air and aerospace; new materials; high technology service; new energy and energy saving; resource and environmental; and high and new technology remodeling traditional industry. Once the firm has obtained approval in one of the abovementioned eight areas by the authorities and received the high and new technology enterprise certificates, the 15% privilege tax rate would be applied.

After our empirical study, we suggest that the company planning to carry out FDI in China should consider the following matters. There are several advantages of low land, material, and labor costs, and also to the lower tax incentives programs. However, there are some operating risks which need to be treated with caution[6]. From the operation strategy point of view, FDI entity should consider an economic-oriented rather than a political-oriented investment location, and choose to develop core competency for competitive advantage, promote brand recognition, expand the market share, enhance the management skill, resource allocation, and maintain a favorable relationship with the government for an effective operating performance (Sanyal and Guvenli, 2000; Ma and Delios, 2007). China has initiated the market economic mechanism. For FDI, there are several problems of economic structures[7]. Evaluating how the tax incentives affect efficiency would provide an insight for current and potential foreign direct investors into China seeking to improve their operating performance and for policymakers considering foreign direct investment.

Note2：Definition of Variables:

$ln\theta$: log of the operating inefficiency.

AREA: dummy variable, when the sample location is the economic development zone or the economic technology development zone, the value is 1, otherwise is 0.

ELEC: dummy variable, when the sample industry is high-technology industry, the value is 1, otherwise is 0.

AREA×*ELEC*: the variable of interaction on *AREA* and *ELEC*.

AREA×*SIZE*: the variable of interaction on *AREA* and *SIZE*.

AREA×*GROWTH*: the variable of interaction on *AREA* and *GROWTH*.

ELEC×*SIZE*: the variable of interaction on *ELEC* and *SIZE*.

ELEC×*GROWTH*: the variable of interaction on *ELEC* and *GROWTH*.

SIZE: log of the total asset.

GROWTH: the growth rate of net sales.

DYEAR5: dummy variable, when the sample year 2005, the value is 1, otherwise 0.

DYEAR6: dummy variable, when the sample year 2006, the value is 1, otherwise 0.

DYEAR7: dummy variable, when the sample year 2007, the value is 1, otherwise 0.

A Study on the Individual Investors' Sentiment and the Institutional Investors' Recommendation Behavior in Taiwan

Dr. Chuang-Min Chao, National Taipei University of Technology, Taiwan
Yi-Ling Huang, National Taipei University of Technology, Taiwan
wateroceanspring@hotmail.com

ABSTRACT

This study investigate investor sentiment and its relation to stock market returns. We find that many commonly cited indirect measures of sentiment are related to direct measures (surveys) of investor sentiment. However, past market returns are also an important determinant of sentiment. Hence, we review the theoretical and empirical evidence for these predictions and present evidence that investor sentiment actually has strong effects. This study applies OLS regression model to examine the relationship between the abnormal trading volume on weekly of individual investors and the emotional variables. It contributes to the extant literature in several ways. First, by directly comparing between the individual and institutional investors, it provides empirical support for analyst "sentiment" in stock market of Taiwan. Second, it employs a more expansive definition of investors' sentiment to include the trading volume, the dividend premium, closed-end fund discount, and return of stock. Finally, this study finds investors' sentiment can affect the price in stock market of Taiwan.

Keywords: Investors' sentiment; Recommendation; Institutional investors

INTRODUCTION

The history of the stock market is full of events striking enough to earn their own names: the Great Crash of 1929, the Tronics Boom of the early 1960s, the Go-Go Years of the late 1960s, the Nifty Fifty bubble of the early 1970s, and the Black Monday Crash of October 1987. All these events have one thing in common: the dramatic changes in stock price were beyond rational explanation and betrayed the presence of irrational forces causing the fluctuations. One of these forces comes from the intuitive judgments of individual investors on the price trend.

According to classical financial theory, individual investors tend to base their investment decisions on whether the invested target is capable of generating a future return exceeding the amount to be invested. An underlying assumption of the traditional theory, however, is that

investors are believed to be rational; they would, for example, endeavor to reduce systematic risks by diversifying their investment portfolios. Even if some investors are irrational, classical theory argues that their demands will be offset by arbitrageurs and similar conclusions for prices will obtain.

According to the Taiwan Stock Exchange statistics, the proportion of individual investors accounts for 69.4 percent in 2007, indicating that individual investors have a significant influence on the Taiwan stock market. But individual investors usually rely on a large number of various media reports, experts' recommendations, companies' announcement of financial conditions and future prospects. The purpose of this study is to evaluate the individual investors' sentiment (i.e., the psychological factor) and its effect on the Taiwan Stock Exchange Market.

A pioneering and well-known set of Shiller(1981), Fama and French(1988), Poterba and Summers(1988), Campbell and Shiller(1988), and Fama and French(1989) studies of sentiment and aggregate stock returns appeared in the 1980s. They were largely atheoretical, testing in various ways whether the stock market as a whole could be mispriced. We find the role of sentiment was left implicit, and the statistical evidence was not usually very strong. Even when statistical inferences seemed robust, the economic interpretation was still unclear.

Therefore, recently, the more and more studies such as Baker and Wurgler (2006), utilize interim advances in behavioral finance theory to provide sharper tests for the effects of sentiment. In particular, in the many behavioral models of securities markets inspired by De Long et al. (1990), investors are of two types: rational arbitrageurs who are sentiment-free and irrational traders prone to exogenous sentiment. They compete in the market and set prices and expected returns. But, arbitrageurs are limited in various ways.

Now, the question is no longer, as it was a few decades ago, whether investor sentiment affects stock prices, but rather how to measure investor sentiment and quantify its effects.
Moreover, this study is going to examine whether the recommendations made by institutional investors are also affect by emotional factors.

LITERARURE REVIEW

Behavioral Finance

Behavioral finance is the application of psychology to financial decision making and financial markets. It is introduced because an understanding of the psychological factors that

affect investment decision making is relevant for the management of both private wealth and institutional assets. Behavioral finance provides insight into individuals' perceptions and preferences regarding financial risk, and also provide a theoretical basis for investment strategies that attempt to exploit deviations from market efficiency.

Table 1

Traditional financial and behavioral finance comparison

Traditional financial – Efficient Market Hypothesis Harry Robert(1967)；Fama(1970)	Behavioral Finance- Prospect Theory Kahneman and Tverskey(1979)
Investors are rational and they are rational to evaluate the assets of value. The market is efficient.	Investors are limited rational and use the normal behavior to replace rational behavior.
Even though some investors are irrational, because of their trading are random so they eliminate the impact on prices and will not cause deviation of systematic.	Irrational investors are not necessarily transactions occurred randomly.
Some investors have irrational behavior, but arbitrage theory of the market let price recover.	Arbitrage is limited market conditions, so that it cannot exert the function of arbitrage

Shefrin(2000) studies the field of behavioral finance into the heuristic-driven bias, frame dependence and inefficient market. As follows：

1. heuristic-driven bias:

The propensity of investors to make mistakes because they rely on crude rules of thumb rather than optimal statistical procedures. The candidate should be able to evaluate the impact of heuristic-driven biases on investment decision making including representativeness, overconfidence, aversion to ambiguity and etc.

(1) availability heuristic:

Tversky and Kahneman (1973) indicate: for easier access to the message, is easy to overestimate the possibility of its occurrence.

(2) representativeness heuristic:

People often refer to past decision-making known as stereotype. Tversky and Kahneman(1973)point out the representativeness heuristic is a people assume commonality between objects of similar appearance, or between an object and a group it appears to fit into. While often very useful in everyday life, it can also result in neglect of relevant base rates and other errors.

(3) overconfidence:

Individuals in decision-making is always a tendency to overestimate their own discretion and decision-making.The overconfidence effect is a bias in which people are correct in their judgements far less often than they think they are. For example, for certain types of question, answers that people rate as "99% certain" turn out to be wrong 40% of the time. Overconfidence is one kind of what is called the miscalibration of subjective probabilities

(4) hindsight:

Hindsight bias is the inclination to see events that have occurred as more predictable than they in fact were before they took place. In psychological experiments of hindsight bias, subjects also tend to remember their predictions of future events as having been stronger than they actually were, in those cases where those predictions turn out correct.

(5) ambiguity aversion

Ambiguity aversion describes an attitude of preference for known risks over unknown risks. Camerer (1995) think that when people come into contact with the investment of a new financial products or the environment, those who will increase because of uncertainty risk premium

(6) quasi-magical thinking:

Magical thinking (Skinner, 1948) occurs when decisions arise from irrational perceptions of optimization, e.g., choosing lucky or favorite items, numbers and rituals. Tversky and Shafir(1992)finds out personally think that some of his behavior can change the established fact and it explained Self-Deception Effect.

2. frame dependence

whereby investors' decisions reflect not only the underlying fundamentals but how decisions are described. Classified as the following five:

(1) house money effect：

Uncertaintylly, sunk costs and sinking profits have an impact on decision-making, and under certain circumstances, previous profits increase the willingness of individuals to participate in game are called(Thaler and Johnson, 1990).

(2) money illusion:

Personal response for nominal prices large than the price in real terms.Kahneman, Knetsch and Thaler(1986) discover that individuals are concerned about changes in nominal wages rather than changes in real wages. Shafir, Diamond and Tversky (1997) think of personal knows affect of inflation but still measure the their wealth by nominal income.Hence, personal feeling would be affected by nominal income

(3) attribution theory:

In the interpretation of individual behavior (internal attribution) and others to act or environmental factors (external attribution), it will generate error.That error becomes source of bias.Daniel, Hirshleifer, and Subrahmanyam(1998) consider the self-attribution

will become more personal over-confidence.

(4) regret and cognitive dissonance:

Shefrin (2000) finds that the individual in order to avoid regret caused self-blame would tend to maintain this status. And Cognitive bias, people would not face the fact

(5) self-control:

Specifically, refers to the emotional control. When the existence of self-control, investors will avoid loss and realize the stock profits.

3. inefficient market

Meaning mispricing stemming from heuristic driven bias and frame dependence.

Investors' Sentiment and Investors' Index

More recent several studies suggest that investor sentiment and trading activities of noise traders influence stock prices(e.g., Chuang and Lee, 2006) because the smart-money investors trade quickly on the basis of fundamental information in an unbiased manner(e.g., De Long Shleifer, Summers, Waldmann, 1990). Some papers have creatively tried to connect stock prices to exogenous changes in human emotions. For instance, Kamstra, Kramer, and Levi (2003) find that market returns are on average lower through the fall and winter, which they attribute to the onset of seasonal affective disorder, a depressive disorder associated with declining hours of daylight. However Petty, Gleicher and Baker(1991) find out the bad feelings would be to investor comparison of information analysis carefully and critical assessment. Wright and Bower(1992) also find the investor do optimistic judgments and decision-making when they are in a good mood state than in a worse mood state.

Therefore, the inexperienced individual investor is more likely than the professional to be subject to sentiment. Barber, Odean, and Zhu (2003) and Kumar and Lee (2006) find in micro-level trading data that individual investors buy and sell stocks in concert, which is consistent with systematic sentiment. Moreover, a growing literature presents evidence of irrational behavior of individual investors in option markets. Options prices rise when the value of the underlying asset has greater expected volatility, and options pricing models such as the Black-Scholes formula can be inverted to yield implied volatility as a function of options prices. Poteshman (2001) shows that option market investors exhibit the same pattern of shortterm underreaction and long-term overreaction to information that has been found in stock markets. Han (2008) finds that investor sentiment about the stock market affects option prices.

On the other hand, Qiu and Welch (2006) and Lemmon and Portniaguina (2006) show that

changes in the consumer confidence measure correlate especially strongly with small stock returns and the returns of firms held disproportionately by individual investors. Chen Ing Lee (2004) and Wei Liang Chang (2006) also point out that Consumer Confidence Index nonetheless correlate highly with changes and predictive capability in stock market of Taiwan. Trading volume, or more generally liquidity, hence, can be viewed as an investor sentiment index. For instance, Baker and Stein (2004) note that if short-selling is costlier than opening and closing long positions, irrational investors are more likely to trade, and thus add liquidity, when they are optimistic and betting on rising stocks rather than when they are pessimistic and betting on falling stocks.

Indeed, many experts use of Dividend premium, Closed-end Fund Discount, Option implied volatility, Equity issues over total new issues, IPO first-day returns, IPO volume and Insider trading etc to measure the emotion of investors. However, Investor sentiment is not straight forward to measure, but there is no fundamental reason why one cannot find imperfect proxies that remain useful over time. At present, there is no unity in the academic definition of investor sentiment. It is usually represent the future of the investment market or an indicator of optimism or pessimism. Hence, this paper discuss some generic issues involved in measuring sentiment and describe proxies for sentiment in Taiwan .

METHODOLOGY

Sample and data sources

The sample companies in this study are the stocks listed in the Taiwan 50 index which contains the Top 50 highest trading volume stocks in Taiwan stock market and listed in the Taiwan Mid Cap 100 which contains the between 51 and 150 trading volume stocks in Taiwan stock market. The data used in this study is observed from 2007 to 2008. We use IBES database which the original recommendation types are categorized as five grades (1 = Strong Buy, 2 = Buy, 3 = Hold, 4 = Underperform, 5 = Sell). This study regroups the data and divides them into three types, namely, neutral, buy, and sell. The contribution of this study is to provide more evidence of the emotional impact on the individual investors as well as the institutional investors.

Table 2

Classification sheet in Stock of foreign capital

Neutral	Experts' Buy Recommendations	Experts' Sell Recommendations
hold	Strong Buy	Sell
market perform	Attractive	underperform
inline	Outperform	
inline with stock	Overweight	

The model

This study applies OLS regression model to examine the relationship between the abnormal trading volume on weekly of individual investors and the emotional variables. Moreover, the multinomial logit model is used to examine the relationship between the emotional variables and the ratings reported by the institutional investors. The emotional variables (or the sentiment indicators) used in this study are the trading volume, the dividend premium, closed-end fund discount, and return of stock.

SUMMARY AND CONCLUSIONS

Then the results will be compared and contrast between the individual and institutional investors and see whether they are affected by the similar underlying emotional factors.

ABSTRACT

The purpose of this study is to investigate the security returns and trading behavior of institutional investors and individual investors in Taiwan stock market around the rating report announcement of foreign institutions. The data used in this study is observed from Jan, 2007 to Oct, 2008. The sample companies in this study are the stocks listed in the TSEC Taiwan 50 Index *which contains the Top 50 high trading volume stocks in Taiwan stock market. The event study method is used, while the market model is used to estimate the expected value of the price, trading volume and transaction numbers. The abnormal returns, abnormal trading volume and the abnormal transactions numbers are therefore calculated and used to examine whether the announcement of the rating report will lead to an abnormal trading behavior of the investors in Taiwan stock markets.*

From this study, we investigate the effect of rating report by foreign institution on different types of investors based on the stock price, trading volume and transaction numbers. That results help researcher to understand the information effect on investors and the duration of the effects under the bear and bull market period. In addition, understanding the different trading behavior of investors helps investors to make better decisions when receiving information.

Keywords: Trading behavior; Event study; Information content

INTRODUCTION

Examining the reaction of financial markets to various micro and macro events has been the subjects of numerous studies. Previous researches (Liu, Smith and Syed, 1990; Foster and Viswanathan, 1988) have noted that stock price and trading volume would be affected by the market information. The purpose of this study is to investigate the security returns and trading behavior of institutional investors and individual investors in Taiwan stock market around the rating report announcement of foreign institutions. In the next section, I review theory relating information value, including the impact of the information and the effect

duration. The third section describes the research design, while the fourth section presents the empirical results. Overall conclusions are discussed in the final section.

LITERATURE REVIEW

In an efficient market, security prices at any given time fully reflect all available information. Previous research documents price reaction to all kind of information in different financial markets. Glascock, Henderson and Martin (1986) find a significant positive price reaction for securities added to E. F. Hutton's "buy" list. Lloyd-Davies and Canes (1978), Syed, Liu and Smith (1989,1990, 1992) report significant positive abnormal stock price responses to the publication of analyst recommendations in The Wall Street Journal 's "Heard on the Street" (HOTS) column . Beaver (1968) introduced trading volume as a means of measuring the degree of consensus among investors with respect to a given information disclosure. He found that trading volume increases significantly at annual preliminary announcement dates, implying that there may be a lack of consensus across market participants in interpreting earnings data. Many recent studies have found that increased trading volume was associated with the release of information. For example, Karpoff (1986) develop a theoretical model to provide a rationale for the use of trading volume in event studies that attempt to identify the information content of an event. Beaver (1968), Bamber(1986) reported that trading volume increased significantly around that trading volumes of targets of tender offers increased significantly during the weeks preceding the announcement of the bid. Lakonishok and Vermaelen(1986) examined trading volume around ex-dividend days and reported that trading volume increased significantly around ex-dividend day.

This study also use "number of transactions" as an information content metric, recent studies by Howard (1982) and Cready (1988) also use number of transactions to measure trading behavior. The transaction numbers was the sum up of each trade, that means each trader was equally and Cready and Ramanan (1990) find that statistical tests employing number of transactions appear to be considerably more powerful than tests employing trading volume in measuring unexpected trading activity.

On the other hand, all kinds of information may cause different investors have different trading behaviors. Because investors may have different trading behaviors due to national customs and habits or the quality, quantity and speed in capturing information, or the differences in information recognition. Hakansson(1977)indicates institutional investors with more resources are better able to interpret complex information. Wu and Lee(2005)explore when the market-wide information declared whether the reactions of different kinds of

investors are consistent. It indicate institutional trading volume respond more sensitively than individual trading volumes in bull market when either good news or bad news is announcement. However, the result is contrary in bear market. Lee, Wu and Wang(2006) finding that domestic investors tend to sell, while the foreign investors tend to buy as good news is announced in the bull market. While domestic investors incline to buy, and the foreign investors incline to sell when bad news is announced either in the bull or in the bear market.

METHODOLOGY

Data

All stocks on the TSEC Taiwan 50 Index during the period 2007-2008 are potential candidates for this study. To be retained in the final sample, the company must have available (1) an rating report announcement by foreign institution (2) non-missing interday trading data on announcement date. All the data were obtained from the TEJ data bank. In cases where we found more than one announcement date for the rating reports, we used the announcement that at least 20 days duration. We then divide our sample into three groups based on different market periods: bull market, neutral market and bear market. Table 1 provides a description of the composition of the final sample.

TABLE 1 Description of the Final Sample

Bull market	Bear Market	Neutral Market	Total
16	29	57	102

Research Design

The research design consists of two stages. The first stage examines the price response to the rating report using abnormal returns at rating report release dates. The second stage using abnormal trading volume and abnormal transactions numbers to examine the trading response to the rating report.

The methodology adopted here is the standard event analysis. First, to estimate the market model for each stock and, then, to compute abnormal returns ,abnormal trading volume and the abnormal transaction numbers associated with each rating report announcement . The abnormal return is the difference between actual and predicted stock returns during a specific time period around the announcement day. The actual return for stock i on day t is given by

$$R_{i,t} = a_i + B_i \times R_{m,t} + e_{i,t}$$

where $R_{m,t}$ is the return on a market portfolio (market index) for day t .The parameter estimates a_i and B_i are obtained by using all available data for trading days -70 to -11 relative to the event date and $e_{i,t}$ is a stochastic error terms. The abnormal returns are computed as follows:

$$AR_{i,t} = R_{i,t} - (a_i + B_i \times R_{m,t})$$

where $(a_i + B_i \times R_{m,t})$ is the predicted stock return base on 60 day estimated period and $R_{i,t}$ is the actual return of stock i on day t. If the market is efficient, security prices should reflect all potential changes in the event outcomes. That is, if the required rate of return on a stock around the event day is identical to that of any other random trading day, one should not be able to make excess returns by trading around all of these event days.

The second stage also use event analysis to compute the abnormal trading volume and abnormal transaction numbers. The actual trading volume for stock i on day t is given by

$$V_{i,t} = a_i + B_i \times V_{m,t} + e_{i,t}$$

Where $V_{m,t}$ is the trading volume on a market portfolio (market index) for day t .The parameter estimates a_i and B_i are obtained by using all available data for trading days -70 to -11 relative to the event date and $e_{i,t}$ is a stochastic error terms. The abnormal trading volume are computed as follows:

$$AV_{i,t} = V_{i,t} - (a_i + B_i \times V_{m,t})$$

$(a_i + B_i \times V_{m,t})$ is the predicted stock trading volume base on 60 day estimated period and $V_{i,t}$ is the actual trading volume of the stock i on day t.

Finally, to compute the abnormal transaction numbers. The actual transaction numbers for stock i on day t is given by

$$TR_{it} = a_t + B_i \times TR_{m,t} + e_{it}$$

where $TR_{m,t}$ is the transaction number on a market portfolio (market index) for day t .The

parameter estimates a_i and B_i are obtained by using all available data for trading days -70 to -11 relative to the event date and $e_{i,t}$ is a stochastic error terms. The abnormal transaction numbers are computed as follows:

$$ATR_{i,t} = TR_{i,t} - (a_i + B_i \times TR_{m,t})$$

$(a_i + B_i \times TR_{m,t})$ is the predicted stock transaction numbers base on 60 day estimated period and $TR_{i,t}$ is the actual trading volume of the stock I on day t.

EMPIRICAL RESULTS

Table 2 shows the market reactions from days -3to +3.We find out a significant increase in abnormal return, abnormal trading volume and abnormal transaction numbers on the day before publication date (day -1).The results are consistent with previous studies (Syed, Liu and Smith,1990;Robert and Timothy,1996)that investigate the trading volume and returns reaction to the release of information. It seems that information has been leaked to the market prior to publication. The abnormal return on day t = -1 maybe due to the advance trading based upon speculation or knowledge about the forthcoming rating information .The average abnormal return on announcement day is 2.27 percent(t-value=1.92).Investors can not get abnormal returns on the day after announcement date. The abnormal trading volume has similar results to abnormal return. It appears that the publication of the rating report cause trading volume to increase on the publication date. It's interesting that the abnormal transaction numbers surrounding the announcements is significantly positive from the day -1 to the day 1.On possible explanation is these translations are come from the individual investors. Because individual investors may trade in very small amount due to these sample stocks are relative expensive. That's why it doesn't has the abnormal trading volume but still has the abnormal transaction numbers in the day = 2.Overall, Taiwan stock market seems very effective to reflect the new coming information. The market work effective may due to the following reasons. First, the sample stocks in our study are the TSEC Taiwan 50 Index stock, which are 50 of the most highly capitalized blue chip stocks and represents nearly 70% of the Taiwanese market. Because of the high fame, investors are relative know and understand these stocks so they have better ability to determine the authenticity of information.

TABLE 2 Market Reactions to the Rating Report by Foreign Institution (Total Sample)

3	0.0763	.628	0.046004	1.626503	0.008171	.185

Next, we take the different market period into consideration. Table 3 shows market reactions to rating reports in different market periods, we find out a interesting result that is market significant response to these rating reports in the neutral period. The possible explanation for this result may be the transactions are come from the individual investors. In the market condition not bright and clear, individual investors need more information and advices from the experts to guide them how to invest and then to adjust their stocks on hand. That's why after the rating report by foreign institutions release we can find a very long duration of significant increase in abnormal transaction numbers in neutral market period.The reason that rating report doesn't have influence on the bull or the bear market maybe also due to the sample characteristics. We can conclude that these sample stocks all the leading company in the industries so they seems become a good choice for investors to hold in the bear market .That maybe the reason we find the abnormal trading volume before the announcement date but could not find any abnormal trading behaviors after the release of rating report. On the other hand, in the bull market when the investors are very optimistic to the market trend, investors may like to invest their money on small scale stock that relatively more potential instead of these blue chips stock. Consistent with the result of Wu and Lee(2005), theyindicate that the return of portfolios with large volumes do not respond more heavily than with small volume despite good or bad news in the bull market.

CONCLUSION

This paper examines intraday trading activity on the TSEC Taiwan 50 Index surrounding the rating report announcements to address the following questions: (1) do these data provide information to investors; and (2) does different kinds of investor affect the usefulness of the information and the speed by which the information is processed.
Abnormal trading behavior including the abnormal trading volume and abnormal transaction numbers suggest that rating report announcements are informative to investors.
This study examines the information contained in rating report announcements and we extend previous research in this area by employing intraday trading data, which allows us to assess the relative informativeness of the rating report announcements across different classes of investors.

We find that abnormal returns could be generated by trading on the day before and the day rating report it is released. Consistent with previous studies, we also find information has leak in advance so that the abnormal trading volume and abnormal transaction all occurring earlier than the announcement day of the rating report. We also find the effects of rating report on abnormal transaction numbers are last longer than abnormal trading volume. However, investors only to trade on the announcement and the day before announcement can get abnormal return..

Overall, there are all kinds of information flow in the stock market and some can simulate investors to have abnormal trading behaviors but investors may not always get the abnormal return. Besides the help of new technology such as internet to accelerated the speed of transfer information, investors in Taiwan sock market over a long period of time to learn and

accumulate the experiences, no debut the Taiwan stock market is work more effective now.

ABSTRACT

This article is intended to detect the powerful factors which influence the suppliers' decisions in partnerships with their customers. Although over the past two decades, the formation of international and inter-firm collaborations has increased substantially, especially in the context of buyer-supplier relationships, empirical validations on the question of when do suppliers risk making specificity investments are limited. Thus, the primary purpose of this study is to go one step further and empirically verify the inter-relationships among strategic drivers, partnership governance mechanisms, relational factors, and supplier's specificity investments.

This model is empirically tested in the context of purchasing relationships between foreign buyers and Taiwan exporting oriented manufactures. Based on the results of this study, several conclusions can be drawn. The first conclusion is that there are significant relationships between relationship characteristics and specificity investments. In addition, there are significant relationships between supplier 's strategic drivers and specificity investments. Concerning the relationship between buyer's SD strategies and specificity investments, the positive influence of supplier incentive on specificity investments is significant. In addition, it was also found that a higher level of competition pressure is significantly positively associated with the level of supplier's specificity investments.

Keywords: Specificity Investments, SD strategies, Strategic Drivers, Relationship Characteristics

INTRODUCTION

This article is intended to detect the powerful factors which influence the suppliers' decisions in partnerships with their customers. Although over the past two decades, the formation of international and interfirm collaborations has increased substantially, especially in the context of buyer-supplier relationships, empirical validations on the question of when do suppliers risk making specificity investments are limited. Thus, the primary purpose of this study is to go one step further and empirically verify the inter-relationships among strategic drivers, partnership governance mechanisms, relational factors, and supplier's specificity investments. By reviewing the literature on buyer-supplier partnership from the fields of industrial marketing, organization theory, strategy, and transaction cost economics, we offer a preliminary examination of following issues.

Firstly, traditionally, through the viewpoint of transaction cost analysis, assets specificity is viewed as a risk should be taken into consideration in governance mode design. However, this study would like to adopt the transaction value perspective to explore whether attenuating uncertainty and seizing the leaning opportunities drawing from supplier's investment in asset

specificity will lead to suppliers risk making specificity investments.

Secondly, in contrast with transaction cost analysis, in which supplier 's specific assets investment is seen as an independent variable to choose an appropriate governance mode in terms of outsourcing or internalization, this study would like to build a full model concerning whether to involve in a highly specific asset investment under a given partnership from a supplier perspective. Thus, supplier 's specific asset investment is seen as a dependent variable in this study, and the influences from relationship characteristics as well as buyer 's deployment on supplier development strategies are included as independent variables. Resource dependence theory, cognition evaluation theory and relation exchange theory are adopted to examine to what extent do different supplier development strategies as well as different relationship characteristics impact on supplier's specific asset investment.

Finally, a comprehensive model discussing supplier's specificity investments in the context of buyer-supplier partnership will be built and empirically tested. Combing multiple theories in the field of interorganizational research, this study aims at building a model in global value chain to integrate supplier's strategic drivers, buyer's governance mechanisms, as well as relational factors to explain when do suppliers risk making specificity investments. This model will be empirically tested in the context of purchasing relationships between foreign buyers and Taiwan exporting oriented manufactures.

LITERATURE REVIEW

Asset specificity

The extent to which one partner's assets are specialized to the other is viewed as key in determining exchange cost. The distinguishing feature of transaction specific assets is that their value would be largely lost if the focal relationship were terminated (Williamson, 1985). Williamson (1985) suggested that idiosyncratic investments stabilize relationships by altering the firm's own incentive structure. By making idiosyncratic investments in a relationship, a channel member creates an incentive to maintain the relationship. Because idiosyncratic investments are essential to certain channel relationships, they are difficult or impossible to redeploy to another channel relationship. Specific asset investment may take a variety of forms. Some examples of idiosyncratic investments in Buyer-supplier relationships are training or dedicating personnel to servicing a specific manufacturer's products, adopting a common order processing system, building specialized facilities to handle a specific manufacturer's product line. In addition, they include a company's set-up of immobile production units near the site of a partner to economize on transportation costs ("site specificity"). They also include mobile resources ("physical asset specificity") and know-how ("human asset specificity"), or investments in generalized production capacity that have been solely make for the purpose of serving the partner (dedicated assets").

Such investments are a necessary part of achieving strategic outcomes because they promise efficiencies in coordination (Williamson, 1984) and have several important relationship-stabilizing properties. They facilitate expectations of continued exchange into the future (Heide & John, 1990) and represent credible commitments to the relationship that are useful in minimizing opportunistic behavior (Anderson & Weitz, 1992; Williamson, 1985).

While recent empirical evidence suggests that investments in these assets can improve

productivity, the decision to invest in specific assets also carries a certain cost (Dyer, 1996). Because to their specificity, investments in relationships cannot be easily transferred to another use and thus limit the investor's flexibility. According to Sollner (1999), inflexibility is a troublesome source of at least three risks that result from entering a close relationship, including: (1) risk of misinterpreting the client's "benefits sought": the risk refers that if a supplier practices relationship selling, but the client does not practice relationship buying, substantial investments may be wasted. (2) risks of imitation and substitution: the risks refer that if the client considers a close relationship to be a beneficial organizational arrangement, competitors might respond. While imitation will increase the supply, substitution will reduce the demand. These responses can become a genuine threat to the original supplier. (3) risk of hold-up: it refers cases in which one party takes advantage of a situation in which the other party can be forced to renegotiate a contract. Thus, if only the supplier makes significant investments, an exploitation hazard exists, and the buyer has the opportunity to extract the supplier 's anticipated surplus.

Relational Factors: Power and Norms

Transaction cost theory has achieved a prominent role in the analysis of governance mechanisms for exchange relationships. However, the assumption of opportunism that underpins this perspective has been challenged. Specifically, in the marketing literature, Hide and John (1992) argue that norms play a central role in structuring relationships between firms and have produced empirical evidence to support this contention. In contrast, Stern and El-Ansary (1992) argue that power is the major means available to achieve coordination and cooperation among channel members. Similarly, in the channel context with asymmetrical power structure between small buyer and big supplier, Berthon et al. (2003) find that norms do not play a significant role. They suggest that mechanisms other than norms are at work, such as power and interdependence. Thus, in this study norms and power are seen as two different kinds of governance mechanisms employed by OEMs under specific network relationship. It is argued that based on these governance mechanisms, an interaction platform of Buyer-supplier relationship is building. To the extent of opportunistic expropriation of suppliers affects their behavior before engaging in follow-up relationships. From the suppliers' perspective observable relationships reflect choices of partners maximizing the expected return on investments in specific assets. Thus, norms and power are seen as two critical context factors influencing supplier's specific asset investment, relationship learning, as well as supplier 's upgrading.

Norms in exchange relationships

Vertical control has been suggested as a functional substitute for ownership in nonintegrated situations, although there is limited understanding of the conditions that enable a firm to establish vertical control in relationships between independent firms (Heide and John, 1992). Heide and John (1992) propose that the presence of certain strong relational norms represents such a condition. Pfeffer and Salancik (1978) mention that norms are commonly of or widely shared sets of behavioral expectations. In other words, a norm is a belief shared to some extent by members of a social unit as to what conduct ought to be in particular situations or circumstances. They argue that norms, which have evolved to coordinate interorganizational behavior, are general in content and apply to issues of trust and predictability. Similarly, Dwyer et al. (1987) in their discussion of the development of expectations between trade parties focused on the concept of trust as one major issue deserving priority, since relational

exchange dominates over discrete transactions. According to Kaufman and Stern (1988), three factors play a most important role in developing attitudinal ties between partners, namely solidarity, role integrity, and mutuality. The norm of solidarity in relational exchange makes the parties seek to maintain and preserve a unique and continuing relationship. Very often the parties develop a strong reputation of trustworthiness and view the particular relationship as important in itself. The focus of the relational norm of role integrity is on the enactment of roles that reflect the parties' promises and expectations. Typically, the parties to a close business relationship enact highly complex roles that reach far beyond the mere exchange of goods. The relational norm of mutuality focuses on the fair distribution of the benefits derived from the relationship as a whole. Keeping in mind the specific context in which this research was conducted-relationships between Buyers-suppliers in the electronic equipment manufacturing industry—flexibility, information exchange, and solidarity (cf. Heide and John, 1992) were deemed to be the relevant relational norm dimensions.

Flexibility refers to the expectation that the appropriate behavior when one of the partners is facing an unanticipated crises is for the other partner to be willing to renegotiate the original terms of the contract to take into account the changes in the contractual environment. Information exchange refers to the expectation that the appropriate behavior for both exchange partners is to communicate frequently, informally, and with full disclosure. Finally, solidarity is the expectation that it is appropriate for exchange partners to work in the best interest of the relationship and that it is inappropriate for them to make moves that secure only unilateral gains (Gundlach, Achrol, and Mentzer, 1995; Heide and John, 1992).

It is found that in high relational norm relationships exchange parties are more committed (Gundlach, Achrol, and Mentzer, 1995) and demonstrate a long-term orientation (Ganesan, 1994) because they are confident that their actions will not be opportunistically abused (Heide and John, 1992). By providing a generalized safeguard against partner opportunism, relational norms make parties more willing to engage in actions that result in relationship continuity. In addition, in a context of asymmetrical commitment in business relationships, Sollner (1999) finds that in the traditional transaction cost framework, the expectation that asymmetrical instrumental inputs in a relationship will have a negative effect on relationship justice as perceived by the supplier (if the supplier has made higher investments) is unconfirmed. Further, it is also found that the buyer's attitudinal inputs have a strong impact on the supplier 's perceived justice if the supplier is "locked-in". On the other hand, in the absence of attitudinal inputs of the buyer (relationship norms), perceived justice of the supplier would be lower. In line with Heide and John (1992), he indicates that relationship norms provided by OEMs not only do serve as a safeguard against opportunistic behavior, but are an important ingredient in all close and long-term business relationships. Thus, it seems that suppliers do not thoughtlessly enter business relationships to get trapped and exploited. Consequently, in high relational norm relationships, expectation of relational continuity is high, which in turn reduces supplier 's perceived risk of hold-up concerning specific asset investment. Thus, we propose that,

Hypothesis 1: In a buyer dominated network, the greater extent of norms between buyer-supplier relationship, the more likely that the supplier will have a positive effect on the willing to invest in idiosyncratic assets.

Dependence structure

According to the social exchange and resource dependence ideas of Pfeffer and Salancik (1978), Provan, Beyer, and Kruytbosch (1980), and others, dependence is critical for understanding interorganizational relationships. Gundlach and Cadotte (1994) define a dependence structure as consisting of two dimensions: the degree of interdependence between parties and the relative balance of power within the relationship. The term, asymmetric dependence, is used to indicate that the dependencies of the two parties are such that one party holds a power advantage over the other. In contrast, equilibrium can exist at any level of interdependence, but the relative balance of power must be equal for an equilibrium state to exist. Following this concept, the variables of central interest in this study are the two dimensions of the transacting parties' dependence structure: interdependence and power asymmetry.

Customer's power advantage. Dahl (1957) defined power as the ability of one individual or group to get another unit to do something. El-Ansary & Stern (1972) applied this concept to distribution channels by defining power as the ability of a channel member to control the decision variables in the marketing strategy of another member at a different level in the channel of distribution. In this study, customer's power advantage refers to the degree of power asymmetry as represented by the extent to which the supplier 's dependence on its OEM customer exceeds the customer 's dependence on this supplier.

Both transaction cost analysis and resource-dependence theory suggest that uneven rewards from exchange relationships will result if either party has an advantage over the other party. Drawing on resource-dependence theorist have proposed hat dependence of actor A on actor B will lead to poor outcomes for A if A's dependence exceeds actor B's dependence on actor A. The reason is that the advantaged firm is able to use its power to achieve its own objectives at the expense of the weaker party as has been discovered in bargaining situations (Pfeffer and Salancik, 1978). In the context of Buyer-supplier relationship, Hakansson (1982) observes that powerful OEMs are able to leverage their position to demand adjustments to agreements without offering compensation. Kalwani and Narayandas' (1995) study of suppliers in the industries where they are usually the weaker party reports that "firms in long-term relationships face lower gross margins over time". The reason is that a customer with a power advantage can demand price concessions and shorter production runs with success because alternative suppliers are available and the disadvantaged supplier has few options other than adjusting. Such demands can severely affect the performance of component suppliers since a single OEM's business often accounts for a sizable share of a supplier 's revenue. Thus, as customers with power advantages are expected to be able to make costly demands on their weaker supplies and receive compliance to these demands. Under this circumstance, should suppliers build close partnership with OEMs through specific asset investment?

There are two different perspectives concerning how the relatively dependent party copes with demands from their more powerful partner. One perspective suggests that relatively dependent suppliers will comply with OEM demands as they want the relationship to continue and hence have no choice but to comply (Provan and Skinner, 1989; Williamson, 1985). The resistance perspective, on the other hand, suggests that the relatively dependent party will actively seek to block OEM demands through countermeasures (Lawler, Ford and Blegen, 1988). We discuss these two perspectives as followings:

The Compliance Perspective. It is argued that suppliers who are dependent on their OEMs are expected to comply more readily with OEM requests. Support for a positive relationship between dependence and compliance derives from a number of different theoretical sources. Firstly, Frazier & Rody (1991) and Scheer & Stern (1992) found that inter-firm power can play a positive role in promoting the effective coordination of channel relationships for both the relatively powerful and the relatively dependent channel member. They argue that more powerful parties may recognize the benefits of strong partner relationships and use non-coercive influence strategies to effect cooperation and joint outcomes. Consequently, the weaker suppliers could put their worry aside this partnership. Further, according to social exchange theory (Dwyer, Schurr, and Oh, 1987; Hallen, johanson, and Seyed-Mohamed, 1991), parties choose to become dependent on their partners when they conclude that the benefits resulting from these investments will outweigh the costs of increased vulnerability.

Although this specific asset investment would enhance supplier's dependence level on OEM, if it could build a leaning platform for competence upgrading or bring more business opportunities, it is worth taking risk. Since, it is established support for a positive relationship between dependence and compliance (see Anderson and Robertson, 1995; Keith, Jackson, and Crosby, 1990), we propose that,

Hypothesis 2: In a buyer dominated network, the greater the power advantage of a customer, the weaker bargaining power of the supplier will be in the network, and hence, the more likely it is that the supplier has to invest in specific assets under the customer's pressure.

The Resistance Perspective. Asymmetric interdependence in exchange relationships creates power imbalance. Supplier relative dependence on a OEM translates into OEM power over the supplier. In other words, it results in enhanced ability by the OEM to control supplier behavior. This is likely to create feelings of animosity, resistance, or revenge that motivate the other to be uncooperative, feud, or retaliate in ways that undermine the relationship. Similar logic led Anderson and Weitz (1989) to suggest that asymmetric power relationships are less stable, due to lower trust and confidence in the future. In addition, as a consequence of increasing OEM power, it is expected that relatively dependent supplier will perceive a greater threat to their freedom of action than will suppliers who are not relatively dependent on their OEMs. According to Reactance Theory (Brehm, 1966), as the perceived threat of constraints on free behaviors increase, the magnitude of reactance behaviors (that is, behaviors intended to undermine these constraints), also increases. Given their relative dependence, manufacturers may have to frequently sacrifice their self-interest in being required to behave in ways that meet the demands of their more powerful OEM. As the constraints on manufacturer self-interest enhancement behaviors increase, it is expected that these suppliers will react to undermine these constraints. Consequently, the supplier will not support specific asset investment.

Hypothesis 3: In a buyer dominated network, the greater the power advantage of a customer, the more unlikely it is that the supplier will invest in specific assets under the customer's pressure.

Interdependence refers to the level of mutual supplier and customer dependence in the relationship. As evident by these definitions, the dependence structure of an exchange relationship is derived fundamentally from each firm's level of dependence on the relationship. For suppliers and customers, a firm's own dependence is determined by the

availability of substitutes and he firm's need for the resources derived from exchanges with the other company.

In contrast to asymmetric dependence, interdependence is expected to have positive consequences for exchange relationships. Firstly, according to bilateral deterrence theory (Bacharach and Lawler, 1981) and social exchange theory's norm of reciprocation contend that, all else being equal, greater interdependence leads to lower conflict, greater cooperation, and greater trust as retaliation poses an ever-greater threat for both partners (Kumar, Scheer, and Steenkamp, 1995). It is expected that interdependence serves to raise the "costs" of acting unilaterally and using coercive influence and provides an effective deterrent to self-serving behavior (Anderson and Weitz, 1992), since dyadic relationships are often embedded in a broader network of supplier-buyer relations, a view strongly expressed by Granovetter (1985) who maintains that such social embeddedness provides a powerful incentive to limit opportunistic acts.

In addition, as argued by Provan (1993) and in consistence with Axelrod's (1984) ideas on cooperation, when outcome interdependence is high, interdependent firms will not necessarily seek short-term goals, but rather look for long-term strategic advantage. The reason is that interdependence discourages OEMs from using their power to demand exchange concessions because such requests will meet resistance and may produce conflict, supply interruptions and product quality lapses. Further, interdependence also provides a mutual incentive for suppliers and OEMs to cooperate. Such cooperation is essential since many aspects of the final product's performance do not fall exclusively within a single member 's domain but rather involve complex systems that draw upon both partners' unique competencies. Many of the recent trends in original equipment manufacturing are motivated by the potential to increase final product performance through such systematic cooperation (e.g., Just-in-Time, supplier involvement in product development, etc.). Under this close partnership, the customer has a strong incentive to maintain the relationship and avoid disruptive disagreements over pricing and other sensitive issues. In other words, goal incongruence does not exist in this close partnership. Hence, when outcome interdependence is high, as in well-established networks, member firms can be expected to make some short-term sacrifices that do not necessarily serve their immediate interests in return for expected long-term strategic advantage.

Thus, when a buyer is highly dependent on a supplier, its own opportunistic acts toward the supplier are likely to have little long-term advantage. Hence, high inter-dependence reflects an increased willingness to cooperate with the primary buyer in ways that are likely to benefit both organizations in the long-run.

Hypothesis 4: In a buyer dominated network, the greater the inter-dependence between OEM and the supplier, the more embedded the relationship will reduce the buyer's opportunisms in the network, and hence, the more likely it is that the supplier will invest in specific assets.

The Strategic Drivers for Suppliers

The final set of hypotheses addresses the contextual conditions that influence the willing of supplier-specific investments. These components include environmental dynamism, learning intent, and customer technical innovativeness.

Environment dynamism

Uncertainty creates information problems in exchange. External uncertainty caused by market dynamism makes it more difficult to predict future contingencies. Another kind of uncertainty comes from technological unpredictability. Given that the setting of this study is supply markets, we define market dynamism as the degree of variability in a firm's supply market (Achol, Reve, and Stern, 1983; Cannon, et al. 2000); and technological uncertainty is defined as the extent of inability to predict accurately the technological changes in the product purchased and its underlying manufacturing processes (Stump and Heide, 1996).

Market Dynamism When suppliers perceive a dynamic, uncertain environment and rising demand for the dyad's outputs, they are more willing to expend the effort to exploit the distinctive aspects of their relationship and coordinate across the dyad. Jap (1999) indicate that it may be that environmental uncertainty motivates suppliers to form close relationships with buyers because it enables the suppliers to obtain valuable downstream information that can aid in demand forecasting and provides a means by which they can cope better with environmental demands.

Technology Uncertainty Uncertainty stemming from technical change has been found have negative effects on vertical integration (Balakrishnan and Wernerfelt, 1986). The rationale is that strategic flexibility and lower asset exposure are preferred when the risks of technological obsolescence are high (Harrigan, 1985). Technological uncertainty arises from high rates of technical change, increases in product complexity, and risks of obsolescence (Zuinn and Hilmer, 1994). However, using data collected in a survey of U.S. purchasing managers regarding their relations with their Pacific Rim suppliers, Celly et al. (1999) find that technological uncertainty increases supplier relationship-specific investments as suppliers attempt to manage the uncertainty associated with change by credibly committing to buyers. Their goal is to secure a steady stream of revenue and/or early information on buyer requirements. Concerning these mixed results, we propose the following two possible hypotheses:

Hypothesis 5: In a buyer dominated network, the greater the environmental dynamism, the suppliers' relation-specific investments increase.
Learning intent

Learning intent entails the firm's goal directed arousal with regard to leaning (Maclnnis et al., 1991). Its enthusiasm for and interest in the internalization of knowledge into the firms knowledge stocks rather than mere observation and noting (Hamel, 1991). Learning intent is the firm's desire to learn. It describes how hungry and ambitious the firm is to learn and build competencies. When a firm's learning intent focuses on the building of a particular competence such as interfirm partnering, the firm will be insatiate and energetic in learning activities pertinent to that competence. Since relationship-specific investment could build up a learning platform for suppliers to learn from buyers, strong learning intent implies that the firm is willing to allocate resources accordingly, thus:

Hypothesis 6: In a buyer dominated network, the greater the supplier's learning intent, the suppliers' relation-specific investments increase.

Customer technical innovativeness

Customer's technical innovativeness refers to the extent to which the customer is engaged the development of new and related technologies (von Hippel, 1988). Anderson, Hakansson, and Johanson (1994) and von Hippel (1988) recognize that suppliers may choose to invest in a customer relationship for reasons other than the benefits derived immediately from the exchange. In markets experiencing consolidation and competitive re-ordering, the choice of an innovative customer may have important consequences for the supplier's performance, given that selling to one customer may preclude relationships with other customers. Collaborating with a customer that falters could have serious consequences for the supplier. Thus, innovative customers should be targeted for developing close relationships. It is argued that innovative customers represent a strategic opportunity to acquire knowledge that can be use in other relationships or markets. In addition, innovative customers tend to be more receptive to supplier product initiatives and are more likely to represent an expanding source of demand. Technological innovativeness may also serve as an indicator of a customer's long-term viability as a source of revenue. Thus, we expect:

Hypothesis 7: In a buyer dominated network, the greater the customer technical innovativeness increases supplier intention for relation-specific investments.

Governance Mechanisms—Supplier Development Strategies

The ability to coordinate internal activities with external supplier networks is one of the most critical strategic weapons for many of today's successful organizations (Krause, 2000; Bessant et al., 2003; Simatupang et al., 2002;Burnes and New, 1996). Suppliers directly impact, either positively or negatively, many competitive dimensions including cost, quality, technology, delivery, flexibility, and profits (Park and Hartley, 2002; Reed and Walsh, 2002; Krause et al., 2000). If capable suppliers exist and are selected, a company can use its supply chain for competitive advantage. As a result, drawing upon resource-dependence theory, it is suggested that buyer should reduce the supplier base and make a long-term contract with one or a few suppliers to raise partner's compliment competence. This practice is beyond the traditional purchasing activities and affects the purchasing firm's management of risk. A reduction of the supplier base is risky in the sense that the purchasing firm might be more vulnerable and dependent on one specific supplier. Further, many buying firms report a serious need for supplier improvements in the areas of quality, cost, delivery, innovation, and product design (Morgan, 1993). Moreover, buying firms indicate that suppliers' future capabilities may not meet the future needs and expectations of buying firms without some type of buying firm intervention (Monczka & Trent, 1995). In response to these concerns, buying firms increasingly use supplier development strategies to raise the performance of their suppliers (Watts & Hahn, 1993). This change has accompanied significant modifications in supply chain management strategies over the last two decades. U.S. industrial firms have shifted from adversarial to cooperative relationships with suppliers (Hartley & Choi, 1996) and consolidated their purchases with fewer suppliers (Krause, 1997) to focus on buying from and improving the performance of key suppliers.

Buying firms now use a variety of strategies to improve their suppliers' performance and capabilities. According to Krause et al. (2000), these supplier development strategies are categorized as internalized or externalized activities. The following supplier development activities represent externalized activities in the sense that firms make use of the external

market to instigate supplier performance improvement. The first one is Competitive Pressure, which is applied by a buying firm to its suppliers, when it uses more than one supplier for a purchased item or service, or is willing and able to switch to an alternate supplier. The second one is Supplier Assessment, which are efforts by buying firms represent in-depth evaluations of suppliers' quality, delivery, cost, technical, and managerial capabilities. By providing evaluative feedback to suppliers, it helps to clarify the buying firm's expectations and provide the supplier with direction for improvement. The last one is Supplier Incentives for improvement, which is provided by buying firms to their suppliers include increased volumes of present business and priority consideration for future business for the best suppliers. All these activities used by buying firms to encourage suppliers to improve with little involvement by the buying firm.

In contrast, internalized supplier development activities represent a direct investment of the buying firm's resources in the supplier. Direct Involvement Activities, where the buying firm directly involves itself in the supplier development effort, entails investments by the buying firm in the supplier through activities such as training and education of a supplier's personnel, and dedicating buying firm personnel temporarily to the supplier. This supplier development strategy deserves special attention because direct development efforts represent transaction-specific investments in the supplier by the buying firm. Thus, the direct involvement strategy represents a risk to the buying firm.

Asset specific investments generate rents. Parties incur the expenses and risks associated with such investments in order to capture the associated rents. If a manufacturer did not experience competitive gains (1) from adapting their production process to fit with that of a supplier, or (2) from training that supplier, there would be no incentive for the manufacturer to make these specific asset investments. While specific asset investments do generate rents, the lapse of time between when costs in making the specific asset investments are incurred, and the benefit from these investments are received, creates the need for relationship continuance for the party that has made these investments (Gundlach, 1994). Manufacturers that have invested specific assets in suppliers (eg. production process adaptation, supplier training) incur costs in the present, while the benefits from these investments only materialize over the long-term (e.g. more efficient production, beter quality components). Having invested specific assets in a supplier (e.g. supplier certification), manufacturers will work forward relationship continuance with that supplier, in order to avoid switching costs (Jackson, 1985), and to enjoy the rents which motivated these investments in the first place. Since opportunism undermines relationship continuance, it is expected that manufacturer asset specificity in a supplier will be inversely related to manufacturer opportunism against that supplier. In contrast, when market control mechanisms are employed, often the expectation of relation duration is shorter. It enhances the extent of uncertainty from the supplier perspective. Under this circumstance, suppliers will be hesitated with the specific assets investment. Based on the preceding, it is posited that:

Hypothesis 8: When manufacturers deploy on internalized supplier development strategy, namely direct involvement activities, it will be inversely related to manufacturer opportunism against the supplier. Hence, the more likely the suppliers will involve supplier's specific asset investments.

Hypothesis 9: When manufacturers deploy on externalized supplier development strategy, namely direct involvement activities, it will be positively related to manufacturer

opportunism against the supplier. Hence, the more unlikely the suppliers will involve supplier's specific asset investments.

RESEARCH DESIGN AND METHODOLOGY

Construct Measurement

The construct measurements of research constructs include relationship characteristics (which is composed of dependence structure, and relation norms), supplier development activities (which is composed of direct involvement, supplier incentives, competitive pressure, and supplier assessment), strategic drivers (including environment dynamics, learning intent, and customer 's technical innovativeness), and supplier's specific assets investment.

Sampling Plan

A sampling plan was developed to ensure that certain types of firms were included in this study. We restrict our interest to relationships between manufacturing supplier firms and their customers. Thus, this study selected the companies in Taiwan who manufacture products and export products to foreign buyers for our sample. Following previous research (Kalwani and Narayandas, 1995), the manufacturers coming from computer and allied equipment manufacturers, machine tool equipment manufacturers, electronics and other electrical equipment manufacturers, automotive product manufacturers, and manufacturers of scientific instruments are the focus of this study. The reason for focusing on these industries is that customer firms in these industries have faced intense competitive pressures at the international level. There is documented evidence that to improve their competitiveness in the ever changing global marketplace is essential. On the one hand, manufacturing firms in these industries have been slashing their vendor lists and getting into long-term relationships with a few suppliers. On the other hand, supplying firms are requested to deploy high level of specificity investments to retain the relationship with focal firms (Kerrin, 2002; Celly et al., 1999). Thus, it is expected that these industries are quite suite for our focus of this study. According to the "Directory of Excellent Exporters / Importers in 2002" provided by Ministry of Economic Affairs in Taiwan, in which the selection of excellent exporters/ importers for award in 2002 was based on the criterion of an annual trade performance of at least US$ 8,500,000, it is found that the numbers of populations for our target industries, in terms of Computer, allied equipment & machine tool equipment (CCC Code, 8401-8485), Electronics & electrical equipment (CCC Code, 8501-8539), Automotive product (CCC code, 602-8907), and Scientific instruments (CCC Code, 9001-9209), are 1805, 1919, 350, 617 respectively. Due to the expected number of sample in this study is 900, it is decided that there will be 300, 300, 100, and 200 companies selected from each above industries as our sample.

For abtained the newest companies' information, the sampling frame is mainly obtained from "Taiwan Exporters (2004)," published by Taiwan External Trade Development Council. The following criteria are used for the selection of sample firms for this study. (1) Only the firms in manufacturing sectors are selected. Trading firms without involving into manufacturing are not included in this study. (2) The total annual exporting volume of the firms should exceed one million U.S. dollars. After screening out the potential name list, a random sampling method is used to select the final sample for this study. Totally, 900 questionnaires were sent to the heads of marketing department of sample firms who were supposed to well understand the constructs of this study.

The data were gathered near two months period beginning in middle August of 2004, ad ending in end September of 2004, including one pilot test and one final survey. For the final survey, a total of 900 survey questionnaires were mailed to the sample firms. Out of 900 sample firms, with follow-up telephone calls, 155 completed and returned the answers. A total of 148 questionnaires were usable, producing a response of 16.44 percent.

Characteristics of Customer Relationships, Sample Firms and Respondents

It is shown that 36.8% of respondents report that their specific customers are belonging to brand manufacturers. Following, the second major relationships in this study are coming from the relationships with electronics manufacturing services（about 29.9%）, the others 32.6% are coming from relationships with retailers as well as trading agency. Concerning the equity investment between supplier and customer, almost all the relationships are belonging to non-equity investment relationship（about 84%）. In addition, regarding the nature of the transaction, more than 37.2% of the transactions coming from general procurement in which the level of interaction between supplier and customer is usually lower than the other types, such as sub-contracting (19.3% in this study), customization (21.4%), and in-processing (8.3%). More than 73% of the respondents report that the sales of this specific customer are less than 20% when comparing with whole sales, while 26.2% of the respondents are reporting their major customer who accounts for more than 20% sales. Finally, about 55% of the respondents report that their relationship duration is less than 5 years, while 31.4% are reporting the relationship duration between 5 and 10 years, 13.6% are of more than 10 years.

In addition, in this study, more than 29.73% of sample firms are belonging to computer related industry, 37.16% coming from electronics related industry, 13.51% belonging to automotive product related industry, and 19.59% coming from scientific instruments industry. More than 58% of the firms operate with a comparatively large scale, whose employees are more than 1500. Only 22.1% of the firms spend annual R&D expenditure less than 3% of sales, the others (about 78%) are more concerned with their innovation capabilities. Finally, more than 68.92% of the respondents are working as upper level managers. It is proposed that they will be full of experience regarding interacting with customers.

Exploratory Factor Analysis

To verify the dimensionality and reliability of constructs of this study, purification processes, including factor analysis, correlation analysis, and coefficient alpha analysis were conducted in this study. Factor analysis examined the basic structure of the data. Correlation analysis assessed the degree of multicollinearity among variables. Coefficient (Cronbach's) alpha measured the internal consistency of each identified dimension.

The results show that all variables within a factor tend to have a high coefficient of item-to-total correlation. This suggests a high degree of internal consistency for each dimension. In addition, the high coefficient of Cronbach's α on each factor further confirms the reliability of the measurement items.

RESEARCH ANALYSIS AND RESULTS

To verify the effects of relationship characteristics, supplier's strategic drivers, and buyer 's SD strategies on the supplier's specificity investments, there are following 5 regression models constructed. The results are shown as Table 2.

Model 1 SI = β11 + β12 * SOW + β13 * BOW + β14 * AGE…….(1)

Model 2 SI = β21 + β22 * SOW + β23 * BOW + β24 * AGE + β25 * CPA+ β26 * INT + β27 * NORM....……..……..(2)
Model 3 SI = β31 + β32 * SOW+ β33 * BOW + β34 * AGE + β35 * UNCER+ β36 * INTENT +β37 * INOVA……(3)

Model 4 SI = β41 + β42 * SOW + β43 * BOW + β44 * AGE + β45 * INVO + β46 * INCEN + β47* PRESS + β48 * ASSES……...……...(4)

Model 5 SI = β51 + β52 * SOW + β53 * BOW + β54 * AGE + β55 * CPA+ β56 * INT + β57 * NORM + β58 * UNCER+ β59 * INTENT + β510 * INOVA + β511 * INVO + β512 * INCEN + β513 * PRESS + β514 * ASSES…… ...(5)

Note: SI= Specificity investments; SOW=Supplier's ownership; BOW=Buyer 's ownership; AGE=duration of relationship; CPA=Customer 's power advantage; INT=Interdependence; UNCER= Environment dynamics; INTENT=Learning intent; INOVA=Customer 's technology innovativeness; INVO=Direct Involvement; INCEN=supplier incentives; PRESS=Competitive pressure; ASSES=Supplier assesment.

Among these equations, relationship characteristics (in terms of customer's power advantage, interdependence, and norm), supplier's strategic drivers (in terms of environment dynamics, learning intent, and customer's technical innovativeness), and buyer's SD strategies (in terms of direct involvement, supplier incentives, competition pressure, and supplier assessment) are the dependent variables in each equation respectively. Supplier's ownership, buyer's ownership, and duration of relationship are the control variables.

We used a hierarchical regression procedure to estimate the above equations. In these 5 models, we use Specificity investment as dependence variable. In Step 1, only the control variables (including Supplier's ownership, buyer's ownership, and duration of relationship) were entered. The explained variance of the control variables entered as a block is not significant ($r^2 = .015$, $F = .694$, $p=.557$). In Model 2, the main effect of relationship characteristics was entered. The explained variance of this main effects is significant (change in $r^2 =0.099$, $F = 2.758$). It shows that only Interdependence has a significant effect on Specificity investment. Thus, our previous hypothesis 2 has been supported. In contrast, the hypothesis 1 and 3 could not find supports from the empirical results.

In Model 3, the main effect of supplier's strategic drivers was entered. The explained variance of this main effects is significant (change in r 2 =0.111, F = 3.094). It shows that Environment dynamics and Learning intent have significant effects on Specificity investment. Thus, our previous hypothesis 4 and 5 has been supported. In contrast, the hypothesis 6 could not find supports from the empirical results.
In Model 4, the main effect of Buyer's SD strateies was entered. The explained variance of this main effects is significant (change in r 2 =0.149, F = 3.595). It shows that Supplier incentives, and Competition pressure have significant effects on Specificity investment. Thus, our previous hypothesis 8 has been supported. In contrast, the hypothesis 9 could not find supports from the empirical results.

Finally, all the explained variables are put into model 5 to identify the more influencing variables. The explained variance of this main effects is significant (change in r 2 =0.237, F = 3.113). It shows that Interdependence, and Supplier incentives are the most influencing variables.

Table 2 The Results of Regression Models of Specificity Investments

Variables	Dependence variable: Specificity investments(SI)				
	Model 1	Model 2	Model 3	Model 4	Model 5
Constant	4.677**	3.441**	2.576**	1.990**	.827
Supplier's Ownership	.419	.312	.351	.336	.274
Buyer's Ownership	-.224	-.169	-.167	-.180	-.072
Duration of relationship	.115	.132	.049	.068	.055
Relationship Characteristics					
Customer's power advantage		-.043			-.064
Interdependence		.138**			.109**
Norms		.040			.0060
Supplier's Strategic Drivers					
Environment dynamics			.187**		.098
Learning intent			.195*		.088
Customer's Technology Innovativeness			.072		-.138
Buyer's SD Strategies					
Direct involvement				.069	-.024
Supplier incentives				.259*	.254*
Competition pressure				.139*	.101
Supplier assessment				.070	.088

Note: **: indicating a significance level of 0.01, *: indicating a significance level of 0.05

DISCUSSION AND CONCLUSION

The major objectives of this study have been to identify the influencing factors of specificity investments by suppliers. Based on the results of this study, several conclusions can be drawn. The first conclusion is that there are significant relationships between relationship characteristics and specificity investments. In addition, there are significant relationships between supplier 's strategic drivers and specificity. Concerning the relationship between buyer's SD strategies and specificity investments, is that the positive influence of supplier incentive on specificity investments is significant. In addition, it was also found that a higher level of competition pressure is significantly positively associated with the level of supplier's specificity investments. In summary, this research makes several contributions to our understanding of the relationships among relationship characteristic, supplier's strategic drivers, and buyer 's SD strategies, and a supplier 's specificity investments. The proposed framework provides a more comprehensive view of the relationships among these constructs than is available from the extant theory.

DETERMINANTS OF INFORMATION SHARING OF MOBILE PHONE USERS

Dr. Chung-Chu Liu, National Taipei University, Taiwan
gereliu@mail.ntpu.edu.tw

ABSTRACT

Mobile phone communications play an essential part in our daily life. Information sharing can improve the speed and spreading of information and news. The purpose of this study is to explore determinants of information sharing of mobile phone users. The author obtained data from in-depth interviews through open-ended questionnaire. Content analysis and literature review were adopted to analyze data. According to the results, this research divides determinants of information sharing into four parts: senders' factor, receivers' factor, context factor, and types of information. The results could be formulated a conceptual framework for empirical study in the future. The conceptual framework is also helpful to mobile phone users to evaluate important factors assessment.

Keywords: mobile phone, mobile phone user, information sharing, literature review, content analysis method, knowledge management

INTRODUCTION

It is very important to understand how mobile service companies should interactive with their customer and deliver services (Parasuraman & Zinkhan, 2002). Consumers' use of mobile communication devices is increasing rapidly, and devices based on mobile technology are ordinary in everyday life (Balasubramanian, Peterson & Jarvenpaa, 2002).The growth in the mobile phone industry has in few years accelerated due to constant technological development. Mobile phones have undergone a huge change from being an engineering product to become one of the most popular consumer electronics products (Catalan & Kotzab, 2003). To know their thoughts of mobile phone users is essential. Achieving and maintaining a good quality focus requires a constant attention to customer requirements, improving processes, training, and communications. The literature on information sharing in the business is growing. Some researchers explored the value of information sharing in a two-level supply chain (Gaur, Giloni & Seshardi, 2005; Lee, So & Tang, 2000). Miranda & Saunders (2002) adopted social construction of meaning perspective on information

sharing topic. Lundberg (2008) used a word-of-mouth approach to informal information sharing. However, information sharing of mobile phone usage get less attention. The essence of all this also lies in sharing knowledge (Gross, 2001). Hence, it is an important thing to find out determinants of information sharing of mobile phone users for mobile phone service companies. To sum up, the purpose of this research is to explore determinants of information sharing of mobile phone users and find prioritizations of factors of information sharing.

LITERATURE REVIEW

There are several theories concerning about informational sharing. First, the theory of reasoned action, it assumes that human beings are usually quite rational and makes systematic usage of information available to them (Fishbein & Ajzen,1975). TRA is a widely accepted model in social psychology to explain human behaviors (Ajzen &Fishbein, 1980).Second, the economic exchange theory, according to the economic exchange theory, individuals will behave by rational self-interest. Information sharing will occur when it rewards exceed its costs (Kelly & Thibaut, 1978). Third theory is the social exchange theory. Social exchange theory concerns intrinsic rewards (Blau,1976). Fourth, the social cognitive theory, Bandura(1986) proposed self-efficacy is people's judgments of their capabilities to organize and execute courses of action required to attain goals. Based on the self-efficacy concept, I proposed that the individual's judgment of his capabilities to contribute to the organizational performance is going to be a major factor affecting information sharing. According to these four perspectives, many factors explain individual's information sharing behavior has been identified, however, there are left something undiscovered. Li & Lin(2006) examined the determinants of information sharing and information quality in supply chain management including environmental uncertainty, intra-organizational facilitators, and inter-organizational relationships. Gathering knowledge is easy, but sharing it is harder. More and more firms are starting to realize that knowledge shared is knowledge smartly deployed and leveraged (Dixon, 2002). In summary, the purpose of this study is trying to verify these theories with empirical data and further investigate some new perspectives that ignore by existent theories.

METHODOLOGY

Data Collection

To identify the components of determinants of information sharing of mobile phone users, this study data are gathered from mobile phone users. In-depth interview,

content analysis, and the analytic hierarchy process are used for data collection and analysis.

Sample

Convenience sampling was used for data collection. There are two stages in this study. First, the concept is formulating by six persons. The six respondent persons were selected from National Taipei University students and employees in Taiwan. A general open-ended questionnaire was administered, which focused on the determinants of information sharing of mobile phone users. A total of six users attended in-depth interviews, ranging in age from 19 to 45. In second stage, there are thirty-nine users selected from twelve companies and universities. 46.2 percentages of the respondents were male, while 53.8 percentages were female. This survey result is used to prioritize the measures of information sharing by analytic hierarchy process method.

Data Analysis

The data obtained by this qualitative study was analyzed using the content analysis method (Rourke & Anderson, 2004; Berelson, 1952; Budd, Thorp, & Donohew, 1967; Holsti, 1969). Five main factors were developed using the following conceptual framework: **1. Mobile phone users:** characteristics of mobile phone users including personality, emotion, and verbal capability (Liu & Chen, 2005; Liu, 2008) 2. **Mobile phone receivers**: characteristics of mobile phone receivers including personality, emotion, and verbal capability (Liu & Chen, 2005; Liu, 2008); 3. **Informational characteristic**: characteristics of information nature including secret information, important information, and interesting (Liu & Chen, 2005); 4. **Situational factors:** some context factors which influence information sharing willingness of mobile phone users including time pressure, on the go, and price discount (Liu & Chen, 2005).

Mutual agreement and reliability

The author used three coders to get the mutual agreement and reliability by coding to a formula [2M/(N+O),M: all agreement numbers，N：coder 1 agree; O：coder 2 agree] As mentioned above, the mutual degree of researcher and coder 1 is 10/12, coder 2 is 7/12, coder 3 is 9/12; coder 2 and coder 3 is 7/12, coder 4 is 7/12; coder 3 and coder 4 is 6/12, using a formula of reliability [n(average mutual degree)/ 1+(n-1)(average mutual degree)]. I got the pretest reliability of this study as 0.87 (4＊0.6389/1+3*0.6389). This reliability is acceptable. The content of coding will be

discussed in the following section.

AHP method

The data in this study are analyzed using a multi-criteria decision making approach called the analytic hierarchy process (AHP). The Analytic Hierarchy Process, developed by Saaty (1977), addresses many of the problems mentioned above. Government and business organizations have used it extensively. Expert Choice, Inc, one of the vendors of AHP software, reports thousands of installations of its namesake product on PCs around the globe. Saaty (1994) claims that AHP is combined logic and intuition, and takes advantage of our ability to rank choices. Many articles have been written on the successful implementation of AHP in various environments that involve a selection or decision (Liberatore, and Miller, 1995).

FINDINGS

This study attempts to identify the determinants and prioritization content of information sharing of mobile phone users. The results are presented below.

Table 1 Prioritization of information sharing of mobile phone users

Determinants of information sharing of mobile phone users	Factors	Items	Weightings	Rank	Total weightings	Total Rank
	Mobile phone user (0.242)	Personality	0.376	1	0.091	4
		Emotion	0.310	3	0.075	7
		Verbal capability	0.314	2	0.075	7
		Inconsistency index =0.00				
	Mobile phone receiver (0.206)	Personality	0.319	2	0.066	10
		Emotion	0.367	1	0.076	6
		Verbal capability	0.314	3	0.065	11
		Inconsistency index =0.00				
	Informational characteristics (0.220)	Secret information	0.420	1	0.093	3
		Important information	0.336	2	0.073	9
		Interesting information	0.244	3	0.053	12
		Inconsistency index =0.00				

	Situational factors (0.332)	Time pressure	0.407	1	0.136	1
		On the go	0.348	2	0.115	2
		Price discount	0.245	3	0.082	5
		Inconsistency index =0.00				

The results state that the weightings and rank of determinants of information sharing of mobile phone users follows the order: **Situation factors** (including time pressure, On the go, and price discount), **informational characteristics** (including secret information, important information, and interesting information), **mobile phone user** (including personality, emotion, and verbal capability), and **mobile phone receiver** (including personality, emotion, and verbal capability).

CONCLUSION AND SUGGESTIONS

This study explored determinants of information sharing users developed four factors from mobile phone users' perspectives and organizational theories. Mobile phone industry has become a very popular topic of discussion. To create useful information, this study gathered data from mobile phone users' perspectives. In-depth interviews, content analysis method, and the analytical hierarchy process were used for data collection and analysis. Based on the results, this study divides determinants of information sharing of mobile phone users into four factors: mobile phone users, mobile phone receivers, informational characteristics, and situational factors. The results show the current situation relating to mobile phone industry and provide a reference for examining their strategies and operating effectiveness. Developing new business model for mobile phone service companies is highly necessary in the future. In addition to the contribution, this study raises some challenges for future mobile phone industry research. However, these are important issues in the dynamics of mobile phone industry evolution with no doubt.

This research has some potential limitations. However, information sharing of mobile phone users is a complex and intangible concept which needed to more explorations. This study is merely exploratory and simply represents an initial attempt to investigate. Further work must be required in several ways since the present work suffers from some weaknesses. First, only a small sample is used, and the first step for any future study should be to use a larger sample. Furthermore, the analysis should be extended longitudinally to understanding the progress and development of information sharing

of mobile phone users or should be applied to corporate with mobile phone service companies.

BUSINESS ETHICS AND QUALITY MANAGEMENT

Dr Fotis Vouzas* and Christina Doufa

***Assistant Professor, Dept. of Business Administration, University of Macedonia, Greece**

vouzas@uom.gr

ABSTRACT

This paper is an attempt to investigate the Business Ethics link to Quality Management. Business Ethics as management practice is well rooted to many organizations but its contribution to quality management implementation programs and practices is not well documented. Today, organizations approach quality using a wide range of frameworks and models for implementation, depending on the work of well known theorists and academics as well as practitioners. The widespread of the new ISO 9000:2000 and the Business Excellence movement through the American and European Quality Awards are the prevailing approaches to quality improvement according to the majority of Quality academics. Both provide a basis for the implementation of a TQM philosophy, a "unique" way of improving organizational performance and attaining competitive advantage.

The main purpose of this paper is to examine the various issues related to Business Ethics such as corporate citizenship, human rights, environmental protection, consumer protection, occupational health and safety, dishonest business practices (corruption, idleness, and weave problems) and investigate the relationship to Total Quality Management. The survey sample consists of one industrial organization certified with the new ISO 9000:2000 series. The data gathering was carried out through extensive and in - depth interviews with several multiple informants i.e. the plant manager, the production manager, the personnel manager, using a semi-structured questionnaire with open - ended questions. The main purpose was to collect data and produce basic information, enabling qualitative observations concerning organizations' Quality and Business Ethics programs and initiatives. The data analysis provides some ground for generalisations, even though subjective judgements were also made from the analysis of the cases.

Keywords: Total Quality Management, Business Ethics, Greece, ISO 9000

INTRODUCTION

Quality has become the most used word in today's discourse. It is used in company's advertisement, annual reports, banners and in the lips of all organization's stakeholders, in government initiatives and even in personal relationships. Organizations worldwide trying to implement various quality initiatives and programs aiming at satisfying customer needs and improving overall organizational performance. However, although the true meaning and the value of quality is gaining ground in all over the world, the figures said a different story. Organizations are facing enormous quality problems in production (defects, scrap), in marketing (customer satisfaction), in logistics (response time, reliability), in finance (quality costs) and in most of their functions, even though the "Quality Revolution" has started according to many authors long time ago.

Some argue that quality is mostly rhetoric and good stories in order for organizations to promote sales and create a "customer-orientation" profile. In United States and in Europe awards were established to promote awareness and provide a basis and a model for TQM implementation. However, the organizations both in US and in Europe were not so enthusiastic about the awards and the numbers are very small in all categories. On the other hand the certification with the new ISO 90000:2000 series of standards is gaining ground and especially in Asia the increase in certified organizations is beyond expectations. But still, many authors state that ISO 9000 is not equal to Total Quality Management but is just a third part quality audit that is not related to final product quality mainly used by organizations as a commercial tool.

Business ethics dissert issues such as corporate citizenship, human rights, environmental protection, consumer protection, occupational health and safety, dishonest business practices (corruption, idleness, and weave problems). There is an increasing demand on focusing at the humanistic dimension and social responsibility of business enterprises. Organizations during the 90's began to invest in formal Business Ethics programs (Weaver, et.al, 1999) especially in the US, by establishing codes of ethics, using telephone lines for reporting ethical concerns and employing ethical officers or creating Corporate Social Responsibility departments. However, according to Donaldson & Dunfee (1994) "the field of Business Ethics has been troubled by a lack of direction ..." and Randal & Gibson (1990) found that research on Business Ethics was methodologically incorrect.

It seems that quality can provide a new agenda and a new direction for the design and implementation of Business Ethics programs and initiatives and create a new language by using a set of frameworks such as Business Excellence models (EFQM , MBNQA) or Quality Management Systems such as ISO 9000 or the ISO 26000 CSR.

In this paper the authors investigate the relationship between quality and Business Ethics by examining the various Business Ethics programs and initiatives such as corporate citizenship, human rights, environmental protection, consumer protection, occupational health and safety, dishonest business practices (corruption, idleness, and weave problems) in a Greek industrial organization.

LITERATURE REVIEW

Total Quality and ISO 9000

One of the most controversial concepts in the history of management theory is the concept of Total Quality Management (TQM). It is considered as a "social movement" (Hackman and Wageman, 1995), a "comprehensive way to improve total organizational performance and quality" (Hunt, 1993) or a "new paradigm in management" (Spencer, 1994; Grant et al., 1994). Its origins can be traced in the work of the -so called- quality gurus, Deming, Juran, Feigenbaum, Ishikawa and Crosby and on the rise and dominance of the Japanese automobile industry in the world markets. TQM emphasizes self-control, autonomy, and creativity among employees and requires active co-operation rather than mere compliance (Wilkinson,et.al. 1991). Hence it could be argued that it has a significant impact on the culture of the entire organization, calling for change, as it is a global philosophy involving all organization's members.

ISO 9000 introduction fifteen years ago created a series of controversies and doubts over the role and the significance of ISO 9000 series on improving product and service quality, achieving internal and external customer satisfaction, and improving performance (Tsiotras&Gotzamani, 1996; Dick, 2000; Van der Wiele et al., 2000; Magd & Curry, 2003; Stevenson and Barnes, 2001; Kartha, 2002.) According to Douglas, et.al (2003) "ISO 9000 is a multi-million-pound industry with many individuals and organizations reliant on it for their livelihood, including quality consultants, lead auditors, internal auditors, supplier auditors,

quality representatives/managers and software designers/sellers as well as the numerous training companies and certification bodies and their employees". However, other authors and among them Kartha (2002) argues that the new standards main purpose is to assist organizations to "identify mistakes, streamline their operations, and be able to guarantee a consistent level of quality".

The new revised standard was launched at the end of 2000 and according to Beckford (2002), is "an attempt to harmonize all the standards and remove the manufacturing bias. Several authors stated that the new ISO9000: 2000 is directed towards performance rather then conformance (Najmi&Kehoe, 2000). Coleman&Douglas (2003) argue that organizations in order to achieve the new ISO 9000:2000 should demonstrate that have quality processes and procedures in place, but they are skeptical about what happens after ISO 9000 certification. Casadesús &Karapetrovic (2005) studying the relationship between the "new" and the "old" ISO found that "the evaluation of the new ISO 9001: 2000 standard is generally positive". Vouzas&Gotzamani (2005) argue that there is no really negative impact but mention that the perceived benefits are less than the previous standard and that the level of reported benefits of ISO 9001/2/3: 1994 decreases with time, evidenced by two empirical studies conducted in 1998 and 2002. Overall argue that there is "an erosion of the perceived usefulness of ISO 9001: 2000 in the future, especially in terms of short-term benefits". Martínez-Lorente & Martínez-Costa (2004) further argue that organizations certified by ISO 9000 "may have gone a part of the way to TQM. However, the authors claim that it is only the "first part of the way, not its end, because there is a large amount of TQM requirements that ISO 9000 does not satisfy". Research on ISO 9000:2000 all over the world is still going on and the perceived benefits and its integration to other quality initiatives is expected to clear the picture and provide a basis for further improvement of the standard (Laszo, 2000; McAdam& Jackson, 2002; Najmi & Kehoe2000,). According to Vouzas&Gotzamani (2005), "careful analysis of the ISO 9000:1994 standards' requirements compared to the basic principles of TQM and the requirements of the two most representative business excellence awards, the European Quality Award and the Malcolm Baldrige National Quality Award, reveals several main shortages of the ISO 9000:1994 standards. The authors stated that lack of strategic quality planning, absence of top management commitment; lack of focus on customer satisfaction, lack of systematic training in quality. Furthermore HR competitiveness, benchmarking, and quality cost measurement are absent, as well as issues related to health, safety and the environment in

a study in Greek EQA awarded organizations. However, many authors believe that the new revised ISO 9000:2000 series of standards is a significant improvement on the previous version in terms of its conceptual simplification, its process-based vision and its acknowledgement of the importance of customer satisfaction as a key requirement for verifying the effectiveness of the quality system (Conti, 2002). The basic principles on which the new standards' requirements are based (as found in the ISO 9000:2000 document) are much more TQM oriented.

Quality and Business Ethics

Douglas Montgomery in an editorial in Quality and Reliability Engineering International Journal (2003) states that organizations embracing the philosophy of Corporate Social Responsibility can enhance their reputation, and gain greater financial returns. Furthermore, argues that quality has a role to play and that Quality has a very strong ethical foundation and all quality gurus' (Deming, Juran) incorporated ethical issues in their writings.

A direct relationship between quality and ethics and social responsibility is that of quality systems such as ISO 9000 and ISO 26000. According to McWilliams, et.al (2006) there is a growing interest on CSR and in ISO 26000 and the main motivations are: coercive, altruistic and strategic. As mentioned earlier ISO 9000 is a Quality Management Systems while ISO 26000 is guidance on social responsibility. Both standards have similarities and difference in their scope, principles and content (Castka & Balzarova, 2008). ISO 26000 can not be certified by a third party, and its scope include issues such as social, environmental and legal diversity in the world and look at them in terms of globalization, climate change, organizational governance and sustainable development, etc. (ISO/TMB/WG/SR, 2006). The ISO 2600 consists of four clauses, the SR context, the SR principles, the SR issues and SR guidance, and its main purpose is to build awareness and created an ethical philosophy within the organization (Castka & Balzarova, 2007).

In the early days of quality movement, authors such as Deming (1986), Crosby (1979) and Peters (1988) stated that quality has a high ethical content. Vinten (1998) states that "TQM is built on a foundation of ethics, integrity and trust. It fosters openness, fairness and sincerity and allows involvement by everyone". Vinten (1998) also believes that "Crisis ethical management comes expensive. The extent of ethical audit depends upon the organisation's

attitude to business ethics and society, as well as to its more immediate stakeholders. Ethical considerations are the only really guaranteed way to ensure this is by the adoption of total quality procedures. There is hardly any management philosophy that is as much adopted by companies as quality management".

According to Svensson & Wood (2005) the core values of quality management should be build upon ethical fundamentals and quality tools and techniques should consider these fundamentals. Quality is about making things right, responsibility for quality lies to all, customer satisfaction is the main drive for success, and profound knowledge is the new name for quality. The main argument is that doing good and doing well is the key to excellence. Organizations can not just invest and focus only on technical-oriented approaches and techniques but rather gave to enhance and utilize their people and contribute to the community. According to Steiner & Steiner (1995) quality, productivity and ethics go hand in hand. Issues such as corporate image, better environment, avoidance of stricter government regulations and the preventions of social problems than their cure are the main elements or aspects of the above relationship. In a study conducted in European organizations, Steiner & Steiner (1995) found that very few organizations of the sample had an ethical culture, and statement or codes of ethics and there was no difference between service and industrial organizations. According to their study results, ethical dimensions should be incorporated to quality management process. Fisscher &´ Nijhof (2005) tried to investigate the implications of Business Ethics for Quality management. The authors argue that quality cannot be managed successfully without an explicit focus on moral values and on the opposite ethical behaviour in a business environment assumes full quality control in order to answer moral questions.

Another aspect of the quality and ethics relationship was examined by Gonzales & Guillen (2002), the ethical dimension of Leadership in Quality. One of the main quality principles is that quality requires top management commitment and that leadership is one of the critical success factors in quality management implementation. The authors state that "the ethical dimension of leadership refers to the right decisions and actions combined with good intentions, and accompanied by moral correctness of behaviours". They suggest that organizations should start building moral trust in their manager's behaviour, by providing them training in ethical issues, give them the opportunity to write ethical statement and create an ethical culture in their function. Svensson & Wood (2005) however found that there are

different expectations and perception between managers and employees concerning corporate ethical issues in TQM.

Finally, in all the so-called Business Excellence models (EFQM model and the Malcolm Baldridge Award) there is a focus on ethical issues and specifically on Corporate Social Responsibility. Impact on society, satisfaction of clients and satisfaction of employees are important elements of the widely adapted EFQM model and the Malcolm Baldridge Award. In this way, quality management leads automatically to moral deliberations and responsibilities towards the different parties in and around an organization (Steiner and Steiner, 1995; Fisscher and Nijhof, 2005).

RESEARCH METHODOLOGY

In this paper, the authors suggest that in order to have a reliable and objective depiction of the Business Ethics on quality improvement frameworks, a thorough examination and analysis should include all the various approaches and perceptions recorded in literature -some of them based on empirical data and some deriving from rhetoric and "good-stories" or "how things ought to be" perspective. The paper examines one industrial organization, a multinational company in the drinks and beverages sector that operates in Greece over 45 years and has a long tradition of corporate social responsibility. The company was among the first organizations in Greece that received the ISO 9000 in the 90's and implementing a series of standards (ISO 9000, ISO 22000, ISO 18001 and ISO 14001) with a strong commitment to quality. The data gathering was carried out through extensive and in - depth interviews asking several multiple informants i.e. the plant manager, the production manager, the personnel manager, using a semi-structured questionnaire with open - ended questions in one of the three plants operating in Greece. The main purpose was to collect data and produce basic information, enabling qualitative observations concerning organizations' Quality and Ethical efforts. The questionnaire was developed based on state-of-the art literature review and consisted of three parts. The first part was questions about the profile of the organization (legal status, number of employees, etc), the second part was about the organizations Business Ethics efforts (policy, programs, initiatives, etc) and the third about the link between quality improvement efforts and Business Ethics and Corporate Social Responsibility. This papers is based on a pilot study of larger scale research aiming at exploring both qualitative and quantitative the link between Business Ethic and Quality. The data analysis provides some

ground for generalizations, even though subjective judgments were also made from the analysis of the case.

FINDINGS

The Company profile

Company is A is one of the biggest organizations in Greece in the Drink and Beverage sector, and the leader in the alcoholic beverages. In the past ten years the company invested almost 300 million Euros in infrastructure and its plants considered the most modern in Europe. The company is a major sponsor of athletic and social events and promotes safe alcohol drinking among young drinkers. The company's advertisement logo is "enjoy responsibly" and in its webpage there are pages dedicate to safe drinking. All company's plants have environmental standards concerning energy consumption (electricity, gas), pollution (water, air, noise) and money spent on introducing environmental friendly production technologies. The company awarded in 1987 with the best award for environmental consciousness and in 1998 with the Corporate Social Responsibility Award. The plant in which the study took place has 300 full time employees and 100 seasonal personnel in approximately 20 specializations. The plant gone through restructuring and infrastructure modifications in the past ten years. From 1996 to 2000 there was a multi-skilling program aiming at enhancing the skills and abilities of the personnel with in majority were coming from the nearby rural community.

Business Ethics

The organization's Corporate Social Responsibility (CSR) issues are in the hands of the Communications Affairs department in the central offices in Athens. The department is new and before that CSR and Business Ethics were handled by the financial department. The main philosophy of CSR in the organizations is that Ethics is everybody's job and all employees from top to bottom are responsible. Furthermore, the company must prove that through everyday practices and culture. Every year the company organizes a CSR conference aiming at building awareness and communicating best practices to all stakeholders.

Employees and management are aware of the importance and value of Business Ethics through the company newsletter and of events taking place inside the organization. The main programs and initiatives introduced and implemented related to the Business Ethics are :

promoting employee participation (many work groups operating at the plant both, functional and cross functional) written commitment of all work groups within the plant on quality and safety, full implementation of ISO 18000, continuous training and coaching, strict numerical goals regarding energy consumption, pollution, recycling, internal and external benchmarking on quality and CSR issues, support of local community, formation of voluntary groups for environmental purposes (cleaning beaches, planting trees on burned forests, etc), schools and university students visits, etc.

However, there are no formal ethical codes that take the form of work practices and responsibilities among employees and managers in the plant. The reason is that people are within the organizations many years and there is no need for written statements and formal ethical policies in the plant according to top management. There are no training programs focused on CSR and Business Ethics on the plant and there are no disciplinary actions in cases of ethical malpractices. The training manager mentioned that the climate is that of a "public organization" meaning that employees enjoy work stability and security and formalities and rules are being incorporated through informal communication.

Over the years the organization and the plant in particular had no incidents of unethical behaviour from managers or employees. The plant manager in cooperation with the management team and the union have day to day communication and the goal is to prevent any actions causing problems (proactive philosophy) inside the plant or affecting customers or the local community. In cases of customer complaints about the product – retailer or final customer- (not proper filling of the bottles, foreign particles inside the bottle, etc) the organization policy is to provide information to the customers and give them the opportunity to visit the plant and the facilities and to get familiar with the production and the quality assurance system.

Today, the organization is trying to be as effective as possible, introducing new technology, utilizing people and techniques and cutting costs. All these are done in accordance with the organizations Corporate Social Responsibility policy and with the change of philosophy. Being effective and financially health depends on ethics and ethics can push organization forward.

Business Ethic and Quality

Quality was always a major concern of the organization since its establishment. The company's products are worldwide known for its supreme quality. The plant is certified with the ISO 9000 since 1994 and as mentioned earlier had two other certifications (ISO 14000 and ISO 18000). The main drive for quality improvement in the plant is the quality improvement teams. The teams were formed with the consensus with the union. Their main goal of the teams is to ensure that quality procedures are understood and implemented without problems. There are a series of financial and non financial incentives in order to promote quality and productivity. Employees get a productivity bonus based on the annual performance appraisal system and there are awards for the best team in the plant. Training is considered an investment because give the opportunity to employees to learn more and become less vulnerable to changes in technology and in systems implementation. The multi-skilling program enhanced employees' capabilities and protects them from being obsolete. This was considered as an ethical-based program from the top management and the employees.

There is a very strong connection between quality and ethics in the plant according to all informants. The plant organization is focused on satisfying customer needs and protecting the public from excessive alcohol drinking. There are annual customer satisfaction surveys and on the spot audits (from the sales department) to the consumer points (supermarkets, café, bars, clubs, etc). The goal is to have zero complaints, zero defects and zero accidents. The company used various quality management techniques and tools such as benchmarking, business process re-engineering, etc in order to monitor and control all quality issues related to ethical problems. Best practices among the company's worldwide plants are articulated and top management people have the opportunity to visit other plants around the world and learn new methods and practices.

The organization is not in the process of applying for the European Quality Award according to the plant manager. Top management is aware that EQA is providing a model for self-assessment and that in the model there is a CSR part. The training manger at the plant said that EQA is the next step and a major challenge for the organizations and for the plant itself. However, believes that many things need to be done before the organization give the green light for the award process such as formal written CSR policy in each plant, appointment of a CSR officer and a long term training program on ethical issues for all personnel.

Finally, ISO 26000 CSR is more than welcomed and the managerial team of the plant believes that is a matter of time to be introduced and implemented.

Conclusions

Business Ethics is a necessity and a major challenge for all organizations around the world. It provides a set of guidelines and a new culture for the future. Quality Management is customer consciousness -both the internal and the external – and its philosophy is a creating a culture in which production is causing no pollution, excessive use of energy and resources, and human traumas. Quality is a mean to prevent ethical problems and change the way organizations think about the product or service and their stakeholders. In quality, financial profit is replaced by value for the people inside and outside the organization. Providing a safe workplace for the employees, keeping the production under environmental standards and creating an ethical new image for the product and the services are the main issues in the ethics-quality relationship. The organization studied is in the process of changing its practices and re-evaluate its policy on ethics. Greece is a country with a long tradition on ethics, from Socrates, Plato and the Greek philosophers, to the new reality.

This paper is a first step of a major research on the Business Ethic and Quality. The research is under way and the authors make the final alterations in the quantitative questionnaire aiming at Greek organizations involved already with CSR and are members of the Greek Network for Corporate Social Responsibility.

ABSTRACT

Information and communications technology (ICT) companies have realised that acknowledging the needs of internal customers is a necessity for successful new product development (NPD). Requirements for products have a tendency to change during NPD, and managing requirements has become a significant challenge for ICT companies. This is accumulated by requirements being interpreted differently in different parts of organisations. Design for excellence (DfX) is a potential way for addressing internal customers and for managing requirements. This study shows that DfX concept is systematically utilised only in some advanced companies, and the same challenges are attempted to address in most organisations by using other methods. DfX practices in smaller ICT companies are compared to the similar practices of a successful large ICT company.

Keywords: Design for excellence, Product development, Requirements management, DfX.

INTRODUCTION

The information and communications technology (ICT) sector is facing continuous change in its new product development (NPD) as products are getting increasingly complicated, and customer segments more fragmented. These changes, together with pressures for shortening development times, and severe price erosion, require multidisciplinary approaches. Successful product development necessitates the integration of engineers, industrial designers and marketing personnel. (Seetharaman et al., 2007; Belt et al., 2008; Cooper et al., 2004).

The early stages of product development are emphasised by many authors (Bralla, 1996; Harkonen et al., 2009; Gatenby and Foo, 1990; Yang et al. 2007). The ability to influence the success of a product development programme is the greatest at the start of the project. The choices made in early NPD, reduce both unnecessary changes towards the end, and total life-cycle costs even after the end of the programme. Design for excellence (DfX) is an organised approach to systematically address the early involvement. DfX and Design for Six Sigma have been two of the most popular concepts in quality management in recent years (Jiang et al., 2007).

Addressing the needs of internal customers has been identified as a key element for successful product development (e.g. Cooper et al., 2004; Gupta et al., 2007). Requirements for products typically change during product development, and requirements management

has become an ever greater challenge for ICT companies. This challenge is accumulated by the fact that requirements are interpreted differently in different parts of organisations. DfX is a potential way for addressing internal customers and for harmonising practices. DfX cannot only be seen as a way to collect internal best practices, but also as a means to disseminate information and realise the implementation of these practices.

This paper analyses one advanced ICT company applying DfX, which is selected as a benchmark company, and seven smaller players attempting to address the similar issues by using different methods. The approaches of different small and medium sized enterprises (SME), large companies, and the selected benchmark company are analysed and compared.

The above mentioned can be condensed into the following research questions:

RQ 1 How does a large ICT company manage its requirements through DfX practices?

RQ 2 How do the other approaches applied by other companies differ from the DfX practices of the large company?

This study addresses the research questions in a qualitative manner both, through literature and analysis of industry interviews.

REQUIREMENTS MANAGEMENT AND DfX

There can be seen two main reasons for evolution of product development processes: (1) market changes, and (2) in-house challenges. Market changes include, tightening competition, changes in customer opinions and spending behaviour, and such. These market changes result in demands to reduce costs and shorten time-to-market targets for NPD (Gatenby and Foo 1990; Pahl et al., 2007; Priest, 1988). In-house challenges relate to company functions and processes, specifically to product development and manufacturing. Requirements tend to change during NPD and meeting the needs of both, internal and external customers, results in pressures for the early NPD stages to consider a vast number of different aspects.

Individual designers have traditionally focused on product itself and the value it can provide to the end-user (Bralla, 1996). Typically, they do not consider the product realisation through the entire life-cycle, including manufacturing, disposal, and such. Only after the design is complete, these issues are addressed, and are left for related departments to solve. This has resulted in cumbersome processes that are time-consuming, inflexible, and prone to errors (e.g. Huang et al., 2001).

Design for excellence

Design for excellence (DfX) is an approach that can be utilised to manage feeding requirements back to product development. X in DfX stands for an aspect under concern, such as manufacturing, testability, reliability, assembly, disassembly, cost and so on (e.g. Jablokow and Booth, 2006; Gehin et al., 2008; Barton et al., 2001; Rungtusanatham and Forza, 2005; Jose and Tollenaere, 2005; Haque and James-Moore, 2004). DfX aims to lower costs, increase quality of products and to reduce time-to-market (e.g. Prasad, 1997; Gungor, and Gupta, 1999; Prasad, 2000). In addition, Zuidwijk and Krikke (2008) emphasise the reusability aspects, while Maltzman et al. (2005) highlight quality and customer satisfaction.

The requirements of manufacturing were the first needs of internal customers that were addressed in the essence of DfX. Examples of the first approaches to address manufacturing

issues include value analysis, value engineering, and produceability engineering (Bralla, 1996; Huang et al., 2001). These methods can be seen to share the same goals as modern DfX. Boothroyd & Dewhurst (1983) are the first ones to utilise design for excellence with their concept of design for assembly. The DfX concept was later broadened into design for manufacturing to include a broader set of manufacturing aspects (e.g. Chang et al., 2005; Stoll, 1988; Chang et al., 2007). Recently DfX methodology has expanded to cover new areas, such as environmental, serviceability, and testing issues (Kurk and Eagan, 2008; Graedel, 2008; Bras, 1997; Coulter and Bras, 1997; Tichem, 1997). It has also become imperative to harmonise product and process design of product families within a supply chain framework. (Lau et al., 2007; Rungtusanatham and Forza, 2005).

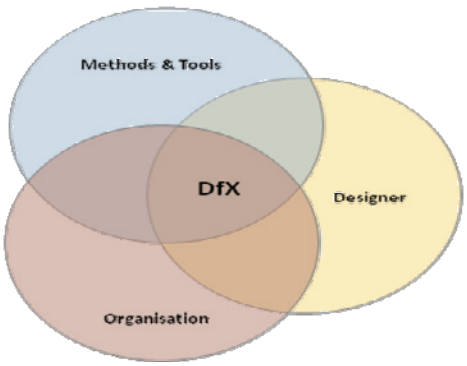
Companies applying DfX have realised how following these principles has an enormous impact on company procedures, and organisation itself (Sheu and Chen, 2007). Adequate communication within a company is required for an effective utilisation of DfX (Skander et al., 2008). Cooperative work, checklists, guidelines, and software tools are utilised to achieve the goals set by different DfX sub-disciplines, (e.g. Huang and Mak, 2003; Eversheim and Baumann, 1991; Boothroyd and Dewhurst, 2008).

The literature also presents some critics for DfX. Applying DFX in large organisations poses difficulties due to complex organisational structures, and overwhelming number of issues to be considered (Herrmann et al., 2004). There are also challenges with teamwork, costs of organisational support, tools required, and so on.

DfX structural components

DfX can be roughly divided into the following three domains: (1) designer, (2) methods & tools, and (3) organisation (see Figure 1). Designer typically is a skilled R&D engineer, who applies DfX principles in practice. Methods can be seen as procedures and guidelines that the designer follows. Typical tools include spreadsheets, software, design structure matrices, morphological charts, and such. Organisational aspects cover issues, such as teamwork, collaboration, communication, processes, and company policies. (Eversheim and Baumann 1991; Poli and Knight, 1984; Huang and Mak, 1997; Meerhamm, 1994; Lang et al., 2002).

Fig. 1 the three identified structural DfX components



At practical level, designer implements DfX, conducts design related decisions, and produces engineering drawings by utilising different tools. Designing is essentially a decision-making process on product features and functions (Cowan et al., 2000). Designer utilises various approaches and tools, however, the key is engineer's ability to produce documents on products and processes. Lang et al. (2002) summarise designer's main activities as:

1. identification, analysis and clarification of problems and needs
2. information gathering
3. idea creation
4. generation of solutions
5. analysing solutions
6. solution optimisation

Iterations are required, and the designer must go through the steps listed above until a satisfying solution is reached. Multiple issues require consideration, resulting in an overwhelming amount of alternatives. Often requirements conflict and designer has to decide which requirement to favour. However, in some cases a solution can benefit the requirements of several DfX sub-disciplines, such as a reduced number of parts resulting in both easier assembly, and higher environmental friendliness (Harjula et al., 1996). In order to find an optimal value within a solution domain, objective measurement, suitable tools and sound judgement are required. The aim should be to make decisions early as possible, however, only when necessary understanding has been gained. (Bralla, 1996; Morgan and Liker, 2006).

Table 1 presents the differences between traditional engineering design, and modern design with DfX.

Table 1 Differences between traditional engineering design and modern design with DfX.

Traditional	Modern with DfX
Consider functional requirements	Consider life-cycle requirements
Address other aspects after design freeze	As early as possible
Overwhelming number of alternatives	Overwhelming number of alternatives
Iterations	One-time-right
CAD tools	Knowledge-based systems
Responsibility over design	Responsibility over whole life-cycle

The work to fulfil DfX objectives can be supported by various methods & tools, which can automate and guide the actual efforts. Because DfX bases on tool-heavy engineering design, DfX tools have gained a lot of attention (e.g. Tichem and Storm, 1997; Watson and Radcliffe, 1998). Recently, the shift has been towards computerisation of tools, and knowledge-based systems, allowing storing and reusing design knowledge (Nomaguchi and Fujita, 2007). In addition, these tools ease the cross-functional integration needed in modern product development process.

Tichem (1997) categorises DfX tools as: (1) design guidelines, (2) stand-alone design evaluation tools, (3) CAD (computer aided design) integrated evaluation tools, and (4) CAD/CAPP (computer aided process planning) based evaluation tools. Design guidelines are lists of qualitative DOs and DON'Ts. Stand-alone design evaluation tools offer systematic approach to evaluating design and redesign. CAD integrated evaluation tools use the power of computerised modelling for analysing design and creating feedback to designer thus helping evaluation (Eversheim and Baumann, 1991). CAD/CAPP based evaluation tools automatically create process plans in addition to CAD output. (Tichem, 1997).

Addressing DfX in practice requires acknowledging the entire organisation, not only an individual designer (Herrmann et al., 2004). DfX implementation requires new procedures and processes as well as organisational changes. In order to support DfX, different measures are used to ease integration of people, processes and tools.

A successful implementation of DfX requires organisational reformulations, clear sharing of responsibilities, and training, but also cultural changes (Herrmann et al., 2004). New practices supporting DfX should be integrated into existing business environment (Huang et al., 2001). Table 2 presents differences between traditional NPD and modern NPD with DfX.

Table 2. Differences between traditional NPD and modern NPD with DfX.

Traditional	Modern with DfX
Technical focus	Organisational support
Business process re-engineering	Continuous improvement
End-user as customer	Downstream as customers
Communication between departments	Collaboration between team members
Departmental knowledge	Knowledge sharing
From upstream to downstream	Both directions
Iterative, emphasis on reviews	Continuous process
Bureaucracy	Empowerment
Departments	Cross-functional teams
Project	Process
Direct communication	Shared communication through systems
Processes on basis of product design	Integrated design
Feedback after identifying problems	Proactive information sharing

In the literature, various issues have been linked to DfX. These issues include cross-functional teams, empowerment, design reviews, standardisation, knowledge sharing, continuous improvement, and such. (Bralla, 1996; Gatenby and Foo, 1990; Tichem, 1997, Cowan et al., 2000; Sheu and Chen, 2007; Huang, 1996a; Herrmann et al., 2004; Lang et al., 2002; Wilkinson, 1998; Cooney, 2004; Aurich et al., 2006).

Due to the nature of DfX, single design engineer cannot sufficiently handle, and know everything that is required during a design process (Bralla, 1996). In order to tackle this problem, cross-functional teams, comprising participants from different life-cycle phases and functions, are established (e.g. Huang, 1996a).

RESEARCH PROCESS

The research process is described in Figure 2. Design for excellence was first studied by using existing literature as the key source. The study was conducted in a large company applying DfX and seven smaller companies to clarify how they address similar challenges. The large company was first analysed and was identified to successfully apply the DfX concept and could therefore be used as a benchmark. The study was then expanded to also cover other companies.

Several workshops were organised in the large company to discuss the practical realisation of DfX. Interview questions were formulated based on the obtained understanding see Appendix A. Altogether twenty interviews were organised in the large company, comprising multiple sites and countries. The interviews included all the DfX managers as well as responsible managers for vital internal processes.

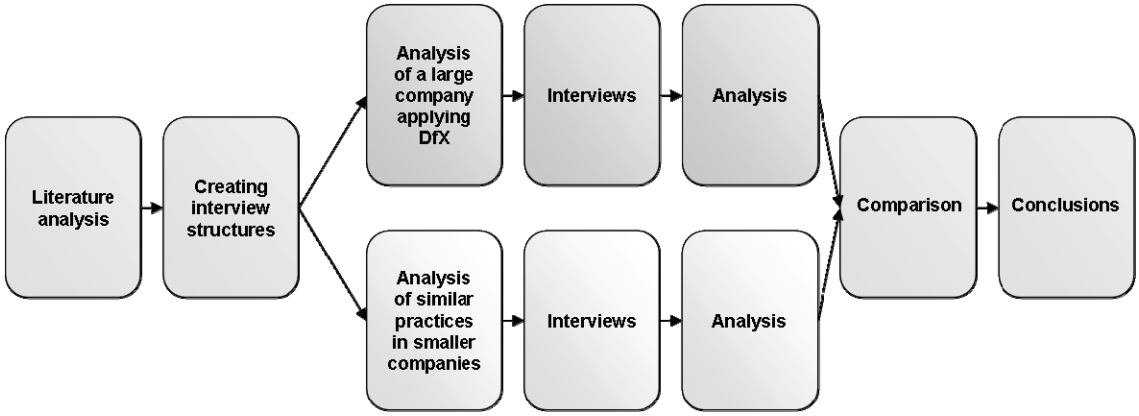
Interviews in the smaller companies include seven companies, where one key person was interviewed in each utilising a slightly different questionnaire, see Appendix B. The

questionnaire was modified as it was assumed that the smaller companies were not necessarily aware of the term DfX.

The research utilised a semi-structured thematic interview approach (see e.g. Merton et al., 1990). The interviews were conducted informally, in a qualitative manner, allowing the interviewees to explain and clarify the cases and topics as entities. All the interviews were transcribed and analysed.

The results were analysed by reflecting them against the existing literature, and comparing the practices of the large ICT player against the smaller ones. The results of the analysis are presented in the section Results and analysis.

Figure 2. The research process



RESULTS AND ANALYSIS

General NPD characteristics

The NPD process in the interviewed SMEs is typically only roughly modelled and documented.

The interviewed large companies utilise a more structured approach to NPD than their smaller counterparts and aim to model their processes. The large companies utilise different documents and methods, such as checklists, templates, milestone reviews, detailed project plans, and manuals. Strict control is applied for processes, including quality reviews, assigned process ownerships and such. Company processes are regularly reviewed and updated.

The benchmark company utilises fully modelled documented NPD process.

Practical approach to internal downstream requirements

The interviewed SMEs have not internalised the concept of DfX, however, they apply practices that are the essence of DfX. Addressing internal requirements is conducted in cross-functional project teams. Often they are forced to operate in a fire-fighting mode, solving problems as they appear without necessarily considering the big picture. These companies rarely reach full optimisation, with proactive addressing of all relevant issues during NPD, and considering total costs over the entire product life-cycle. Practical requirements optimisation, and problem solving is, nevertheless, in critical issues conducted together with

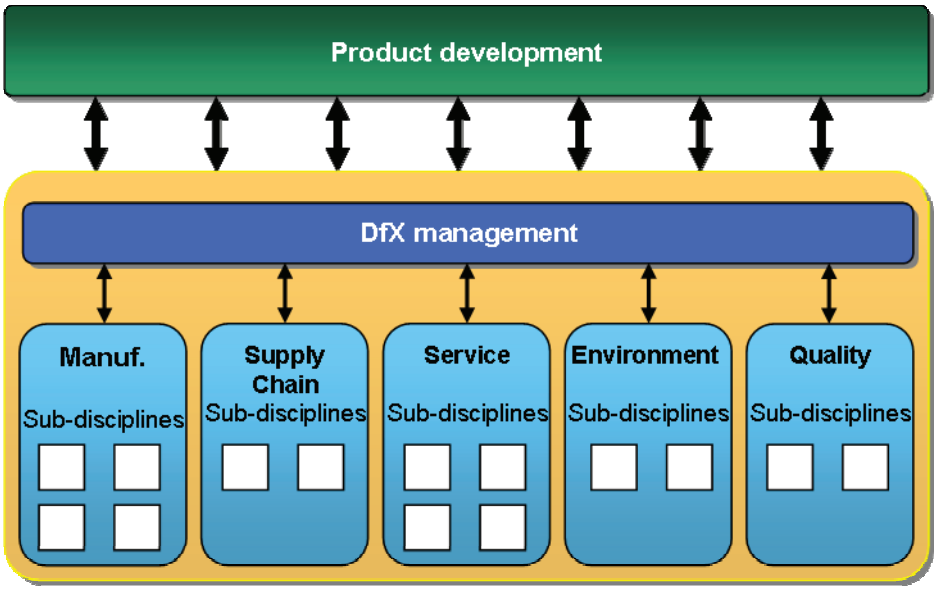
manufacturing sub-contractors. Internal requirements are rarely considered systematically during pre-study phase, and when considered, this occurs during product development.

The large interviewed companies address DfX related issues, regardless of not necessarily utilising the term. Internal requirements are addressed through concept owners collecting requirements from internal customers, and utilising cross-functional project teams. These practices are integrated in company quality systems. However, know-how does not sufficiently accumulate as requirements are only occasionally documented in the form of design guidelines, checklists and manuals. In software development, each programmer is responsible for the aspects of later phases, such as unit tests. Companies utilise programmer / tester pairs, and daily milestone meetings, to achieve functional agility and to address testing needs. In contrast to SMEs, large companies attempt to systematically optimise the entire development chain and total costs. There is focus on DfX related issues already during the pre-study phase, and separate research/piloting/evaluation projects are utilised.

In the benchmark company, the role of DfX is to ensure that the needs of manufacturing, supply chain, after-sales service, environment and quality are taken into account already during product development. Manufacturing, supply chain, service, and quality have all been divided into relevant sub-disciplines, managed by assigned persons. The benchmark company has a common DfX management organisation, which coordinates different DfXs and communicates their needs into product development. DfX is seen to aid the company to optimise different matters from the perspective of total costs, as DfX sub-discipline managers are required to justify their requirements from the cost viewpoint. Figure 2 describes the DfX system of the benchmark company.

Design for excellence has been conducted for a long period of time in the benchmark company, and is seen to function well. At a higher level DfX provides principles and general guidelines for product development, and at practical level, DfX means exact, often numerical, requirements, tools, design rules. The application of DfX concept has expanded from manufacturing to cover a wider set of activities, including supply chain aspects, reliability, environment and such.

Figure 2 the DfX system of the benchmark company.



Knowledge transfer

Knowledge transfer in relation to internal requirements in the studied SMEs, is conducted by utilising learnings from previous projects, feedback from prototypes and pilot projects. Personal communication and meetings are seen to dominate over proper documentation, and the emphasis is on latter part of NPD process. In addition, the interviewed SMEs utilise knowledge transfer to/from customers and subcontractors.

The interviewed large companies have a more systematic approach to knowledge transfer, compared to their smaller counterparts. They use feedback from previous projects prior to start new ones. Feedback from prototypes and internal training also aid in transforming useful knowledge into relevant guidelines. The emphasis of knowledge sharing is on documents and different forms of electronic communication, such as DOORS® tool are utilised. Communication, at all levels inside the organisation, and among partners is attempted to organise well.

The benchmark company has appointed separate discipline owners for each DfX sub-discipline, who are the key actors in knowledge transfer. In addition, the overall DfX management collects best practices and attempts to further develop common communication tools and methods. The benchmark company has an aim to formulate requirements into exact instructions, and general guidelines that are easy to comprehend by product development. Regular training is also arranged within the company. The data system tools used in practice include Focal Point™ for management aspects, and DOORS®, for more practical engineering purposes.

Managing DfX aspects

The interviewed SMEs utilise ordinary project management solutions for handling internal requirements. These solutions include utilisation of project managers and project meetings for coordination of DfX related aspects. In addition, some SMEs have separate meetings for different design areas to ensure proper coordination. Typically, the responsibility of production manager includes assuring the inclusion of manufacturing requirements, either through personal attendance, or appointing someone from the production organisation.

The interviewed large companies use similar project management solutions as the SMEs. In addition, some of them utilise new product introduction (NPI) groups to assure fluent production ramp-ups, and separate supply chain management (SCM) groups for outsourced production. The company quality organisation has also an influence over managing DfX aspects.

The main difference between the benchmark company and other interviewed companies is the separate DfX organisation and appointed DfX discipline owners. This arrangement enables the benchmark company to manage requirements through total cost calculations, and written guidelines and data systems, making requirements management more systematic and effective. The experience by the benchmark company highlights that DfX is a concrete way to manage complex and sometimes conflicting requirements. Other companies tend to utilise more or less ad hoc solutions and are forced to operate more in a fire-fighting mode. However, noteworthy is that a smaller company does not necessarily have acute needs to be as structured in their requirements management.

Table 3 summarises the central findings of the empirical results.

Table 3 Addressing internal downstream requirements in product development

Issues	SMEs	Large	Benchmark
NPD characteristics	roughly modelled and documented	moderately modelled process - checklists, templates, milestone reviews, detailed project plans, manuals - strict supervision - quality reviews - process ownerships - processes updated 2-4 times a year	fully modelled well documented
Practical realisation	cross-functional project teams fire-fighting mode instead of full optimisation practical optimisation and problem solving together with manufacturing sub-contractors heavy focus on design phase, only minor during pre-study	cross-functional project teams concept owners collect requirements from internal customers design guidelines – partially design manuals - only occasionally integrated in company quality system each programmer is responsible for downstream aspects, e.g. unit tests programmer / tester pair – agile sw development checklists, reference manuals, coding guidelines emphasis on pre-study daily milestone meetings attempts to systematically optimise separate research/piloting/evaluation projects	Guidelines, training cross-functional teams cost calculations

Knowledge transfer	lessons learned from previous projects pilot projects knowledge transfer between partners feedback from prototypes personal communication and meetings instead of proper documentation	after-sales feedback prior to project start internal training feedback from prototypes communication at all levels electronic communication emphasis of knowledge sharing on documents useful knowledge is transformed into guidelines DOORS tool knowledge transfer between partners	discipline owners DfX management organisation requirements formulation internal training design guidelines DOORS & Focal point tools
Management	project manager project meetings separate meetings for different design areas production manager	programme meetings NPI group company quality organisation milestone meetings SCM group for outsourced production programme manager	programme manager programme meetings NPI group company quality organisation DfX management milestone meetings DfX owners

CONCLUSIONS

Addressing the needs of internal customers has been identified as a key element for successful product development. Requirements for products typically change during product development, and requirements management has become an ever greater challenge for ICT companies. This paper analyses one advanced ICT company applying DfX for managing requirements, and seven smaller players attempting to address the similar issues by using different methods.

The advanced benchmark company has a separate DfX organisation and appointed DfX discipline owners to manage requirements. This arrangement enables the company to manage

requirements through total cost calculations, and written guidelines and data systems, making requirements management more systematic and effective. The experience by the benchmark company highlights that DfX is a concrete way to manage complex and sometimes conflicting requirements. This study proves, in contrast to some literature, that DfX is not a philosophy, but rather works through principles and tools.

Other companies tend to utilise ad hoc solutions and are forced to operate more in a fire-fighting mode. Requirements management is addressed as a project management issue, and through prototyping, the focus being more towards the end of NPD. Communicating requirements is based more on undocumented personal communication and project meetings. However, projects aim to clarify and document lessons learned.

Other companies could learn from the benchmark company, and its systematic practises for managing requirements and addressing the needs of internal customers. Companies should consider what the key internal issues to be addressed are in their business context. Especially larger companies could learn from the systematic approach of the benchmark company in relation to DfX. However, smaller companies do not necessarily have acute needs to be as structured in their requirements management, and the needs of internal customers can be addressed effectively by using less systematic methods.

This study concentrates on analysing a limited number of companies in one business sector. The obtained results could vary to some degree, should a wider set of companies, or different business sectors, be included in the study. This study was qualitative in nature interviewing relevant managers involved in DfX related issues. A different research approach might lead to slightly different conclusions.

Potential topics for further study include studying how other advanced companies manage their DfX approaches. Examples from other business sectors would also be beneficial.

APPENDIX A

Questionnaire

Name
Title
Organisational unit

1. Please describe what you understand with requirements management and requirements? (Specifications, needs, constraints, etc.)
    - How do requirements relate to your area of responsibility

2. Where does your organisation unit get its requirements?
    - What type of requirements – please give examples

3. To which organisational units, within the company, do you set requirements?
    - What type of requirements – please give examples

4. How are requirements prioritised?
    - How would you develop the prioritisation of requirements

5. What are the main challenges relating to requirements management form your organisational unit's perspective – How would you attempt to rectify these issues?

6. How do you view DfX (Design for Excellence)?

7. How does the view over requirements vary – in your opinion – in different parts of the company (for example different sites, different functions: product development, production etc.)?

8. How have the changes in the company organisation influenced requirements management?

APPENDIX B

Company:
Business sector:
Main products:
Turnover:
# of employees:

Questionnaire

1. What are your main products? What kind of value does your company provide to its customers?
2. Who are your main clients?
3. Could you describe your product development process?
4. How do you manage requirements in your product development? What type of requirements?
    a. Who are the stakeholders that set the requirements (internal, external)?
    b. How are the requirements categorised and prioritised?
    c. Do the requirements change during product development / product life-cycle?
5. How are the needs of the following actors in the value chain acknowledged during product design?
    a. Production
    b. Testing
    c. Packaging
    d. Logistics
    e. Service/maintenance
    f. Disassembly
    g. Sub-contractors
    h. Environment
    i. Others?

Practices

6. How do you acknowledge the product life-cycle in practice?
    a. Requiremenets management
    b. Product design
    c. Cross-functional teams
    d. Data systems
    e. Others?
7. What type of cooperation is there between product development and the following phases (production, testing, packaging, etc.)?
    a. Timing / during which phase?
    b. How is the communication arranged?
    c. Do you simultaneously develop the product, and the following phases? How?
8. How do you manage life-cycle aspects during product development?

    a. Coordination/management?
    b. Reviews
    c. Assessment
    d. Intensives/penalties?
9. What type of challenges do product development and the following phases face in their cooperation?
    a. What type?
    b. How do you currently attempt to solve these challenges?
    c. What is your view to improve the situation in the future?
10. What type of tools and data bases does your product development utilise? How is the product life-cycle acknowledged?
    a. Engineering tools
    b. Management tools
    c. How are the data systems, data bases, linked to these tools?

11. Are the following concepts used in your company, How?
    a. Concurrent/simultaneous engineering / integrated design,
    b. Taguchi method / robust design,
    c. Quality function deployment (QFD),
    d. Product life-cycle management,
    e. Cross-functional teams?
12. Do you use DfX?
13. Other comments?

KNQWLEDGE CREATION AND INTELLECTUAL CAPITAL OF BANKS

Dr. Kuang-Hsun Shih, Chinese Culture University, Taiwan,
shihsteve33@gmail.com
Doctoral student Hsiao-Chen Chang, Chinese Culture University, Taiwan,
Jean91525@gmail.com

ABSTRACT

Purpose *– This paper collates academic definitions and measurements of knowledge creation and intellectual capital, and conducts a survey of the Taiwanese banking industry to establish an understanding of the sources of knowledge creation, and its relationship with creation of intellectual capital in domestic banks.*

Design/methodology/approach*– This paper adopts the knowledge management measurement to examine the formats of knowledge creation on evaluation of relationship between different elements in the intellectual capital of banks by structural equation modeling (SEM).*

Findings*– The performance of knowledge creation has significant influence on the accumulation of subsequent human capital. The performance of human capital exhibits significant influence on structural capital and customer capital. The performance of customer capital reports significant influence on the formation of structural capital.*

Research limitations/implications *– The ability to create knowledge is highly relevant to intellectual capital in the banking industry. Companies should define their own robust mechanisms for knowledge creation to improve their ability in knowledge creation.*

Practical implications *– The managers in the banking industry should identify the ways to cultivate in-depth contents of intellectual capital and have comprehensive development on intellectual capital to create differentiated advantages and boost corporate competitiveness.*

Originality/value *– The importance of tangible assets is waning that has been gradually shifted to knowledge and intellectual capital, and thus, knowledge management has become an important strategy in corporate competition. Organizations have been redefined as platforms that can create knowledge and accumulate intangible, intellectual capital.*

Paper type *– Research Paper*

Keywords: knowledge creation, intellectual capital, financial institution management, financial services operation.

INTRODUCTION

The arrival of a knowledge-based economy has caused the diminishing importance of

tangible assets. Knowledge has become a powerful tool for corporate competition. Guthrie (2001) suggested that successful companies do not gain benefits with only tangible assets, and they mainly rely on access to intangible information and knowledge creation as their major resources for success. The traditional concept of evaluating enterprise value and performances with tangible assets has gradually given way to a focus on intangible knowledge development and integration ability. Intangible knowledge development and integration ability is a set of thorough management skills that can develop and restructure human capital, structural capital, and customer capital of an organization. With systematic integration, internalization, and the advantage of knowledge benefits, companies are able to create core competitiveness. Wu (2002) indicated that for knowledge-type companies, creation, accumulation, sharing, and integration of knowledge are the momentum for the creation of corporate value and sustainable operations. Creation, management, measurement, and evaluation of core intellectual capital will be an important indicator of the value of corporate competitiveness in the future.

Since the implementation of the Financial Holding Company Law in 2001, many financial holding companies have been established. These companies can be divided into three systems, securities and investments, banking, and insurance, as based on their operations. Different from the manufacturing industries, the financial service industry provides knowledge-based products or services. Although securities and investments, banking, and insurance sectors are all under the financial service industry, they have different industrial characteristics. The securities and investment industry focuses on professional services provided by personnel; the banking industry emphasizes on the flows of overall infrastructure; and the insurance industry centers on customer relationship management. Although they have differing focuses, the purpose is the same: the construction of intellectual capital for the company and enhancement of market value. The financial industry has begun integrating professionals and market needs long ago to realize profits from financial knowledge and risk management. Due to the characteristics of the banking industry, it has to stay abreast of the business cycles of all other industries. Meanwhile, the banking industry is highly regulated in its operations. Over recent years, under the influence of financial liberalization and internationalization, the banking industry has seen noticeable changes in their business environment. This, combined with fierce competition, has created tremendous pressures for banks. In an environment of high uncertainties and looming crises, banks should not only more efficiently integrate their work force, financial assets, and other tangible assets, but also improve their ability in the management of intellectual capital to achieve sustainable operations. For the banking industry, it is imperative as to how to use techniques in knowledge management to accumulate intellectual capital to cope with an increasingly changing environment.

Most previous literatures addressing intellectual capital have focused on the correlation between intellectual capital and organizational performances. There are relatively few discussions on the relationship between knowledge creation and intellectual capital, and even fewer studies on such a relationship in the banking industry. The core competitiveness of the banking industry is highly reliant on the ability of management teams to systematically manage knowledge and experience. It also depends on whether they are able to create sophisticated skills catering to the intellectual capital of their organization to effectively manage risks and create profits.

The accumulation of intellectual capital and knowledge creation is closely related (Rezgui and Yacine(2007); Lin, Liu, Hsu, and Wu (2008)). Intellectual capital is generated via systematic integration of knowledge. It is particularly so for the banks, because the knowledge required for banking operations is more complex than in most industries. Such knowledge is known for their diversity and abstractness. From the selection of the management team, the development of professional skills of employees, nurturing of the creativity of employees, accumulation of innovative and creative capabilities, screening of customer groups, management of customers' loyalty, and the management of trademarks and brands to develop and manage strategic partners, all sources of enterprise value through the creation and management of corporate knowledge. This paper examines the empirical studies on knowledge creation and intellectual capital to generalize the important factors concerning knowledge creation and intellectual capital. The major purpose is to explore the relationship between knowledge creation and intellectual capital through the construction of the correlation patterns between these two elements. In addition, this paper also aims to examine the relationships between human capital, structural capital, and customer capital. With the deployment of the correlation patterns between knowledge creation and intellectual capital, this paper hopes to provide practical suggestions for the reference of the management of domestic banks.

LITERATURE REVIEW

1. Definition of Intellectual Capital

"Intellectual capital" was first proposed by Galbraith (1969), as a form of knowledge, intellect, and brainpower activity, which uses knowledge to create value. A company can create differentiated advantages with this capital; it highlights the gap between market value and book value. The importance of intellectual capital has been widely acknowledged by scholars. Stewart (1997) indicated that intellectual capital refers to the aggregation of all

knowledge and competences of employees that can bring about competitive advantages for companies. Any intellectual materials that can create wealth, such as knowledge, information, techniques, intellectual properties, experience, learning ability of organizations, and customer relationships, can be the most valuable assets and most advantageous tools in competition. Shaikh (2004) and Phusavat and Kanchana (2007) suggested that any knowledge capabilities stemming from manpower, creativity and innovation, organizational structure or affiliated parties can be classified as intellectual capital, providing it can store and convert knowledge for value creation in the future or translate implicit knowledge of employees into explicit knowledge for organizational structurization. Schiuma and Lerro (2008) believe that human, relational, structural and social capital as the four main knowledge-based categories building the knowledge-based capital of a region and find that policy makers for the definition of policies oriented towards the development of regional knowledge asset domains to develop regional innovation capacity. Walsh, Enz, and Canina (2008) indicated that the investments of companies in the enhancement of human capital, structural capital, and customer capital would increase their organizational values.

Some scholars widely define intellectual capital as the knowledge owned and applicable by organizations. Dzinkowski (2000) regarded intellectual capital as the total inventor of capital or knowledge-based resources owned by an organization. Therefore, intellectual capital is the intellectual properties or intellectual assets transferred by knowledge. Al-Ali (2003) stated that intellectual capital is the knowledge, experience, and brainpower of employees, as well as the knowledge resources stored in the database, systems, workflows, cultures, and management philosophy within an organization. Bontis (2004) proposed that intellectual capital is a stock of knowledge at a given time. Schiuma and Lerro (2008) argued that the most important activity in the management of intellectual capital is the improvement of organizational flows and management techniques to create knowledge assets.

Other scholars proposed that intellectual capital is intangible assets within an organization. Mayo (2001) stated that intellectual capital is the synonym of knowledge, information, intellectual properties, experience, and other intangible assets. Mason (2006) indicated that intellectual capital is an intangible asset. It can be defined as “the aggregation of the employees and internal structure of a company”. Intellectual capital includes three types: (1) delivery and management system of company information; (2) the abilities of employers and employees, and when the employees leave, the company loses the intellectual capital; (3) the relationship connectors with external organizations, such as relationship with customers, goodwill, and reputation.

Other scholars define intellectual capital with different perspectives. Rastogi (2000) stated that intellectual capital is the ability owned by an organization as a whole to constantly face existing and potential challenges, and respond in a creative and effective manner. McElroy (2002) suggested that intellectual capital should include social and innovative capital that enhances the internal value of companies with mutual trust, mutual benefits, shared values, networks, and norms. Petty, Ricceri, and Guthrie (2008) argued that intellectual capital is the link between personal knowledge within group of an organization, and it can serve as a basis for decision-making.

2. Constituents of Intellectual Capital

The definitions and the elements used to measure intellectual capital can be somewhat different across industries, and therefore, the measurement methods can be different as well. Some scholars divide intellectual capital into two types. Petty and Guthrie (2000) defined intellectual capital as "structural capital" and "human capital". Human capital refers to employees' competences and human resources of external parties accessible by companies. Structural capital refers to elements, such as corporate flows, software systems, and supply chains. Joia (2000) also divided intellectual capital into "human capital" and "structural capital". The difference is whether the capital can be bought. Human capital is not tradable and not owned by the organization, it is a result generated by professional knowledge and skills of employees. According to the positions within and outside the organization, structural capital can be classified as "flow capital", "innovation capital" and "relationship capital". Flow capital is the internal operational flows of an organization, and the external operational flows of the organization with other parties. Innovation capital refers to the ability to create new knowledge with existing resources and is the result of an organization's culture. Relationship capital is the interaction between the organization, customers, suppliers, contractors, and other affiliated parties.

Dzinkowski (2000) divided intellectual capital into three types: human capital, organizational (structural) capital, and customer (relationship) capital. Human capital refers to employees' knowledge, education, professional certificates and qualifications, work-related know-how, work assessment, mentality assessment, innovations, aggression, and the ability to respond and change. Organizational capital refers to intellectual properties and infrastructure assets, such as patents, copyrights, design rights, trade secrets, trademark services, management philosophy, corporate cultures, management procedures, information systems, and network systems. Customer capital refers to customers, customers' loyalty, distribution channels, corporate partners, good contracts, and licenses.

Roos, Bainbridge, and Jacobsen (2001) divided intellectual capital into three types: human, relationship, and organizational. Human capital refers to employees' capabilities, skills, and intelligence. Relationship capital refers to the relationships between all related parties and stakeholders. Organizational capital includes workflows, systems, structures, trademarks, intellectual properties, and other intangible assets owned by the companies, but cannot be shown in the balance sheets. Meanwhile, Shih (2008) measured intellectual capital with 4 dimensions, as based on the characteristics of intellectual capital in the financial service industry. These 4 dimensions are human capital, innovation capital (training & development), flow capital (IT system), and customer capital. The conclusion is that customer capital of the financial industry is dependent on employees' training and product development. However, the correlation with the investment in IT systems (as flow capital) is relatively low. The enhancement of innovation capital is hinged on high-calibre human capital. This is how the creation flows work for the intellectual capital of the financial industry.

3. Knowledge Creation

For a country or a corporation, knowledge is a foundation required for survival and development. Knowledge is the main input/output for companies. The absorption, digestion, and production of knowledge will become the main activities of companies. Therefore, knowledge will become the cornerstone of sustainable competitive advantages for companies. Banking is a typical knowledge-intensive industry, as it involves the activities of knowledge exchange. Hence, knowledge is the source of core competitiveness for the securities and investment industry. The first step of knowledge management is the creation of new knowledge. The creation of new knowledge may come from within or without an organization. The process of knowledge creation within an organization may be through learning, research & development, experience accumulation, and learning by doing. The source of external knowledge can be absorbed and generalized via interactions with suppliers, customers, and competitors. Chang and Lee (2008) indicated that the capability to obtain knowledge can positively and significantly affect knowledge administrative and technical innovation. The research also shows that external environment and organizational culture have significant interaction effects with knowledge accumulation capability on organizational innovation.

Nonaka and Takeuchi (1997) suggested that the creation of knowledge is gained via the interaction of implicit knowledge and explicit knowledge. The process of knowledge conversion is required to generate new knowledge. The conversion process includes 4 elements (Figure 1):

- Socialization

Socialization refers to the process for implicit knowledge to become explicit. It is mainly through passing down and sharing personal experiences, and thus, there is no need to go through written words. For example, knowledge passed down from a master to a disciple. However, socialization is a rather limited knowledge creation pattern. While the disciple can learn skills from the master, neither the disciple nor the master has a systematic understanding of the skills because their knowledge may not be converted into the explicit. It is impossible to allow the whole organization to easily use all knowledge.

- Combination

  Combination is the process for implicit knowledge to become explicit knowledge, mainly through storage, combination, and classification to make the explicit knowledge systematic. For instance, a CFO of a company collates information throughout the organization to compile it into a financial report. The financial report is a new knowledge because it combines information of different sources. However, the combination does not really expand the current knowledge base of the company.

- Externalization

  Externalization is the process for implicit knowledge to become explicit knowledge. The sharing of knowledge is mainly through metaphors and conceptual assumptions. For example, a CFO of a company does not actually produce a conventional financial report, but rather, he develops an innovative budgetary control method, which is based on implicit knowledge he has accumulated over years of experience.

- Internalization

  Internalization is the process for explicit knowledge to become implicit knowledge, mainly via inspections and applications. The process socializes, externalizes, and combines the explicit languages, texts, pictures, or information, and then internalizes it into personal knowledge. In other words, when the whole organization is able to share the new explicit knowledge, other employees can start to expand, extend, and redefine their implicit knowledge.

Marr, Gupta, Pike, and Roos (2003) divided the sources of knowledge creation into three types: autopoetics, cognitivists, and connectivists, as shown in Figure 2. Autopoetics refers the development of personal knowledge amid difficulties in delivering information and knowledge because the sources of the knowledge are personal interpretations or translated data within an organization. The master and disciple system is an example. Cognitivist refers to authentication, collection, and dissemination of propaganda information as the main activities of knowledge development. An open organization develops more accurate and precise knowledge through the absorption of new information. Knowledge development can be stored systematically within a system based on general principles. This type is mainly to construct a solution in order that the created knowledge can be systematically shared. The

common approach is to formulate a set of standardized operational procedures (SOP). Connectivists and cognitivists have a lot in common. The only difference is that in connectivists, there is no predefined solution. Rather, it is believed that the source of information stems from the connection of information. Therefore, knowledge creation should focus on the exchange and sharing of information. The usual approach adopted by companies is brainstorming and workshops, and the connecting approach is team-oriented. It is regarded that knowledge creation relies on the communication of internal information. The relationship between individuals is like independent networks within an organization, and knowledge exists in the interchanges of the networked information. Knowledge creation is focused on the disseminated and delivered informational flows within an organization.

From \ To	Implicit Knowledge	Explicit Knowledge
Implicit Knowledge	Collectivity: process of creating implicit knowledge via experience sharing (common knowledge)	Externalization: implicit knowledge expressed with metaphors, analogies, concepts, or assumptions through models (conceptual knowledge)
Explicit Knowledge	Internalization: knowledge passed down with words and stories or made into manuals and documents (operational knowledge)	Combination: the process of forming a knowledge system by making concepts systematic (systematic knowledge)

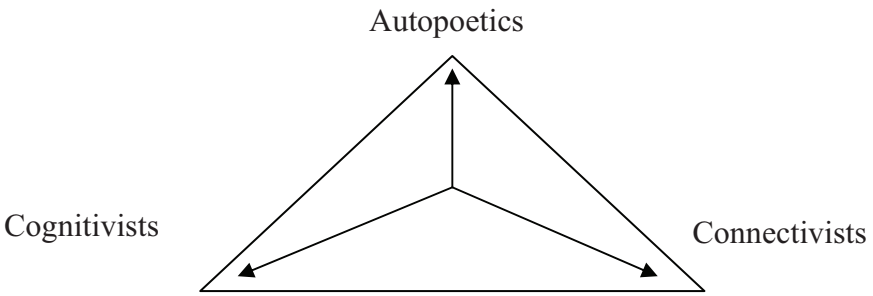

Figure 2 Types of Knowledge Creation; Source: Marr et al. (2003)

RESEARCH METHOD

1. Research Structure

This paper constructs its research structure, as shown in Figure 3, in accordance with the characteristics of the banking industry, and literature addressing types of knowledge creation and structure of intellectual capital.

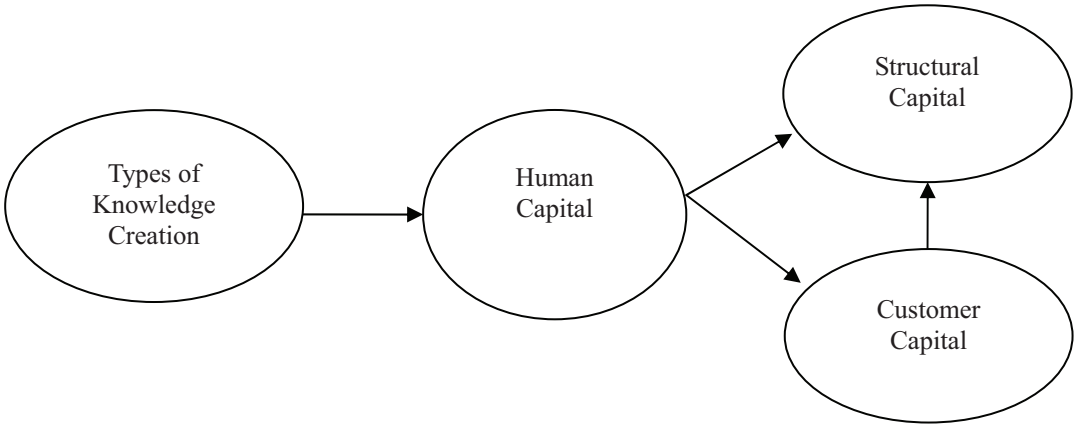

Figure 3 Research Structure

2. Research question

Al-Ali (2003) suggested that intellectual capital is employees' knowledge, experiences, and brainpower, as well as the knowledge resources stored in the databases, systems, flows, cultures, and management philosophies, and is the aggregation of all these resources. Afiouni (2007) proposed that the management activities in human capital and knowledge management help to improve operational performances of an organization. Meanwhile, Schiuma and Lerro (2008) indicated that the most important activity in the management of intellectual capital is to improve knowledge assets of organizational flows through diverse methods that improve organizational performances. This paper first examines the relationship between knowledge creation and intellectual capital of the banking industry. Knowledge creation uses employees as a medium. Intellectual capital can only be created with resource investments and management in a systematic method within an organization. Therefore, this paper assumes that knowledge creation and human capital of the banking industry are correlated.

As far as the contents of intellectual capital are concerned, Reed (2000) suggested that the contact between employees and customers enable employees to understand customers' needs and provide better responses. From the customers' end, they can determine the services that their organization should improve or increase. It facilitates the conversion of human capital into customer capital. Kaplan and Norton (1996) also indicated that the interactions between employees and customers may trigger absorption of information, and it can transform knowledge formats for the organization. They can be stored within the organization so that

information can be shared with others. In other words, the better competences employees have, they more they are able to understand customers' needs and develop customer relationship capital to boost customers' satisfaction. Greiner, Böhmann, and Krcmar (2007) stated that an organization whose business strategy requires process efficiency (product/process innovation) should rely primarily on a codification strategy (a personalization strategy). In addition, both Sveiby (1998) and Chareonsuk and Chansa-ngavej (2008) indicated that the companies with abundant human capital could not only boost the operating efficiency, but also accumulate solid structural capital. High-caliber employees and leaders constantly provide services catering to the needs of different customers or partners, in order to establish, maintain, and develop customers' relationships. This results in the accumulation of customer capital. To sum up the above literature review, this paper examines the correlation between knowledge creation and human capital of the banking industry, and analyzes the correlation between human capital, structural capital, and customer capital of the banking industry.

3. Research tools

This paper adopts the knowledge management measurement proposed by Bukowitz and Williams (1999), as a reference structure to examine the formats of knowledge creation. This measurement focuses on the evaluation of intellectual capital. It covers the day-to-day information gathering of organizational members, personal learning on the job, value creation for the re-utilization of knowledge, and the feedback of knowledge flow cycles to the knowledge management system of companies. Meanwhile, this paper refers to Marr et al. (2003) as the major structure of the formats of knowledge creation to be examined. The measurement for human capital (as part of intellectual capital) is designed by modifying the 5 questions proposed by Youndt, Subramaniam, and Snell (2004). The measurement for organizational capital is based on the 4 questions of Youndt et al (2004), with an emphasis on storage in memory devices of an organization, established organizational knowledge, and systematically recorded experiences. Meanwhile, the measurement for customer relationship capital is developed by modifying the questions designed by Bontis (1997) to assess customer capital. In addition, this paper refers to the measurements and indicators proposed by Stewart (1997) and Dzinkowski (2000) for human capital, structural capital, and customer capital.

EMPIRICAL ANALYSIS

1. Data collection

The sample population includes 6 branches of privately owned commercial banks, 3 branches of state-owned banks, and 1 branch of a credit cooperative. There were 15 to 20 questionnaires issued to sales personnel and supervisors, with at least 3 years in service, at each branch. A total of 500 questionnaires were released, with 194 were recovered. The following table shows the basic data of the respondents of the effective questionnaires. (Table 1)

2. Reliability and validity analyses

All the dimensions of this study report Cronbach's α over 0.7, reaching high reliability standards, which indicate that the measurement design is highly credible. Table 2 shows the detailed data. Meanwhile, content validity refers to the fitness of the contents of the measurement tool. The verification of content validity in social sciences depends on the professional knowledge of researchers. It is also possible to identify appropriate and relevant measurements from literature or employ the assistance of experts to determine the fitness of the contents, to enhance content validity, and ensure questionnaire effectiveness. The development of measurement tools in this paper is based on generalization of literature reviews. All the sources are referenced in relevant empirical literature. The questions are modified after interviews with experts. Therefore, the questionnaire in this paper should carry a certain degree of content validity.

Table 1 Sample Characteristics

Sample characteristics	No. of Samples	%	Accumulative %
Sex			
Male	63	32.5	32.5
Female	131	67.5	100
Age			
20~29	114	58.8	58.8
30~39	67	34.5	93.3
40~49	11	5.7	99
50~59	1	0.5	99.5
Above 60	1	0.5	100
Marital status			
Single	144	74.2	74.2
Married	50	25.8	100

Tenure			
Below 5 years	131	67.5	67.5
6~10 years	42	21.6	89.1
11~15 years	14	7.2	96.3
16~20 years	2	1.1	97.4
Above 20 years	5	2.6	100
Education			
College	46	23.7	27.3
University	115	59.3	83
Post graduate	33	17	100

Table 2 Summary of Dimension Reliability

Dimension	No. of items	Cronbach's α
Autopoetics	7	0.842
Cognitivists	7	0.812
Connectivists	7	0.798
Human capital	9	0.922
Structural capital	10	0.897
Customer capital	8	0.904

3. Structural Equation Modelling (SEM)

Figure 4 shows the parameter estimates of the structural model of this paper. Afterwards, an inspection of the estimates of the model and assessment of the overall fit indicators and modification index (MI) can be made to evaluate model fit.

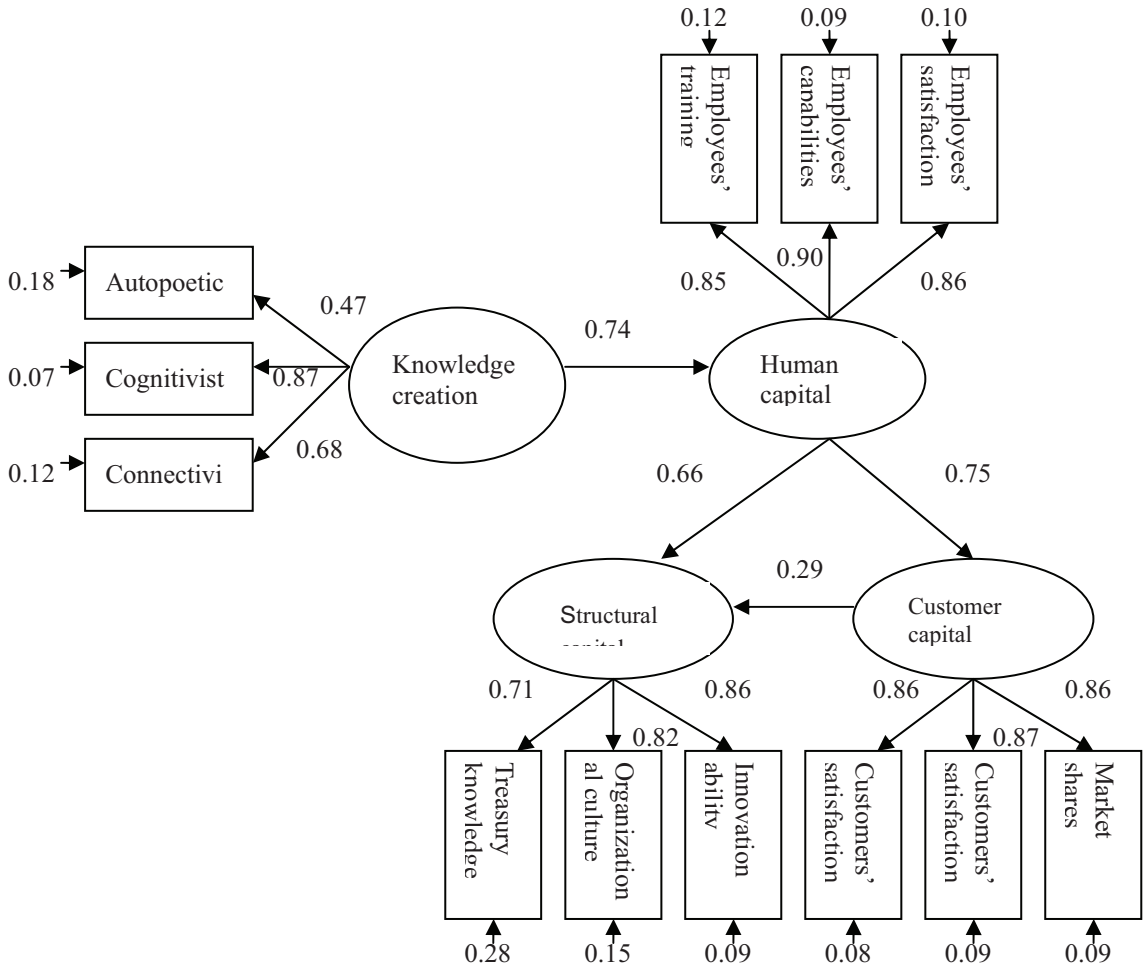

Figure 4 Standardized Parameter Estimates of Path Analysis

4. Measurement Results of Observed Variables & Selection of Estimation Methods

Table 3 shows the averages and standard deviations of observed variables. Meanwhile, according to the skewness and slopes of individual variables, Kline (1998) made the following comments on coefficients of skewness and coefficients of kurtosis. He suggested that when the absolute value of the coefficient of the skewness of the distribution of variables is greater than 3, it could be regarded as extremely skewed. If the absolute value of the coefficient of kurtosis is greater than 8, it has reached a critical point. If the coefficient of kurtosis is greater than 20, it is seriously critical and can be regarded as an extreme case. If the coefficient of skewness or kurtosis has such an issue, it is necessary to consider the estimation methods not subject to the variable distribution. The coefficients of skewness for the observed variables, in this paper, range from -0.484 to 0.327, and the coefficients of kurtosis range from -0.354 to 2.032. The results show that an estimation method, with a normal distribution, does not seriously affect the robustness of the estimates. Therefore, this

paper uses the maximum likelihood estimation method as its model.

Table 3 Measurements of Observed Variables for Path Analysis

Potential Constructs & Observed Variables	Average	Standard Deviation	Coefficient of Skewness	Coefficient of Kurtosis
Knowledge creation				
Autopoetics	4.06	0.48	-0.484	2.032
Cognitivists	3.60	0.55	0.117	0.063
Connectivists	3.79	0.48	-0.063	0.224
Human capital				
Employees' training	3.33	0.68	-0.074	0.245
Employees' capabilities	3.34	0.65	0.226	-0.354
Employees' satisfaction	3.41	0.63	-0.028	-0.310
Structural capital				
Treasury knowledge	3.23	0.75	-0.102	-0.080
Organizational culture	3.39	0.69	-0.314	-0.008
Innovation ability	3.52	0.60	0.087	-0.121
Customer capital				
Customers' satisfaction	3.57	0.57	0.312	0.090
Customers' loyalty	3.39	0.61	0.327	-0.066
Market shares	3.49	0.59	0.099	-0.191

5. Validation & Analysis of Research Issues

This paper uses a structural equation model for validation and analysis of the examination of reasonability of the research structure and the results of the research issues. Table 4 shows the validation results of the structural model. The standardized coefficients of knowledge creation and human capital are 0.74, and t-value is 7.18, $P<0.001$, reaching statistical significance. The results indicate that knowledge creation has positive, and direct, influence on human capital. Meanwhile, Cognitivists and Connectivists are considered the main knowledge creators in the banking industry. The standardized coefficient between human capital and structural capital is 0.66, t value is 6.47, and P is less than 0.001, also reaching statistical significance. These numbers suggest that human capital has positive and direct influence on structural capital. The standardized coefficient between human capital and customer capital is 0.75, t value is 9.70, and P is less than 0.001, also reaching statistical significance. These numbers suggest that human capital has positive and direct influence on customer capital. The standardized coefficient between customer capital and structural capital

is 0.29, t value is 3.24, and P is less than 0.001, also reaching statistical significance. These numbers suggest that customer capital has positive and direct influence on structural capital.

Analysis results show that, the methods of knowledge creation by employees in the banking industry have direct and significant influence on the formation of human capital. The direct impact of human capital on customer capital is significantly greater than that of human capital on structural capital. The direct impact of customer capital on structural capital is the smallest.

Table 4 Validation Results of Structural Model

Research Issue & Path	Standardized Coefficient	Standard Error	t value	P
Knowledge creation -> Human capital	0.74	0.19	7.18	***
Human capital -> Customer capital	0.75	0.07	9.70	***
Human capital -> Structural capital	0.66	0.10	6.47	***
Customer capital -> Structural capital	0.29	0.10	3.24	**

Note: ** indicates P<0.01; *** indicates P<0.001

In addition, the higher the model fit, the higher usability the model has, as far as the model fit assessment is concerned. That also means that parameter estimates are more meaningful. This paper refers to absolute fit indicators, incremental fit indicators, and goodness of fit index recommended by Hair, Anderson, Tatham, and Black (1998) for the validation of overall fit. Table 5 shows all the overall fit indicators. Among the absolute fit indicators, the GFI value of this model is 0.932, RMR value is 0.016, and RMSEA value is 0.066, all within an acceptable range, as suggested by past scholars. Huang (2004) suggested that if the RMSEA value is between 0.05 and 0.08, it implies a good fit.

As far as incremental fit indicators are concerned, the AGFI value of this model is 0.877, NFI value is 0.948, CFI value is 0.977, and IFI value is 0.977. All the values reach the standards suggested in literature, with the exception of AGFI. However, the AGFI is fairly close to the standard. Meanwhile, among the goodness of fit index, the PNFI value of this model is 0.618 and PCFI value is 0.636. They are both greater than 0.5, reaching the standards suggested by previous scholars.

Table 5 Overall Model Fit of Path Analysis

Fit Indicator	Criteria	Validation Value	Result
Absolute Fit Indicators			
P	P>0.05	0.004	Close
GFI	>0.9	0.932	Compliant
RMR	<0.05	0.016	Compliant
RMSEA	<0.05	0.066	Close
Incremental Fit Indicators			
AGFI	>0.9	0.877	Close
NFI	>0.9	0.948	Compliant
CFI	>0.9	0.977	Compliant
IFI	>0.9	0.977	Compliant
Goodness of fit index			
PNFI	>0.5	0.618	Compliant
PCFI	>0.5	0.636	Compliant

CONCLUSION AND SUGGESTIONS

The purpose of this paper is to examine the correlation between knowledge creation and intellectual capital of the banking industry, as well as the correlation between human capital, structural capital, and customer capital, as the three types of intellectual capital. The research finds that knowledge creation in the banking industry has positive and direct influence on human capital. The smoother the channels are for employees to create knowledge, the higher the human capital of the banks; as a result, there is positive influence on structural capital and customer capital of the banks. In other words, with comprehensive knowledge creation mechanisms, banks can effectively enhance their intellectual capital. This finding is consistent with that of Schiuma and Lerro (2008), that the most important activity in management of intellectual capital is the creation of knowledge variety. It can improve the flows of knowledge creation for an organization, and accumulate more knowledge assets. Meanwhile, as far as the sources of knowledge creation are concerned for employees in the banking industry, cognitivists are the most important and have the most significant influence on human capital, followed by connectivists. Autopoetics reports the least influence on human capital.

Intellectual capital consists of human capital, structural capital, and customer capital. This study finds that human capital in the banking industry reports positive, and direct, influence

on structural capital and customer capital. Customer capital also exhibits positive and direct influence on structural capital. Namely, banks with rich human capital not only boost their operational efficiency, but also accumulate good structural capital. High-caliber employees develop customer relationships with their professional knowledge, experience, and capabilities and promote the accumulation of customer capital. Meanwhile, interactions between employees and customers trigger more digestion and absorption of information so that information can be shared within the organization, and thus, the accumulation of structural capital increases. This finding is consistent with Shih (2008), who suggested that human capital has the same positive influence on structural capital and customer capital in the financial service industry. However, it is in contrast with the statement that structural capital exhibits negative influence on customer capital.

As far as the perception of the dimensions of intellectual capital by the employees in the banking industry is concerned, this paper finds that employees' competences are the most important element of human capital, followed by employees' satisfaction and employees' training. When it comes to structural capital, innovation ability is the most important, followed by organizational culture and treasury value. In terms of customer capital, customers' loyalty is the most important, followed by customers' satisfaction and market shares. In other words, employees' competences, satisfaction, and training have positive influence on structural capital and customer capital. Customers' loyalty, satisfaction, and market shares also exhibit positive influence on structural capital.

The ability to create knowledge is highly relevant to intellectual capital in the banking industry. Companies should define their own robust mechanisms for knowledge creation to improve their ability in knowledge creation. The sources of knowledge creation should include autopoetics, cognitivists, and connectivists. For autopoetics, domestic banks should improve their mentoring systems in order to convert the implicit knowledge not able to be expressed with words or texts within the organization into explicit knowledge. For cognitivists, banks should establish and integrate a variety of IT systems to facilitate the exchange and sharing of knowledge. Examples are databases, work samples, and instruction manuals within the organization. It is also possible to invite highly seasoned professionals to give speeches and encourage employees to sit for examinations to obtain certificates and qualifications. As far as connectivists are concerned, banks should provide all kinds of formal, and informal, communication channels, such as job rotations, discussions, intranet forums, meeting rooms, and tea areas to enhance the ability of the organization to create knowledge.

The managers in the banking industry should identify the ways to cultivate in-depth contents of intellectual capital. They should have comprehensive talent development programs for

their human capital by providing complete training and education to expand the professional knowledge and skills of employees. They should encourage employees in a timely manner to enhance employees' satisfaction. In terms of structural capital, the mangers should strive to improve the operational flows of their companies by enhancing the innovation capabilities and bettering the value of the knowledge treasury within their organizations. As far as customer capital is concerned, they should provide high value added products and services, as well as a clean and comfortable environment to maintain a good long-lasting relationship with customers. Xu and Walton (2005) and Liew (2008) suggested the integration of knowledge management (KM) and customer relationship management (CRM) is a strategic issue that has strong ramifications in the long-term competitiveness of organizations. This will increase customers' satisfaction and loyalty, and hence, market shares. For domestic banks, the interaction and mutual influence of human capital, structural capital, and customer capital will benefit the accumulation of intellectual capital, create differentiated advantages, and boost corporate competitiveness.

ABSTRACT

This paper presents a study of developing the action-oriented concept of managing traditional knowledge by applying of an intellectual capital process to the Mea-hiya community, Chiang Mai, Thailand. The research has been identified through exploratory research conducted in co-operation with Mea-hiya community cultural council by using qualitative methods.

The paper discusses that the intellectual capital process has much to offer in illuminating how strategies are identified and responded directly to the community cultural situations. The process tries to be realistic by heaving a measuring method which means the process is more quantifiable. The paper describes the process of how strategies were formulated, development and deployed in shifting the Mea-hiya community to manage their traditional knowledge systematically.

Keywords: Intellectual Capital, Traditional Knowledge management, public strategy.

INTRODUCTION

Today, we live in a global village that has an increasing complexity which makes each party interdependent of each other. The global changes have led some people to adopt a new attitude in appreciating the concept of ownership and sole benefits of the ownership (Convention on Biological Diversity, 1992). These attitudes have expanded to cover the usage of the traditional knowledge of the community. Nowadays, current disputes are caused by two main factors. 1) Misuse of the community's traditional knowledge which leads to the disrespect of the traditional knowledge. 2) Exploitation of community traditional knowledge without receiving any permission from the community or sharing it to the community (WIPO, 2006).

Thailand is blessed with her community's traditional knowledge which is deemed as the nation's precious resource. However, the abundance in the community's traditional knowledge has induced many disputes. First, the piracy of traditional knowledge, this problem is partly due to the lack of intellectual property protection. From a comprehensive study, it is apparent that Thailand does not have an appropriate law to handle these type of issues (Setsirote, & Donavanic, 2005). Second, the way of life in Thailand has been constantly changing. After World War II, there had been three waves of development for the Thai local community. The first wave began in the 1960s with the government's attempt in bringing new technology to the local community. The second wave was in the 1970s when people from the local community migrated to find work in the urban area. The third wave was in the 1980s with the penetration of television into almost every rural household, and with an increasing number of rural children entering secondary education. Thus, these three waves have brought upon a new attitude, lifestyle, and modern beliefs to the local people within their community (Bager, 2003). Third, there is a lack of local cultural managing to conserve the traditional knowledge. Traditional knowledge is a community capital; however, communities still lack the process to manage the cultural heritage systematically. For example, local people use story telling as a method of transmitting traditional knowledge from generation to generation especially within their family (Chiyasak, Rajchagool, Pinyosinwat, Kesmanee, Apakaro, & Yodmongkon, 2007). Telling story requires a good interpretation. But due to the changes, people might interpret and understand things differently based on their experiences. This misunderstanding leads to a misuse and a misleading of their traditional knowledge.

This study seeks to develop the new concept of managing traditional knowledge by applying the intellectual capital process that is recommended for the Thai local community (the Mea-hiya community, Chiang Mai, Thailand). The structure of the paper is as follows: a literature review on related issues is presented at the second section. The third section presents the research framework. The fourth section presents the findings, the fifth section presents discussion and the last section presents the conclusion.

LITERATURE REVIEW

Report on Case study of Improper Exploitations of Cultural Property and Folklore

Chiyasak et at, 2007 examined case studies in 4 regional parts of Thailand: north, northeastern, central and south. The results of the study showed that, at all regional parts, Thai cultural property and folklore have been exploited improperly, but the characteristics and forms of those problems were different; for example, problems about race, acceptance and social equality, problems about improper exploitation of cultural heritage such as cultural distortion, improper exploitation of cultural heritage for commercial purposes, and personal claims for the intellectual property right in cultural heritage that must be belonged to the community property; thus, community members face some problems about the exploitation of such cultural heritage.

Regarding case studies on improper exploitations of intellectual property, the Researcher examined the case of registering the Hmong traditional embroidery as an intellectual property in the North and of constructing hotels at public areas of Cha-am Beach. According to such case studies, it is evident that such cultural heritage has been exploited improperly; individuals or business entrepreneurs claimed for the intellectual property right in the community cultural heritage. In the above cases, ones playing prominent roles in claiming for the community right were community members who actually own that cultural heritage. They formed a group requesting all related government bodies to solve their problem. This shows that the community takes a significant role in protecting its own cultural heritage. Therefore, the Researcher conducted an additional study on the development direction and changes of a local community and practice of Muslim community for Zakat case at Lad Bua Luang Community, Phra Nakon Si Ayutthaya. The results confirmed that community power was essential for any movement to protect the cultural heritage in each area.

Thai legal protection on traditional knowledge

According to studies on related laws of Thailand, some provisions associated with traditional knowledge, which is defined herein as intangible cultural heritage, have been set forth in laws; namely, a) The Constitution of the Kingdom of Thailand, B.E. 2550 (A.D. 2007) in 3 Sections: Section 66, Section 86(2) and Section 289. However, those provisions do not give explicit definitions, which possibly cause the ambiguity while the scope of related wordings is based on the different understanding among persons involving in drafting the Constitution and persons to be further enforced by such provisions; b) Patent Act, B.E. 2522 (A.D. 1979); and c) Copyright Act, B.E. 2537 (A.D. 1994). For b) and c), they seem relevant to the right in the traditional knowledge, but, after a close look, both laws are not designed for the traditional knowledge protection; hence, certain fundamental principles as well as their essence are different from those of traditional knowledge such as right given to a person and community right, etc. As a result, it deems inappropriate to use those two laws to protect the traditional knowledge (Sersirote, & Donavanic, 2005; Pullvanich, 2005). Nevertheless, there are another 2 acts appropriate for studying the guideline of laws on traditional knowledge protection, including d) Plant Protection Act, B.E. 2542 (A.D. 1999) e) the Protection and Promotion of Traditional Thai Medicine Act, B.E. 2542 (A.D. 1999) and f) Historical Sites, Materials, Arts and National Museum Act, B.E. 2535 (A.D. 1992). These three acts contain specific qualifications and protection guidelines close to the traditional Thai knowledge; for example, establishing the exclusive right for intangible objects for an individual right holder or a particular group, or the authority given to local organizations to take into account the commercial exploitation of plants as well as making agreements on profit sharing, etc (Chiyasak et al., 2007).

Intellectual Capital (IC)

Intellectual Capital (IC) is defined as the sum of a company knowledge (its' members) that is contributed to an improved competitive position of the organization by adding value to the

defined key stakeholders (Edvinsson, 1997; Marr, 2004). In the knowledge economy, competitive advantage of business relies on values of ICs that allow businesses to create, innovate, and achieve better productivity (Stewart, 1997). Skandia was the first company who developed an IC reporting model named the Navigator (McConnachie, 2007). Skandia distinguished IC into two categories, the structural capital and the human capital. Structural capital is defined as infrastructure that organizations develop to commercialize their human capital. It includes both direct and indirect support, and for each there are both physical and intangible elements (Edvinsson, & Sullivan, 1996). Structural capital includes customer capital (external) and organizational capital (internal). Organizational capital consists of innovation and process capitals. Process capital is the sum of a company's know-how. Innovation capital includes intangible assets and intellectual property which is the source of renewal for the company. Human capital is defined as the collective capabilities of the employees' competence, attitude and intellectual agility (Roos et al., 1997). This asset includes experience, skills, and know-how of the employees.

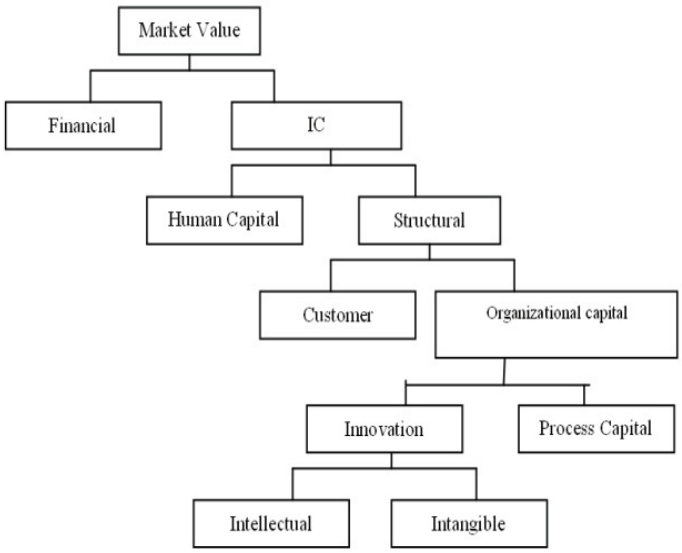

Figure 1. Skandia Model

Source: Roos et al., 1997

Since the start of the Skandia model in mid 1990s, the model has been criticized for its failure for not taking into account a major component of intangible value called social capital (McElroy, 2002). Social Capital refers to connections within and between social networks (DeFilippis, 2001). It focuses on the value of relationships between people forming an organization or community which is a core concept in business, economics, political science, and sociology. Social capital can reduce the information transferring cost and promote corporation (Bueno, Salmador, & Rodriguez, 2004). In the late 1990s, the concept gained popularity, by serving as the focus of the World Bank research program (World Bank, 2005)

and has become the main subject of several mainstream books. The following are four main approaches to social capital.

Social Capital Approach	Main Ideas
Economic development theories	Confidence, civic behavior and associativity strengthen the social networks, contributing to the sustainable economic development
Social responsibility and ethics	Social capital expresses the degree of social integration and responsibility with respect to the whole society and its agents and group. It is based on values and attitudes, such as confidence, corporation, safety, principles, ethics, and compromise
Corporate governance	Ethics and corporate governance codes have a positive impact on the creation of social capital, stimulating the solidarity and overcoming market imperfection
IC	Social capital is a component of IC. It is based on a set of values and the subsequent indicators such as confidence, royalty, sincerity, compromise, transparency, solidarity, responsibility, honesty and ethics

Table 1. Main conceptual approaches of social capital

Source: (Bueno, Salmador, & Rodriguez, 2004)

According to Bueno, Salmador, & Rodriguez, (2004) they propose the evolutionary IC model that had been modified with social capital (figure 2). The model is based on three main intellectual capital components which are human capital, structure capital, and relational capital. The researchers pay special attention to the relational capital. The relational capital consists of business capital and social capital. Social capital consists of social integration capital refers to the relationship between organization and its stakeholders and social innovation capital refers to the set of process and relationship that initiate the innovation (McElroy, 2001). In addition, Bueno, Salmador, & Rodriguez, (2004) also categorize social capital into six areas which are “first, solidarity and social cohesion; second, economic development of the environment; third, commitments of efficient corporate governance; forth, commitments acquired with the scientific and technological development; fifth environmental protection; and sixth defense of cultural and artistic heritage”. Thus, IC process can be applied not only to the business domain, but also to the social domain; in particular to the intangible traditional knowledge.

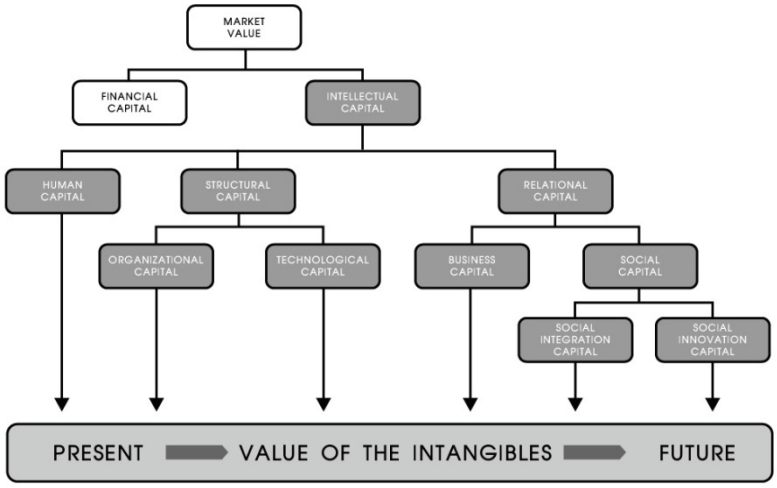

Figure 2. Evolutionary intellectual capital model

Source: Bueno, Salmador, & Rodriguez, (2004)

The case study in this paper explores the IC process that illustrates its practical and pragmatic approach which offer a bridge between the conceptual thinking and practical approach provide a basis for practical tools and methodology for developing, implementing strategy to manage community traditional knowledge.

RESEARCH FRAMEWORK

The research framework is to study the implementation of an intellectual capital system to the Mea-hiya community in Chiang Mai, Thailand by using an intellectual capital process model. The research has been identified through exploratory action research conducted in co-operation with Mea-hiya community cultural council. The research is conducted by using qualitative methods such as documentary research, semi-structured interviews, observations, participatory observations, and focus groups. The target samples interviewed have a direct connection or relationship with community traditional knowledge and its significance. The theme for the semi-structured interview questions was created from literature review. A pre-test of the questions examined to four target samples for adjustment. After the interviews, transcriptions of the interview were made as soon as possible. Data analysis of this research is based on qualitative approach. The content analysis and thematic extraction are used. The documents and the data form interviewees shall be transcribed and analyzed. All text is read line by line and marked margin note. The knowledge & opinion from the participants is analyzed and given systematic coding. The potential themes are identified by grouping examples from the text and then the text is categorized and termed.

The intellectual capital process model is the suggested means for the management of community traditional knowledge toward a local community-based organizational paradigm. A four step-approach (Figure 5) aimed at successful acquisition of the proposed model is

recommended. The design criteria for the community cultural management process model required it to include the following element:

Stakeholders' identification is the first step of the process. Once the list is complete, it is then analyzed by consultation continuum (Bridgman & Davis, 2004) as analyzing tools. The second step is a creation of strategies. The stakeholders' needs and expectations of community traditional knowledge would be the strategy of the community cultural council. Then the needs and expectations are listed and prioritized as strategies. The third step is to translate stakeholders' strategies into action plans which are indicated as key success factors. The needs and expectations found in the previous step must be used to identify the Key Success Factors (KSFs). The final step of the process is to measure the achievement of each KSF by putting indicators that reflect its purpose. Appropriate indicators can be selected carefully by the stakeholders if they indentify the true essence of the KSFs. Rarely does only one proxy provide an accurate measure. Most cases more than one indicator is needed to get a clear and correct picture (Roos et al., 1997).

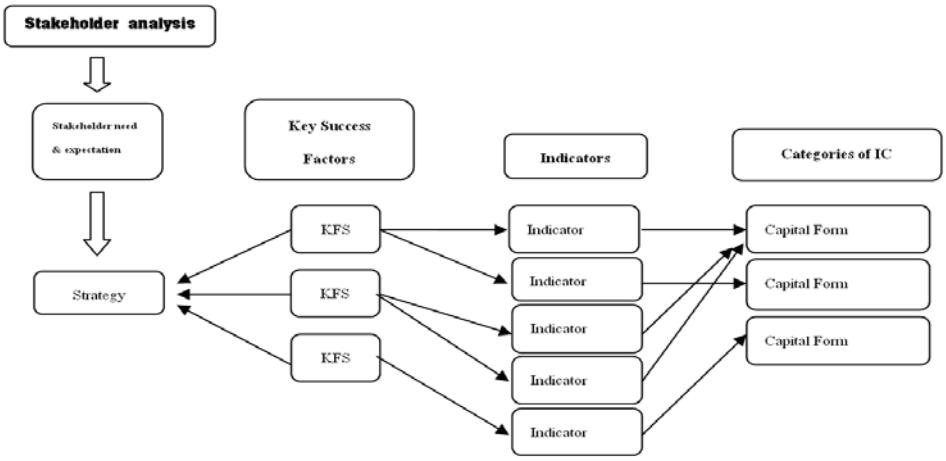

Figure 3. Community Cultural Management Process Model

The case study: The Mea-hiya Community

The Mea-hiya community is located in the Chiang Mai province. Mea-hiya is an urban community with a population of 16,683 (Mea-hiya municipality, 2007) located at 15 kilometers in the southern area of Chiang Mai. The Mea-hiyas are the original Lour tribe community with more than 700 years of history. Their long history creates a fertilization of traditional knowledge which is considered as the cultural heritage of the community.

Since the community is very close to the Chiang Mai province (the second biggest city in Thailand), the Mea-hiyas have rapidly developed in the economic side. In 1990, the main road was built pass through the center of the community. This caused some major changes in the area. Modern trade centers have started a business of selling a huge selection of household goods. All of a sudden, the Mea-hiyas have become a part of the urban city. People from the outside started moving to live and work in the community. The community

has now become more dependent on the outside market and on outside knowledge. The third wave of development has hit the Mea-hiyas continuously and effectively; therefore, the way of life in the Mea-hiya community has changed tremendously..

All these changes have affected the Mea-hiyas' traditional knowledge. The term of occupation has changed when urban growth draws people to urban work. Agriculture which was considered the main profession had suddenly vanished. The way of thinking, behaving and believing is so much different now when it is compared to the pastSome cultural ritual like the Tan Loua Pha Joew festival have now vanished because it does not fit in their way of life anymore. Some cultural ritual performances have changed and are different from the way their ancestors performed because the community does not have a standard reference as a guideline to perform a ritual correctly. Changing the way to perform causes a misunderstanding of the meaning of the ritual. This might also lead to others following in the wrong direction. Moreover, the Mea-hiya community had often at times experienced a big misunderstanding issue. One of the unique rituals called Leang-Dong which has been performed in Mea-hiya for hundreds of year was disseminated to the public by the outside media in 2007. Without an explanation of the reasons behind the ritual, the story caused a stir and was followed by some heavy negative criticism. The central government also came to investigate the incident and the community had to report in clarifying their action. This incident destroyed the community's reputation badly.

FINDINGS

From the observation and document research

The research found that The Mea-hiya community founded a cultural council to manage their traditional knowledge. The cultural council is supported by their local government (man, money and material). The council objectives are to formulate policies and support cultural activities (Mea-hiya Cultural Council Const. Sec 6). However, there are some flaws that should be mentioned. As for a start, the local government has a high influence to manage cultural activities because the government staff handles most of the job. The people in the community haven't really participated fully in managing their cultural activities. Second, most of the activities are conducting annual cultural festival and rituals (Mea-hiya Municipality, 2007). The council is missing in the action to conserve, preserve and protect their community knowledge. This shows that the council does not have the precise policies and strategies to provide a systematic way for the community to preserve, transmit, and protect their traditional cultural knowledge.

From the intellectual capital process

Seven key stakeholders are identified. These seven key stakeholders have a high direct relevance to cultural activities in the Mea-hiya community; Local government, cultural council, local leader, temple, school, local philosopher and villager. Table 2 presents the

prioritizing of key stakeholders who are the most important to the community's cultural domain by using consultation continuum (Bridgman & Davis, 2004). The research identifies the local government as having the highest level of participation to the cultural domain of the community. This is due to the fact that the local government has all the resources for supporting and providing for the community. The local government also has a legitimate authority in controlling the community's activities. The second highest stakeholder is the Mea-hiya cultural council. The council's role is to be the central manager of the cultural function within the community. All annual cultural activity is conducted by the cultural council. The local leader and the temple are the next highest stakeholders. These stakeholders are recruiter. They can gather the villagers, call a meeting and assign a job to a person. The next are schools. The schools support the cultural activities by attending meetings, sending students to join the events and sometimes conduct cultural activities for students in the school. Next is the local philosopher who provides consultations and the last one is village who participates in activities.

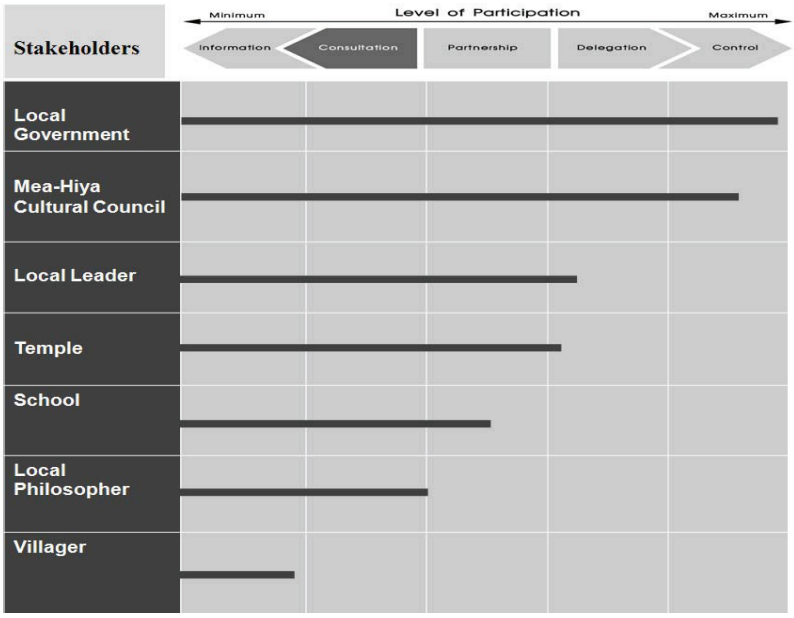

Table 2. level of participation

In order to develop strategies, the stakeholders' need and expectation is needed to verify the representatives of each stakeholder group selected (35 representatives are selected). Nineteen needs and expectations are indentified and categorized into five strategies (Table 3). From the stakeholder's strategies, the focus group is conducted to indentify the strategies' Key Success Factors (KSFs). Ten KSFs are indentified (Table 4). This step provides the needs and expectations to be more quantifiable. As a result, the community's cultural council will have specific actions to reach their goals.

Stakeholders	Needs & Expectations	Stakeholders' strategies
Local Government	• To conserve, support and restore the local culture • Cooperation from citizen (private, household, temple and school)	S1: To conserve, support and restore the local culture
Mea-hiya Cultural Council	• To disseminate the right information to the public • To conserve local culture • To supporting the youth for cultural development	S2: To promote community cooperation
Local Leader	• Cooperation (government, villager, school and temple) • Budget supporting	S3: To focus on children and school for cultural development
Temple	• Cooperation • Children and school are important "for cultural development" • To make cultural inventory from local philosopher	S4: To make traditional knowledge inventory from local philosopher and expertise
Local Philosopher	• To make cultural writings from people with expertise of that specific field • Cooperation • To disseminate the right information to the public	S5: To disseminate the right information to the public
Villager	• Cooperation • Budget supporting • Transfer the cultural knowledge to children	
School	• To make cultural writings from local philosopher and expertise • Local history study • Focus on the youth	

Table 3. Stakeholder's strategies

Stakeholders' strategies	KSFs
S1: To conserve, support and recover the local culture	S1K1: Increase budget
	S1K2: Policy support
	S1K3: Constructing a Mea - hiya history center (for learning)
S2: Community cooperation	S2K1: Strong Networking
	S2K2: Supporting "the Three Generations Center"
S3: To focus on Children and school	S3K1: Local history subject in schools
	S3K2: Create the youth groups & support Activities
S4: To make document from local philosopher and expertise	S4K1: Intensive seminars
	S4K2: Focusing on local philosopher
S5: To disseminate the right information to the public	S5K1: Strong Public relations

Table 4. Key Success Factors

The key stakeholders selected 30 indicators for the ten strategies (Table 4). However, in this case, the stakeholders try to select the easiest and uncomplicated indicators based on their understanding; such as the number of the people who are involved in the activity or the number of seminars. Both examples are easy to count. In addition, the 30 selected indicators are put together and arranged according to the particular outlook of the community intangible capital. Sixteen indicators link to structure capital, twelve indicators link to relational capital and eleven indicators link to human capital (Table 5). Relational Capital and Human Capital were found to be almost equal in importance, but Structure Capital was especially important.

Thus, the direction of Mea-hiya community cultural management is to focus majorly on structure capital. The result concurs with that Structure Capital is the most important part for Mea-hiya community because it serves as an initial stage vehicle to manage their traditional knowledge.

Stakeholders' strategies	KSFs	Indicators
S1: To conserve, support and restore the local culture	S1K1: Increase budget	S1K1I11: The increasing percentage of the local government budget S1K1I22: The amount of money that is supported by local private units
	S1K2: Policy support	S1K2I13: The number of cultural public policy S1K2I24: The strategic planning of the cultural policy S1K2I35: The number of projects/activities which relate to cultural policy
	S1K3: Constructing a Mea - hiya history center (for learning)	S1K3I16: The number of members S1K3I27: The number of media alternatives for studying S1K3I38: The number of subject manual to guide people's learning
S2: To promote community cooperation	S2K1: Strong Networking	S2K1I19: The number of people who involve in the projects/activities. S2K1I210: The number of project/activity that use participation process S2K1I311: The percentage of people that satisfy the projects/activities
	S2K2: Supporting "the Three Generations Center"	S2K2I112: The number of member S2K2I213: The number of people who are involve in the projects/activities. S2K2I314: The number of project that collaborates with all three generations
S3: To focus on Children and school	S3K1: Local history subject in schools	S3K1I115: The number of students that study the cultural subject S3K1I216: The number of subjects in the school curriculum which can integrate cultural concept S3K1I317: The number of local philosophers who are involve in teaching activities
	S3K2: Create the youth groups & support Activities	S3K2I118: The number of children who are involve in the projects/activities S3K2I219: The number of activities S3K2I320: The amount of budget
S4: To make cultural inventory from local philosopher and expertise	S4K1: Intensive seminars	S4K1I121: The number of seminars S4K1I222: The number of cultural subjects and inventories S4K1I323: The number of local philosophers and experts involve in the activities S4K1I424: The number of training program in cultural subject for the villagers
	S4K2: Focusing on local philosopher	S4K2I125: The number of local philosophers that are recognized and admired S4K2I226: A program to look after the well being of local philosophers S4K2I327: The number of cultural inventory that come from local philosopher's knowledge
S5: To disseminate the right information to the public	S5K1: Strong Public relations	S5K1I128: The number of media alternatives partnership S5K1I229: The number of project that collaborates with external organizations S5K1I330: Good image on part of the community

Figure 4. Strategy, Key Success Factor & Indicators

KSFs	Indicators	Capital Focus
S1K1:	S1K1I11: The increasing percentage of the local government budget S1K1I22: The amount of money that is supported by local private units	Human focus
S1K2:	S1K2I13: The number of cultural public policy S1K2I24: The strategic planning of the cultural policy S1K2I35: The number of projects/activities which relate to cultural policy	
S1K3:	S1K3I16: The number of members S1K3I27: The number of media alternatives for studying S1K3I38: The number of subject manual to guide people's learning	
S2K1:	S2K1I19: The number of people who involve in the projects/activities S2K1I210: The number of project/activity that use participation process S2K1I311: The percentage of people that satisfy the projects/activities	Structure focus
S2K2:	S2K2I112: The number of member S2K2I213: The number of people who are involve in the projects/activities S2K2I314: The number of project that collaborates with all three generations	
S3K1:	S3K1I115: The number of students that study the cultural subject S3K1I216: The number of subjects in the school curriculum which can integrate cultural concept S3K1I317: The number of local philosophers who are involve in teaching activities	
S3K2:	S3K2I118: The number of children who are involve in the projects/activities S3K2I219: The number of activities S3K2I320: The amount of budget	
S4K1:	S4K1I121: The number of seminars S4K1I222: The number of cultural subjects and inventories S4K1I323: The number of local philosophers and experts involve in the activities S4K1I424: The number of training program in cultural subject for the villagers	Relational focus
S4K2:	S4K2I125: The number of local philosophers that are recognized and admired S4K2I226: A program to look after the well being of local philosophers S4K2I327: The number of cultural inventory that come from local philosopher's knowledge	
S5K1:	S5K1I128: The number of media alternatives partnership S5K1I229: The number of project that collaborates with external organizations S5K1I330: Good image on part of the community	

Table 5. Mea-hiya Community Capital Focus

DISCUSSION

The intellectual capital process provides many key benefits to Mea-hiya community.

First, the key stakeholders are selected. This means every part of community can participate in the process since the beginning. The process allows the community to focus on the right stakeholders who are the most important to the community's cultural domain (seven key stakeholders are identified for Mea-hiya community). This step provides an opportunity for the community to solve a problem due to the minimum of participation from the people in the community for managing their cultural activities.

Second, the five precise strategies are settled. The research adapts a new idea to the process. Instead of creating strategies from top down, the stakeholders' needs and expectations of community traditional knowledge would be the key element for creating the strategy of the community cultural council. The strategies which are form from the community's stakeholder can respond directly to any situation than the strategy that is formed by the central government. Such an idea includes a plan to conduct activities that will provide the community the preservation, transmission, and protection of their traditional knowledge. According to Riege & Lindsay, (2006), in order to develop strategies and identify related issues, an organization should consult with targeted groups of stakeholders. The consultation provides a better environment to facilitate debate and develop more equitable strategies. The organization needs to have a clear and transparent structure and process to keep stakeholders and their consultation focused (Byrne and Davis, 1998). In addition, the stakeholders can formulate strategies by sharing and participating from the beginning. The action of participation creates a sense of belonging in managing their traditional knowledge for the whole community. The cultural council can initiate actions to respond directly to the stakeholders demands.

Third, by using the intellectual capital process model, the community can put the strategies into practice. For successful implementation of an IC system, there needs to be a linking of the selected IC measures to the strategies (Shulver, Lawrie, & Andersen, 2000). The strategies must be used to identify the Key Success Factors (KSFs). The KSFs are a list of must do activities to achieve the strategic goals. This step provides the needs and expectations to be more quantifiable. As a result, the community's cultural council will have specific actions to reach their goals (ten KSFs are selected). Since the stakeholder's, themselves, formulate the KSFs, they are willing to take on the responsibilities. This step of the process creates some opportunities to fix the problems within an organization using identified strategies which otherwise would be forgotten due to the focus primarily on their short-term goals (Roos et al., 1997).

Fourth, the process strives to be realistic by having a measuring method in the process. This means that the process is more quantifiable. The aims of measuring is to identify the knowledge component of an organization in order to manage them so they can continually improve their performance (Marr, Schiuma, & Neely, 2004). Since this community is dealing

with non-financial data, the difficulty in measuring intangibles is because all indicators selected are proxies for the KSFs (years of experience, hours of training, and etc). However, appropriate indicators can be selected carefully by the stakeholders if they indentify the true essence of the KSFs. Rarely does only one proxy provide an accurate measure. Most cases more than one indicator is needed to get a clear and correct picture (Roos et al., 1997). In addition, the 30 selected indicators are put together and arranged according to the particular outlook of the community intangible capital. Fifteen indicators link to structure capital, twelve indicators link to relational capital and eleven indicators link to human capital (Table 7). Thus, the direction of Mea-hiya community cultural management is to focus majorly on structure capital. The relationship capital and human capital are nearly equal focus.

CONCLUSION

The paper discuss that traditional knowledge disputes have become a worldwide issue and Thailand does not have an appropriate law to protect the nation's tradition knowledge. Consequently, Mea-hiya community does not have an appropriate law to protect traditional knowledge and does not know how to systematically manage their traditional knowledge. To manage the community traditional knowledge systematically and practically, this exploratory action research conducted in co-operation with Mea-hiya community developed the new concept of managing traditional knowledge by implementing an intellectual capital system. Even intellectual capital system is a business oriented concept and seldom applied to non-business approaches, especially in the traditional knowledge area. And even the intellectual capital system is not perfected (can not solve all the problems) but the real added value of the IC system is to provide a new perspective to an organization. The intellectual capital model is a process that put strategy in action. It is grounded in the organization's identity and strategy to understand who you are, and who you want to be. Since the process start with stakeholders analysis that means the real key person in the cultural field are selected and asked. This allows every part of the community participate in the process from the beginning. Key stakeholders' knowledge and opinion is considered to formulate strategies. Thus, the strategies respond directly to the situation in the community. The translation of the strategies into KFSs provides an opportunity to fix the problem that many organizations have. The problem is that the strategies tend to be forgotten by almost everybody in the company because the focus of the organization meeting with their short-term goals. Up to this step, the process is not doing anything out of ordinary. The process of creation of strategy and KFSs are established practices in many academic and practitioner community. The challenging of the process is to measure each KFS. The way to measure the achievement of each KFS is to put indicators to reflect the KFS. The aim of measuring is to identify the knowledge component of organization in order to manage them so they can be turned into continuous performance improvement. This process is practical and quantifiable. Furthermore, during the selection of KFSs and indicators, the stakeholders need to participate and provide their knowledge to generate these matters.

ABSTRACT

Knowledge management (KM) is deemed an essential activity for business entities to survive or obtain competitive advantages, and the process of knowledge sharing especially affects the performance of KM implementation. However, this always involves varied and complex human behavior, and the interactions among organization members and organizational practices are deeply related to the organizational climate as well as to information technology. Hence, this research is first based on the viewpoint of behavioral science to explore the factors influencing knowledge flow in organizations, and then aims to evaluate the revised CHAT model as a mechanism for detecting potential barriers and relationships among them within. In addition, we verify the research findings by way of questionnaire collection and analysis, and finally present a relatively comprehensive approach and research propositions for academics or practitioners to better manage KM implementations.

Keywords: Knowledge Flow, Knowledge Sharing, Barriers to Knowledge Flow, Knowledge Management, CHAT

INTRODUCTION

Knowledge is a fundamental asset for firms. People bring knowledge and experience to the situation when they address complex, unstructured problems, and as they interact during the process of problem solving, creating, using, and sharing knowledge [1]. Knowledge has been described as information combined with experience, context, interpretation, and reflection [2, 3]. Knowledge is embedded and flows through multiple entities within a firm, including individuals with domain expertise, specific best-known methods, or lessons learned from similar experiences, documents, routines, systems and methods. Increasingly, knowledge is distributed across individuals, teams, and organizations. Therefore, the ability to create, acquire, integrate, and deploy distributed knowledge has emerged as a fundamental organizational capability (Sambamurthy and Subramani 2005; Phusavat, Kess et al. 2008; Soosay and Hyland 2008). Knowledge management is the discipline of enabling individuals in an organization to collectively acquire, share and leverage knowledge to achieve organizational objectives. KM is evolving into a strategically important area, and is closely related to an organization's static substance and dynamic process knowledge [4]. Broadly, it can be viewed as the process by which organizations leverage and extract value from their intellectual or knowledge assets. Effective KM can enhance efficiency and productivity, ultimately help achieve long term corporate goals, and is thus truly a goal-directed and value-added activity [5]. However, KM may achieve nothing without clear goal setting and appropriate methods, since staff interactions and consequently human behavior decide the quality of KM implementations as well as how smoothly the knowledge flows. Due to the current complex and turbulent environment, non-linear relationships, the holistic nature of data, knowledge and wisdom, all of which interact with human behavior [6], need to be

considered when examining KM. In addition, among the existing mechanisms of knowledge delivery and sharing, information technology (IT) is probably the most essential [7, 8], and thus IT-based knowledge management will be discussed further in this study. Knowledge flow is concerned with developing channels or networks between knowledge providers and seekers. In an organization, knowledge flow is fundamentally driven by communication processes and information flows [9]. The mechanisms of knowledge flow can carry, share, and accumulate knowledge when it goes through from one individual to another. In addition, the approach for coordinating the knowledge flow process with the workflow process can provide an appropriate way to model the distributed work process [10], since, in essence, the process and outcome of knowledge flow are mainly affected by human behavior. Extending the idea that knowledge comes from people and their activities, one of the approaches selected as the initial model is the cultural historical activity theory (CHAT) [11]. It emphasizes contextual factors and proposes that human activity is mediated by cultural signs such as: words, tools, and communities, which cause changes in that activity, and thus also affect people's opinions and attitudes. Furthermore, CHAT can maintain a holistic view of the problem and allow for the messiness of context and diversity [12]. Different from previous research, we first focus on the nature of knowledge and KM activities, starting from the human activities literature in social science and then combining different but comprehensive views from academics and practitioners to develop a model for simply, broadly and deeply studying the activities of KM in business entities, especially with regard to knowledge flow. Therefore, the main purposes of this study are as follows.

(1) To evaluate the revised CHAT as a framework for business entities to comprehensively observe and manage knowledge management implementation.

(2) To explore the relevant factors which affect knowledge sharing or transferring as well as the barriers to knowledge flow.

(3) To further discuss the relationship among barriers to knowledge flow and the managerial implications. This is an empirical study to conduct qualitative and quantitative research on knowledge sharing and transferring from the perspective of knowledge flow in organizations. Hence, in section one, the basic concept of the framework for exploring and constructing what and how those relevant factors affect knowledge sharing and integration are demonstrated, with the theoretical framework and related literature reviewed in section two. Section three describes our research methodology for exploring factors influencing knowledge flow based on a revised CHAT model, and then we will further verify and validate the research findings both through qualitative and quantitative analysis. In section four, we discuss the research results and findings, and briefly explain the related managerial implications as well as the limitations of this work.

THEORETICAL FRAMING

Knowledge basically comes from people, and is a complex concept, with a number of factors determining the nature of knowledge creation, management, valuation, and sharing [13]. Since human behavior plays a critical role in knowledge management activities, we first review the social science literature related to human activities and then select the cultural historical activity theory (CHAT) as the initial model for studying the activities of KM. CHAT has been widely used in previous studies on education, information system and knowledge management [12, 14-16]. Different from the rationality and bounded rationality models [17-19], CHAT emphasizes contextual factors and proposes that human activity is mediated by cultural signs such as words, tools, and communities, which cause changes in

that activity, and thus peoples' attitudes and opinions. Consequently, CHAT has four components: subject, object, tool, and community. The four elements influence the outcome of a human activity, and particularly the related mental activities [14]. CHAT motivates analysts to seek out and explain the internal contradictions and socio-cognitive dissonance embedded in collaborative work practices [20], and hence it takes human activity, particularly mental activity, as the basic component in purposeful human work [21]. The fundamental CHAT principle is thus the unity of consciousness and activity, where "the human mind emerges and exists as a special component of human interaction with the environment" [16]. The mind can therefore be analyzed and understood only within the "context" of an activity. The four components of CHAT can be seen in Figure 1. "Subject" refers to the active, cognizing individual or social group with consciousness and will. "Object" refers to that towards which the subject's cognitive or other activity is directed. Not only is the object altered through interaction with the subject, but knowledge develops only through the interaction of the subject and object. An "activity" is undertaken by a human "subject" motivated towards an "object", producing outcomes and mediated by "tools" and "community".

[Take Figure 1 about here]

Insights from the Existing Literature

Knowledge Flow

Knowledge flow is defined as the movement and availability of information; and the literature notes the human conduits of such flows [10, 22]. It is concerned with developing channels or networks between knowledge providers and seekers, and knowledge flow in an organization is fundamentally driven by communication processes and information flows [9]. Moreover, organizational knowledge flows can be greatly facilitated if knowledge is codified, i.e., packaged into formats that allow its transmission to other subunits [23]. In addition, coordinating the knowledge flow process with the workflow process can provide a better way to model the distributed work process [10]. Consequently, to better understand the mechanisms and barriers affecting the outcome of knowledge sharing and knowledge integration, we present the determinants of knowledge flow as follows. In general, knowledge flow is most likely influenced by four factors: the knowledge transferred, the source, the receiver, and the context in which the knowledge flow takes place [9, 24, 25]. Without noting the "context", Zhuge (2002) indicated three crucial attributes of knowledge flow: direction, content and carrier. Bock and Kimfound (2002) found that the expected associations between knowledge sharers and expected contribution to the organization are major determinants of individual attitudes toward knowledge sharing [26]. However, these determinants may become barriers if not applied appropriately. KPMG's survey [27] suggested that the biggest barrier to organizational knowledge usage is a blocked channel between the knowledge provider and seeker. Blockages arise from causes such as temporal limitations, lack of staff motivation and willingness, as well as lack of incentives. Jain et al. (2006) conclude that the strongest barriers are lack of rewards and recognition, lack of time, and lack of formal and informal activities to cultivate knowledge sharing [5]. In addition, a culture that does not provide sufficient support, lack of interaction between knowledge providers and receivers, lack of a sharing system, a physical work environment that restricts knowledge sharing, a lack of trust among staff [28], fear of knowledge being misused by taking unjust credit for it, poor verbal/written communication and interpersonal skills, and inappropriate use of IT systems are all the obstacles to knowledge sharing activities [29]. Dixon (2002) believed that lack of absorptive capacity, the assumption behind the question (i.e. the context), the relationship between knowing and identity, confidence in the source of knowledge and the

suitability of the knowledge for the project are all drivers as well as inhibitors of knowledge sharing [30]. Ndlela and du Toit (2001, 2008) indicated that people related issues, including unwillingness to share knowledge and lack of leadership commitment, as well as time and resource constraints, could be barriers when trying to implement a KM program [31-33]. Synthesizing the related literature reviewed above, we classified the factors influencing of knowledge flow into the following categories:

Knowledge characteristics

Many studies have found that the characteristics of the knowledge being transferred are the most influential factor for effective knowledge flow [34-36]. Casual ambiguity and the unproven nature of the knowledge are two major things which hinder flow. Casual ambiguity emerges when the precise reasons for success or failure in replicating a capability in a new setting cannot be determined. This is common because tacit knowledge is embodied in human skills, and thus it is difficult to measure its marginal contribution. In addition, knowledge without a proven record of past usefulness is also more difficult to transfer [25].

Knowledge sources

Riege concluded that the barriers concerning the sources of knowledge are lack of time, fear of reducing or jeopardize job security, low awareness and realization of the value and benefit of knowledge sharing, poor communication skill, fear of losing the ownership of intellectual property and lack of trust in others [37]. Dixon (2002) indicated that knowledge sharing is a voluntary action. Hence, efficient sharing depends on the willingness of individuals to signal to the organization which knowledge they possess and to share it when requested. However, individuals and teams that have invested resources in building up a specific competence may not be willing to share this knowledge with others unless they are given the right incentives for doing so [13, 30]. On the other hand, Dixon also pointed out that when making decisions based on external knowledge, it is critical for the knowledge receiver to have confidence in the source.

Knowledge receivers

A precondition for the knowledge receiver is that they have sufficient prior related knowledge to assess the value of the new information, (i.e. absorptive capacity) [30, 38], and also not resist using knowledge from outsiders (not-invented-here, or NIH syndrome) [39]. Szulanski (1996) classified the barriers concerning knowledge receivers as lack of motivation, including NIH syndrome, lack of absorptive capacity and lack of retentive capacity [25]. Riege (2005) mentioned that lack of trust in the accuracy and credibility of knowledge due to the source is a barrier to receivers using knowledge from outsiders. In addition, culture, language, technology, discipline and level of experience all have influences on absorptive capacity [30].

Contextual factors

Context is defined as “a wider dynamical process of which the cognition of an individual is only a part” [40]. Nonaka and Konno (1998) tried to define “context” by introducing the concept of “ba”, which is an open space where participants with their own contexts can come and go and the shared context can continuously develop. This space can be physical (e.g. an office or dispersed business space), virtual (e.g. e-mail or a teleconference), mental (e.g. shared experiences, ideas, ideals), or any combination of these [41].

Context helps to determine the features of a practice [42]. Knowing how context emerges and transforms is significant if we want to understand how people create, use and share knowledge. Context has been recognized by many KM researchers as being a crucial component to improve the understanding of knowledge [43]. During problem solving processes, people develop and modify their inter-subjective understanding, and as a consequence of these processes, the context emerges and transforms. In turn, context influences what knowledge people choose to create, use and share, and thus influences what problems can be addressed and how they are solved [1]. Next, we categorize the contextual factors concerning knowledge flow barriers into "the relationships between the knowledge sources and knowledge receivers", "organizational context" and others, which are described in detail as follows:

(1) Relationships between knowledge sources and knowledge receivers Individual perceptions of approachability, credibility and trustworthiness mediate knowledge import and sharing. Lack of contact time, interaction and differences in experience level between knowledge sources and receivers are the barriers to knowledge sharing [37]. Szulanski (1996) found that there are "arduous relationships" between knowledge sources and receivers and the success of such relationships depends to some extent on the ease of communication and on intimacy. In addition, unawareness on both ends of the transfer is another barrier to knowledge sharing, and the larger the organization, the greater this problem is. The relationship herein is this a complex web of interdependent social and organization networks [44].

(2) Organizational context Szulanski (1996) believed that a barren organizational context leads to the stickiness of knowledge transfer [25], while formal structures and systems, sources of coordination and expertise, and the behavior-framing attributes of the organizational context facilitate attempts to transfer knowledge.

Culture and cultural characteristics constitute a key determinant of managerial practices [45], and consequently may have a great impact on the process of knowledge transfer within and among organizations [46]. Brown and Woodland (1999) also noted that organizational culture can be a major barrier to both organizational and individual learning [47, 48]. There are three components of organizational culture that are related to effective knowledge sharing, namely a clear organizational vision and goals, trust, and social networks [49], all of which can exert positive effects on employee knowledge-sharing capacities. Meanwhile, De Long and Fahey (2000) identified four ways in which culture influences the behaviors central to knowledge creation, sharing and use [48]. First, culture, and particularly subcultures, shape assumptions about what knowledge is and which knowledge is worth managing. Second, culture defines the relationships between individual and organizational knowledge, determining who is expected to control specific knowledge, as well as who must share it and who can hoard it. Third, culture creates the context for social interaction that determines how knowledge will be used in particular situations. It represents the rules and practices that determine the environment within which people communicate. Fourth, culture shapes the processes by which new knowledge is created, legitimated, and distributed in an organization. De Long and Fahey (2000) warned that low-trust cultures constrict knowledge flow and suggested that managers develop a strategy and specific interventions to align the firm's culture in support of more effective knowledge use. In addition to organizational structure and culture, time constraints [50, 51], poor organizational incentives [51, 52], legal and policy constraints [53], lack of leadership, low level of co-worker supervision, inadequate company resources, a poor physical work environment, lack of formal and informal spaces to share and the too large size of business units [36, 37, 54-56] also inhibit the collection of

embedded knowledge in a written form.

The mechanisms for knowledge flow basically contain the "tangible" mechanisms, such as telephones, discussion rooms or computer networks, and "intangible" mechanisms, such as unscheduled meetings, informal seminars, or coffee break conversations [63]. Riege (2005) pointed out the potential technological barriers to knowledge sharing involved a lack of integration of IT systems and processes, the unrealistic expectations of employees, lack of compatibility between diverse IT systems, a mismatch with individuals' needs, a lack of employee familiarity and experience with new IT systems, a lack of training regarding such familiarity, and a lack of communication about the advantages of the new IT systems to employees [37]. Drawing from prior discussions, we summarize and classify the relevant factors influencing KM as well as the barriers to knowledge flow in Table 1, using five dimensions based on the CHAT model and Lin's findings [12].
(3) Other contextual factors Doz, Santos et al. (2001) indicated that geographical dispersion, context differentiation and the competitiveness within business units [35, 37, 57] all influence the process of knowledge sharing between units in complex organizations. In addition, a shared language also plays an important role in the knowledge sharing process [58], as people tend to build up their own boundaries, often creating overly technical terminology so that others cannot participate in what they do [59]. Dixon (2002) conducted interviews and found that when sharing knowledge, the knowledge sharer will need to know why the question is being asked as well as the context in which the question is embedded. Moreover, when making decisions, the sharer should further examine how the situation the knowledge provider is describing fits the application that the receiver has in mind [30]. According to Koskinen (2005), knowledge is acquired and transmitted through symbols with an efficiency that will vary depending on the characteristics of the communication channels used for transmission, such as face-to-face, telephone, written personal, written formal and numeric formal. Minimizing the loss of information caused by the use of a single channel requires either the simultaneous activation of several channels of communication [59-61].

(4) Inadequate/ mechanisms Knowledge flow is concerned with developing channels or networks between knowledge providers and seekers, and seems to be the most practical area in knowledge management [9]. KPMG's [27] survey suggested that the biggest barrier to organizational knowledge usage is a blocked channel between providers and seekers. Ruddy (2000) argued that improving knowledge sharing in a meaningful way requires a "delicate marriage of technology with a keen sense of cultural or behavioral awareness". But technology that works effectively in some contexts may fail in others, and the key issue is thus how to choose and implement a suitable technology that provides a close fit between people and the organization [37, 62]

[Take Table 1 about here]

Knowledge Sharing

Knowledge sharing can be defined as activities for transferring or disseminating knowledge from one person, group or organization to another, including both tacit and explicit knowledge [64]. Fernie et al. (2003) believed that explicit knowledge lends itself easily to sharing, while the sharing of tacit knowledge is argued to be of a more complex nature, because it is difficult to extract from the knower [65]. Shin, Holden et al. (2001) regarded knowledge distribution, transformation, dissemination, transference and sharing as all analogous to knowledge sharing with regard to the knowledge management value chain [9]. Some researchers have argued that knowledge sharing is the product of socialization, and is a

process of knowledge creation [13, 65]. From the viewpoint of knowledge-based systems (KBS), Correa da Silva et al. (2002) defined knowledge sharing as "the process of conveying knowledge embedded into one KBS to another" [66]. Shin, Holden et.al. (2001) believed that knowledge sharing is the dyadic exchange of knowledge between source and receiver, and that it is one of the most important and common managerial issues. Balasubramanian et al. (1999) presented a "knowledge mill" framework for describing knowledge management processes-capture, transformation, classification, maintenance, discovery and dissemination. The dissemination process, i.e. sharing, determines how people gain access to the knowledge content, with the objective of making it easy for people to find what they are looking for. Davenport and Prusak (1998) defined knowledge management as a process of capturing, storing, sharing, and leveraging knowledge [2]. Bock and Kim (2002) indicated that sharing knowledge is often unnatural, and people may be reluctant to do so if they think their knowledge is personally valuable and important [26]. Therefore, based the theories of economic and social exchange, they developed a model concerning knowledge-sharing behavior. Economic exchange theory concerns extrinsic benefits, which emphasize rewards and incentive programs, while social exchange theory concerns intrinsic rewards, which engender feelings of personal obligation, gratitude and trust.

CHAT model and knowledge flow

Since CHAT attempts to explain the complexity of human and mental activities, and Hasan and Gould (2001) proposed a sense-making activity model based on CHAT, we regard it as suitable for describing KM activities. Figure 2 presents how the CHAT framework can be applied to sense-making activities. In addition, CHAT has been used to describe the relationship between a subject and an object, which is analogous to the knowledge source and the knowledge receiver in the process of knowledge flow. Therefore, the CHAT framework should be able to provide the structure and substance for this research, while at the same time maintaining a holistic view of the problem and allowing for the messiness of the contexts and diversity of stakeholders' perspectives [12, 14].

[Take Figure 2 about here]

In order to comprehensively frame the theoretical perspectives and assumptions that are available for knowledge flow research, we based our work on the initial idea of cultural historical activity theory [11, 21], and adopted the revised CHAT as our theoretical framework [12]. CHAT allows us to carve the theoretical landscape into five domains: subject, object, tools, community and outcomes, and the domains may contain most of the factors concerning knowledge flow. "Subject" refers to "knowledge source"; "object" refers to "knowledge receiver"; "community" refers to "context", and "tools" refers to "mechanisms". Figure 3 presents how CHAT can be applied to describe knowledge flow determinants.

[Take Figure 3 about here]

RESEARCH METHODOLOGY AND ANALYSIS

To test the proposed research model (i.e. the revised CHAT model), we adopted in-depth and face-to-face interviews for concept building and transcript generating, the survey method for data collection, and then examined our propositions by using a questionnaire with a five-point Likert scale (from "strongly disagree" to "strongly agree"). This research was

exploratory and qualitative in nature, and consisted of two phases. Phase I was the literature review and in-depth interviews to explore the mechanisms and barriers regarding knowledge flow and KM activity under a revised CHAT framework (see Figure 2). In order to further evaluate and comprehensively confirm the propositions from phase I, the questionnaire was used to validate the propositions from phase 1. The research process is shown in Figure 4.

[Take Figure 4 about here]

Research Framework

According to both the theoretical and practical concerns, we explored the factors influential to knowledge flow in business based upon the revised CHAT framework [21] and Szulanski's findings [12, 25]. Although there was a similar study was done by Lin et al. (2008), it only conducted CHAT in a single hospital, where the activities are totally different from those in a business. Thus, we extended the revised CHAT model with some modifications to be suitable for exploring the barriers of knowledge flow in commercial entities and its various activities.

This study not only used the four elements of "subject" ("knowledge source"); "object" ("knowledge receiver"); "community" ("contextual"), and "tool" ("mechanism"), but also adopted the factor of "knowledge sharing and transferring" which was emphasized in Szulanski's work [25] and specified as a vital construct of knowledge flow. The most important assumption of CHAT is that all human and mental activity is mediated by the use of tools and the community in which it occurs [14], and thus in this study we assumed that all the elements of knowledge flow affect the outcome of knowledge sharing and integration. Secondly, knowledge sharing and integration are perceived as an "activity" in the CHAT approach. The research framework is shown in Figure 5.

[Take Figure 5 about here]

Measurement and Data Collection

Phase I Study

We conducted in-depth interviews with the managers of the selected sample companies and got twelve transcripts in total. The size of the participating companies ranged from medium and large-sized manufactures to multinationals, employing workforces of between 450 and 19,000. In addition, all of the firms were selected according to the best practice of KM in Taiwan. The interviews were performed from August 2006 to July 2007. All individual in-depth interviews were face-to-face and lasted for between sixty and ninety minutes, were audio-taped and transcribed verbatim. Observation and informal conversations also constituted an important part of the data collection process. In the process of data-organization, we adjusted the classification framework continuously. If any information was ambiguous or insufficient, we contacted the respondent again to confirm the data. Consequently, three researchers who were familiar with KM implementations conducted the content and context analysis, thoroughly reviewing all the transcripts and classifying statements by themes, and then jointly reviewing each statement. Any disputes about the status of statements were discussed until ideally a consensus was reached.

Phase II Study

In order further evaluate and verify the propositions which were generated by content analysis in Phase I, a questionnaire was developed with each item measured on a five-point Likert scale (from "strongly degree" to "strongly disagree") for further testing [67]. After all of questionnaires were reviewed both by academics and practitioners, 30 samples were selected for a pilot survey preformed from March 20th to April 10th 2008. In order to increase the response rate and reduce the delivery cost, an electric questionnaire was used to collect data from randomly selected listed companies in Taiwan. A One-Sample T-test was used to test the hypothesis (H1: $\mu \geq 3.5$ and H1: $\mu \geq 4$) with a 95% confidence interval (p-value is 0.05) for responses about the mean, where the data are a random sample of independent observations from an underlying normal distribution.

ANALYSIS AND VALIDITY

Results from the Phase I Study and Construct Validity

Based on the results of the face-to-face interviews and qualitative analysis, the related themes are summarized in Table 2. All of them were reviewed at least twice review by three coders and confirmed by the participants in this study. After the discussions with the experts who participated in this research, it was confirmed that the revised CHAT model was suitable for studying the activities of KM implementation. In addition, some other important issues concerning knowledge were uncovered, leading to the development of more research propositions. Lastly, the barriers to knowledge flow were classified into five categories, and the relationships among them are also discovered. After much analysis and discussion, 1,145 themes were chosen, with 862 themes that two or more coders agreed on. As a result, the degree of inter-coder agreement is 75.3%, and the reliability of this research is 85.9%. This also indicates the classification between the coders reveals a consistent viewpoint.

[Take Table 2 about here]

We summarize some the themes and statements regarding the association between barriers to knowledge flow with the material in Table 3, as excerpted from the interviews. It not only shows which barriers affect others, but also suggests additional research propositions for further testing. The casual relationships or the stories behind them are also worth investigating in order to observe and manage KM activities. We present the well-ranked factors in Table 2 and the associations among barriers in Table 3 as the proposed research propositions (as well as the questionnaire's measurement items, shown in Table 4) to further test in Phase II.

[Take Table 3 about here]

Results from Phase II and Construct Validity

A total of 109 usable responses were returned, yielding an effective response rate of 60.55%. In this phase, the reliability (internal consistency) and construct validity were established by Cronbach's α method and item-total correlation. As shown in Table 4, all of the questions were found to be highly reliable, with a Cronbach's α of greater than 0.7 [68, 69]. As seen in Table 5, the Cronbach's α of the questionnaire was 0.887, which means not only did the questionnaire have high consistency and that the answers were highly reliable, but also that the questionnaire did not need any item to be changed to increase the reliability. The item-total correlation was used to measure criterion-related validity. The correlation between each of the remaining 20 items and their sum was calculated, and is shown in Table 4. Nunally

(1978) recommended that items with Item-Total Correlations (ITC) below 0.4 should be excluded [68, 70], and thus items 5 and 6 were dropped from further propositions testing. In addition, the Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy and Barlett's sphericity test were conducted to verify the questionnaire. A KMO value greater than 0.7 is viewed as acceptable [71], and Table 5 shows that the questionnaire achieved this and that the results of Barlett's sphericity test were also significant (p-value = .000). Excluding items 5 and 6, the results show the questionnaire was suitable and representative for subsequent proposition testing. In addition, a five-point Likert scale was employed in the questionnaire to measure the degree of acceptance of the propositions. A t-test for dependent samples helped us to take advantage of one specific type of design in which an important source of within-group variation (which can be considered an error) can be easily identified and excluded from the analysis [72]. Consequently, it is significant when the mean of the degree is more than 3.5 or 4. In this study, we used a one-sample t-test with test values of both 3.5 and 4 (H1: $\mu \geq 3.5$ and H1: $\mu \geq 4$, one-tailed test) with a 95% confidence level (p-value at 0.05) to check the significance of the propositions. The test results are shown in Table 6, and comparing test values 3.5 and 4, most of the items, excluding 2 and 7, were marginally accepted when the test value was 3.5. Furthermore, for strict evaluation, there are five items, 3, 14, 16, 17 and 20, which were acceptable when the test value was 4. This shows that the importance of these five items, and thus they are worthy research propositions.

[Take Table 6 about here]

DISCUSSION, IMPLICATIONS, AND LIMITATIONS

Discussion

KM ensures that knowledge flow can take place across organizational or geographical boundaries [73]. The interaction between the business insiders and data miner is actually a knowledge sharing process, and the content is the knowledge of the organization [8]. To ensure the good practice of KM, it is important to find the boundaries and barriers which exist in the knowledge flow, in order for managers to take remedial steps to improve the situation and let the knowledge flow more freely. As our first step, we selected the revised CHAT as appropriate for exploring barriers to knowledge flow, and those barriers can be classified into five categories, namely: characteristics, source barriers, receivers, contexts, and mechanisms. Different from the previous research, which only focused on a single hospital, we broadened the scope to businesses to explore the barriers to knowledge flow and their causes and associations within organizations. We found, not surprisingly, that the KM related activities were more complex and various in businesses than in a single hospital, and the revised CHAT model was also confirmed as a suitable tool for managers to observe and manage KM activities in their organization. More surprisingly, we found that the most important and common barriers may be quite different in different organizations, and that it is thus essential to comprehensively understand the nature of KM activity and the association among barriers in a business. In this way, the research findings were separated into two aspects for detailed discussion. One of these was about the nature of the barriers to knowledge flow. After the phase II study, we found that it is reasonable to combine the dimensions of source, receiver and context as a single dimension, organizational climate, and thus the five dimensions can be reduced to three: knowledge characteristics, organizational climate, and mechanism. The second area for detailed discussion was about the associations among barriers, and the results are as follows:

(1) As shown in Table 2, the organizational structure is the top ranked factor, and is thus the most important factor for KM implementation.

(2) Extending the preliminary viewpoint, as shown in Tables 2 and 4, the organizational climate of knowledge sharing is the most general and crucial point for knowledge flow, and includes three dimensions - knowledge source, knowledge receiver, and contextual factors, and this also fits our initial assumption and the proposed revised CHAT model, which emphasized human behavior. Lazarove and Tarique (2005) argued that effective knowledge sharing occurs when there is a fit between individual readiness to share knowledge and organizational receptivity to knowledge. The intention and attitude of knowledge receivers also influences the outcome of such sharing, and thus the practice is closely associated with "people" [74, 75]. In addition, Gottschalk (2006) suggested developing an organizational culture (ranking third in Table 3) that facilitates and rewards knowledge sharing. Empirical studies have also shown that the greater the anticipated reciprocal relationships are, the more favorable the attitude toward knowledge sharing will be [76]. As Gee-Woo et al. [77] noted, effective knowledge sharing cannot be forced or mandated, and firms desiring
to institutionalize knowledge-sharing behaviors must foster an appropriate work context.

(3) With regard to the characteristic of knowledge, the factor of ambiguity is ranked second (as shown in Table 2). The ambiguity of knowledge itself is the critical barrier for knowledge sharing or transferring, and if the knowledge itself is unproven it may also impeded

knowledge flow. The characteristics of the knowledge transferred also affect the outcome of knowledge sharing, and it should be both useful and applicable. Finally, when knowledge is codified and stored, sharing is better facilitated [78].

(4) With regard to the mechanism of knowledge flow, the tangible mechanism: IT is obviously important but not crucial for knowledge implementations. Hence, how sophisticated the information technology itself is may not be as important as whether or not most members in an organization realize the advantages of both IT and KM... Another important factor about the mechanism is that integration of IT and processes, which also echoes previous research that saw IT and process reengineering, i.e. maintaining high-quality information technology, as essential as organizations move toward a "system of systems" and a "team of teams" [79, 80]. As Bhattacherjee mentioned (2006), IT managers can benefit from knowing what influence processes can be used to motivate organizational members' acceptance of IT and under what circumstances these processes are likely to succeed or fail. The tool-based mechanism and integrative are the major approaches to enhance employee knowledge sharing. It has also been noted that the flexibility inherent in an inquiring system is particularly useful for information acquisition, knowledge sharing, and organizational learning.

(5) There are certain factors that most people intuitively think are important, but which may not really be so in practice, such as knowledge being proven or not, rewards, knowledge receiver's retentive capacity, lack of contact time and interaction, unawareness of knowledge, lack of leadership, different language, technological terminology, and so on. For example, especially, uncertain and changing environment requires knowledge management activities that place more emphasis on the cognition of most members around their chief goals and less emphasis on leadership in an organization, these cognitive factors are related to the mental maps of individuals and organizational decision makers [79] Finally, according to the discussion and findings from phases I and II, the most relevant important factors are: poor

communication skills, difficult relationships between sources and receivers, lack of learning culture, poor organization structure, and lack of integration of IT systems and processes, leading to the following research propositions (see table 6):

Proposition 1: It's hard to express knowledge clearly if the knowledge providers' communication skills are poor. Proposition 2: Difficult relationships among knowledge providers and receivers may affect knowledge sharing and flowing. Proposition 3: Lack of learning culture may deter knowledge sharing and flowing. Proposition 4: The structure of an organization may deter the coordination of both knowledge source and receiver and thus further deter knowledge sharing and flowing. Proposition 5: Lack integration of IT systems and processes may deter knowledge sharing and flowing.

Managerial Implications

It is important that KM researchers be aware of, understand, and build upon the work in the existing literature. However, the previous research generally focused on exploring the factors related to success, while it may now be more valuable and helpful to have a model that takes a holistic view and aims to find the relevant factors which can detect the needs of an organization and assist managers in KM implementation. Thus, there is no optimum approach to KM implementation, but it is possible to develop an appropriate approach if there is a suitable model for observing KM activities, such as the revised CHAT framework and its relevant factors of knowledge flow. In addition, we also presented a discussion of KM activities knowledge flow barriers based on a review, interpretation, and synthesis of a broad range of the relevant literature. Knowledge may be tacit and explicit, it can refer to an object, a cognitive state, or a capability, and may reside in individuals or groups [81]; notably, KM activities involve a diverse set of behaviors. Different from the other management activities such as MIS, KM focuses more on human behavior and the organizational climate for its implementation [77], it strongly emphasis the comprehensive atmosphere of sharing and learning culture in an organization. The organizational climate is actually dynamic in nature, and teeming with the interactions among people and the organization. In short, KM is a human intensive and workforce oriented managerial activity. While leadership is crucial for management activities in any kind of organization, in KM it is not possible to rely only on a few leaders. The coordination with and understanding of most of the workforce is more important and relevant than leadership. Hence, in this research, we can infer that the revised CHAT model is suitable for KM implementation. It can not only be broadly applied to detect the barriers of knowledge flow, and can also help observe the relationship among barriers and search for particular solutions in different situations, but it is also useful for managers aiming to dynamically manage their KM activities. The research results reasonably confirm the propositions that we initially put forward, and showed the barriers which negatively affect knowledge sharing, thus implying that addressing these issues will enhance the performance of KM.

Limitations and Further Work

From the observation during the research period, although we found the empirical results do support the proposed revised CHAT model, however, there are some limitations or challenges worth noting. First of all, due to the exploratory nature of this study, the scales developed and used are necessarily experimental and the data is limited, and thus we regard this research as an illustration of theoretical ideas rather than as a definitive test. Secondly, the face-to-face interviews and transcriptions were very time-consuming, and therefore were limited to either small numbers of participants or long-term observations, which is the main

reason why qualitative and qualitative methods were combined to raise the reliability and validity in this research. Finally, the factors may be incomplete and unsuitable for any commercial organizations. In addition, Hsiao et al. [82] mentioned that the rapid pace of innovation outdates knowledge so quickly that documenting it is of limited value. Furthermore, the different national cultural norms may shape employee's attitudes, behaviors and motivation, which may pose challenges for managers of international organizations [83, 84]. Furthermore, there are some related issues worth further study, such as whether the CHAT model can be extended to the study of "organizational performance", since the associations between KM and organizational performance is what managers care about, but this has not yet been explored in the literature. Another area for future study is to replace the constructs of knowledge sharing and knowledge integration with other KM functions such as knowledge acquisition, knowledge storage.

ACKNOWLEDGEMENTS

This work was supported by National Science Council, Taiwan, R.O.C., under Grand NSC 96-2752-H-006-002-PAE. In addition, we especially appreciate comments from the experts who participated in this research and the data collection support from Ya-Chen Ko, from the Institute of Information Management at National Cheng Kung University.

THE RELATIONSHIP BETWEEN SOCIAL CAPITAL, ORGANIZATIONAL LEARNING, KNOWLEDGE INTEGRATION MECHANISM, AND HUMAN CAPITAL: A CONCEPTUAL FRAMEWORK

Ru-Jen Lin, Lunghwa University of Science and Technology, Taiwan
rjlin@mail.lhu.edu.tw

ABSTRACT

In the era of knowledge economics, human resource capital is a vital strategic asset in business activity. How to utilize social capital to strengthen human resource capital is one of urgent research issues of the contemporary human resource management field. However, human resource management research has so far ignored the mediating role of organizational learning and knowledge integration mechanism in the research model regarding the relationship between social capital and human capital. In this study, we employ organizational learning and knowledge management mechanism as mediating variables to explore the impact of social capital on human capital. We propose to sample the first three thousands manufacturers of the Commonwealth through the confirmatory factor analysis, structure equation modeling (SEM), and hierarchical regression modeling statistics approaches. The relationships among social capital, organizational learning, knowledge integration mechanism, and human capital will be examined, and the mediator impact of organizational learning and knowledge integration mechanism on the causal relationship between social capital and human capital will be verified.

Keywords: human capital, organizational learning, knowledge integration mechanism, social capital

INTRODUCTION

In the era of knowledge economics, the most important strategic resources in an organization are the intangible assets of human capital and social capital which can create and sustain a market advantage (Barney, 1991; McEvily and Marcus, 2005; McEvily and Zaheer, 1999). Social capital is defined as the embedded ties and relationship structure through trust and reciprocity between network members that they are willing to share the information and resources to acquire new knowledge and complementary assets (Dyer and Hatch, 2006). Based on the trust among the customer, supplier, and the partner relationship, the effects of embedded ties enhance the capability of new product innovation. Drucker (1992) indicated

that post-capitalist society is the era of knowledge economics and knowledge society. Human capital gradually increases the competitive advantage and plays a critical role in value creation for an organization. Adler (1988) and Reich (1991) assert that the importance of human capital is an efficient management and a kind of the equity asset in an organization. Recently, facing dynamic competition and radical technology change, managers have recognized that how to strengthen social capital and human capital is a vital strategic issue for human capital management decisions. Wang and Chang (2005) find that human capital directly affects innovation and further influence performance. Therefore, management should put the most effort on human capital.

According to most of organizational learning literature, the major discussion of social capital and human capital focused on the two main issues: (1) to investigate the effects of social capital and human capital on the competitive advantage; several empirical studies have examined the positive contribution of social capital and human capital on innovation performance, financial performance, and market performance (e.g., Capaldo, 2007; McEvily and Marcus, 2005; Subramaniam and Youndt, 2005); and (2) to investigate the effect of social capital on human capital; the firms enable to enhance their human capital effectively through a good external embedded ties relationship. Numerous studies advocate that social capital enriches employees' knowledge by internal and external network relationships (e.g., Colemen, 1988; Forgensen, 2004; Martinez-Torres, 2006; Reed et al., 2006; Wu et al., 2006).

However, how to use social capital to strengthen human resource capital is one of the imperative research issues in the contemporary human resource management (HRM). Human resource management research has so far ignored the mediating role (the contingency factor) of organizational learning and knowledge integration mechanisms in the research model regarding the relationship between social capital and human capital. From the standpoint of the dynamic environment, firms acquire knowledge through external social capital and transform employees' knowledge effectively which is largely dependent on the organizational learning (Lane and Lubatkin, 1998; Zahra and George, 2002). And knowledge integration makes the information and skills gained from internal and external expansion activities and integral component of the routines that guide the firm's future strategic actions (Teece et al., 1987). Based on this theoretical viewpoint, social capital exhibits the contribution of human capital. However, consideration of organizational learning as a mediator is neglected. Therefore, based on the dynamic capability view, we consider there is not only direct influence between social capital and human capital, but also influential mediators of organizational learning and knowledge integration mechanism. The reason for considering knowledge integration mechanism as a mediator in this study is that knowledge integration mechanism is a key element affecting all the internal and external knowledge integration

from the organizational employees (Luigi et al., 2007) as well as a direct influence on human capital. The purpose of this study is to explore the impact of social capital on human capital and employ organizational learning and knowledge integration mechanism as mediating variables.

LITERATUR REVIEW

Social Capital

In 1970, sociologists addressed the idea that social capital elaborated embedded relationships by the leverage of mutual trust and information exchange to create and strengthen individual wealth and social assets (Burt, 1997). After 1990, numerous scholars of human resource management or strategic management treated social capital as the sum of intellectual capital and competitive advantage (Chung et al., 2000; McEvily and Zaheer, 1999; Uzzi, 1996). Social capital originally referred to the relational resources, knowledge embedded, and utilized by interactions among individuals and their network of interrelationships (Loury, 1977; Nahapiet and Ghoshal, 1998). In this study, social capital indicates that network groups identified with the norms of embedded ties, common vision, and mutual benefit to apply embedded ties to share their information and resources to acquire new knowledge and complementary assets (Dyer and Hatch, 2006; Prabhu et al., 2005). This research extends Inkpen and Tsang (2005) and Nahapiet and Ghoshal (1998)'s perspectives to present trust, embedded ties, and cognition as the dimensions of social capital.

1. *Trust*

   Mayer et al. (1995) claim that trust has been viewed as an aspect of expectation and cognitive resources. When the two parties begin to trust each other based on the antecedent of mutual economic advantage and fair trade, then they are more willing to share their resources and solve their problems without worrying that they will be taken advantage of by the other party. Thus, trust implies the exchange or combination of resources to create values for network groups (Parkhe, 1998; Kale et al., 2000).

2. *Embedded Ties*

   According to the view of Gulati (1999) and McEvily and Marcus (2005), organizations facilitate embedded ties by encouraging interactions, reciprocity, information sharing, and join problem-solving in groups and networks. Several scholars also assert that the strong ties possessed by long-term cooperation among network members enable organizations reinforce their innovation capabilities (Larson, 1992; Uzzi, 1997). Similarly, primary firms have a better network system, obtain more abundant and various knowledge resource and competitive advantage (Capaldo, 2007; Nahapiet and Ghoshal, 1998).

3. *Cognition*

   Cognition is embodied in attributes like common beliefs, goals, and vision that facilitate a

common understanding of collective goals and proper ways of acting in a social system. These attributes of cognition promote individual and group actions benefiting the whole organization as well as an imperative dimension of social capital (Adler and Kwon, 2002).

Organizational Learning

Previous empirical studies regarding organizational learning focused on the results of organizational learning activities (Argyris and Schon, 1978; Senge, 1990). According to human resource management, organizational learning is based on the process of employee individual learning in the organization internally. Firms also recognize external environment change and adopt all kinds of operational knowledge modification to sustain business. In this study, organizational learning is defined as the process by which firms store and transfer employee individual experiences in databases through employee internal and external learning and experience storage in order to enhance the innovation performance (Bontis et al., 2002; Huber, 1991; Grant, 1996).

Huber (1991) and Crossan et al. (1999) develop four constructs related to organizational learning: knowledge acquisition; information dissemination; information interpretation; and application. Firms acquire knowledge from external different sources and integrate knowledge. Consequently, they would transform into new information or experience which increases their employees' knowledge and strengthen their innovation performance (Kogut and Zauder, 1992; Inkpen and Dinur, 1998; Yeung et al., 2007). Finally, firms conducting organizational learning would perform better in assimilation, integration, and application of knowledge in terms of absorptive knowledge (Cohen and Levinthal, 1990; Smith, 1995). Several scholars measure the integration of organizational knowledge from internal and external information and sources. Internal integration is the capability to focus on higher level of integration processes for extensive coordination between different specialized departments within an organization. On the other hand, external integration is the capability to link information and knowledge from their suppliers, customers, join venture partners, or external sources (Iansiti and Clark, 1994; Petroni, 1996). Knowledge application is the capability to apply the knowledge to modify the strategy, resolve problem, and improve performance within an organization (Gold et al., 2001).

To summarize the above ideas, knowledge assimilation, knowledge integration, and knowledge application are three dimensions of knowledge learning. In our study, we treat knowledge learning as mediating variables for the relationship between social capital and human capital.

Knowledge Integration Mechanism

Knowledge integration is defined as the process by which managers determine what has been learned, evaluate its potential importance in which the new knowledge can be used (Olson et al., 1995; Zahra et al., 2000). Therefore, knowledge integration mechanism is defined as the process of searching for and transferring knowledge trough the inter-department knowledge acquisition, analysis, interpretation, and integration (Olson et al., 1995; Zahra et al., 2002). In general, the structure and process focus on the actions taken to achieve functional integration (Griffin and Hauser, 1996). However, knowledge can be integrated formally or informally (Grant, 1996). In this study, we adopt Zahra et al. (2000) suggestions from formal integration perspective to define it as the process by which knowledge have gained from internal and external expansion.

To summarize the previous ideas, this study identified four dimensions of knowledge integration mechanism with knowledge acquirement, analysis, transmission, and integration.

Human Capital

Subramaniam and Youndt (2005) define human capital as the knowledge, skills, and abilities owned and utilized by individuals. Human capital represents the knowledge, skills, experience and abilities employees possess that bring unique and strategic value to firms (Barney, 1991; Ulrich and Lake, 1991). Generally, human capital usually focuses on education and training to improve their skills and experience in order to increase production performance (Becker, 1976; Schultz, 1996; Parnes, 1984). Firms may internalize employment and build employee skills through education and training; they may also externalize employment by outsourcing agents (Rousseau, 1995). The potential benefits of internalize employment encompass stable the firm's stock of skills and capabilities (Pfeffer and Baron, 1988), better coordination and control (John and Hill, 1988). Externalizing employment may provide organization with more options in both the number and types of workers used (Pfeffer and Baron, 1988; Tsui et al., 1995).

Snell and Dean (1992) assert that human capital can be influenced by massive sources of the firm's unique cultures and strategies. In the resource-based view, human resource practices that are unique, value, rare and useful can provide competitive advantages (Khatri, 2000). Therefore, the strategic value and uniqueness of human capital function refers to employee's knowledge, skills, and experience enable a firm to enact strategies that improve the operational efficiency and effectiveness, exploit market opportunities, and/or neutralize potential threats (Barney, 1991; Ulrich and Lake, 1991; Lepak and Snell, 2002).

Based on Subramaniam and Youndt (2005), Barney (1991), and Ulrich and Lake's (1991)

works, this study identified five dimensions of human capital with employee skills, knowledge, experience, strategic value, and uniqueness.

HYPOTHESES DEVELOPMENT

Social Capital and Organizational Learning

Regarding the relationship of trust in social capital and organizational learning, Burt (1982) indicated that a high trust will benefit firms to acquire diverse knowledge and information from embedded ties. Smith et al. (2005) also indicated when firms acquire more diverse external knowledge which will enhance all employees to absorb, integrate and apply new knowledge learning capability. Garcia-Morales and Llorens-Montes (2006) and Senge (1990) indicated that network members in high trust relationship facilitate individual absorbing and applying external knowledge to fit environmental dynamic changes. Similarly, network members embedding in a high trust will reduce barriers of sharing and communicating information and facilitate inter-firm knowledge transfer, absorption and application to enhance organizational learning effects (Dyer and Singh, 1998; Gulati, 1999).

Concerning networking in social capital and organizational learning, few scholars believe that strong tie networks are likely to be largely redundant network mechanism that detracts from organizational learning; but numerous scholars suppose that strong tie networks are likely to facilitate knowledge sharing and better interaction to strengthen organizational learning (Burt, 1992). Clark (1989) found that good networking between suppliers and manufacturers in Japan auto industry makes the centre automaker proactively willing to assist their suppliers in improving product quality and solving problem to effectively promote suppliers' knowledge integration and application capability (Dyer and Hatch, 2006). Several customer relationship management studies have shown that firms utilize information technology to establish embedded ties with primary customers that promptly help it to acquire more multi-market and technological information to stimulate knowledge transfer (Payne and Frow, 2000).

Referring to the dimension of cognition in social capital and organizational learning, network members possess common beliefs, goals, and vision that will create the culture of joint problem-solving. Clark (1989) indicated that suppliers who join in early new product development with their manufacturers will facilitate mutual knowledge learning through processes of join solving product quality and productive problems. Similarly, Ritter and Walter (2003) investigated customer involvement in the customer relationship management and indicated that primary customer actively participates in the process of early new product development and join product problem-solving in the market position, the manufacturer will

effectively cumulate the absorptive and applicative market knowledge and capability. In addition, Kale et al. (2000) empirical study showed that alliance partners enrich their technology knowledge by join problem-solving in development processes which enable to create patent assets. Based on these ideas, we construct the following hypothesis.

H_1: Trust, network ties and cognition of social capital has positive influence on organizational learning.

Social Capital and Knowledge Integration Mechanism

Knowledge integration is defined as the process of searching for and transferring knowledge trough inter-department knowledge acquisition, analysis, interpretation, and integration (Olson et al., 1995; Zahra et al., 2002). In order to ascertain the value of knowledge interpretation, the importance of new knowledge, and the capability of knowledge integration, firms must actively drive knowledge integration mechanism through efficient processes and structures in acquiring knowledge from high trust networks (Zahra and Nielson, 2002). Additionally, network members who realize the importance of high trust and common belief and objective may actively participate in all kinds of associations for knowledge exchange and information sharing (Frank and Richard, 2000; MacEvily and Zaheer, 1999). Firms possess a knowledge foundation more diverse and broad and will reconstruct varied knowledge elements for creating the new market opportunity (Kogut and Zander, 1992). Therefore, managers urge to develop knowledge integration mechanism to promote knowledge absorbable and applying capabilities (Galunic and Rodan, 1998).

Dyer and Hatch (2006) indicated that firms develop knowledge specificity by establishing network relation-specific between firms and primary suppliers or customers. However, knowledge specificity is embedded in some specific domains of experienced employees and obstructs knowledge reconstruction and transfer (Subramani and Venkatraman, 2003; Galunic and Rodan, 1998). Therefore, firms actively impel knowledge integration mechanism through experienced employee specific knowledge to enrich knowledge transfer and transmission (Luigi and Atuahene-Gima, 2007). Based on the discussion above, we propose the following hypothesis:

H_2: Trust, network ties and cognition of social capital has positive influence on knowledge integration mechanism.

Organizational Learning and Human Capital

Human capital is defined as employee skill, experience, knowledge and competence conducting economic activities in an organization to create both strategic value and

uniqueness in order to increase productivity (Lepak and Snell, 1999; Snell and Dean, 1992; Subramaniam and Youndt, 2005), here strategic value enables improved efficiency and effectiveness, exploit market opportunities, and neutralization of potential threats (Barney, 1991; Ulrich and Lake, 1991; Lepak and Snell, 2002). Regarding the relationship between organizational learning and human capital, Cohen and Levinthal (1990) argue that value judgment, assimilation, and commercial application from external knowledge are critical to accumulate the employees' knowledge, experience, and capability in an organization. Leonard-Barton (1992) and Itami (1987) emphasize that the employees' absorption through internal and external knowledge integration and sustained product development will effectively promote knowledge value and technological uniqueness which are the intangible assets in an organization.

Bontis and Fitz-enz (2002) propose that knowledge and technology for improving management and product innovation by in-house employees will gradually accumulate employee personal experience and knowledge storage. In other words, there are a positive influence between knowledge application and human capital in an organization. Based on the above discussions, we construct the following hypothesis.

H_3: Organizational learning has positive influence on human capital.

Knowledge Integration Mechanism, Organizational Learning, and Human Capital

With regard to the relationship between knowledge integration mechanism and human capital, knowledge integration mechanism is defined as the integrating process of organizational learning to ensure knowledge sharing, utilization and practice between departments to enhance employee knowledge and experience storage (Kumar and Seth, 1998). Madhavan and Grover (1998) propose that knowledge integration mechanism plays the role of periodic information and knowledge feedback through the integrative process and structure. Obviously, knowledge integration mechanism has a positive impact on organizational learning.

Galunic and Rodan (1998) argue that firms confronting a considerable variation in external broad knowledge obstruct the absorptive capabilities of knowledge, experience, and technology; therefore, firms for the sake of reinforcing knowledge absorptive capability of employees develop knowledge integration mechanism to increase the stored accumulation of human capital (Galbraith, 1973). On the other hand, Hoppe and Postrel' (1999) indicate that firms run the risk of knowledge transfer and diffusion that will influence internal employee knowledge integration. At this time, firms must develop knowledge integration mechanism to reinforce organizational learning and accumulate human capital. To summarize the above ideas, we propose that knowledge integration not only strengthen knowledge absorption,

integration, and application on organizational learning, but also effectively promote quality and quantity of human capital. Based on the above discussion, we propose the following hypotheses:

H_4: knowledge integration mechanism has positive influence on organizational learning.

H_5: knowledge integration mechanism has positive influence on human capital.

RESEARCH DESIGN

This paper will apply structural equation modeling (SEM) to examine the empirical data from Taiwan's marketing firms. This approach allows the simultaneous investigation of measures and the hypothesized model. There were two statistical methods to analyze the hypothesized relationship. First, we would apply confirmatory factor analysis to extract factors of dimensions in terms of social capital, human capital, organizational learning, and knowledge integration mechanism. Second, we would use SEM model to testify the meditating roles of align relationships among social capital, human capital, organizational learning, and knowledge integration mechanism on the relation between social capital and human capital.

Research Conceptual Model

Based on previous hypotheses developed, this paper formulates the conceptual research model as Figure 1.

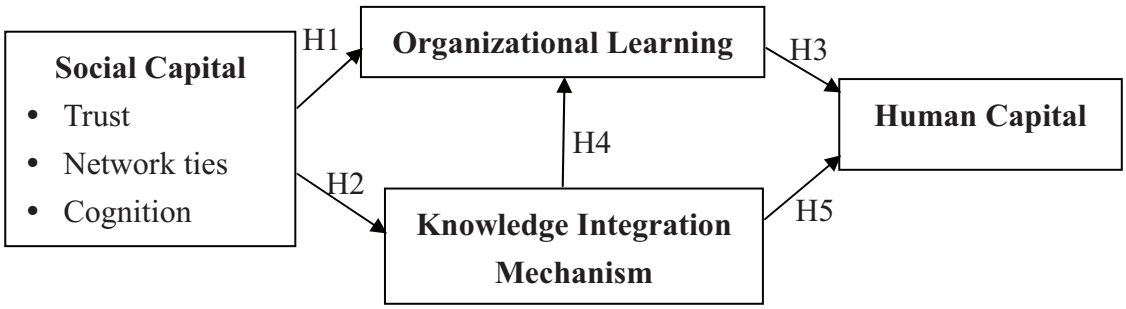

Figure 1: the conceptual research model

Sample and Data Collection

Based on previous literature, this paper explores the meditating roles of organizational learning, and knowledge integration mechanism on the relationship between social capital and human capital. The conceptual research model in this paper can serve as an initiation for further empirical study. This paper will use confirmatory factory analysis and structure

equation modeling (SEM) and hierarchical regression modeling statistics approaches to test the data collected from the first 3,000 manufacturing firms in Taiwan. In the other words, the mediator impact of organizational learning and knowledge integration mechanism on the causal relationship between social capital and human capital would be tested.

For the robustness of the study, we will test non-response bias in the data as well. In order to promote the response rate, we will contact target plant managers either by phone or letter to stimulate professional interest and improve our survey participation. Each of the variables was measured with a 7 point Likert scale (1 = strongly disagree, 7 = strongly agree).

Measurements

Based on the previous literatures, this paper identifies four dimensions in terms of social capital, human capital, organizational learning, and knowledge integration mechanism. Next, this paper will discuss measurements of these dimensions, respectively. Each of variables was measured with a 7 point Likert scale (1 = strongly disagree, 7 = strongly agree).

1. *Social Capital*

   Social capital indicates that based on network groups identified with the norms of networks, common vision, and reciprocity to apply embedded ties to share their information and resources to acquire new knowledge and complementary assets (Dyer and Hatch, 2006; Prabhu et al., 2005). This study adopts Nahapiet and Ghoshal (1998) and Inkpen and Tsang (2005)'s suggestions to develop trust, network ties, and cognition dimensions of social capital as the measured variables.

2. *Organizational Learning*

   Organizational learning is defined as firms acquire internal and external experience and knowledge thereby transferring to be the stored knowledge in databases or applying all kinds of organizational operational activities to improve the innovation capability (Huber, 1991). This study adopts Kumar and Seth (1998) and Luigi et al. (2007)'s suggestions to develop knowledge assimilation, knowledge integration, and knowledge application as the measured variables.

3. *Knowledge Integration Mechanism*

   Knowledge integration mechanism is defined as firms acquire, analysis, interpret, and integrate internal and external experience and knowledge through cross-functional structure and procedures (Zahra and Nielson, 2002). This study adopted Kogut and Zauder (1992), Crossan et al. (1999) and Gold et al. (2001)'s suggestions to develop the structure and process of knowledge integration mechanism as the measured variables.

4. *Human Capital*

   Human capital is defined as the knowledge, skills, and abilities owned and utilized by individuals. Human capital represents the knowledge, skills, experience and abilities

employees possess that bring unique and strategic value to firms (Barney, 1991; Ulrich and Lake, 1991). This study will adapt human capital aspects of Nahapiet and Ghoshal (1998) and Inkpen and Tsang (2005), and develop a seven-point scale to assess the overall skill and expertise of an organization's employees.

The questionnaire is reviewed and pre-tested by experts including managers and university faculty in the field of human resource management. Using convenience sampling method, the survey questionnaire will sent to manufacturing firms in the computer industries which are obtained from 2007 Taiwan 3,000 Manufacturers Directory. Respondents to the survey will be expected plant managers in their firm. In order to raise the response rate, we will contact plant managers of target plants by phone and by letter to stimulate professional interest and improve survey participation.

Control Variables

As a result of this study emphasis on the relationship between social capital and human capital that may be affected by of organization learning and knowledge integration mechanism as mediating variables. Firm size and the number of employees maybe affect the result of human capital (Florin et al., 2003). Therefore, this study will use firm size and the number of employees as the control variables. In addition, Pennings, Lee, and Witteloostuijn (1998) considered that human capital has high correlation with firm size and firm age. Therefore, this study not only uses firm size, but also firm age as control variables.

Statistical Methods

The conceptual research model explores the effects of social capital on human capital using organizational learning and knowledge integration mechanism as mediating variables is presenting in Figure 1. Statistical methods include: confirmatory factor analysis, structure equation modeling, and hierarchical regression analysis.

1. *Confirmatory Factor Analysis*
   Confirmatory factor analysis will be applied in this study which extracts factors of social capital, human capital, organizational learning, and knowledge integration mechanism with the principal component analysis. The principle components analysis will take the eigenvalue greater than one as the factor analysis criteria for our measured variables.
2. Structure Equation Modeling (*SEM)*
   A SEM methodology will be employed to test the hypotheses and the results of this analysis suggested to fix several indexes, such as chi-square test=6.13; the goodness-of-fit index [GFI]=.91; norm fit index [Nfi]=.96 (Bagozzi and Yi, 1988). The confirmatory

factor analysis (CFA) is to align the relationships among the social capital, human capital, organizational learning, and knowledge integration mechanism to test the convergent validity and discriminant validity.

3. *Hierarchical Regression Analysis*

   In order to further elaborate the mediation effects of the organization learning and knowledge integration mechanism on social capital and human capital, this study conducted hierarchical multiple regression to determine the best linear combination (Baron and Kenny, 1986), respectively entered variables in three stages as follows; 1 the causation between the independent variable and the mediating variable; 2.the causation between the independent variable and dependent variable; 3.mediating variables involved in regression models, based on the regression variable significant to determine the partial or full mediation effects of knowledge integration mechanism and organization learning.

Reliability and Validity Analysis

The reliability analysis uses Cronbach's coefficient alpha to judge the multi-dimensional construct of social capital, human capital, organizational learning and knowledge integration mechanism. All of the multi-item measures has to be $\alpha>0.70$, an indication of sufficient reliability (Churchill, 1979).

All measures were drawn from previous related research and aligned with the conceptual aspects of each construct. The questionnaire was pre-tested and modified by 2 academics in order to insure the survey content validity and measurement scales appropriateness. We will perform confirmatory factor analysis with Varimax rotation for data and then tested the measurement model for all items with a CFA for convergent and discriminant validity of the focal constructs.

Convergent validity concerns whether multiple measures of the same construct are in agreement. According to Anderson and Gerbing (1988), convergent validity can be tested with a measurement model pattern coefficient on its posited underlying construct is significant. The CFA use the following approach: the results of this analysis suggested to fix several indexes (chi-square test=6.13; the goodness-of-fit index [GFI]=.91; norm fit index [Nfi]=.96), and the CITC values are above 0.55 for the degree of the social capital, human capital, organizational learning, and knowledge integration mechanism exhibiting acceptable convergent validity.

Discriminant validity is an assessment of the extent by examining whether the indicators' estimated pattern coefficients loaded significantly on expected factors but not on other factors

of interest.

CONCLUSION

The most important strategic resources in an organization are the intangible assets of human capital and social capital which create and sustain a market advantage (Barney, 1991; McEvily and Marcus, 2005; McEvily and Zaheer, 1999). In this era of knowledge economics, at the standpoint of the dynamic environment, firms acquire knowledge through external social capital and transform employee knowledge effectively which is largely dependent on organizational learning (Lane and Lubatkin, 1998; Zahra and George, 2002). Knowledge integration makes the information and skills gained from internal and external expansion activities on integral component of the routines that guide the firm's future strategic actions (Teece et al., 1987). However, several previous studies of human resource management research has so far ignored the mediating role of organizational learning and knowledge integration mechanism in the research model regarding the relationship between social capital and human capital. Therefore, this study employs organizational learning and knowledge management mechanism as mediating variables to explore the impact of social capital on human capital. The relationships among social capital, organizational learning, knowledge integration mechanism, and human capital will be examined, and the mediator impact of organizational learning and knowledge integration mechanism on the causal relationship between social capital and human capital will be verified. Consequently, this conceptual framework would provide academics and practitioners for further investigation and basic of an empirical study in the near future.

APPENDIX

1. The following items had this stem and response format: "To what extent do you agree with the following items describing your organization's social capital? (1= strongly disagree; 7= strongly agree)."

Social Capital: Network Ties	Strongly Disagree←→ Strongly Agree						
1. Your company exists in embedded ties with suppliers from business activities.	1	2	3	4	5	6	7
2. Your company exists in embedded ties with suppliers from operational activities.	1	2	3	4	5	6	7
3. Your company links computer system directly with suppliers.	1	2	3	4	5	6	7
4. Your company has compatible computer system with suppliers.	1	2	3	4	5	6	7
5. Your company provides specific assets or equipment for suppliers.	1	2	3	4	5	6	7

6. Your company invests specific assets or equipment to your suppliers which is unable to shift to other companies.	1	2	3	4	5	6	7
7. Your company will consider the impact on suppliers when making important decision.	1	2	3	4	5	6	7
8. Your company is willing to cooperate with suppliers and would not disrupt this cooperation easily.	1	2	3	4	5	6	7

Social Capital: Trust Strongly Disagree←→Strongly Agree

1. Your company has high level of mutual trust with suppliers.	1	2	3	4	5	6	7
2. Your company can reliably communicate with your suppliers.	1	2	3	4	5	6	7
3. Your company has a high level of commitment to your suppliers.	1	2	3	4	5	6	7
4. Your company often communicates with suppliers face to face.	1	2	3	4	5	6	7
5. Your company share resource and technology with your suppliers.	1	2	3	4	5	6	7
6. Your company applies mutual complementary trough cooperation with suppliers.	1	2	3	4	5	6	7
7. Your company integrates different resource and capabilities with suppliers for synthesis.	1	2	3	4	5	6	7

Social Capital: Cognition Strongly Disagree←→Strongly Agree

1. Your company has a consistent goal of partnership with suppliers.	1	2	3	4	5	6	7
2. Your company shares a common goal in partnership with suppliers.	1	2	3	4	5	6	7
3. Your company can cooperate with organizational operation process with suppliers.	1	2	3	4	5	6	7
4. Your company is willing to make adjustment and change to fit the partnership.	1	2	3	4	5	6	7
5. Your company is willing to combine your efforts to obtain success with suppliers.	1	2	3	4	5	6	7

2. The following items had this stem and response format: “To what extent do you agree

with the following items describing your organizational learning? (1= strongly disagree; 7= strongly agree)."

Organizational Learning	Strongly Disagree←→Strongly Agree
1. The learning attitude of employee in the company has a positive impact on firm's performance.	1 2 3 4 5 6 7
2. Your employees eager to learn.	1 2 3 4 5 6 7
3. Your company changes its attitudes to enhance employee's learning aspiration for future development.	1 2 3 4 5 6 7
4. Employee continuing education is an investment, not an expense.	1 2 3 4 5 6 7
5. Employee's ability to learn is the key to improve achievement.	1 2 3 4 5 6 7
6. You company is concerned with the spirit of teamwork spirit than other companies.	1 2 3 4 5 6 7
7. Your company is concerned with cross-functional teamwork practices than other companies.	1 2 3 4 5 6 7
8. Your employees are better aware of your vision than other companies.	1 2 3 4 5 6 7
9. Your employees often share more knowledge and experiences than other companies.	1 2 3 4 5 6 7
10. Your employees utilize more knowledge and experience sharing than other companies.	1 2 3 4 5 6 7
11. Your company audit more failure and success endeavors than other companies.	1 2 3 4 5 6 7
12. Learning is regarded as the routines to evaluate persistent learning capability of employee.	1 2 3 4 5 6 7

3. Compare to other companies in your industry, please rate the extent you agree with knowledge integration mechanism at the following indicators (1= strongly disagree; 7= strongly agree).

Knowledge Integration Mechanism	Strongly Disagree←→Strongly Agree

1. Your company improves more tangible performance of sales revenue and intangible performance of culture and management than other companies through strategic alliances.	1	2	3	4	5	6	7
2. Your company systematically integrates more market survey or customer feedback than other companies.							
3. Your company integrates the results of market survey and customer feedback in strategic planning.	1	2	3	4	5	6	7
4. Your company reviews integrated data from departments to create the operational strategy.	1	2	3	4	5	6	7
5. Your company would integrate product line strategies of customer needs based on the external environment and internal adjustment.	1	2	3	4	5	6	7
6. Your company would integrate existing knowledge making the operational strategy, such as existing database and draw support from alliance member capability to reach win-win situation.	1	2	3	4	5	6	7
	1	2	3	4	5	6	7

4. Compare to other companies in your industry, please rate the extent you agree with your company's human capital at the following indicators (1= strongly disagree; 7= strongly agree).

Human Capital Strongly Disagree←→Strongly agree							
1. Employees are the greatest assets of our company.	1	2	3	4	5	6	7
2. Your company provides much incentive for employee continuing education. e.g., incentive pay	1	2	3	4	5	6	7
3. Your company provides employee periodic training program.	1	2	3	4	5	6	7
4. Employees always discover new products and new market opportunities.	1	2	3	4	5	6	7
5. Your employees work together to confront crises.	1	2	3	4	5	6	7
6. Your employees are recognized great achievers for enhancing the organizational performance.	1	2	3	4	5	6	7
7. You think your employees are bright and highly skilled.							
8. Your employees possess expertise.	1	2	3	4	5	6	7
9. Your employees follow your company's belief and goal.	1	2	3	4	5	6	7
	1	2	3	4	5	6	7

ABSTRACT

Ontology allows web content to be represented in a structural form by a finite list of vocabularies and their relationships. Thus, the concept of ontology and its related mediation methods is capable of enhancing the collaboration among Knowledge Management (KM) approaches that only focus on managing organizational knowledge. Those KM approaches are developed in accordance with organizational KM strategies and business requirements without the concern of system interoperation. In this research, a collaborative inter-organizational KM network is proposed to provide a platform for organizations to access and retrieve inter-organizational knowledge in a similar domain. Ontology and its mediation methods are applied to the proposed KM network to enable heterogeneous Knowledge Management Systems (KMSs) from different organizations to communicate, cooperate, exchange as well as reuse knowledge with one another. A selection framework is also proposed to assist organizations in choosing suitable ontology mediation approaches. The retrieved inter-organizational knowledge could be used to support organizational KM process. While knowledge engineers could reuse inter-organizational knowledge to create and evaluate organizational knowledge, general users are benefit from the effectiveness and efficiency in searching for relevant inter-organizational knowledge within the network.

Keywords: Ontology, Mediation, Mapping, Merging, Integration, Knowledge Management

INTRODUCTION

Over the past two decades, a lot of efforts have been placed in order to integrate heterogeneous information systems. This integration is essential because systems of different characteristics would be able to communicate, cooperate, exchange information as well as reuse knowledge and services with one another. Especially in the era of the Internet, a transaction can hardly be completed without making use of others' data, information, knowledge and services. For instance, when customer is shopping in an online store, s/he may need to seek comments on the quality of a particular product from an external forum. Once s/he decides to purchase the product, the online store will have to contact related financial institutes for payment verification and confirmation. The online store is also required to arrange delivery service with

shipping company. Such a simple online shopping transaction would involve interoperation of at least three heterogeneous information systems, the complexness could be imagined if it is a multi-million trade that involves the participation of more enterprises.

Artificial intelligence researchers first applied the concept of ontology in intelligence system development so that knowledge could be shared and reused among artificial intelligence systems. Ontology as a branch of philosophy is the science of what is, of the kinds and structures of objects, properties, events, processes and relations in every area of reality (Smith 2003). Ontology can be further elaborated as a particular system of categories accounting for a certain vision of the world (Guarino 1998). The term, ontology, was then borrowed by artificial intelligence community and Tom Gruber's definition was widely accepted within the community: an ontology is an explicit specification of a conceptualization while a conceptualization is an abstract, simplified view of the world that we wish to represent for some purpose (Gruber 1993). Later on, Borst (1997) refines Gruber's definition by labelling an ontology as a formal specification of a shared conceptualization. Based on Gruber's and Borst's definitions, Studer, Benjamins and Fensel (1998) make the following conclusion: 1) an ontology is a machine-readable specification of a conceptualization in which the type of concepts used and the constraints on their use are explicitly defined, and 2) an ontology should only capture consensual knowledge accepted by large group of people rather than some individual. By representing knowledge with representational vocabulary in terms of objects and their interrelated describable relationships, inference engine and other application program from one intelligence system will be able to understand the semantic of knowledge in another knowledge base.

The popularity of the semantic web further magnifies the importance of ontology. The Semantic Web is the extension of the current one, in which web content is represented in a structural form within ontologies by a finite list of vocabularies and their relationships (Berners-Lee 2001). In this way, ontologies enable computer program, software agent and search engine to understand the semantics, thus making it possible for them to process the web content. Ontologies also provide a shared understanding of a domain which is necessary to overcome differences in terminology from various sources (Antoniou and Harmelen 2004).

Unfortunately, it is unrealistic to expect all individuals and organizations will agree on using one or even a small set of ontologies (Bruijn et al. 2006). The adoption of such an approach is problematic. On one hand, it is lengthy and non-trivial to define and maintain a large globally shared ontology, on the other hand, the globally shared ontology approach may hinder a system from reflecting its actual business requirements due to the fact that design of the system is restricted by terminologies defined in the ontology (Leung, Lau and Fan 2007). Researchers such as Berners-Lee, Hendler and Lassila (2001) state that there would be a large number of small domain specific ontologies developed by communities, organizations, departments or even individuals. While multiple ontologies allow system to be designed according to its actual requirements without committing to a particular set of terminologies, data heterogeneity caused by multiple ontologies has become an obstacle for the interoperation of systems. Since vocabularies and their relationships defined in the ontologies are inconsistent, therefore it is impossible for one system to understand and reuse other ontologies unless the ontologies are reconciled in some form. The above inconsistent problem caused by multiple ontologies is commonly termed as ontology mismatches.
This research describes the three main meditation methods used to reconcile mismatches between heterogeneous ontologies. The research also investigates the application of ontologies

and its mediation methods in the aspect of Knowledge Management (KM). The rest of the Chapter is organized as follows. Section 2 describes various approaches of ontology mediation. Section 3 discusses the application of ontology and its mediation methods in KM. This includes the development of a proposed mediation selection framework and ontology-based collaborative KM network. Finally, conclusion is given in Section 4.

APPROACHESPPROACHES OF ONTOLOGY MEDIATION

Based on the actual requirements, organizations and individuals are expected to develop their own ontologies of different languages, scopes, coverage and granularities, modelling styles, terminologies, concepts and encodings. To reuse other ontologies of different types, ontology mediation is required to reconcile mismatches between heterogeneous ontologies so that knowledge sharing and reuse among multiple data sources can be achieved (Predoiu et al. 2006). There are three major kinds of ontology mediations which include mapping, merging and integration. Ontology mapping is a process of relating similar concepts and relations from different ontologies to each other in which the correspondences between different entities of the two ontologies are formulated as axioms in specific mapping language (de Bruijn et al. 2006). Since the involved ontologies do not require any adaptation, ontology mapping often specifies just a part of the overlap between ontologies which is relevant for the mapping application (Scharffe, de Bruijn and Foxvog 2006). Two common approaches used to establish mapping between ontologies are listed as follows.

- The first approach is to relate all ontologies to a common top-level ontology so that different ontologies are mapped together indirectly by the top-level ontology (de Bruijn et al. 2006). Consequently, conflicts and ambiguities can be resolved since concepts used in different ontologies are inherited from the common ontology. However, this approach has three major drawbacks. First, constructing a large-scale common top-level ontology from scratch is never a simple task. Even if we take a simpler path by merging various local ontologies together, the experiences of building the Suggested Upper Merged Ontology (SUMO) tell us that the actual merging processes are trickier than expected, not only because there is inconsistency between chunks of theoretical content but also because there were structural differences between the local ontologies (Niles and Pease 2001). Second, this approach can only be adopted in a relatively stable environment where maintenance is minimal because a substantial amount of resources and overheads are required to maintain a common top-level ontology. Third, established mappings between local ontologies and top-level ontology can easily be affected by the elimination and addition of local ontologies as well as changes in either local or common ontologies because local ontologies are related indirectly with each other through the common ontology.
- Rather than mapping all ontologies to a common top-level ontology, one-to-one mapping approach requires mappings to be created between each pair of ontologies (Predoiu et al. 2006). The lack of a common top-level ontology in this approach makes it possible to be adopted in a highly dynamic environment. This advantage may be offset by the lack of common terminologies, thus increasing the complexity of defining mapping between local ontologies. Another major drawback of this approach occurs when a large number of heterogeneous ontologies are involved in the interoperation. Such an interoperation will greatly increase the amount of mappings and extra effort is required to control and maintain the mappings.

The second type of ontology mediation is merging. Unlike mapping that links two separate ontologies together in a consistent and coherent form, ontology merging creates a new ontology (in one subject) by unifying two or more different ontologies on that subject and it is

usually hard to identify regions of the source ontologies from the merged ontologies (Pinto and Martins 2001). As compared with mapping that keeps the original ontologies unchanged, merging requires at least one of the original ontologies to be adapted so that the conceptualization and the vocabulary match in overlapping parts of the ontologies (Ding et al. 2002). While a majority of semantic web researchers foresee the main stream would switch to the approach of developing enormous amount of small domain specific ontologies, McGuinness et al. (2000) argue that some of the industries or organizations still require to develop very large and standardized ontology, for instance, SNOMED CT is a comprehensive clinical ontology developed by the College of American Pathologists that contains about 344,549 distinct concepts and 913,697 descriptions (Lussier and Li 2004). Theoretically, it is more efficient and effective to merge existing ontologies than to build a large ontology from scratch. In practice, the process of ontology merging is more than just simple revisions, improvements or variations of the source ontologies since the involved ontologies are developed by different people for different purposes with different assumptions and using different vocabularies (Pinto and Martins 2001).

One of the most important phrases in the process of ontology mapping and merging is ontology matching. In general, ontology matching can be defined as the process of discovering similarities between two ontologies with the purpose of establishing semantic relationships in between (Studer, Benjamins and Fensel 1998). It determines the relationships holding between two sets of entities that belong to two discrete ontologies. In other words, it is the process of finding a corresponding entity in the second ontology for each entity (for example, concept, relation, attribute and so on) in the first ontology that has the same or the closest intended meaning. This can be achieved by analysing the similarity of the entities in the compared ontologies in accordance with a particular metric (Ehrig and Sure 2004). Ontology matching (or similarity computation) can be processed exploiting a number of different techniques. To provide a common conceptual basis, researchers have started to identify different types of ontology matching techniques and propose classifications to distinguish them, for example, Shvaiko and Euzenat (2005) propose a classification that consists of ten ontology matching techniques. Another example is the classification framework developed by Leung, Lau and Fan (2001). Their framework provides an effective method to identify seven types of matching techniques and its related executive approach simply by examining the input of mediation system. The seven types of techniques are string-based, linguistic resources, constraint-based, alignment reuse, graph-based, taxonomy-based and model-based.
Finally, the third type of ontology mediation is integration. Pinto & Martins (2001) define ontology integration as a process of building an ontology in one subject reusing one or more ontologies in different subjects and it is always possible to identify regions of the source ontologies from the integrated ontologies. Source ontologies may need some sort of refinements before they can be aggregated, combined and assembled together to form the resulting ontology. It is also important to include ontology integration in the early stage of the ontology building process, preferable during conceptualization and formalization, so as to simplify the overall ontology building procedure.

APPLICATION OF ONTOLOGY IN KNOWLEDGE MANAGEMENT

The concept of ontology and its related mediation methods can also be applied to solve the interoperation problem in the distributed KM environment. At the very beginning, KM is emerged with the purpose of preserving and capitalizing on organizational knowledge for the future benefit of organizations. KM encourages organizations to create and use knowledge continuously for the innovation and enhancement of service, product and operation.

Simultaneously, it also aims to improve the quality, content, value and transferability of individual and group knowledge within an organization (Mentzas et al. 2001). This is achieved by organizing formal, direct and systematic process to create, store, disseminate, use and evaluate organizational knowledge using the appropriate means and technologies.

Nonaka, Toyama & Konno (2001) suggest that there are four methods to create organizational knowledge by means of interaction between explicit and tacit knowledge. While tacit knowledge is personal, complex and hard to communicate and formalize because it is gained through individual insights overtime and is resided in human, mind and body, explicit knowledge is structured, relatively simple and can be captured, recorded, documented, codified and shared using formal and systematic language (Goh 2002). The first method to create knowledge is socialization. It is the process of developing new tacit knowledge from tacit knowledge embedded in human or organization through experience sharing, observation and traditional apprenticeship. The second method is called externalization. This is the process of turning tacit knowledge into new explicit knowledge simply by transforming tacit knowledge in the form of document such as manual and report. The third method is combination. This is the process of merging and editing "explicit knowledge from multiple sources" into a new set of more comprehensive and systematic explicit knowledge. The last one is called internalization. This is the process of embodying explicit knowledge as tacit knowledge by learning, absorbing and integrating explicit knowledge into individual's tacit knowledge base.

The second and third stages of KM, store and disseminate are often linked with technologies. Explicit knowledge created is collected and stored in some sort of database or knowledge base in which the users can access using "search and retrieve" tools, intranets, web access and applications, groupware and so on (Alavi and Leidner 1999). The retrieved knowledge can then be used by knowledge workers to add value to current business process, implement and coordinate organizational strategy, predict trends in the uncertain future, deliver new market values, create new knowledge, solve existing problems and so on (Bailey and Clarke 2001). The fifth stage of KM is knowledge evaluation. This phrase eliminates incorrect or outdated knowledge (Alavi and Leidner 1999). In other words, organization must keep creating new knowledge to replace any knowledge that has become invalid.

Unfortunately, it is shown that some of the KM approaches, ranging from industrial specific, theoretical, to procedure-wise, are incompetent to cooperate with the current distributed knowledge environment, especially those that are designed to manage merely organizational knowledge, for example, the re-distributed KM framework is developed to manage organizational help desk knowledge (Leung and Lau 2006). Those approaches are tailor-made according to different organizational KM strategies and business requirements without the concern of system interoperation. The lack of interoperability means that heterogeneous Knowledge Management Systems (KMSs) from different organizations are not able to communicate, cooperate, exchange as well as reuse knowledge with one another. Wagner and Buko (2005) argues that knowledge-sharing in an inter-organizational network allows a richer and more diverse body of knowledge to be created as compared with sharing in one organization.

The non-collaborative KMSs have several disadvantages for both knowledge workers and knowledge engineers. In terms of knowledge workers, they have to spend a lot of time and effort to look for relevant knowledge from different KMSs because they are often required to

access knowledge from other knowledge sources in order to complete their works in the knowledge explosion era, for instance, an investment manager has to retrieve company's financial report, share performance report and regional economy reports from external sources if s/he wants to adjust the proportion of a particular share in the investment portfolio. In terms of knowledge engineers, they have to waste a lot of resources in creating and updating organizational knowledge even though the same knowledge is available in other KMSs. As external source of knowledge is essential for organizational performance, a new inter-organizational KM practice is required to enhance the interoperability among independent KMSs and to encourage the sharing of knowledge across organizational boundaries in their business networks (Oinas-Kukkonen 2005).

Nevertheless, the absence of a common language or standardization has put up a barrier to prevent the collaboration of KMSs (Sheth 1999). Although the emergence of middleware technology has provided a way to enhance the interoperability of KMSs, the concept of middleware can hardly be accommodated in the era of the Internet as each pair of KMSs are required to implement a tailor-made middleware for interoperation (Leung, Lau and Fan 2007). Since a single KMS is interconnected with a huge amount of systems via the Internet, it is impractical to customize and install a middleware for each connection. Another deficiency of middleware is that even if the involved systems only undergo minor modification, the middleware may require a complete re-construction.

Ontology-based Collaboration Inter-organizational Knowledge Management Network

Let us consider the following scenario. At the University A, if an academic researcher is in need of information systems (IS) related literatures (for instance, literatures related to "inter-organizational KM"), the first thing s/he can do is to access the website of the university library. S/he can then type in a set of keywords in the search interface of the library website to determine whether the relevant literatures are available in the library. If it does, then s/he can choose to pick up the literatures from the library or download them in soft-copy format. If not, s/he will have to search again in various literature knowledge bases subscribed by the library. Literature knowledge bases allow subscribers to retrieve literatures such as journals, conference papers, books or other forms of manuscripts. Unfortunately, this process needs to be repeated for every single knowledge base until s/he can find the desired literatures. Each knowledge base contains different sets and types of literatures based on publishers or disciplines areas such as IEEE Xplore (IEEE) and ACM Digital Library (ACM) mainly contain computer related journals and conference papers that are published by IEEE and ACM respectively whereas Australian Digital Theses Program stores thesis of any disciplines produced by postgraduate research students at Australian universities. Finally, if s/he still cannot find any related literature, s/he may choose to search again using other search mechanisms such as Yahoo and Google.

In this research, we propose to use ontology and its related mediation methods to solve the collaboration problem of heterogeneous KMSs in the Internet environment. Ontology is incorporated to allow explicit knowledge to be annotated in the form of machine processable metadata. Although different organizations possess their own set of ontologies, the mediation methods are capable of reconciling the underlying heterogeneities of ontologies. In this way, the concept of ontology and mediation enables organizational KMS to understand incoming request and the returned knowledge, thus making it possible for them to collaborate and communicate with each other. We argue that the knowledge reusability and mismatches reconcilability of ontology and its related mediation methods can further contribute towards reformation of existing KM frameworks that focus only on managing organizational knowledge. Therefore, we propose to develop an ontology-based collaborative inter-organizational KM network that provides a platform for organizations to access and reuse inter-organizational knowledge with a similar domain. Here, inter-organizational knowledge is defined as a set of explicit knowledge formalized and created by other organizations. In the network, the

formalized inter-organizational knowledge is reusable in a way that it can be retrieved by any organizations to support their own KM processes in terms of knowledge creating, storing, dissemination, using and evaluation.

Each network should only contain knowledge of a specific domain to ensure knowledge workers can retrieve relevant knowledge in an efficient manner, for example, an IS network should only provide knowledge in the discipline area of IS. Once an organization recognizes the need for a certain type of knowledge, the organization can invite other organizations and knowledge providers with the same knowledge domain to establish a network together. For example, given that academic researchers in IS discipline have to access different knowledge bases in order to obtain the desired knowledge, the library at this university decides to invite other libraries and academic publishers to establish a knowledge network that contains only IS knowledge. When the network for a particular knowledge matures, organization in need may choose to join instead of establishing new one. Within a network, each organization or knowledge provider must commit to a mutual agreement to allow other participants to access an agreeable portion of ontology and the associated knowledge in its knowledge base. Besides, a single organization or knowledge provider can commit to more than one network of different domains. For instance, the library of the University A may choose to commit to networks of IS, economics, mechanical engineering, education and chemistry whereas IT help desk of Company A may choose to commit to network of other hardware and software providers' knowledge bases.

Selection Framework for Ontology Mediation

Before continuing the description of the proposed network, the participating organization must first make four important decisions related to ontology mediation. Figure 1 illustrates a selection framework for ontology mediation in the form of a matrix. The first decision is whether to adopt top-level ontology or one-to-one as the network level mapping approach. As this decision is on the network level rather than an organizational aspect, the organizations as a whole must compromise in order to select the most appropriate mapping approach for the benefit of the entire network. The decision process should include a thorough assessment and discussion from the aspects of resources, expertise and frequency of modification among all organizations in the network. The top-level ontology approach can only be applied to an environment where maintenance effort is minimal even though such an approach can provide a better mechanism to resolve conflicts and ambiguities. Whenever a minor modification is performed in one of the ontologies in the network, the shared ontology used in the top-level ontology approach may need a complete reconstruction. The organizations must also make sure that they have sufficient resources and expertise to build the shared ontology. If frequent maintenance is required or resources and expertise are insufficient, it may be more appropriate to use the one-to-one approach.

The second decision is whether to perform mediation automatically or semi-automatically. Mediation can be performed semi-automatically which requires the support of automatic tools as well as human intervention. The forms of support provided by automatic tools include similarity computation, post-mediation verification, validation, critiquation as well as conflict recognition and resolution. Although semi-automatic mediation could have a better performance than the manual one in terms of accuracy, it still substantially relies on human efforts and can be time consuming. Without human intervention, the process of semi-automatic mediation cannot be completed, thus compromising accuracy of the mediation result. As semi-automatic tool is not capable of supporting mediation on-the-fly, it would be ideal to perform mediation automatically. Unfortunately automatic tools are unable to detect and interpret concepts that do not have close correlation. Moreover, it may also fail to handle any unforeseeable situations as the tool is designed to perform mediation under certain pre-

defined conditions. However, if automatic mediation is adopted and inference mechanism is built on top of it, then inaccurate results can reduce the value of the mediation process.

The third decision is whether to adopt merging, mapping and/or integration as the desired mediation method for each organization. Each organization can choose one or more methods based on its own need. The concept of mapping enables ontology to be developed in response to its actual business requirement and is more suitable in a fluctuant business environment. Here, fluctuant business environment refers to an environment where organizations need to modify their ontologies in a frequent manner. Unless ontology has undergone major modification, simple modification, such as adding or deleting a concept from ontology, may merely require updating the mappings accordingly. Alternatively, merging is an appropriate method for creating an ontology that combines common views of multiple source ontologies. In other words, the merged ontology should include all possible correspondences and differences among the entire set of source ontologies. As a result, the merged ontology could act as 1) a single ontology used to substitute individual source ontology, 2) a shared ontology (reference point) used in top-level ontology mapping approach, or 3) an organizational ontology that includes all possible views of other organizations' ontologies. Unlike merging, integration selects only opposite modules from individual source ontologies to form an integrated ontology. Thus, integration is appropriate for organizations to customize ontologies based on their own needs. For example, the library at University A can customize a KM-based ontology by integrating portions of ontologies derived from other libraries and other academic publishers.-The final thing needs to be considered is whether to adopt single or multiple matching techniques. In the decision process, organization must also take into consideration execution duration, acceptable level of matching accuracy and resources level for implementation. In general multiple strategies are expected to generate more accurate result than single matching technique; however it is not always the case. The choice of aggregation algorithm and cut off point also plays an important role in determining the level of matching accuracy. When choosing multiple strategies as its matching technique, organization must conduct a series of experiments with the purpose of finding the right combination of multiple strategies, aggregation algorithm and cut off point to produce the most accurate result. Compare with single matching technique, multiple strategies are relatively difficult to design and implement and it requires longer execution time.

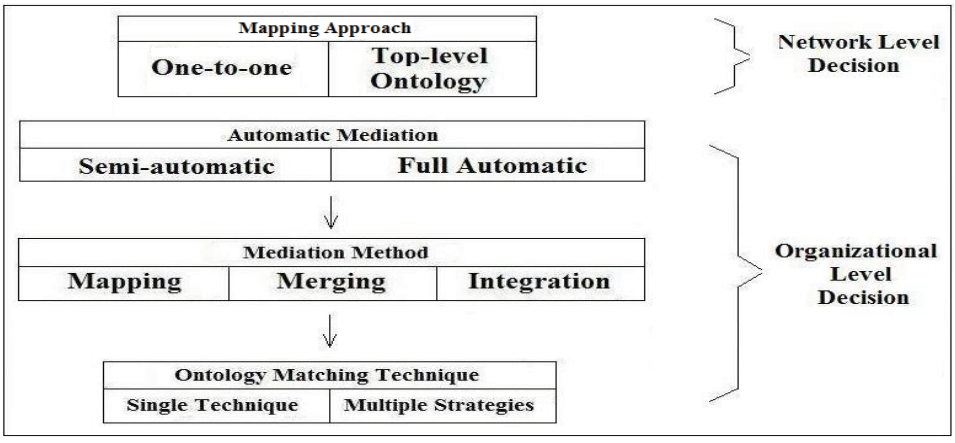

Figure 1: Selection Matrix for Ontology Mediation

The reconcilability of ontology mediation allows the participating organizations to reuse inter-organizational knowledge within the network even if there are fundamental differences among organizations in terms of KMS structures and formats. Under mutual agreement, organizations are permitted to retrieve inter-organization knowledge and the retrieved knowledge can be reused to support the five stages of KM process. Conventionally, technology has very limited contribution in knowledge creating stage especially in socialization, externalization and internalization where tacit knowledge is involved. For example, word processing tools can be used to record and visualise explicit knowledge in externalization and internalization, whereas communication tools such as email and telephone provide platforms for exchanging explicit knowledge in socialization.

However, ontology merging tool can provide a practical way to create knowledge by combining two or more ontologies together semi- or automatically in the network. This can be achieved on both network and organizational level. On the former level, merging tool is capable of creating a shared ontology for top-level mapping approach that contains common views of all organizational ontologies in the network. On the latter level, organization can create its own domain specific ontology by merging relevant ontologies from other organizations within the network. In addition, ontology integration tool provides an alternative way to create knowledge. Using integration method, organization can create its own knowledge by integrating relevant parts of ontologies from other organizations in the network into its own ontology building process. As a result, both merging and integration tool enable organizations to reuse not only the contents of other ontologies but also their associated inter-organizational knowledge stored in the knowledge bases of other organizations. While ontology merging and integration are never a trivial task even with the assistance of automatic tools, they are still less demanding than building it from scratch.

Knowledge dissemination tool allows user to retrieve and use knowledge from organizational knowledge repository. If user cannot find suitable organization knowledge, s/he has to seek from other external sources. This can be achieved by creating mappings among ontologies of different organizations either semi- or automatically with the support of ontology mapping tool. The established mappings allow one KMS to access another KMS in the same network. Besides, it is also practical for mapping to be performed on-the-fly. In this case, automatic mapping tool is responsible to look for, select and establish mapping with the most relevant concepts and properties from other ontology in the network. Whenever the required knowledge is not available in the organizational repository, the KMS is able to retrieve and deliver inter-organizational knowledge in a “black box” through the establishment of mappings. In addition, inter-organizational knowledge can be reused to support knowledge evaluation process. This is accomplished by setting up dedicated mapping between two or more ontologies. Once a piece of inter-organizational knowledge is updated, this it will be translated into a suitable format and delivered from source knowledge base to the target automatically via the pre-established mappings. To demonstrate the reconcilability of ontology mediation and reusability of inter-organizational knowledge in the network, let us consider the following scenario.

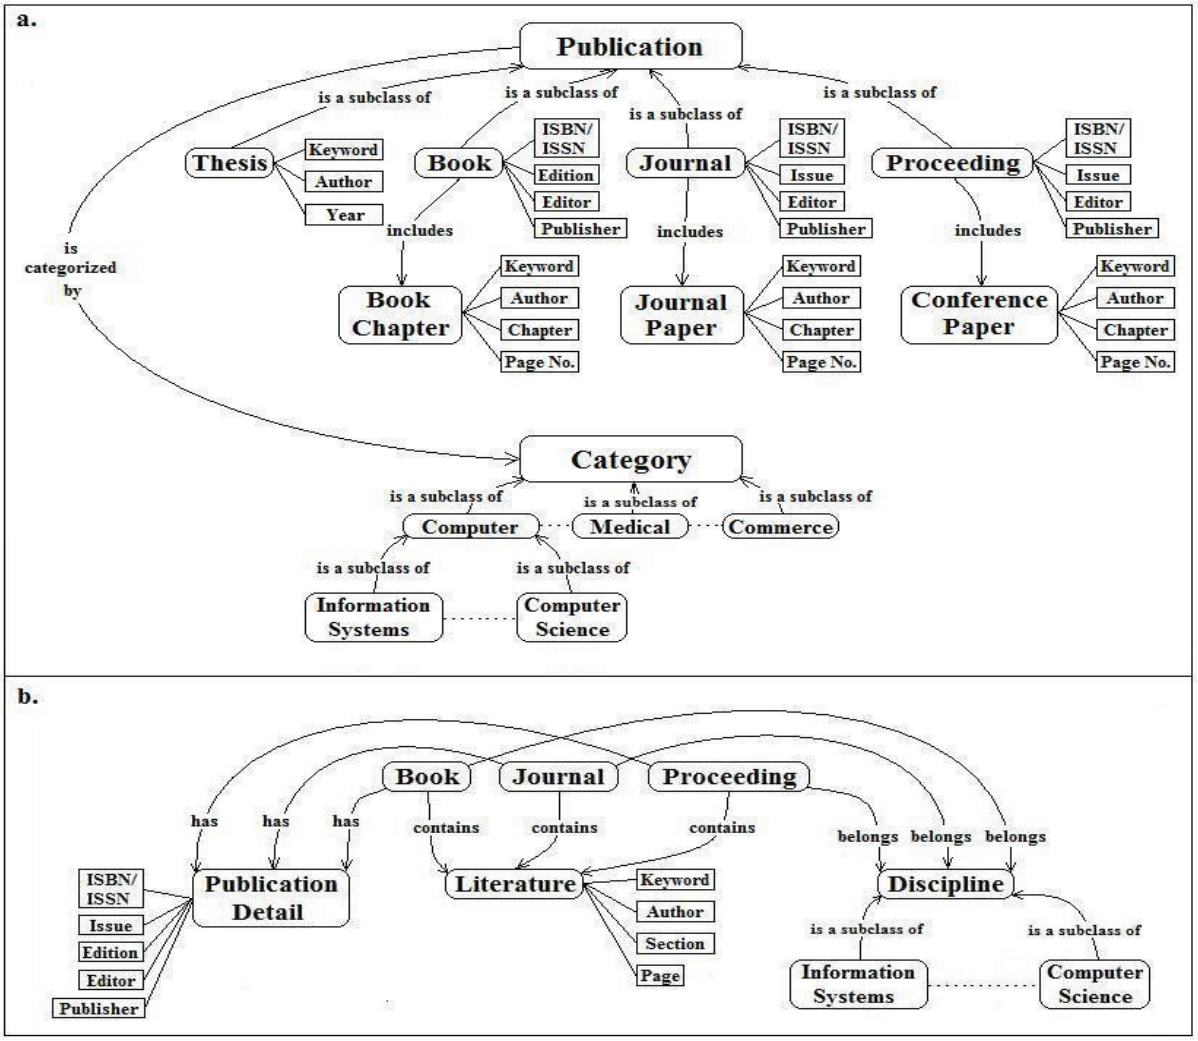

Figure 2: Partial View of the Classification Ontology Adopted in (a) Library of University A and (b) Publisher XYZ. Round Rectangular Nodes Represent Concepts. Rectangular Nodes and Labels on the Arcs Represent Properties

Assuming University A realizes that there is an increasing demand for IS related knowledge, and this demand cannot be satisfied with current collection of publications in the library. Consequently, University A decides to invite knowledge providers and libraries of other universities to establish a network that contains IS related literatures which include libraries of University B, University C, University D, Publisher ABC and Publisher XYZ. Except for University D, all other participating organizations possess ontologies. Figure 2a shows a partial view of the classification ontology adopted in the library of University A. In this ontology, the publication concept has concepts that include book, journal, proceeding and thesis as its subclasses and each subclass is described by a set of properties such as International Standard Book Number (ISBN), International Standard Serial Number (ISSN), and publisher. Concept category and its subclasses are used to distinguish publications into different subjects such as concept computer, medical, commerce, computer science and so on. Given that this network only supports IS related knowledge, therefore the library of University A is willing to share publication that belongs to concept computer and its subclass information systems. As publication may contain chapters written by different authors, the ontology reflects it by including concept book chapter, journal paper as well as conference paper and their related properties as an extension of concept book, journal and proceeding respectively.

Figure 2b shows a partial view of the classification ontology in Publisher XYZ. There are three major concepts in this ontology, that is, concept book, journal and proceeding. Each concept has a set of publication details (such as issue and edition), contains a set of literatures and belongs to one discipline (such as information systems). The above three components are represented by concept publication detail, literature and discipline respectively. Similar to University A, Publisher XYZ also agrees to share literatures that are classified under concept information systems.

After careful consideration, the six organizations have reached a mutual agreement not to adopt top-level ontology as the network-wide mapping approach. This decision is based on the fact that there will be many more organizations wishing to join the newly established network, so the shared ontology built for the top-level ontology mapping approach may require to undergo a series of reconstructions. Although they have sufficient expertise and resources to build and reconstruct the shared ontology, it is not cost effective to do so. In addition, the reconstruction works will definitely affect the stability and performance of network-wide mediation because the shared ontology will be mapped by all other ontologies as a reference point. At this moment, the organizations prefer to use one-to-one mapping approach. However they have agreed to review the mapping approach after the organizations wishing to join the network stabilized.

As the library of University D does not possess ontology, the library has to create one in order to fulfil the requirement of joining the network. Instead of building the ontology from scratch, the library decides to reuse ontologies from other organizations and integrate them into its own development process using ontology integration method. However, the chosen ontologies must be similar to the library's actual classification in terms of publication and discipline in order to minimize the degree of modification. For example, the concept publication and its subclasses in the ontology of University A are more appropriate than those defined in Publisher XYZ as the subclass thesis; book, journal and proceeding defined in the ontology of University A are very similar to the actual classification used in the library of University D. Based on the criteria, the library reuses only a portion of the two ontologies that include the concept publication and its subclasses derived from the ontology of the University A as well as the concept discipline and its subclasses derived from the ontology of Publisher XYZ (see Figure 3). In the ontology development process, the library of University D can reuse not only the ontologies of other organizations; it also has the inter-organizational knowledge associated with the instance of the integrated ontology. As illustrated in Figure 3, the softcopy of the thesis described by the instance of the integrated ontology, thesis "Turning User into First Level Support in Help Desk: Development of a Web-based User Self-help KM System" in discipline IS, can be captured from the knowledge base of the University A and stored in the knowledge base of University D. This integrated ontology created by the library of the University D has resulted in additional function. By establishing dedicated mappings between the integrated ontology and its ontology providers (that is, the ontologies of University A and Publisher XYZ), the associated publication captured in the knowledge base of University D can be automatically updated as long as there is an revised version generated from the ontology providers. In this case, when the thesis "Turning User into First Level Support in Help Desk: Development of a Web-based User Self-help KM System" has undergone a minor revision in the knowledge evaluation process, the revised thesis will not only be stored in the knowledge base of University A, it will also be broadcasted to other KMS through the dedicated mappings that includes the knowledge base of University D. To allow general user to retrieve and use inter-organizational knowledge, organizations are required to establish

mappings between its own ontology and ontologies of other organizations in this network. As shown in Figure 4, each broken line represents a mapping between a pair of concepts or properties that belong to two different ontologies. Making use of string-based and linguistic resources matching techniques, two similar concepts from the ontologies of University A and Publisher XYZ are mapped with each other. For instance, two identical concepts (such as journal) and two properties that are synonyms (such as section and chapter) from the ontologies of University A and Publisher XYZ are mapped together.

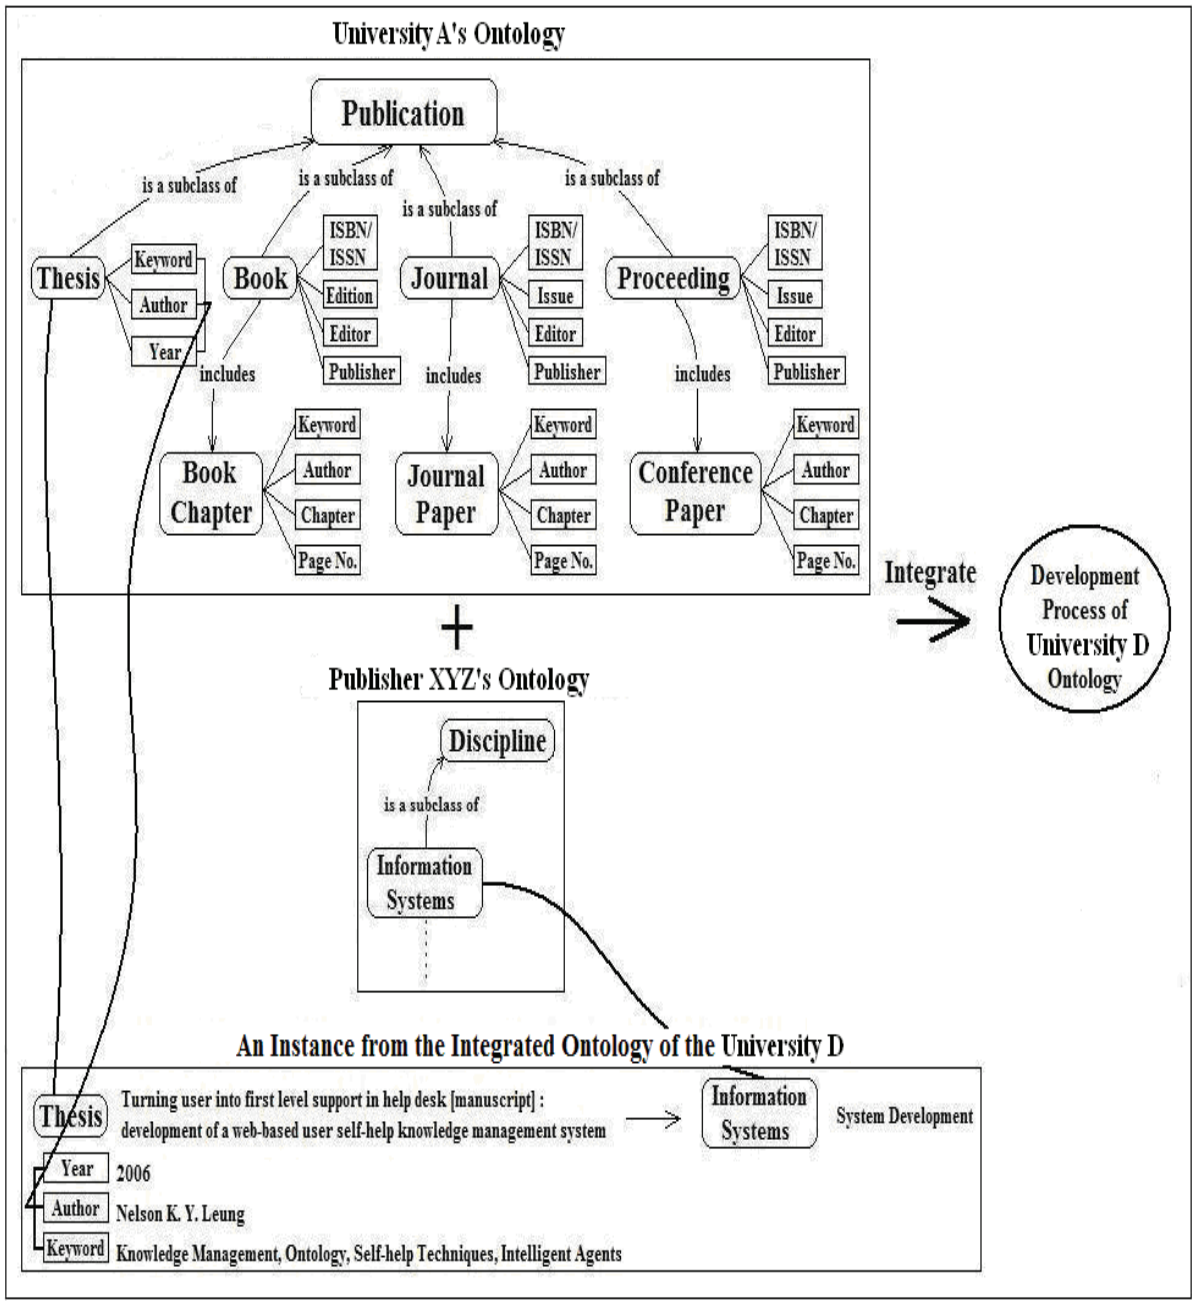

Figure 3: Process to Develop University D's Ontology Using Integration Method

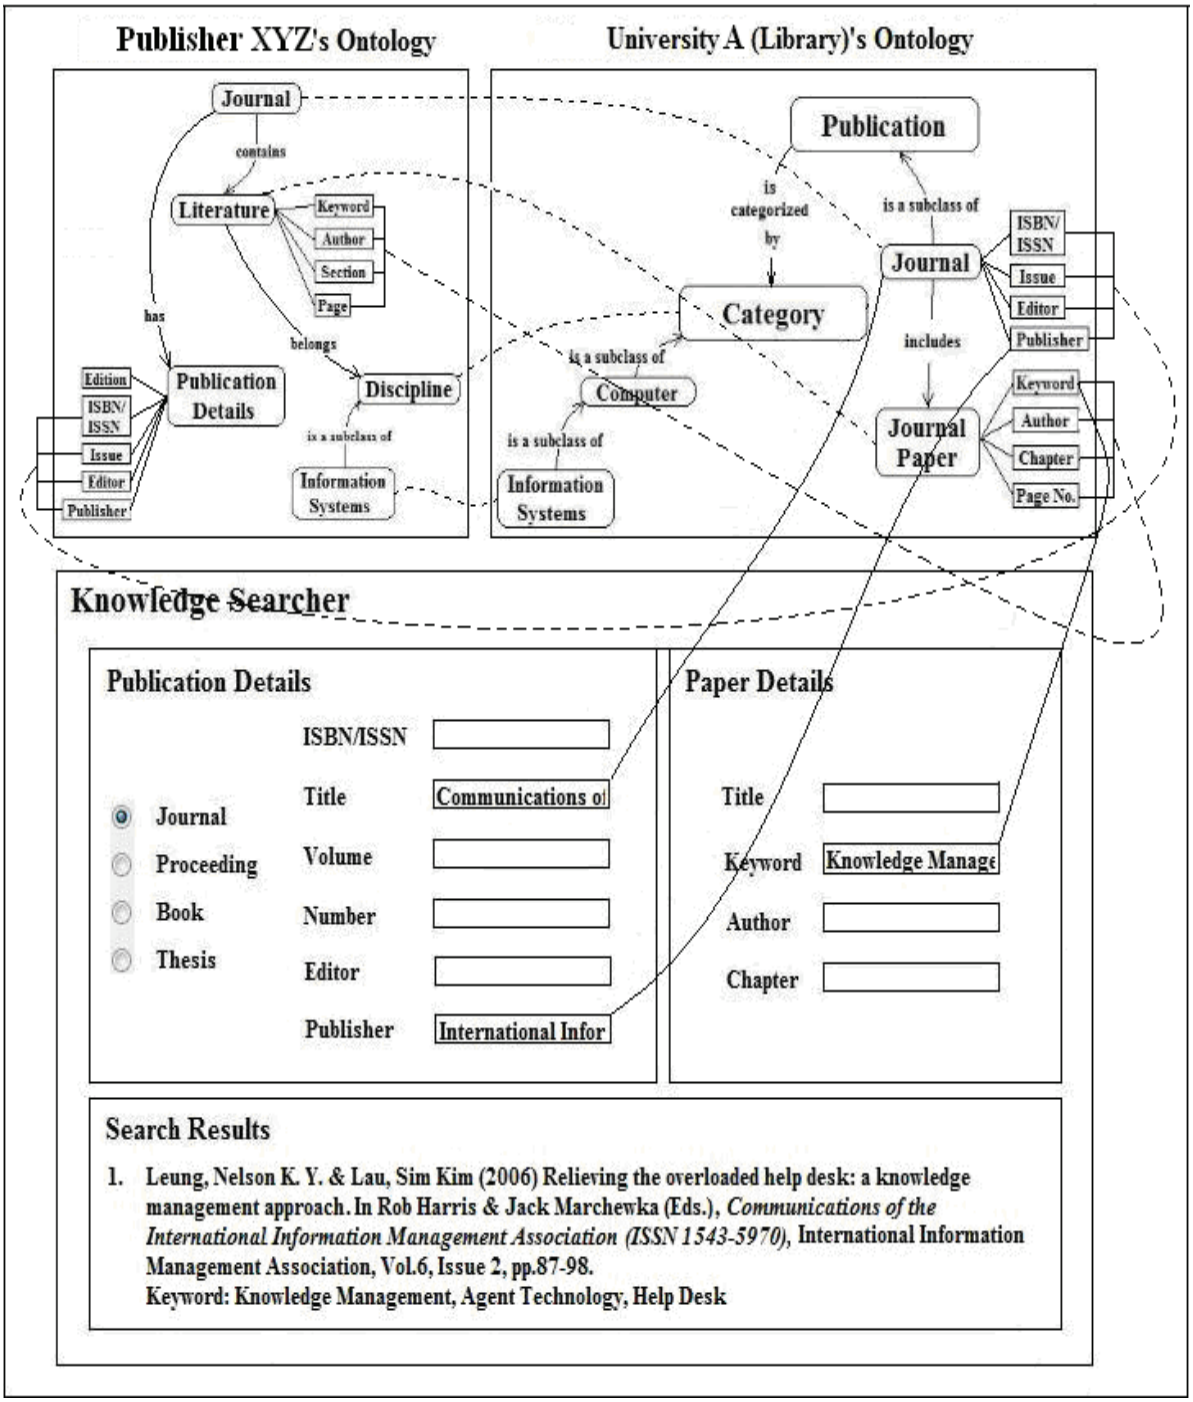

Figure 4: Inter-organizational Knowledge Retrieval and Reusing Process

In Figure 4, a user is searching for suitable journal papers by filling in data on title, publisher and keyword fields on the "knowledge searcher" which is designed to be used as a search interface for the KMS at the library of University A. Since the KMS cannot provide journal that satisfies this query, the system begins to search other KMS including Publisher XYZ. The mappings allow the KMS of Publisher XYZ to understand the incoming query. For example, the details provided in the title, publisher and keyword fields on the search interface are similarly referring to the concepts journal, property publisher and property keyword that belong to the ontology of Publisher XYZ. As long as the requested journal is available in the knowledge base of Publisher XYZ, it will be delivered to the search interface of University A.

Subsequently, the journal will be displayed as if it is retrieved from its own knowledge base. In other words, the entire inter-organizational knowledge retrieval and displaying mechanism are performed in a "black box" manner.

CONCLUSION

The organization based KM approaches have caused collaboration problem in which organization is not capable of reusing inter-organizational knowledge even though the required knowledge is available in knowledge bases of other organizations. An ontology-based collaborative inter-organizational KM network is proposed to solve the problems. To establish the network, a selection framework is proposed to assist organizations in choosing suitable ontology mediation approaches, ranging from mapping approaches, levels of automation, mediation methods to matching techniques. The knowledge reusability and mismatches reconcilability of ontology and its related mediation methods enable organizational KMSs to understand the incoming request and the return knowledge, thus making it possible for them to collaborate and communicate with each other. By annotating knowledge explicitly in the form of machine processable representation, organizations joining the network can access, retrieve and reuse domain specific inter-organizational knowledge to support the five stages of organizational KM process. While knowledge engineers could reuse inter-organizational knowledge to create and evaluate organizational knowledge, general users are benefit from the effectiveness and efficiency in searching for relevant inter-organizational knowledge within the network.

REVIEW: INTERDISCIPLINARY RESEARCH OF OPTIONS THEORY AND MANAGEMENT INFORMATION SYSTEM

ABSTRACT

First applied in the finance field, Options Theory (OT) has now been applied successfully in a several other fields. OT is well suited for applications in the Management Information Systems (MIS) field. In the last two decades, MIS researchers have used OT in many discrete cases; however, the theory still holds great potential for other MIS applications. The purpose of this article is to review research on OT in the Management Information Systems (MIS) field. The paper reviews OT and suggests further ways it may be useful for MIS. Several directions for future research are advanced, and questions for future inquiry highlight what is known and what needs to be learned. The paper explores current global trends and past uses of OT by MIS researchers within a framework. Our objective is to broaden discussion of OT in the MIS field, facilitate theory development, close gaps in existing knowledge, and uncover areas where research is needed. We believe that MIS researchers will benefit from our study.

Keywords: IT investment, Options theory, Review

INTRODUCTION

Since the 1970s, Options Theory (OT) has emerged as an important tool in the finance field. Besides being used for evaluating investment opportunities, it has been extended to analyze many critical issues, such as managerial behavior, and partnership dynamics. It has also been used successfully in many disciplines such as psychology, engineering, and general management. Because OT provides a perspective by which we may assess managerial behavior, MIS researchers have also shown a steadily increasing interest in the theory because of the way it can explain many specific context phenomena.

However, despite the importance of OT to MIS research, there has been surprisingly little research using a framework to plot global OT research. This lack of a framework for global interdisciplinary theory may confuse some MIS researchers because they may not perceive how their work fits the context of a global framework. Thus, the lack of a global view may hamper the development of OT in the MIS discipline. For these reasons, a comprehensive framework is long overdue.

The purpose of this paper is to bridge this gap. We present a comprehensive survey of OT literature in the MIS field, explain the relationships between previous studies, and present a detailed framework of previous works that brings together disparate streams of thoughts. It is hoped that the framework will give researchers a better understanding of the role of OT in MIS. Moreover, we make several suggestions for future research.

The remainder of the paper is organized as follows. First, we introduce OT, and explain why the theory has such vital relevance to MIS scholars. Second, we present a typology of OT and then

describe, compare, and contrast the modules with each other. Third, we propose a comprehensive framework that represents current knowledge and areas that require further investigation. Finally, we turn to a discussion of several major considerations that MIS researchers need to address when applying OT in MIS studies.

Options Theory: Overview and Basic Concepts

It was not until the late 1960s that the breakthrough Nobel Prize winning works by Black and Scholes (1973) and Merton (1973) provided a rigorous way to price options. Based on Ito Calculus and the concept of dynamic portfolio hedging, the derivation of a differential equation with the value of a call option for determining the boundary conditions resulted in the now famous closed-form Black-Scholes formula. Their outstanding work created a new paradigm of derivatives pricing, and resulted in the rapid development of option pricing and interdisciplinary financial engineering. Since that time, a variety of derivative pricing models, such as the binomial model by Cox, Ross and Rubinstein (1979), have been developed. Hull (1998) provides a non-technical introduction to options pricing theory.

Option pricing theory has been applied in many areas. An option is defined as the right, but not the obligation, to take investment action on a real asset at a predetermined cost, called the exercise price, for a predetermined period of time. Myers (1974) first recognized that option-pricing theory could be applied to real assets and non-financial investments. OT offers a new and more realistic way to value strategic opportunities and uncertainty, because traditional valuation methods, such as Net Present Value (NPV), do not provide values for strategic investments and uncertainties. In contrast to NPV, Options Theory manifests as a collection of call options or put options embedded in capital investment opportunities.

Myers considered that discretionary investment opportunities, such as those presented by growth options, capture the real value of a project. By making a primitive phase investment, a project is implicitly equivalent to buying an option. The option holder has the right, but not the obligation, to exercise an option. Thus, the option's payoffs are asymmetrically distributed due to the limited liability of the option. By their nature, options create an asymmetrical payoff. In essence, they shift the possible distribution toward a more favorable pattern.

The idea of applying OT in strategic capital budgeting and valuing opportunities marks a second revolution in options theory. Following the progress made by Myers, Kester (1984) and Dixit and Pindyck (1995) suggested the use of option-based techniques by which managerial flexibility, implicit in investment opportunities, could be valued. They stressed the importance of the irreversibility of most investment decisions, and the ongoing uncertainty of the environment in which these decisions are made. Kulatilaka and Marcus (1988) also discussed the strategic value of managerial flexibility and its option-like properties. Trigeorgis (1993) used this theory to deal with features and problems associated with the valuation of projects. In addition, many useful OT valuation techniques, described by Copeland and Antikarov (2001), have been demonstrated as alternative techniques for decision-making and valuations.

It was not until the extension of options theory to real assets that the door was opened to opportunities for other fields. Derived from the pricing of financial options, researchers

discovered many new ways to use the theory. OT is also applicable to options comprised of "real opportunities". In addition to theoretical development, applications of OT are growing fast for tasks like business strategy design, capital budgeting, making decisions about entering new markets, and contract negotiations. OT has been applied in several areas, ranging from natural resources development, real estate, R&D, and pharmaceuticals to manufacturing, and government regulations. Because of the MIS field's unique characteristics, many MIS scholars have discovered that a number of context-unique problems, such as how to value strategic IS/IT investments, can be re-examined from the perspective of OT.

Many of the properties inherent in MIS can be interpreted as different types of options. For example, MIS managers and designers face a common difficulty in that most IS/IT projects are inherently risky and uncertain, both financially and technologically, especially so given the rate of change in high technology and our deregulated economy. Consequently, solid methods for valuing prospective investments are necessary so that development strategies may be justified. In such an atmosphere, we must consciously manage risk, and we can do so most effectively by developing options that may be exploited depending on future possibilities. To summarize, OT provides a way of thinking that enables several kinds of flexibility, which we describe in the next section.

Research Methodology

Our methodology for identifying OT studies proceeded in three stages (Webster and Watson, 2002). First, using key words, we queried journal databases. We reviewed articles published in periodicals from 1980 to the first part of 2005 and browsed the titles of articles in leading journals and conference proceedings (1974 through 2005). Journal databases included the ABI/INFORM database. Articles were selected if they satisfied the following criteria: 1) OT is applied in the MIS field; 2) The research methodology is well described; 3) The research results are available and complete.

The journals found in the ABI/INFORM database were:

- MIS Quarterly
- Communications of the ACM
- Decision Support Systems
- Information Systems Research
- Journal of Management Information Systems
- Management Science
- Communications of the AIS
- Harvard Business Review
- Management Science
- Sloan Management Review
- Information and Management

The next step involved a search of bibliographical references for various articles on options and related topics. As suggested by Webster and Watson (2002), to ensure variety in our search scope, our methodology covers relevant literature on the topic and is not confined to one research

methodology, one set of journals, or one geographic region. Since the MIS field draws on several reference disciplines, such as computer science, management science, cognitive science, and organizational behavior, some articles that focus on issues of interest to these disciplines could be considered part of the MIS literature at some level of abstraction. We used the Social Sciences Citation Index and the Web of Science to identify additional candidate articles. The decision to include these additional journals was based on two reasons: 1) several journals known to publish OT articles were not included in the ABI/INFORM database; and 2) many of these additional journals are recognized by MIS experts as being important to the field of OT. Each of the following journals was manually searched for the same 31-year period.

- Journal of Finance
- Journal of Financial Economics
- Journal of Financial and Quantitative Analysis
- Journal of Financial Economics
- The Quarterly Review of Economics and Finance.

To ensure the reliability of the final list of included articles, we required each article to be peer discussed. On all included articles, agreement was made by at least two reviewers. For approximately 75 percent of the articles, there was agreement on the selection by all three reviewers. Each article was then discussed until there was agreement on which articles should be included in the final set.

A Framework for Analysis of the Role of OT in MIS

In this section, a comprehensive framework is presented to help MIS researchers better understand how to apply OT more rigorously, identify the discrete development and critical knowledge gaps, and guide future research. The key assumptions and questions when applying the OT technique are described at the same time. Our framework is placed on a hierarchy for clearly identifications of the relationships among previous works. (See Figure 1)

To formulate problems related to IT investment opportunities, two models have been used to describe uncertainty and model the evolution of strategic opportunity processes, i.e., the continuous-time model and the discrete model, as shown in Level 1. The discrete model, developed by Cox, Ross and Rubinstein (CRR, 1979), subdivides continuous time into discrete periods; underlying asset movements can be described within specific time slots. Following the CRR research, Trigeorgis (1993) developed a lognormal, meaning the logarithm of the price has a normal distribution, transformed binomial tree that applies to stock prices. The strength of the two models lies in their simplicity, and they are good models to use when dealing with a small number of tree levels. The CRR model and the lognormal transformed binomial tree are the two most important discrete models that have been used to describe uncertainty in the OT field, as shown in Figure 1.

Although discrete models are excellent tools for option pricing when a multitude of vague information needs to be taken into account, they do have inherent shortcomings resulting from the complexity of a discrete formula increasing exponentially as the number of iterations increases. Fortunately, with the advance of computers, complex calculations can be performed,

despite these conditions. A well-structured spreadsheet algorithm may aid complicated calculations greatly. For this reason, most people utilize a discrete model to solve problems that consider simple options.

The simple evaluation method provided by these methods results in implications for management. Managers are in favor of a simple evaluation method that can help them make decisions. However, problems with more complex options, for example, a path-dependent tree such as a switch option and a compound, or recombination problems caused by a jump in underlying asset values, cannot be evaluated by these discrete methods. Thus, in Figure 1, we can see that these options are not available for the tree model panel.

[Figure 1 here]

Continuous-time models provide a way to overcome these problems. Based on the argument of an arbitrage expression, a partial differential equation can be derived, the solution of which gives the value of a call option. The actual equation used may be the well known Black and Scholes formula. Dixit and Pindyck (1994) derive their outstanding work by using the derived Partial Differential Equation (PDE) instead of constructing a discrete tree. The benefit of continuous-time models is that the different options have similar PDEs, and we just need to apply some specific boundary conditions for the PDE to be solved. This property makes it easier to apply the continuous-time models to MIS instances.

Because options models depend on some specific assumptions, their appropriateness should be determined, according to different scenarios. There are several models by which the movement of the underling assets of options may be described. Standard Brownian Motion is one of the most fundamental notions of stochastic process modeling, and it forms the basis of modern options theory. In a Geometric Brownian Motion process, the price of an underlying asset is described as a diffusion process with a drift rate; while in a jump process, the price may increase or decrease sharply because a sudden event, such as a major success in R&D or the failure of a lawsuit. The Mean Reverting Motion Process describes an average characteristic, such as one that fluctuates according to a seasonal effect. We identify three motions of underlying asset value in level two in Figure 2.

[Figure 2 here]

At the next level, Level 3, we must distinguish and clarify what options are present. The six types of flexibility in the OT literature studied by Trigeorgis (1993) are partially mapped and extended at this level. Types of options include: 1) the growth option, which occurs when an early stage investment is used for follow-up investments (Majd and Pindyck,1987, Pindyck,1988, Taudes,1998); 2) the option to abandon a project if it is unsuccessful, which occurs if the market conditions deteriorate severely, and allows the management to abandon current operations and recoup the salvage value of capital equipment and other assets (Myers and Majd, 1990); 3) the option to switch an input mix or output mix (Kulatilaka, 1993, Kulatilaka and Trigeorgis, 1993); 4) the option to alter the operating scale, which provides the flexibility to expand or contract a

project's scale (Pindyck, 1988, Kogut, 1994); 5) the option to abandon enables a company to cancel a project midstream if the business environment changes dramatically. (Keil, 2000); and 6) the compound option, for options interact in various ways, the value of the interacting multiple options is not equivalent to the sum of the individual options. These options must be carefully reconfigured before making strategic decisions (Trigeorgis, 1993).

Moving to the next level in Figure 1, there are two ways to determine option value. The first is the analytical solution, and can be seen in examples such as the Black and Scholes Formula, where, under their assumptions, the value of the option depends on the current value of the underlying asset, the exercise price, the instantaneous risk-free rate, the variance of return of the underlying asset, and the time to exercise the option. Additional research into model development includes the works by Brennan & Schwartz (1977), Kester (1984), McDonald & Siegel (1986), and Paddock & Siegel & Smith (1988). The models developed by Margrabe (1978), McDonald and Siegel (1986), and Carr (1988) provide well-known analytical solutions.

We can only apply the formula to a case directly if the problem suits the assumptions. However, for some types of options it can be difficult, even impossible, to find an analytical solution to the differential equation. In such cases, it is necessary to apply numerical methods that estimate the value of the option. Many methods have been proposed to tackle the option-pricing problem numerically. They can be divided into three main classes: finite difference methods (first introduced by Brennan & Schwartz (1977); Monte Carlo simulation methods (introduced by Boyle (1977); and lattice methods first proposed by Cox, Ross and Rubinstein (1979). In the next section, we will discuss MIS research, methodology and problems focused upon, identify the position of the research within our framework, and, most importantly, identify gaps in MIS research that would be good territory for future study.

Options Theory Research in the Management Information Systems Territory

Options Theory (OT) is especially valuable for projects that involve both a high level of uncertainty and opportunities to dispel that uncertainty as new information becomes available (Copeland, 2001). Since decisions made in the implementation of IT projects are contingent on unknown future states, OT is suitable for redefining decision-making behavior via strategic business thinking. In the context of implementing large IT projects, it can help resolve uncertainty by creating preliminary modules or prototypes; or it may help in the development of an infrastructure that increases future competency. These options generate additional value in terms of managerial flexibility because they enable managers to make decisions until the uncertainty factors are resolved. As a result of the direct applicability of OT, most MIS researchers focus on capital budgeting in the MIS context.

MIS researchers have long recognized the fact that many IS/IT investment projects possess uncertain, option-like characteristics. Some researchers have applied OT to IT investment decision-making (Dos Santos, 1991, Clemons, 1991, Kambil et al, 1993). Taudes (1998) showed that OT can used to evaluate software growth options as a sequential exchange option for a SAP R2 upgrade problem. In 1987, the options focus was used in an analysis of the timing of the deployment of point-of-sale (POS) debit services by the Yankee 24 shared network of New England (Benaroch, 1987). Later, Benaroch (2000) employed a version of the Black-Scholes

option-pricing model to obtain reliable values for Yankee 24's investment timing option. Other research emphasizes that it is important to understand and hedge risks in IT projects based on OT (Kumar, 2002). Benaroch (2002) illustrates how OT can be applied to an IT investment that entails the establishment of an Internet sales channel. Finally, Balasubramanian (2000) and Sambamurthy (2003) emphasize the application of options thinking to business strategy to facilitate agility. Next, we discuss how the relative positions of each of these research studies fits into our framework.

At Level 1, because the option value is context dependent, different assumptions must be appropriately set to fit different problems. We see the economy that PDEs or tree models provide when they are used in formulating problems, but note that *most* MIS researchers use analytical solution formulas to solve PDE problems. There have been few attempts to develop context-specific models, except for Campbell (2002), who attempted to exploit the certainty of early cash flows by providing a rationale for the early exercise of an investment option. *Still, no* MIS researchers have yet attempted to model options characteristics on their own with continuous-time models. Instead, they resort to ready-to-go close-formed formulas, such as Black and Scholes' approximation, when modeling investment opportunities as options with uncertainty.

Further discussion is warranted. Because the options models were developed based on specific assumptions, factors dealing with their appropriateness should be scrutinized for different scenarios. Although there are standardized models, such as the well known Black and Scholes formula, which can be used to calculate option values, analytical models only provide solutions to general form cases and are not suitable for broad applications. Thus, direct application of Black and Scholes formula or other closed-form formulae is inappropriate for contextual problems. For example, in a multi-stage IS/IT investment project, the options are interdependent, resulting in a compound option (Trigeorgis, 1993). Interactions generally depend on several characteristics: the type, separation, degree of being "in the money" or "out of the money"; the order of the options involved; and factors that impact on the joint probability of the model. The cumulative effect of options dictates that the value of individual options in a series of cascading options may be reduced, or enhanced, by interaction with other options, i.e., individual options can contribute value in a substitutive, additive, or complementary way (Benaroch, 2002). For more sophisticated options, however, these standardized methods are not helpful and more advanced approaches are necessary (Geske and Shastri, 1985, Trigeorgis, 1993; Perlitz et al, 1999).

In Level 3, we identify three motions of underlying asset value. Most previous works have focused on the standard Geometric Brownian Motion Process, in which the price of an underlying asset is described as a diffusion process with a drift rate. In many MIS related problems, we see a number of underlying asset price movements that behave like a jump process, i.e., the price increases or decreases sharply because of a sudden event, such as a major R&D success or a failure brought about by a lawsuit. Moreover, few previous works have focused on the Mean-Reverting Motion Process, used to describe a characteristic, such as seasonal effect in revenues for a high-tech company. Future studies should describe asset price evolution using a dynamic model to model the real world settings.

In level 4, as we argue through systematic analysis, the characteristics of MIS tend to require a close-form formula. Analytical solutions are derived based on specific assumptions and are limited by their applicability. For example, the Black and Scholes formula offers a simple method of options pricing, but it is derived from the simpler European option, not the compound American option. Hence, it cannot deal with compound options. Moreover, the model is limited to a single factor of uncertainty.

We further investigate research issues among studies of OT in an MIS context (See Table 1). The review of literature in this area reveals that most applications of OT have involved projects with well-defined risk characteristics. Studies range from a focus on active management (Kumar, 2004), to evaluating investment in new information technologies with concepts from OT (Dos Santos 1991, Kumar 1996), and capital budgeting.

[Table 1 here]

Among the issues discussed, we can see that, for MIS, option pricing theory has been used primarily for capital budgeting. The main emphasis of OT research concerns the inability to properly measure the costs and benefits associated with a specific information management project. Many authors have used OT to deal with problems associated with the valuation of projects that exhibit flexibility, resulting in a number of papers that concern valuation. Table 1 lists the range of applications covered by these studies. Though volumes of MIS research have been produced, it is notable that, in the MIS field, more realistic modeling of uncertain factors that apply to real world cases has been neglected. Figure 1 shows our framework, in which each leaf node indicates a potential direction for future research. Because of the narrow focus of most MIS research in the past, there are many areas still to be researched, and these are accorded a place in the framework. Developing flowcharts for different corporate investment decisions and projects for management to utilize is important for MIS efforts.

In addition, the application of OT to a broader set of issues is another missing component of the current efforts in this area. More effort is needed to uncover a good analogy of OT in MIS contexts. Keli (2000) made an outstanding cross-cultural study of the escalation of commitment behavior in software projects. Such attempts of drawing OT to explain MIS phenomenon is a valuable try.

A more important finding is that the number of empirical articles exceeded the number of non-empirical articles that focus on purely conceptual work. Empirical research includes such as that Quigg (1993) conducted an empirical test of options pricing models, while Bendoly and Kaefer (2004) conducted an empirical study on the strategic timing of ERP on B2B e-commerce technology efficiencies. MacDougall (2003) empirically examined four manufacturing technology investments.

Using OT in Future Research

Further research in the area of OT should focus on case surveys, demonstrating to industry how OT fits and improves evaluation models. It would be exciting to look into building OT into MIS, and develop a general methodology to evaluate flexibility in the future.

The first of several considerations arises as a result of possible bias in the selection of papers from various reference disciplines and journals. Despite an extensive approach, the selected sample is not exhaustive. Expanding the sample to include journals outside mainstream MIS or relevant OT research could provide a valuable view of the role of OT in MIS that would otherwise be missed.

Second, though awareness of using OT is growing among MIS researchers, the number of papers available on the subject is limited. Further research that MIS applied OT would surely progress within the bounds of the current research framework. Years from now, the current situation can be critically analyzed. Directions for future thinking, made to further past research efforts and prepare for future researchers, based on the review of existing scientific articles, can bridge gaps in knowledge.

OT can provide a potential service to the MIS field, as illustrated in Figure 3. The figure combines the supply chain concept with the components of the information infrastructure of a firm. Information infrastructure, specifically for MIS projects, consists of hardware, software, applications, and networks (Laudon, 2004), and needs to be efficiently managed in order to achieve a competitive advantage.

“Hardware” expenditure invariably requires critical capital budget decisions, as the expenditures for hardware will be massive, and are made in an uncertain business environment. As stated earlier, OT is best suited to capital budget decisions, such as those made for the hardware infrastructure of a firm. Therefore, it is critical that OT be applied to MIS, resulting in clarification of the option to abandon a project, and the option to implement timing decisions.

OT can also contribute to the “software” component because of its ability to analyze the flexibility value embedded in the software upgrade decisions, and the decision for outsourcing. IS/IT human resource management can apply switch options to analysis the value of recruiting permanent or temporary staff. The “applications” can benefit from the OT thinking by setting application portfolio priorities according to a project’s benefits and uncertainties. This is very different to traditional thinking, which only considers the benefits of projects. In addition to the above components, OT can help companies re-think their strategies, such as software reuse with a new perspective of flexibility value. Traditionally, expensive alternatives in capital budgeting will be discarded even it may bring future flexibility. OT demonstrates that as long as the flexibility may contribute to the expensive project in the future, the project is worth undertaking. Moreover, OT can help explain the phenomenon that most software debut with imperfect bugs version to acquire market share as soon as possible and improved in future versions rather than debut a flawless but time-consuming version.

[Figure 3 here]

In addition to applying to inside an organization, OT thinking contributes to strategic management in supply management. The strategic relationship cannot be explained with tradition tools, such as NPV. A company can evaluate the value of partnership with its suppliers. Using option to switch can help the management to evaluate flexibility. In addition, OT helps make more efficient contract between the company and its supplier by risk sharing. For example, a contract with a flexible order quantity may be designed to solve the problem of over-stocking under uncertainty. A company can change the scale of production, and switch the output mix to its customer under environmental uncertainty. In summary, applying OT thinking contributes to exploring the relationships between nodes in the value chain, each of the components provides future research issues for companies to gain more competitive advantages over competitors.

So far, we have discussed how OT can be applied by a single company. We now examine the potential applicability of OT from another perspective, that of different levels of competition. Next, the industrial concept of markets is introduced. We consider three different levels of competition: monopoly; duopoly; and complete competition.

- A monopoly is observed in Figure 4 when we consider only the area in the figure that is within the smallest square dotted line, and ignore the remainder of the figure. Within this small area, there are no competitors to the firm. No competitor payoff exists in this condition. The company can make decisions independently as there are no others.
- A duopoly is illustrated by the area within the medium square dotted line. There are only two firms, Firm A and Competitor B, and no external competitors in this condition. A payoff chart for competitors can be made in this condition. Firm A and Competitor B affect each other. Each company can best compete if it considers the strategy of the other. It is a two-person game.
- Complete competition is illustrated by the entire figure. There are many firms, including Firm A, Competitor B, and Competitors X, Y, and Z. All the firms in the industry affect each other. It is an n-person game.

[Figure 4 here]

The impact that a firm feels from the external environment varies according to the intensity of the competition in the industry. OT studies in MIS have focused on a single company's opportunity. In reality, however, most opportunities are shared; therefore, a company faces competitive forces that result in a dynamic equilibrium. It is critical to evaluate the strategic value of competitive markets, especially in the fiercely competitive IT sector. In contrast, a firm with a monopoly only needs to consider how long it should defer its strategy opportunity to maximum option value, rather than to consider its competitors.

A rigorous framework addresses the manifold problems that arise when making decisions such as investments under conditions that include uncertainty and competition. Previous OT models categorically assume a monopolistic or perfectly competitive framework. These OT models do not allow for strategic interaction, and assume generally inappropriate conditions, such as

symmetric uncertainty, in investment opportunities. The opportunity can be configured rigorously to the MIS context.

When one degree of competition arises, it is a duopoly; in a more competitive environment, all market players share the value for the market opportunity. Traditionally, two approaches have been used to deal with this issue. One approach models the competitive entries as exogenous shocks. For example, Dixit and Pindyck (1994), Trigeorgis (1991, 1996) and Li (2002) use a Poisson Jump Process to describe the arrival of a competitor in the market. Another approach used is the application of game theory, a Nobel Prize winning work advanced by Nash (1950). Smit and Ankum (1993) extended game theory. Game Theory and OT form an excellent combination for evaluating IT strategy, a combination that may change the face of information economics. Game Theory describes inter-player strategies, and OT justifies the actual value of the feasible strategies described by analyzing payoffs. The first attempt to model external competition, using an estimated entry or a random entry of competitors, was made by Kim and Sanders (2002). Game theory concepts, including strategic interaction between firms, have not been addressed in OT models for the IS/IT industry.

Future MIS researchers must be able to assess the impact that a change makes in accordance with the many unique characteristics inherent in MIS. Technology investment often occurs in conditions of uncertainty, with externalities and in contexts of preemption. Moreover, many long lasting phenomena in MIS can be re-examined, such as: timing of the debut of software, regardless of bugs; problems in supply chain vendor switches; and negotiations between several parties in contracts.

Since OT assesses the value of strategy flexibility, decisions are examined each time new information arrives during the deferral period. As OT optimizes investment strategy in light of new information, it should play an important role in MIS.

Summary and Conclusions

OT has been accepted in many fields because it provides a useful way to understand the value of strategies and opportunities. As a result of OT research, progress has been made in various fields, including patents, investment decision practices, and knowledge management.

The use of OT in MIS is still young. The discussions, issues, and ideas set forth in this paper should stimulate interest in incorporating OT in the field of MIS. Based on the use of OT in existing MIS research, the paper presents an analysis of how OT has been used on a broad range of relevant literature. The paper provides the following guidelines for researchers:

1. An overview of OT for those who wish to understand and use the theory in MIS research. Different perspectives and taxonomies of knowledge are reviewed and discussed, and ideas from diverse research are integrated into a framework.

2. The paper identifies proper application of OT, thus enabling effective development. It seeks to build awareness and understanding of significant works in the field, providing a diversity of perspectives and approaches to MIS and more specific research of OT.

3. It help future theorizing and makes research suggestions regarding OT and the MIS field based on past research, thereby forming a potential basis for future research.

We suggest two ways that OT may play a part in future MIS applications. Implementation is a tradeoff between easy of use and precise brought by complicated modeling and calculating:

1. Offer a simple implementation procedure to help make strategic decisions. Friendly packages can be prepared for ease of use, and powerful computers can allow sophisticated models to be built. This reduces criticism of OT for its complex mathematics.
2. Incorporate realistic risk factors in modeling MIS. The more risk factors used to describe uncertainty, the more complex it will be.

From this review, it is evident that the rich discussion regarding OT applications that took place in the field of financial economics has extended to the unique MIS context, but not fully. The potential benefits as well as the methodological problems in applying options pricing theory in R&D project evaluation merit further consideration. Case studies and empirical studies will play a crucial role in justifying more real-world MIS applications.

The ultimate effort is to develop simple and precise pricing formulas for unique MIS context formulating and to develop a powerful decision support tool. No matter what method is adopted, OT is an excellent tool that will certainly have a place in future MIS applications.

ABSTRACT

Implementations of ERP systems have been reported to provide a number of benefits for many companies. However, several studies also illustrate that achieving such benefits from the use of ERP systems can be difficult. In this context, one of the main challenges is to ensure adequate quality of the data in the ERP system. To support the evaluation of ERP data quality and to improve the understanding of data-related problems, this paper proposes a classification model of ERP data. The proposed classification model builds on a discussion of existing data quality classifications. The relevance of the classification model is illustrated by presenting three case studies where ERP data issues have been studied.

Keywords: Enterprise resource planning, ERP systems, Data quality, Master data management

INTRODUCTION

It is a widely accepted maxim that decisions are no better than the data on which they are based. Data are fundamentally important for all companies, since almost any activity in a company requires data. To be more specific, data are created and used in all daily operations, data are critical inputs to almost all decisions, and data implicitly define common terms in an enterprise, which makes data a significant contributor to the organization culture [10]. Therefore, it is of critical importance that data are of adequate quality. According to Redman [15], studies to produce estimates of the total cost of poor data quality have proven difficult to perform, but at least three proprietary studies have yielded estimates in the 8-12% of revenue range. However, Redman [15] claims that, informally, 40-60% of the expense of a service organization may be consumed as a result of poor data. Häkkinen and Hilmola [6] argue that marginal data inaccuracies (e.g. 1-5%) may not necessarily represent a major problem in manufacturing, but that such inaccuracies will have direct effects in terms of lost sales and operational disruptions in the after-sales organizations.

A typical source of data quality problems is that the same data are stored and maintained redundantly in different systems. Vayghan et al. [22] argue that normally large enterprises manage data at a local level (e.g. department or location), which results in the creation of 'information silos' in where data are redundantly stored, managed, and processed. Thus, inconsistency often occurs. Mohania and Bhide [12] claim that the information integration problem has become the biggest pain point for enterprises today. According to Mohania and Bhide, the growth of organizations invariably leads to creation of multiple isolated data sources that are disconnected from each other, leading to reduced efficiency. In this context,

ERP systems have been promoted as a panacea for dealing with lack of data integration by replacing inadequately coordinated legacy systems [2;8]. However, it is often a difficult task to implement an ERP system into an organization, and often such projects do not produce the expected benefits [3;6;11;21;26]. In this context, it has often been argued that the quality of data/information is a major determinant of ERP success [19;23;25;27;29]. In fact, it has been suggested that data problems get intensified when using ERP systems, because the ERP modules are intricately linked to each other, for which reason poor quality data input in one module can negatively affect the functioning of other modules [14].

Since it is essential for the success of an ERP project that the needed data can be found in the ERP system and that these data are of adequate quality, there is a need for continuously evaluating the ERP data, both during implementation and when using the ERP system. The question in focus of this paper is how to evaluate ERP data during these phases. Thus, this paper proposes a classification model to evaluate ERP system data. The relevance of the classification model is illustrated by presenting three case studies and relating these to the classification model. The classification model may also be applicable for the evaluation of data in other types of information systems, but to avoid additional complexity this discussion is not included in the paper.

The remainder of the paper is structured as follows: In section 2, the characteristics of ERP data and concepts of data quality are investigated. Next, in section 3, based on a discussion of relevant literature, a classification model of ERP system data is proposed. In section 4, three case studies are presented and subjected to the proposed classification model. The paper ends with conclusions in section 5.

ERP DATA

Data, information and knowledge

As a basis for the discussion of ERP data, it can be useful to distinguish data from information and knowledge. With regard to data and information, there seems to be general agreement on the meaning of these terms. Davenport and Prusak [4] define data as "discrete, objective facts about events" and information as data transformed by the value-adding processes of contextualization, categorization, calculation, correction, and condensation. Zack [28] provides the definitions "data represent observations or facts out of context, and therefore not directly meaningful" and "information results from placing data within some meaningful context, often in the form of a message". In a similar vein, Newell et al. [13] define data as "providing a record of signs and observations collected from various sources" and information as when "data are presented in a particular way in relation to a particular context of action". On the other hand, the meaning of the term 'knowledge' is far more debatable. This discussion often relates to if knowledge should be perceived as being of an impersonal and static nature versus being personal and related to action. The first perspective on knowledge can be traced back to Plato's "Theaetetus" (c.400 BC) in the form of the definition 'justified true beliefs'. In spite of some criticism of this definition, it is frequently found in contemporary management literature, however, often in softer versions, i.e. with reduced emphasis on the 'truth' part (according to Fuller [5] and Newell et al. [13]). As a representative of the personal and action-oriented view of knowledge, Tsoukas and Vladimirou [20] provide the definition: "knowledge is the individual ability to draw distinctions within a collective domain of action, based on an appreciation of context or

theory, or both". However, a deeper discussion about the meaning of the term ‘knowledge’ is beyond the scope of this paper, which, as mentioned, has its focus on data.

ERP data

In a business context, the concept of 'data' involves two interrelated components, 'data models' and 'data values' [15]. A data model is a definition of entities (classes), their attributes (properties), and relationships. An example of an entity is 'employee', which could hold the attributes 'ID', 'name', 'date of birth', 'address', etc. The employee could have a relationship to the entity 'ERP project', implying that the employee is involved in this project. The data value for the employee attribute 'ID' could be '01-77-98'. When such data are stored they become data records. Unlike other typical resources, data can be readily copied, shared and combined in many ways. Thus, compared with other resources, data presents some special challenges to be aware of, not the least to ensure that data are of adequate quality.

Vayghan et al. [22] classify the data that most enterprises deal with into the three categories: master data, transactional data, and historical data. However, it seems that 'historical data' is merely a status that the first two can obtain, rather than a category of its own. Thus, the focus of this paper is on ERP master data and transaction data. Master data are the basic characteristics of instances of business entities, such as customers, products and suppliers. Typically, master data are created once, used many times and do not change frequently [8]. In ERP systems, master data are usually used across several application modules in the transactions that are registered. Transaction data describes relevant events in a company, and each transaction record has a time dimension, a value, and references to other data. Samaranayake [16] provides a list of common transaction data and associated master data, which is reproduced in Table 1.

Transaction Data	Associated process/module	Master data involved
Planned order	MRP (Material Resource Planning)	Material master and BOM
Production order	Production order creation	Material master(s), BOM, Operations routing, Cost centre(s)
Purchase order	Purchase order creation	Material master, Vendor
Sales order	Sales order creation	Material master, Customer
Maintenance order	Maintenance order creation	Equipment, Task list, Work Centre

Table 1: Common transaction and master data [16]

Knolmayer and Röthlin [8] argue that capturing and processing master data is error-prone activities where inappropriate information system architectures, insufficient coordination with business processes, inadequate software implementations, or inattentive user behaviour may lead to disparate master data. Knolmayer and Röthlin give the example that if an employee does not find required master data within reasonable time, the employee may be tempted to swiftly create duplicate data in order to continue carrying out business tasks. Also, mistyping names, addresses, and other data fields contributes to data redundancy.

Data quality

The business data of a company can be more or less useful, depending on the quality of the data. As a basis, Park and Kusiak [14] define 'data quality' as "the measure of the agreement between the data views presented by ERP and that same data in the real world". Lederman et

al. [9] provides a more pragmatic definition of data quality as 'fitness for purpose'. However, more detailed definitions of data quality in the forms of classifications have been produced.

Ballou and Pazer [1] divide data quality (DQ) into four dimensions, as shown in Table 2. They note that the accuracy dimension is the easiest to evaluate, since this merely is the difference between the correct value and what actually was used. They argue that the evaluation of timeliness can be done in a similar manner. The completeness dimension is also relatively straight forward to evaluate, as long as the focus is on if data is complete or not, rather than how many percent complete some data is. On the other hand, an evaluation of consistency is a bit more complex, since this requires that two or more representation schemes are present in order to compare [1].

DQ dimension	Meaning
(1) Accuracy	The recorded value is in conformity with the actual value
(2) Timeliness	The recorded value is not out of date
(3) Completeness	All values for a certain variable are recorded
(4) Consistency	The representation of the data value is the same in all cases

Table 2: Data quality dimensions [1]

Wand and Wang [24] investigate data quality dimensions used in literature. They apply the perspective that lawful states of the real-world are represented as states in information systems, i.e. a mapping between relevant things of the real-world and the data in an information system. The argue that two conditions must hold for a real-world system to be properly represented: (1) every lawful state of the real-world system should be mapped to at least one lawful state of the information system; and (2) in principle, it should be possible to map an information system state back to the "correct" real-world state. Their classification of intrinsic data quality dimensions is shown in Table 3.

Intrinsic DQ dimension	Meaning
(1) Complete	Each real-world state is mapped to an information system state
(2) Unambiguous	No two real-world states are mapped to the same information system state
(3) Meaningful	No meaningless information system states; Real-world states are mapped to meaningful information system states
(4) Correct	A real world state is mapped to a correct information system state

Table 3: Intrinsic data quality dimensions [24]

Strong et al. [18] provide a division of data quality that goes beyond intrinsic quality dimensions. This is shown in Table 4. They argue that while the first three dimensions can be observed relatively isolated, representational data quality dimensions are underlying causes of accessibility problem patterns. In other words, if a representation cannot be understood by some user, then this can be seen as a form of access-limitation.

DQ categories	DQ dimensions
(1) Intrinsic	Accuracy, Objectivity, Believability, Reputation
(2) Accessibility	Accessibility, Access security
(3) Contextual	Relevancy, Value-added, Timeliness, Completeness, Amount of data
(4) Representational	Interpretability, Ease of understanding, Conciseness/consistency of representation

Table 4: Data quality dimensions [18]

Building on existing literature, Shanks [17] presents a data quality classification, which is based in semiotic theory (the use of symbols for conveying information) and includes both product-oriented and service-oriented aspects of data quality. This is shown in Table 5.

Semiotic level	Meaning	Goal of the representation
(1) Syntactic	The form of symbols rather than their meaning	Correct and consistent
(2) Semantic	The meaning of symbols	Complete and accurate at particular points in time
(3) Pragmatic	The usage of symbols	Useful and usable
(4) Social	The understanding of the meaning of symbols (different stakeholders)	A shared understanding of the representation is achieved

Table 5: Data quality dimensions [17]

Besides the four described classifications others also exist (see e.g. [7]). These are excluded based on arguments of being similar to the ones described, less recognised, or not as relevant for the purpose of this paper, i.e. to create an operational classification model for evaluating ERP data quality.

A CLASSIFICATION MODEL FOR EVALUATION OF ERP SYSTEM DATA

The purpose of this section is to create a classification model for evaluation of ERP system data. Thus, as a starting point, it needs to be defined which dimensions are relevant for evaluation of ERP data.

Discussion of data quality dimensions and categories

As discussed in the previous section, different ways of perceiving data quality exist. To start with, it can be argued that the dimensions defined by Ballou and Pazer [1] (accuracy, timeliness, completeness, and consistency) are intrinsic data quality characteristics. The debate in this context is if the 'timeliness' dimension is more contextual that intrinsic, as Strong et al. [18] claims it is. This paper takes the opposite position by arguing that at the point of time where the timeliness of some data is evaluated, this data is either up-to-date or not, and, thus, an intrinsic quality. This perspective is also supported by Ward and Wang [24] who argue that untimely data is manifested in the form of wrong, meaningless or ambiguous representations. Furthermore, Wang and Wand [24] systematically deduct four data quality dimensions with intrinsic focus (complete, unambiguous, meaningful, and correct).

The intrinsic quality dimensions defined by Strong et al. [18] (accuracy, objectivity, believability, and reputation) differ somewhat from the two previous definitions. Strong et al. do not argue for this selection besides showing how these dimensions can be part of typical data quality problem patterns. In particular the last two intrinsic data quality dimensions of Strong et al. seem to relate to the subjective judgements of users, or at least this is what the

chosen terms indicate. Since the term 'intrinsic' denotes something that is specific to an element and which is wholly independent of other elements, then this kind of use seems to contradict the term. Thus, these dimensions are not included in the understanding of intrinsic data quality dimensions in this paper.

Strong et al. [18] define the three extrinsic data quality categories, accessibility, contextual, and representational, where the latter is described as an underlying cause of accessibility problems. Strong et al. define data of poor contextual quality as data with little value added or data of little relevancy for the tasks of data consumers. Thus, contextual data quality may be perceived as a way of describing the usefulness of the data. If seeing representational data quality as a sub-area of accessibility data quality and applying the mentioned interpretation of contextual data quality, this leaves the data quality categories: intrinsic, accessibility, and usefulness.

The last data quality classification by Shanks [17] can at the first two levels, i.e. syntactic and semantic, be perceived as intrinsic data quality dimensions. On the other hand, the pragmatic and the social level cannot directly be put into this category. As defined by Shanks, measurement of data quality at the pragmatic level is done by the use of stakeholder rating, while at the social level, data quality is measured by user surveys. In an ERP perspective, the pragmatic level should not be seen as an alternative to correctness at the syntactic level. If data are stored in a way that in some contexts are useful, but the data are not correct at the syntactic level, this could imply that the data in other contexts are problematic, e.g. if statistics based on such data present a wrong picture of the reality. Instead, the pragmatic level may be seen as placed on top of the intrinsic level, as a level where the decisions of storing certain types of data are made based on the usefulness of these. In an ERP context, the social level may be seen as the level where agreements on formats and standards for data are established. Thus, this level does not contribute directly when evaluating ERP data quality, but can rather be seen as input to the ERP system management.

A classification model of data quality

Based on the discussion in the previous section, the following three data quality categories are applied for the creation of a data quality classification model:

1) Intrinsic data quality dimensions: completeness, unambiguousness, meaningfulness, and correctness (based on [24])
2) Data accessibility dimensions: access rights, storage in ERP system, representation barriers, etc.
3) Data usefulness dimensions: relevancy, value-adding, etc.

The first two data quality categories (intrinsic and associability) are the easiest to measure and/or observe, while the third (usefulness) is more difficult to evaluate because it is more subjective. Additionally, the first two categories are more critical than the usefulness category, since poor data accessibility and intrinsic data quality are factors that make some daily operations impossible, while ERP system data of little usefulness to much extent can be ignored. Thus, from an operational perspective, an evaluation of the two first categories is most important. Based on the first two categories of data quality dimensions, a two-by-two matrix can be created. This is shown in Figure 1, where it should be noted that since

companies cannot expect to achieve perfect data quality, it is generally satisfactory that a small part of data is of poor quality with regard to intrinsic and accessibility dimensions.

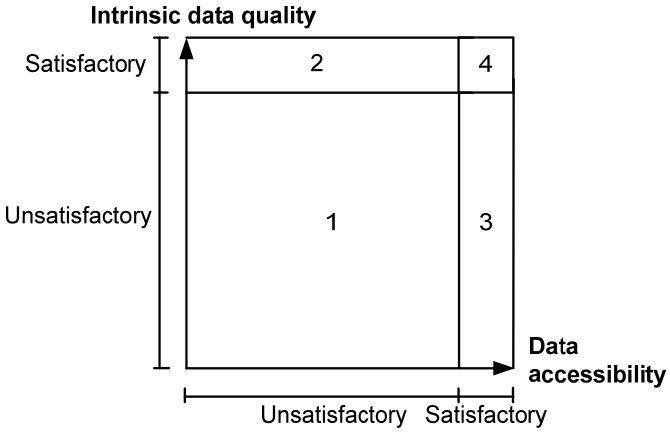

Figure 1: Intrinsic and accessibility quality of ERP system data

In area 1 of Figure 1, both the intrinsic quality and the accessibility of ERP data are at an unsatisfactory level. In such cases, the expected benefits from using an ERP system are typically not achieved, but, on the other hand, many problems are encountered. In area 2, the intrinsic quality of the data implemented in an ERP system is at a satisfactory level, but for some reason users cannot retrieve all relevant data from the system. In cases where the data are stored in the ERP system and the problem is that users cannot access this data, either because of poor knowledge of the ERP system or limited user rights, it would normally not require big efforts to fix such issues. On the other hand, if the problem is that relevant enterprise data is not stored in the ERP system, great efforts to correct this are normally required. Often the problem of not having all the relevant data stored in the ERP system is the result of the fact that some users conduct their daily operations without registering the necessary data in the ERP system. Changing the habits of such employees, therefore, is a central task. Area 3 represents a scenario where the necessary data can found in the ERP system, but the intrinsic quality of these data is unsatisfactory. This means that, although the necessary data can be retrieved, decisions based on these data may have negative effects. Area 4 represents what should be the aim of ERP projects, namely to achieve a situation where the data stored in the ERP system are of satisfactory quality with regard to intrinsic and accessibility dimensions.

Data usefulness

The three defined data quality categories allow the creation of two additional matrices, i.e. intrinsic data quality in relation to data usefulness, and data accessibility in relation to data usefulness. These two matrices and the typical patterns to be aware of (dotted arrows) are shown in Figure 2 and subsequently discussed.

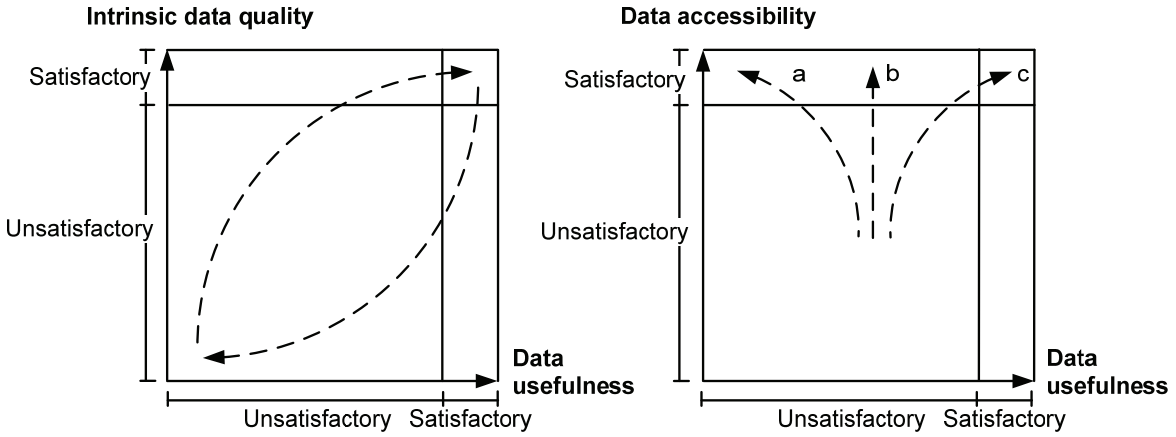

Figure 2: Intrinsic and usefulness quality of ERP system data

First, in the matrix to the left in Figure 2, from a common sense perspective, it seems that if the intrinsic data quality decreases, this would lead to more non-useful data being stored in the ERP system, because if the users begin to question the validity of data, they would also be more reluctant to use such data. On the other hand, it seems that if the intrinsic data quality is increased, this in time would imply that the stored ERP data are found increasingly useful.

In the matrix to the right in Figure 2, three typical patterns are defined. Path 'a' represents a situation where, for instance, it is decided to begin registering a new type of data, but it later turns out that this data is not used for anything after all. Path 'b' represents a situation where data are registered in the ERP system (or existing data in some way is made accessible to users), but where the increased amount of data does not make existing data more valuable and where the additional data holds a similar percentage of non-useful data. This could for instance be a situation where a field in a sales form is filled out each time an order is created, although these data are not used for anything. Path 'c' represents a situation where the usefulness of existing data is increased because of adding additional data. This can for instance be a situation where the existing sales data are not found useful for making sales statistics because of being incomplete, i.e. many sales have not been registered. However, when updating the system with the previously unregistered sales data, suddenly the existing sales data become useful for making sales statistics, because they are now part of a complete picture.

CASE STUDIES

To illustrate the usefulness of the proposed classification model, this section presents three case studies of ERP projects.

Method

In 2007, a questionnaire survey was carried out with the purpose of investigating the use of ICT (information and communication technology) in Danish SMEs (small and medium-sized enterprises). The total number of companies contacted was 182, which resulted in 95 answers. From the 95 companies that answered, three companies were chosen for more in-depth case studies. The companies were chosen randomly within the part of the companies that had implemented an ERP system, used by multiple departments in the company. Through November and December 2008, the case studies were carried out by conducting

semi-structured interviews of 3-4 hours, with subsequent questions by phone in the cases where this was needed. In each company, the managing director and a representative from either the IT department or the ERP system super-users were interviewed. The interviews were given on the promise of anonymity, for which reason the three companies are named A, B and C. Table 7 shows the overall information about the three companies.

Company	A	B	C
Turnover (2008)	~35 mill. €	~25 mill. €	~60 mill. €
Salaried staff	~60	~25	~80
Hourly paid employees	~55	~10	~120
Company type *	CTO, MTO, MTS	Wholesaler	MTO
Industry	Agriculture equipment	Insulation products	Printing solutions
ERP system	SAP Business One	Navision 5.0	SAP R3

* CTO: Configure-To-Order, MTO: Make-To-Order, MTS: Make-To-Stock

Table 7: Basic company information

Company A

Before implementing SAP Business One, company A used a less known trade-specific ERP system. By the end of 2004, company A decided to replace the old system, and the new ERP system was bought 3 months into 2005. The implementation project was planned to last three months, and this deadline was kept. The test period lasted only 14 days before taking the system into use in daily operations. During the three month long implementation project, some employees were sent on courses, and workshops about the system were held. The project preparation also included the creation of blueprints and conduction of various analyses. The ERP project manager was a person from the purchase department who had experience with the ERP system. This person received additional training in the system.

Several problems were experienced during the start of the shakedown phase. In the opinion of the interviewed, one problem was that not enough time had been spent on giving all areas of the ERP system the attention that they deserved before taking the system into use. Thus, some of the customisations of the system were later found to be superfluous, while other parts of the systems needed customisation in order to fit the business processes of the company. In all, many customisations of the ERP system were made in order to adapt the system to the company. Another consequence of the short implementation phase was that a rethinking of item-groups was not done prior to the implementation, for which reason many item-groups were not implemented in a manner fitting the logic of SAP Business One. This implied several data problems, and by the end of 2008 the company was still working on restructuring this part of the data. Besides poorly structured data, also erroneous and incomplete item master data were migrated to the new ERP system, and some types of data were not even stored in the new system because of the short implementation phase. For instance, many prices were missing. The unfortunate consequence of the poor data quality was that when making inquiries involving item data in the ERP system, the data extracted were not reliable.

At the end of 2008, the continuous work of improving data associability and quality reached a state where the data were close to being of a satisfactory accessibility and quality. In connection with this, positive effects of the project have been achieved. This includes that data are more accessible, more extensive, and of better quality, which implies improvements related to purchases, economic control, quality of the specifications delivered to customers, and certainty of delivery. In a communication perspective, positive effects have been

achieved in the form of fewer errors, fewer misunderstandings, and less time spend on communication. One of the initiatives to ensure better data quality was a decision of that it is only the technical department who have user-rights for the creation of master data for new items. However, still much can be improved. A problem that the company is currently facing is that although the required functionality for some task can be found in the ERP system, in many cases employees prefer to extract data and manipulate this data in spread sheets, e.g. for budgeting. Also, data for new items are firstly defined in spread sheets before being registered in SAP. The company has recognised that this is a problem, since this procedure results in redundant data. Thus, at the time of the case study, the company was investigating how to improve their current procedure.

Company B

Company B took Navision 5.0 into operation in January 2008. From project initiation to the ERP system was taken into use took about 2 months. Prior to this project, the company used a ten year old installation of Navision, which could not be updated. The main reason for choosing Navision 5.0 was to make the migration of data as easy as possible. During the implementation phase, workshops were held in a limited extent in order to define the new system and inform employees. However, no real education of employees was carried out. The implementation team initially consisted of 3-4 consultants, but company B found that these consultants were poorly coordinated and did much of the same work, for which reason they demanded to use only one of these consultants. Initially, the basic ideology of company B was not to let the new ERP system decide how their processes should be carried out. However, after discovering the cost and complexity of ERP system customisations, this point of view was softened and compromises were made. For instance, the company only made minor adjustments to how the ERP system defined inventory management, although originally having planned large customisations.

During the data migration from the old to the new ERP system, great problems were encountered because of poor master data. This was an unfortunate consequence of the fact that master data had not been maintained much in the old ERP system. Thus, during the two month long implementation phase, there was not enough time for reviewing data for all of their about 16,000 items. The result was that after having taken the ERP system into use, about a year was used on correcting master data, in particular related to items, debtors, and creditors. During this period, many problems were encountered because of the faulty ERP data. An effect of this was that many users did not trust the information that the system provided when generating certain reports. Thus, the use of the ERP system reports has been very limited until the time of this study.

In spite of the data-cleaning project, company B still experiences the problem that all received items are not being registered in the system, for which reason all relevant data cannot be found in the ERP system. According to the IT manager, it can be a bit tedious to register such in the ERP system, for which reason this is sometimes neglected at busy times. In this context, also difficulty in using the new system is considered to be a main barrier for data proper use. To prevent that items arrive in stock without being registered, employees in this function are controlled once in a while. Also, company B has bought customisations of the ERP system that force employees to type in certain data in order to carry out specific operations. Another problem in company B is that some item data are created outside the ERP system. About half of the item names and prices are first described in a catalogue, which

is not synchronised with the ERP system. The company recognizes that this is problematic and plans to introduce a policy where all item master data are created in the ERP system, while the catalogues are made based on exports of these data. For the financial part, the ERP system is not fully applied. For instance, although that annual accounts are created in the ERP system, these are later exported to Excel and modified. Many of these modifications are not registered in the ERP system, for which reason all such ERP system data are not reliable.

The use of the ERP system has also had some positive effects. Compared to the old system, the new system has improved features on the economic side (i.e. better reports and overviews), the system enables auto-payment to the bank (which has implied fewer errors), and the system supports electronic invoices. Also, according to the IT- manager, the new system ensures that most relevant data are registered. An indirect positive effect of the ERP project has been that many documents have been digitalised, i.e. the flows of physical papers have been minimised. However, all in all, the interviewed of company B do not think that they have achieved significant positive effects from replacing their existing ERP system compared to the resources used on the project.

Company C

Company C applies the ERP system SAP R3. Before implementing this they had been using a less known finance system. SAP R3 was taken into use in 1999 after an about 9 month long implementation phase (system configuration, system customisation, and data input). However, it took about 2½ years before the system was fully running in all areas, compared to the 1-1½ years expected at project start. Also, the budget for the project was exceeded so the project ended up costing more than twice as much as defined in the original budget.

During the implementation phase, a representative from each department was appointed, and these persons participated in common workshops where the ERP system was configured, customised, and tested. The workshops were aided by SAP consultants and held 1-2 times each week in nine months. The department representatives were given the responsibility of educating their colleagues. Both during and after the implementation, many resources were used on customising the system to make it appear like the old ERP system. The company estimates that 30% of their current ERP system is customisations.

The ERP project faced great problems in the start of the shakedown phase, which partly can be attributed to big ambitions of what to register in the system, i.e. down to ‘screw-level’. This approach made it very time-consuming to create new items, for which reason many employees took shortcuts that resulted in missing and faulty ERP data. Thus, after some time it was decided to leave out items at such a detailed level in the ERP system. Currently, the ERP system holds about 80,000 item numbers, where around 25,000 are in use. Company C considers it to have been a great problem that the consultants used for the project were too inexperienced and had too little understanding of the business processes and the needs of the company. Therefore, the first consultancy was replaced by another shortly after having taken the system into use. Also, company C experienced great problems related to master data during the first years of use. The problems relates to that master data (such as item numbers and names) were sometimes registered multiple times, while at other times all required fields were not filled out. This, for instance, made it impossible to make useful statistics based on these data. In order to solve this problem, great resources were used on training employees in proper use of the ERP system. Additionally, company C is considering allowing only central

persons to create item master data, but is afraid that this may imply waiting times when creating purchases and sales orders.

The company sees many benefits achieved from the system as it is now, but questions if the project has been worthwhile when considering the many problems and the cost of the project. Company C considers the main benefit of the system to be that data are more accessible and the quality has been increased significantly. Also, a positive indirect effect of the project has been that the company has gone from having most information only in paper form to now having almost all information stored digitally, including drawings.

Discussion

As the case studies show, all the three companies faced great problems related to ERP data quality. Furthermore, none of the three companies can at present time be said to have achieved satisfactory levels of both intrinsic data quality and accessibility. In all three cases, at initiation of the ERP project, the importance of data management was neglected, which implied great use of resources and time on correcting data. If the focus in this phase had been more on ensuring adequate data accessibility and quality, it seems that many problems could have been avoided and many resources saved. In Figure 3, the courses of company A, B, and C from the time of taking the ERP system in use until the time of the case studies are illustrated in a principal manner. As seen, the cases represent much similar patterns, i.e. cases where it at some point is recognised that the ERP data quality is unsatisfactory, for which reason many resources are used on raising the intrinsic data quality and the data accessibility.

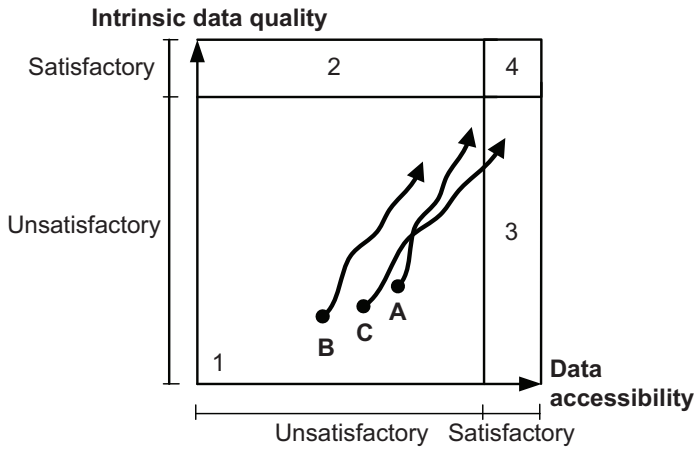

Figure 3: The development of ERP data quality in the three case companies

The three cases to some extent confirmed the claimed relationships between data usefulness and intrinsic data quality, and between data usefulness and data accessibility. In the cases studied it was experienced that low intrinsic data quality made the usefulness of such data low (e.g. by not being able to use the data for statistics), while raising the intrinsic data quality made the data more useful. Concerning the relationship between data usefulness and accessibility, the three paths defined in the right side of Figure 2 were recognised by the interviewed, i.e. deciding to register a new type of data that later turns out not to be used, registering data sets that includes non-useful data, and increasing the usefulness of existing data by adding additional data.

CONCLUSIONS

In literature it has been pointed out that many ERP projects face problems related to inadequate data quality. To deal with this issue, this paper investigated the concept of data quality in an ERP system context. To start with, literature on data quality was investigated, and based on this the paper engaged in a discussion of which data quality categories are relevant when evaluating ERP system data. The paper argued that from an operational perspective three main categories of data quality dimensions are particularly relevant to consider in ERP projects: (1) intrinsic data quality dimensions; (2) accessibility data quality dimensions; and (3) data usefulness dimensions. Of these categories, the paper argued that for evaluation of ERP data, intrinsic and accessibility data quality dimensions are the most important, since these are the easiest to measure and cannot, as useless data, be ignored in daily operations. Thus, a 2-by-2 matrix with these categories of dimensions was defined, each axis divided into 'unsatisfactory' and 'satisfactory' states. Additionally, the paper presented the two matrices of the remaining two combinations of data quality categories, i.e. data usefulness in relation to intrinsic data quality and data accessibility respectively. By using the matrices, the paper described the typical patterns that are likely to occur in ERP projects.

To investigate the relevancy of the proposed classification model, three ERP projects were investigated. Although the cases had been selected more or less randomly, all the three selected companies had faced great problems related to ERP data quality. In the beginning of all three ERP projects, the companies had neglected the importance of data management, for which reason they later had to use many resources on correcting data. In a general perspective, during the course of all three projects, all three companies represented a move from unsatisfactory levels of data accessibility and intrinsic data quality towards being close to accomplishing satisfactory levels, although none of the three companies at the time of the investigation could be said to have achieved satisfactory levels in both categories of quality dimensions. With regard to the suggested causalities between data usefulness in relation to intrinsic data quality and data accessibility respectively, these were to a large extent confirmed by the case studies.

In summation, this paper has proposed a classification model for evaluating data quality in ERP projects. Besides, two types of causal relationships between data quality categories have been presented. The three case studies confirmed that the classification model is suited for describing ERP data quality and that the claimed relations between data qualities categories corresponds with practice.

ABSTRACT

There is a general scarcity of models and frameworks for evaluating Web-based information systems quality. Traditional theories and models in the fields of the information systems (IS) and marketing can be extended to address this issue. Particularly, we believe that deeper theoretical developments are needed to study the "IS quality" in the online environment context and its impact on the customer satisfaction in a relational mutichannel exchange area. Based on the DeLone and McLean IS success model and the SERVQUAL framework, we propose a Web-based IS quality (WISQ) model. This model examines the impact of the Web-based IS quality factors (Web-based system quality, Web-based content quality, and online service quality) on the customer satisfaction. Further research into developing, validating and empirically testing the model is proposed.

Keywords: Web-based IS quality, customer satisfaction, DeLone and McLean's IS success model, SERVQUAL, relational multichannel service provider.

INTRODUCTION

In the management information systems (IS) research, IS quality was identified as one of the most important determinants of the IS success. DeLone and McLean (1992) proposed information quality and system quality as two components of the IS quality. In 2003, they added service quality as a third new component in an updated IS success model. In this model, information quality, system quality, and service quality became the drivers of the user satisfaction (as a measure of IS success). Later, DeLone and McLean (2004) applied their updated model to organize e-commerce success metrics identified in the literature and demonstrated how it can be used through two cases studies.

DeLone and McLean (1992) applied information communication theory in dividing the IS quality into system quality and information quality, but their 2003 updated model adds service quality and new paths to their original IS success model that are not encompassed by their original theory base (Ding and Straub 2007). This renders the 2003 model interesting, but not completely coherent. On the other hand, other studies in the IS field were focused on

the IS service quality only and they have applied the marketing-originated SERVQUAL instrument to studying the quality of the human service provided manually by the IS department. "Unfortunately, and ironically, many service functions have been automated via sophisticated information technologies, and, in spite of this development, studies of IS service have tended to ignore ITs that are rapidly becoming an embedded characteristic of service. Overall, these problems saddle DeLone and McLean 2003 IS success model with an essentially manual view of IS service" (Ding and Straub 2007, p.1).

Although traditional IS success model can be extended to investigating e-commerce success, they need further refinements to meet the specificities of the Web-based information systems. The DeLone and McLean work (1992; 2003) helps researches in understanding different aspects of IS quality and success, but we think that it needs further development and validation before it could serve as a basis for the selection of appropriate Web-based IS success measures. Particularly, we believe that deeper theoretical developments are needed to re-examine the IS quality concept in the online environment context as well as its impact on customer satisfaction in the relational mutichannel exchange area.

In fact, there are several raisons which motivated the refinement of the DeLone and McLean's 2003 model to adopt it to the Web-based IS in the multichannel service provider context. First, DeLone and McLean suggested that their updated IS success model can be adapted to the measurement challenges of the new e-commerce world. They defined e-commerce as the use of the Internet to facilitate, execute, and process transactions which involve a buyer and seller, and the exchange of goods or services for money. However, this definition is too narrow in comparison with the notion of Web-based IS because it focuses on online shopping only. In fact, Web-based Information system is larger than the use of the Internet and it goes beyond the fulfilment of the electronic transactions. The Web-based information system can be defined as a dynamic and distributed platform for interactive World Wide Web application solutions in order to perform several business functions (information provision, communication, distribution, and customer service).

Second, DeLone and McLean's e-commerce definition is inserted in a transactional perspective rather than relational perspective. Transactional perspective considers that customers and service providers engaging in existing exchange do not expect future exchange. On the other hand, relational perspective is based on intensive coordination, mutual commitment and anticipatory of future ongoing interactions between customers and service providers (Ding and Straub 2007). Understanding relationship marketing requires distinguishing between the discrete transaction and relational exchange (Morgan and Hunt 1994). Discrete transaction has a distinct beginning, short duration, and sharp ending by performance. Relational exchange traces to previous agreements and is longer in duration, reflecting an ongoing process (Dwyer, Schurr, and Oh 1987). In the services marketing area, Berry (1983) states that relationship marketing is attracting, maintaining, and enhancing customer relationships. Berry and Parasuraman (1991) consider that relationship marketing concerns attracting, developing, and retaining customer relationships. In this sense, the transactional perspective privileged by DeLone and McLean (2004) is not suitable for the service provider perspective which is based on long term exchanges between firms and ultimate customers, as particularly recommended in the services marketing area (Montoya-Weiss et al. 2003).

Finally, DeLone and McLean (2004) defined service quality as the overall support delivered by the service provider, applies regardless of whether the support is delivered by the IS department or a new organizational unit or is outsourced to an Internet service provider. In this case, the IS service quality, as a component of the overall IS quality, focuses mainly on human-delivered service. However, this viewpoint needs to be adjusted to recognize the new reality of service businesses today, businesses that are either reengineered or thoroughly automated through the application of sophisticated IT such as Web-based technologies (Ding and Straub 2007; Molla and Licker 2001).

In this study, we take into account these lacunas in the refinement of the updated DeLone and McLean Model to assess to Web-based information systems quality. To avoid ambiguity, we define Web-based IS quality (WISQ) as the degree to which Web-based information system is able to provide value to customers and to effectively and efficiently fulfil their needs as well as to offer them supports in the online self-service manner. Looking at this definition, two things become apparent. First, we emphasize the pure self-service character of Web-based IS which refer to technologies-based self-service. Thus, our approach avoids the conceptual overlaps inherent in many previous IS studies, which mix up online service factors with people-based service elements.

Second, this definition goes beyond the online shopping and the use of the Internet to execute transactions (e-commerce). In effect, we focus on Web-based IS which enable customers to accomplish several activities (search information, ask questions, take requests, obtain sophisticated solutions to problems) and to interact extensively with the service provider via a Web interface in order to retrieve desired benefits. Therefore, we adopt the relational perspective characterised by a high degree of communication and interaction between service providers and customers.

In a multichannel environment context, service providers may reach customers using a mix of channel formats (online and offline) and their objective is to distribute resources across the channel mix to satisfy customers (Montoya-Weiss et al. 2003). Cross-channel synergies are particularly important in relational exchange contexts in which customers choose from different channel formats that belong to the same firm. Therefore understanding what drives customer online satisfaction is an important step in creating complementarity between online channel and offline channel for the service provider.

In this study, we examine the relationships between Web-based IS quality and the customer satisfaction in a relational multichannel context. Using the IS success models and theoretical developments in relationship marketing, we developed WISQ model. This model examines the impact of three Web-based IS quality factors (Web-based system quality, Web-based content quality, and online service quality) on online customer satisfaction which, in turn, affect the overall satisfaction.

This paper is organised as follows. First, we develop the theoretical background of the IS success model. After that, we discuss the use of it in the online environment context. Next, based on these section, we present our Web-based IS quality model. Finally, we present the conclusion and future research directions in the end of the paper.

INFORMATION SYSTEMS SUCCESS MODELS

To organize diverse research, as well as to present a more integrated view of the concept of IS success, DeLone and McLean (1992) introduced a multidimensional model of IS success. Based on the classic communication theory (Shannon and Weaver 1949; Mason 1978) as well as conceptual and empirical research in management information systems (MIS) during the period 1981-1987, they categorized IS success into six major dimensions: system quality, information quality, use, user satisfaction, individual impact, and organizational impact. These dimensions (or many aspects of IS success) are drawn together into a descriptive model (figure 1). According to this model, system quality and information quality singularly and jointly affect both use and user satisfaction. In addition, the amount of use can have a positive or negative effect on the degree of user satisfaction and vice versa. Use and user satisfaction are direct antecedents of individual Impact which should eventually have some organizational impact.

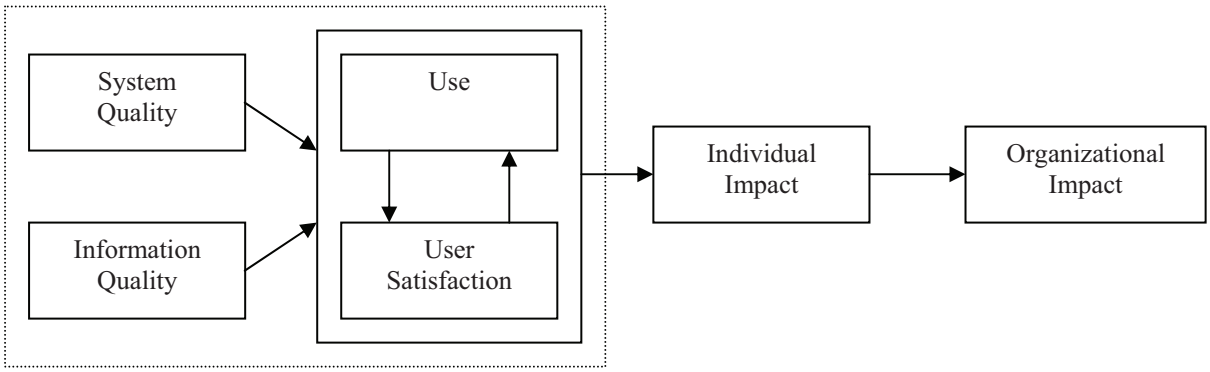

Figure 1: DeLone and McLean's 1992 Model of IS Success

The six dimensions of the IS success model are examined at three different levels: technical level (system quality), semantic level (information quality), and effectiveness or influence level (use, user satisfaction, individual impact, and organizational impact). It is possible to look into the DeLone and McLean model from two angles: the left hand and right hand sides of the model.

The left hand side of the model establishes the relationships among system quality, information quality, use, and user satisfaction. Some researchers (e.g. Livari 2005; Seddon and Kiew 1996) have produced empirical evidence to support these relationships. Furthermore, the left hand side of the DeLone and McLean model identifies the antecedents of the two most widely used IS success's criteria (use and user satisfaction). In addition, it identifies the factors that affect user satisfaction that are system quality and information quality.

Livari (2005) tested the model of information system success proposed by DeLone and McLean using a field study of mandatory information system. The results of his study showed that perceived system quality and perceived information quality are significant predictors of user satisfaction with the system, but not of system use.

The right-hand side of the model assumes linear causality between user satisfaction, individual impact, and organizational impact. However, organizational and technological

discontinuities and the existence of exogenous factors operating between the different levels militate against such linearity assumptions (Molla and Licker 2001). In this sense, a system which is successful by user satisfaction measures may not necessarily produce positive individual impact or positive organizational outcomes. The criticisms addressed to DeLone and McLean' IS success model include mixing variance and process models in one package, and the unreality of unidirectional relationship among use, user satisfaction, individual impact and organizational impact (Seddon 1997).

For the reasons listed above, we are focused on the left hand side only, and particularly on the antecedents of user satisfaction. These antecedents are system quality and information quality. They represent the two IS quality components in the original DeLone and McLean model. System quality represents the success at the technical level. It focuses on the desired characteristics of the information system itself which produces the information. Multiples measures (ease of use, usefulness of system, flexibility of system, system reliability, etc.) of the information processing system itself are reported by DeLone and McLean (1992) reflecting the engineering-oriented performance characteristics of the systems in question.

In this study, we are interested in ease of use and usefulness as two relevant measures of system quality. Theses criteria were identified as the two most widely used determinants of information systems use and user satisfaction. This will be developed with more details later. On the other hand, information quality represents the success at the semantic level. It focuses on the quality of the information system output. It reflects the desired characteristics of the information that the system produces, primarily in the form of reports. Several measures are given by DeLone and McLean (1992) such as accuracy, relevance, completeness, and timeliness.

In 1995, Pitt, Watson and Kavan presented an augmented IS success model which was adapted from DeLone and McLean (1992). Pitt et al. (1995) added service quality as a new dimension to the DeLone and McLean original model. SERVQUAL, an instrument developed by the marketing researchers, is proposed as a possible measure of IS service quality. After examination of content validity, reliability, convergent validity, and discriminant validity, the authors concluded that SERVQUAL is an appropriate instrument for the measure of IS service quality.

Later, DeLone and McLean proposed an updated IS success model in 2003. The updated model is based on the empirical and theoretical contributions of researchers who have tested or discussed the original model. The primary improvements to the original model include the addition of service quality to reflect the importance of service and support in successful IS. While system quality focuses on the desired characteristics of the system and information quality on the desired characteristics of the information, service quality focuses on the desired characteristics of service delivered by the system. The antecedents of user satisfaction in the model of DeLone and McLean (2003) are consequently Information quality, system quality, and service quality. These dimensions represent the IS quality components in the updated DeLone and McLean model (figure 2).

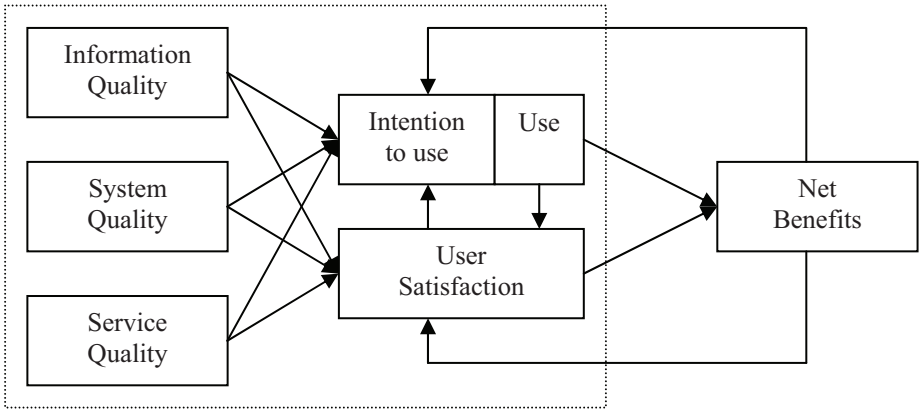

Figure 2: DeLone and McLean's 2003 Updated Model of IS Success

UTILIZATION OF THE IS SUCCESS MODELS IN THE ONLINE ENVIRONMENT CONTEXT

The dominant view of IS service in the extant IS research focuses on human-delivered service (Ding and Straub 2007). In this case, the human agent plays a significant role in the IS department considered as an organization subunit that provides direct end-users support services (e.g.: training, documentation, and maintenance) for satisfying users IS needs. This viewpoint needs to be revisited to be aware of the new reality of service businesses which are either reengineered or automated through the application of sophisticated information systems (Ding and Straub 2007). One well-known example is Web-based information systems that provide customer with direct service. In the online environment, the primary Web-based IS users are customers or suppliers rather than internal users. Web-based information system is not a simple Web presence. It allows users to achieve several works automatically without the intervention of the human agent. It enables users to search information, ask questions, and take requests. It can also provide sophisticated solutions to customer problems. Web-based IS revolutionized the way organizations provide information related to their services. Users can specify what information is to be presented, in what order or arrangement, using which colors and so on (Molla and Licker 2001). Thus, Web-based information system is a dynamic and distributed platform for interactive World Wide Web application solutions in order to perform several business functions such as information provision, communication, distribution, and customer service. It facilitates intra-and inter-firm processes, systems integration, and enables doing business electronically (Tan, Xie, and Li 2003).

The most common use of web-based IS is to enhance existing traditional channel by a new online channel. Today, many self service web-based technologies that do not call for the direct involvement of human service agent are being used by service organizations (e.g.,

online travel services, online banking services, online package tracking services, etc.). In those cases, the web-based Information systems serve as the central medium of exchange between a service provider and its customers and significantly reduce the interpersonal encounter that formed the core of the most customer satisfaction (Molla and Licker 2001). Therefore, the quality of online service influences customer satisfaction with the overall service offered by the service provider. The service quality become an important dimension of the web-based information systems in the Internet environment and the researchers are required today to include service quality as a third component of the IS quality.
In fact, Molla and Licker (2001) suggested that the original DeLone and McLean IS success model could be extended to measure e-commerce systems success. They proposed a partial extension and respecification of the DeLone and McLean's 1992 model to e-commerce systems. The system quality and information quality components of the IS quality are replaced by e-commerce system and content quality. Molla and Licker (2001) argued that these two dimensions require additional constructs that are not captured by the traditional system quality and information quality measurements. In addition user satisfaction is replaced by customer e-commerce satisfaction as a dependent variable to e-commerce success. Also, trust and service are added as new antecedents of the customer satisfaction.

Based on the Molla and Licker's e-commerce success model and as well as the IS success model which was revisited in 2002 and extended in 2003, DeLone and McLean (2004) proposed to measure e-commerce success. They applied their updated model to organize the e-commerce success metrics identified in the literature and demonstrated how this model can be used through two case examples. They defined e-commerce as the use of the Internet to facilitate, execute, and process business transactions.

DeLone and McLean (2004) identified three aspects of the IS quality in the Internet environment: system quality, content quality, and service quality. System quality reflects the desired characteristics of a Web-based information system. They considered that when the users are customers, their use is typically volitional, and this means that poor ease of use and usefulness of the Web-based IS functions (as a relevant measures of system quality) can affect negatively customer usage and satisfaction. In addition, DeLone and McLean (2004) argued that new measures of the content-quality dimension are needed because of the mass customization development occurring in the Internet environment. They considered that content quality refers to the desired characteristics and presentation of information in the Web-based information system. Finally, they introduced service quality which represents the overall value and support delivered by the service provider. In this sense service quality can be measured by the effectiveness of online support capabilities (DeLone and McLean 2004).

Based on marketing exchange theory and the DeLone and McLean's 2003 model, Ding and Straub (2007) proposed alternative nomological linkages among the three IS quality components as well as new paths depicting their impact on user satisfaction. They investigated the theoretical interrelationships among information quality, system quality, and service quality. Ding and Straub (2007) argued that, with sophisticated Word Wide Web based application solutions, the conceptual separation of systems from service needs to change. These technological applications not only assist human agent in serving customers, but they can replace them entirely.

Ding and Straub (2007) applied marketing exchange perspective to examine IS service related concepts and scenarios for developing their information system quality model (figure

3). In this model, the service quality mediates the relationship between system quality and user satisfaction on one hand, and the relationship between information quality and user satisfaction on the other hand in a positive direction.

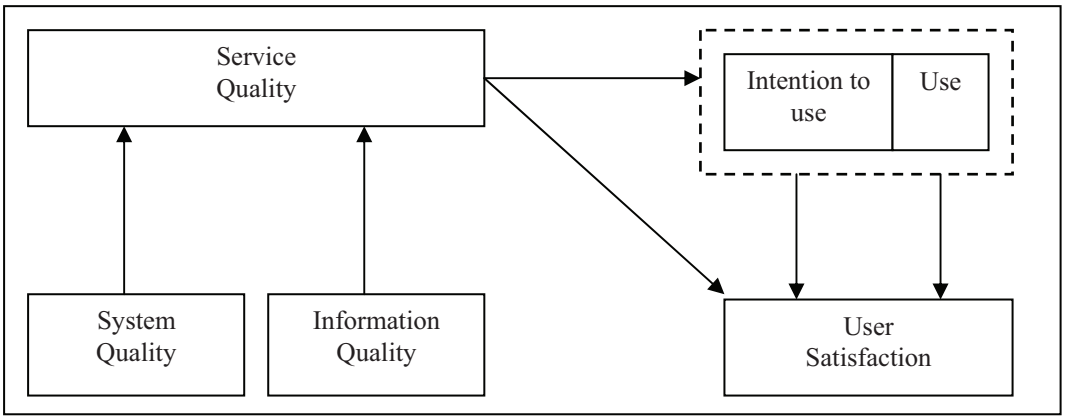

Figure 3: Ding and Straub'2007 IS Quality Model

WEB-BASED INFORMATION SYSTEMS QUALITY AND CUSTOMER SATISFACTION

Based on the DeLone and McLean's 1992 IS model which has been updated in 2003 and extended to the online environment context, and also on the theoretical development in the relationship marketing domain, we developed our conceptual model of the Web-based information systems quality (WISQ) as presented in figure 4. The WISQ model presents three IS quality components: Web-based system quality (WSQ), Web-based content quality (WCQ) and online service quality (OSQ). These components have a positive direct impact on the online customer satisfaction which, in turn, has a positive impact on the overall satisfaction.

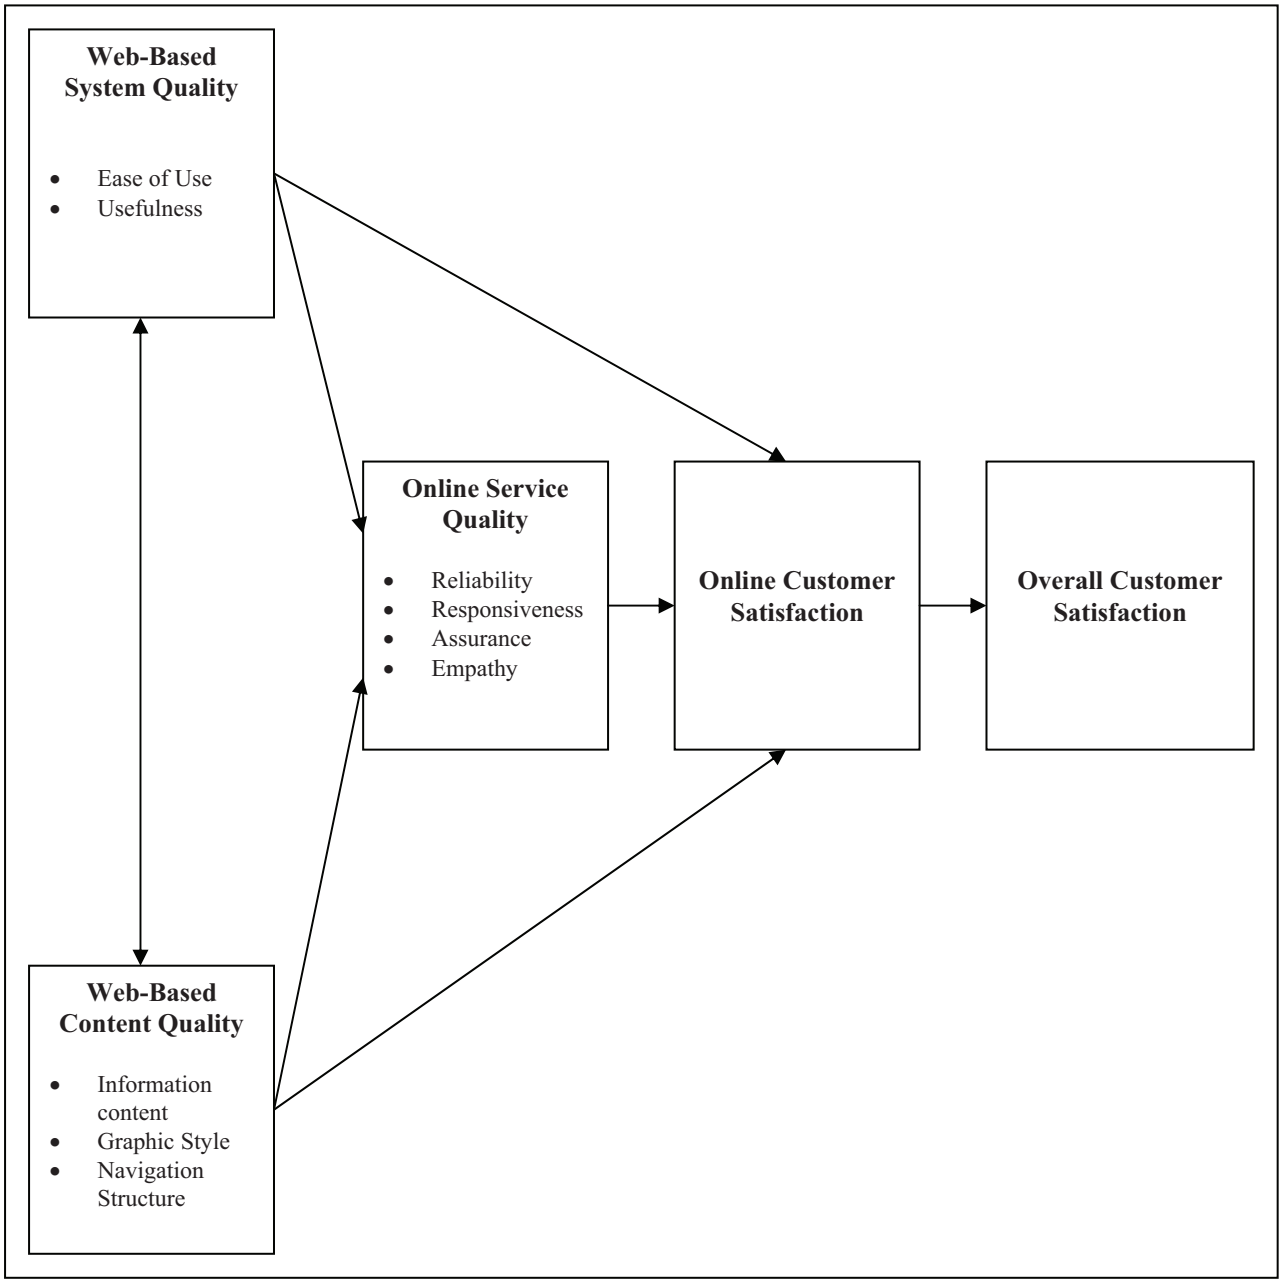

Figure 4: Web-Based IS Quality Model

Components of the Web-based IS Quality

The Web-based IS quality has three components: Web-based system quality, Web-based content quality, and online service quality which are interrelated.

The Web-based system quality refers to the desired characteristics of the Web-based IS itself and focuses on the technical capabilities of the Web site that enables favourable interactions with the customer. This component of the WISQ is closest to constructs such as perceived usefulness and perceived ease of use examined by IS researchers as a significant antecedents to various technology acceptance outcomes, and as a relevant determinants of user

satisfaction. In this study, perceived usefulness represents the degree to which a customer believes that using the Web-based information system would enhance his job performance. A system high in perceived usefulness, is one for which a user (customer) believes in the existence of a positive use-performance relationship (Davis 1989). On the other hand, perceived ease of use refers to the degree to which a customer believes that using a Web-based information system would be free of effort. An application perceived to be easier to use than another is more likely to be accepted by users (Davis 1989). Several findings suggest that, in some cases, customer satisfaction in the online environment is significantly higher than in traditional channel due the ease of use and usefulness of the Web-based IS. For example, Devraraj et al. (2002) found that perceived usefulness and ease of use are key determinants of consumers' attitude, assessed by their satisfaction with the online channel. Their findings support also that satisfaction with the online channel (electronic commerce channel) leads to customer channel preference. Devraraj et al. (2002) concluded that success criteria in IS research can be applied to online environment. They mentioned that TAM (technology acceptance model) components ease of use and usefulness are important factors in determining online satisfaction and preference channel.

Therefore, we propose to conceptualize Web-based system quality (WSQ) as a second order construct with two first-order constructs: perceived usefulness and perceived ease of use. These two dimensions taken together can offer more explanation about the WSQ as a multidimensional construct. Previous research notes that a second order approach represents a theoretically strong basis for capturing complex measures which are multidimensional in nature such a Web-based system quality (e.g., McKinney, Yoon, and Zahedi 2002).

Web-based content quality (WCQ) refers to the desired characteristics and presentation of information in the Web-based information system and focuses on the customer (user) web interfaces. Our construct "content" includes the quality and variety of information, the use of text, graphics, and multimedia as well as the navigability. Therefore, this component of the WISQ includes three subdimensions: Web site information content, graphic style, and navigation structure. In this sense, Web-based content quality is a second order construct with three first-order constructs. This conceptualization of WCQ as a multidimensional construct is consistent with previous studies in information systems research (Agarwal and Venkatesh 2002; Palmer 2002). In effect, web site information content refers to the quality of informational material that appears on the Web site. Based on prior research on the dimensionality of information, Montoya-Weiss, Voss, and Grewal (2003) suggested that three broad characteristics can describe the quality of information content in an online context: information utility (the extent to which content is perceived as useful); information accuracy (the perceived correctness or integrity of the content); and information timeless (the degree to which the content is perceived as fresh and up-to-date). By referring to Montoya-Weiss et al. (2003), we define graphic style as the tangible aspect of the Web-based information system that reflects the "look and feel" or perceived attractiveness of a Web site. Montoya-Weiss et al. (2003) conceptualized graphic style as the virtual equivalent of traditional retail store atmospherics. Graphic style reflects web site design and the appropriate use of multimedia content (Agarwal and Venkatesh 2002; Palmer 2002). Navigation structure refers to "the organization and hierarchical layout of the content and pages in a Web site" (Montoya-Weiss et al. 2003, p. 449). Palmer (2002, p. 155) defined navigability as the sequencing of pages, well organized layout, and consistency of navigation protocols. This characteristic governs a user's forward, backward, and lateral movement through a Web site and evaluates the links to the needed information (Montoya-Weiss et al. 2003; McKinney et

al. 2002). Several researches supported that Web-based content quality (WCQ) is a significant antecedent of the online customer satisfaction. For example, Palmer (2002) found that user satisfaction (as a measure of the Web site success) is significantly associated with the navigation (organization, arrangement, layout, and sequencing) and content (amount and variety of information). Also, McKinney et al. (2002) verified the positive impact of information content and system design on the Web-customer satisfaction.

The third component of the WISQ is the online service quality (OSQ) which refers to the overall value and support delivered by the service provider online via the Web-based IS. SERVQUAL, a widely used instrument in marketing research to measure customers' expectation and perception of service (Parasuraman et al. 1985), was adapted to measure IS service quality (e.g. Pitt, Watson, and Kavan 1995, 1998; Jiang, Klein, and Crampton 2000; Jiang, Klein, and Carr 2002). In the Internet context, SERVQUAL instrument has been applied also to assess the factors associated with Web site success (e.g., Liu and Arnett 2000) and online channel satisfaction (e.g., Deveraj et al. 2002; Zhu et al. 2002). For instance, Liu and Arnett (2000) measured service quality as quick responsiveness, assurance, empathy, and following-up service. In another study, Deveraj et al. (2002) utilized the SERVQUAL items in a single survey to operationalize consumers' perceived service quality through reliability, responsiveness, empathy and assurance of the online channel. In this study, we retain these four dimensions to assess the online service quality. The tangible dimension of SERVQUAL instrument is not included for the lack of significance of this dimension in previous study (e.g. Jiang, Klein, and Crampton 2000; Jiang, Klein, and Carr 2002). Reliability refers to the ability of Web-based IS to perform the promised service dependably and accurately. Responsiveness refers to the willingness of web-based IS to help customers and provide prompt service. Assurance reflects the ability of Web-based IS to inspire trust and confidence. Empathy represents the ability of Web-based IS to provide caring and individualized attention to customer. Consequently, online service quality (OSQ) is conceptualized as a second order construct with the previous dimensions as four first order constructs. Other authors adopted the same hierarchical service quality approach for electronic services, which includes several dimensions and subdimensions (Fassnacht and Koese 2006; Parasuraman, Zeithaml, and Malhotra 2005).

Web-Based IS Quality and Customer Satisfaction Relationship

Satisfaction refers to an ex post evaluation of consumers' experience with the service and is captured as a positive feeling, indifference, or a negative feeling (Anderson 1973). In the service-related industries which mobilize sophisticated customer-oriented Web-based IS, it's difficult to differentiate the experience with the service delivered itself and the experience with the system used to deliver the service. For providers in many service industries (e.g. insurance, professional services, banking, travel) the service delivered is highly intertwined with the system (Ding and Straub 2007; Molla and Licker 2001). Therefore, the customer's satisfaction reflects both his experience with the service and with the system which distributes it.

In multichannel service providers' context, we differentiate online customer satisfaction and the overall customer satisfaction. We define the online customer satisfaction as the evaluation of an emotional reaction or feeling of a customer in relation to his/her experience with all aspects of a Web-based information system. On the other hand, we define overall satisfaction

as an ex post evaluation of customers' experience with the overall service delivered (online and offline) which is captured by a positive feeling, indifference, or a negative feeling.

Defined in such way, customer online satisfaction can serve as a dependant variable which is affected by the three components of the Web-based IS quality: Web-based system quality, Web-based content quality, and online service quality. In addition, the overall satisfaction is, in turn, affected by the online satisfaction. In a relational, multichannel context, customers can have experience with multiple channels which have both competitive and complementary effects. Competitive effect is present when higher perceived service quality of one channel over another will lead to channel preference, and complementary effect occurs when higher perceived service quality of all channels will lead to higher overall customer satisfaction (Montoya-Weiss et al. 2003). When Web-based information system is perceived to offer high service quality in complementary manner with traditional channel, we expect that the online customer satisfaction will be higher, and consequently the overall satisfaction with service provider will be greater.

In our conceptual model (figure 4) the three components of Web-based IS quality (WSQ, WCQ, and OSQ) affect directly customer online satisfaction which contributes to the overall customer satisfaction. The relationship between Web-based IS quality and customer satisfaction is based on the previous IS success models (e.g., DeLone and McLean 1992, 2003), but the link between online satisfaction and overall satisfaction is new and is inspired by the theoretical developments in marketing and IS research in the Internet context (e.g., Montoya-Weiss et al. 2003; Devaraj et al. 2002).

In addition, because of our focus on the service context, we position online service quality (OSQ) as the central mediating factor in our model. Modelling service quality as mediator is consistent with prior research in marketing that has shown service quality perceptions are important drivers of customer's satisfaction (e.g., Fassnacht and Koese 2006; Parasuraman et al. 2005; Zeithaml et al. 2002). In their empirical study, Montoya-Weiss et al. (2003) demonstrated that, in the relational multichannel environment, online channel service quality mediated the relationship between the Web-based content quality (information content, navigation, and graphic style) and the overall satisfaction with the service provider. Modelling service quality as mediator is consistent also with recent research in the field of IS. For example, Ding and Straub (2007) note that the overwhelming proportion of service delivery will be carried out through systems rather than human agents and the provider will render service to its customer primarily through many self service Internet-based technologies. In their alternative IS quality model, Ding and Straub (2007) state that service quality mediates the relationship between IS quality (information quality and system quality) and user satisfaction.

Finally, in our conceptualization of the Web-based IS quality, we consider that Web-based system quality and Web-based content quality can interact together, and the one can influence the other. The reciprocal effect is due to the complementarity between these two Web-based IS quality components which are evaluated at the technical level. The technical capabilities of the Web site that enable favourable interactions with the customer (WSQ) can influence the characteristics and presentation of information in the user web interfaces (WCQ), and vice-versa.

SUMMARY

While a Web-based IS can be considered as a Kind of information systems, thus providing the justification for the application of IS theories, their specific characteristics in terms of connectivity, interactivity, and open-standard network integration distinguish them from pre-Internet information systems (Zhu and Kraemer 2005; Zhu and Kraemer 2002). Therefore, any effort to extend IS success models and measures to the online environment context needs to consider the unique characteristics of the Internet. On the other hand, the similarities between Web-based IS and the traditional IS motivate and extending original models such as IS success models to Internet domain (Molla and Licker 2001). Through theoretical discussions of how system quality, information quality, and service quality are related to each other and to user satisfaction, this research applies and extends a part of DeLone and McLean'2003 IS success model to the Internet environment by developing a Web-based IS quality (WISQ) model. Thus, using the IS success models, as well as the SERVQUAL framework, we conceptualized the WISQ and its impacts on online customer satisfaction, and overall satisfaction in the multichannel service provider context. Further research is required to improve both the theoretical base and operational constructs of the WISQ and develop reliable and valid measurement instruments. Future empirical studies will examine also how the Web-based IS quality factors are related to each other and how they affect downstream construct such as customer satisfaction. The implications of the research should help service providers see better how Web-based IS quality can affect positively the online customer satisfaction which, in turn, can influence positively the overall customer satisfaction in a relational multichannel area.

ABSTRACT

As fewer and fewer children are born each year, not only family structure has changed, the proportions of elderly persons in many countries also have increased significantly. Consequently, home healthcare services for the elderly have become a new and promising business. The objective of this project is to integrate information technology into the business models of healthcare system. The first year's goal is to design a business model of home healthcare system by evaluating the market through gathering information like the percentage of elderly population, the scale of heath care market, and the actual demands for healthcares for the elderly in the society. The goal for the second year is to integrate the information technologies such as the radio frequency identification, global positioning system, global system for mobile communications, and hospital information system to construct a business model of the healthcare system. In addition, this paper also aims to replace the current passive and manual way of searching missing patients with the help of the information technology. Further, the project plans to establish a system which provides monitoring schemes such as indoor residence monitoring, outdoor activity area monitoring, emergency rescue, and remote monitoring modes. Results of these studies should provide important insights for the development of healthcare systems integrated with information technology for the future.

Keywords: healthcare services, information technology, business models, radio frequency identification, M-business

BACKGROUND

As fewer and fewer children are born each year, combines with advancement in medical science which extends the average life span of humans, the proportion of elderly persons has increased significantly in many societies. In response to elderly's growing population, the healthcare market for the elderly has grown considerably, and definitely has become one of the promising industries. As the proportion of the elderly continues to rise, governments should plan early to meet the upcoming massive healthcare demands.

Aging population structure and its influences

Due to extended average life spans and decreasing population growth, Taiwanese population's aging speed is among the fastest in the world, only next to Japan. According to Taiwan's Council for Economic Planning and Development's (CEPD) estimate, by the year 2026, elderly population will reach 4.82 millions, a staggering proportion of 20%. And by the year 2051, elderly proportion will reach as high as 35%. CEPD expects Taiwan to enter an aging society by the year 2018. According to Industrial Technology Research Institute (ITRI) Biomedical Department, domestic medical care market will grow 440% from US$24.6 billion in 2001 to US$108.9 billion by 2025. Field experts and organizations strongly encourage that a complete healthcare system should be set up as early as possible.

Taiwan's current policies

Currently, government has provided different degrees of healthcare for the elderly in accordance with regulations stipulated by the "Senior Citizens Welfare Act". According to Enforcement Rule 7 of this Act, local authorities, if necessary, are responsible for encouraging and rewarding private enterprises for setting up various types of welfare institutions for the elderly. Therefore, current mechanism of healthcare for the elderly is guided by Senior Citizens Welfare Act. In addition, the Ministry of the Interior has enacted two ordinances: "Establishment Standards of Senior Citizens' Welfare Institution" and "Permit and Management Regulations for the Establishment of Private Senior Citizens' Welfare Institutions" which give specific guidance for the buildings, facilities, equipments and workers of senior citizens' welfare institutions.

With the advancement in communication technology, in 2008 the government has included "Telecare" industry into the plan to develop newly service industry in 2008. By combining information technology applications, following projects are being implemented:

1. Department of Health: Telemedical Plan, a communication plan between medical center and remote medical units.
2. Department of Health: National health insurance family doctor integrative nursing care system plan.
3. Legislative Yuan: Long term nursing care pilot plan. The purpose is to build a strategic blueprint to guide future healthcare system.
4. Department of Health: build and maintain a long term caring information plan which covers the entire healthcare system to provide long term care for long term disabled persons, until they have improved or recovered certain functions.
5. Ministry of Economics: Integration of caring service information system application research. Establish a comprehensive hearth care service industry alliance and build a system which can provide professional health and nursing care even when patients are at home.
6. Ministry of Economics: Telemedical plan. Combining various fields like preventive medical science, information communication, and emergency medical service to allow people who require caring can send physical data through GPRS or ADSL broadband to information center.
7. Ministry of Economics: U-care flagship plan. Assist institutions in community care,

home care, and emergency care for the elderly.

8. Legislative Yuan: 3 phase plan between now to 2015. In the first phase (2007-2009), the central government speeds up the healthcare development policy by declaring healthcare industry as one of the promising industries in the future.

Relevant measures taken by other countries

Currently, many countries have applied information and communication technologies to increase the quality of healthcare system. More specifically, relevant applications are:

1. MobiHealth plan by European Union
   Combining wireless communication technology with Body Area Network (BAN) which automatically transmits patients' bio-signals from sensors attached to their bodies.
2. IdeaTel plan by New York State
   Through information equipment which allows patients to check various diabetes figures and receives test results at home.
3. Tele-homecare System by Japan
   Panasonic Company has designed a series of equipment specifically for patients with chronic illnesses and can be used at patients' own homes. Patients can have direct video conference with medical personnel. Taking advantage of its R&D strength, Panasonic has set up Matsushita Nursing Home Company which operates its own nursing home business.

However, in order to set up a complete healthcare system, other than governmental policy support, it still requires a comprehensive healthcare mechanism like an integrative business model, to facilitate and smooth out the actual operation. Currently, public elderly welfare systems along with private elderly healthcare institutions not only are mostly regional, but their resources may overlap in certain areas. This is caused by unclear positioning of the healthcare mechanism. As for the Telecare plan which the government has been promoting but not very successful because it failed to integrate two major parts: medical resource and information technology; thus unable to provide an integrative operation flow and business model. An operable business model should incorporate RFID, Mobilized medical service, and hospital related information technologies to develop a system for elderly healthcare.

LITERATURE REVIEW

Worldwide medical industry and regulations

Economic prosperity has brought about major scientific growth in the medical industry. In most advance countries, healthcare service sector accounts for about 6% of their GDP. According to a WHO publication, providing medical services internationally has become ever more important. Particularly, U.S. vendors have been providing commercial distant medical services to several countries in the Middle East. For example, the country Jordan has set up distant medical service network with Mayo hospital of the U.S. Similarly, China, Taiwan, Macau, and other Southeast Asian countries have set up distant diagnosis services.

However, health and social service industries usually are banned from providing cross country services. One of the reasons is to ensure medical safety. Most countries have restrictions in areas such as medical service providers (doctors, therapists, nurses, and etc.,), companies, institutions,

and organizations in the medical system (clinics, hospitals, and nursing homes), and other business entities (equipments and medicine suppliers and insurance companies). This is a very common situation in most countries. Therefore, the most a medical firm can do as to providing cross country service has narrowed down to simply providing tangible products and insurance service. As for the intangible professional medical judgments, cares, and institution operation know how, it has been a common understandings that all international firms must follow strict local regulations. The following is a table of various governing laws of England, Germany, Japan, and Taiwan..

Table 1. Comparison of healthcare laws between different countries

	England	Germany	Japan	Taiwan
1. legal structure				
Legal name	● National Health Service and Community Care Act	● Soziale Pflegeversicherung ● Bundes-soziahilfegesetz	• Various Insurance laws (nursing & elderly welfare) • Elderly Welfare Act • Physically handicapped Welfare Act • Mentally Retarded Welfare Act • Mentally Handicapped Welfare Act	• Senior Citizen Welfare Act • Physically and Mentally Disabled Citizens Protection Act • Mental Health Law • Clinical Nurse Law
Supervising authority	● Department of Health ● Local Authority (Director of Adult Social Services DASS)	● Federal Department of Health ● Federal Long Term Nursing Care Commission ● Local Authority	● Ministry of Health, Labor, and Welfare: policy making ● City authority：policy execution	●Department of Interior ●Local Authority
2. applicable subjects				
Age	Citizens age 16 and above or handicapped	Citizens	Citizens age 40 and above or handicapped	Citizens age 65 and above or handicapped
Asset Check	• (health service：x • community care)	• Nursing insurance payment：x • Social Welfare payment：x	• Nursing insurance payment：x • Welfare Benefits	Welfare benefit：(depends on asset evaluation)

3. Demand Evaluation				
Evaluating Institution	All health and social needs must be evaluated by a committee authorized by the local authorities before services can be provided. Committee members include doctors, nurses, therapist, social workers, and other professional personnel.	Follow medical insurance service procedures ((nursing insurance law 18)	The city authority designates a nursing home to do the evaluation first, than a committee (members are experts of various fields in the industry) will make the final nursing decision.	Local authority's long term nursing care management center
Demand Level	4 levels： 1. critical 2. Substantial 3. Moderate 4. low	3 levels： 1. first level: needs nursing care at least once per day 2. second level: needs nursing care at least 3 times per day 3. third level: needs nursing care all day	Nursing is classified into six levels： 1. Level 1 2. Level 2 3. Level 3 4. Level 4 5. Level 5 6. Need support

Medical and nursing care scope of Taiwan

According to a report by CEPD, Taiwan has entered an aging society in year 1993, and is expected to enter into an aged society in year 2018. The demand for healthcare has continued to increase as a result. However, according to a government industrial classification table, medical nursing care is not even a category. However, CEPD has classified the medical care institutions into several categories; from emergent to chronic, technical to non-technical long term care

services (see chart 1).

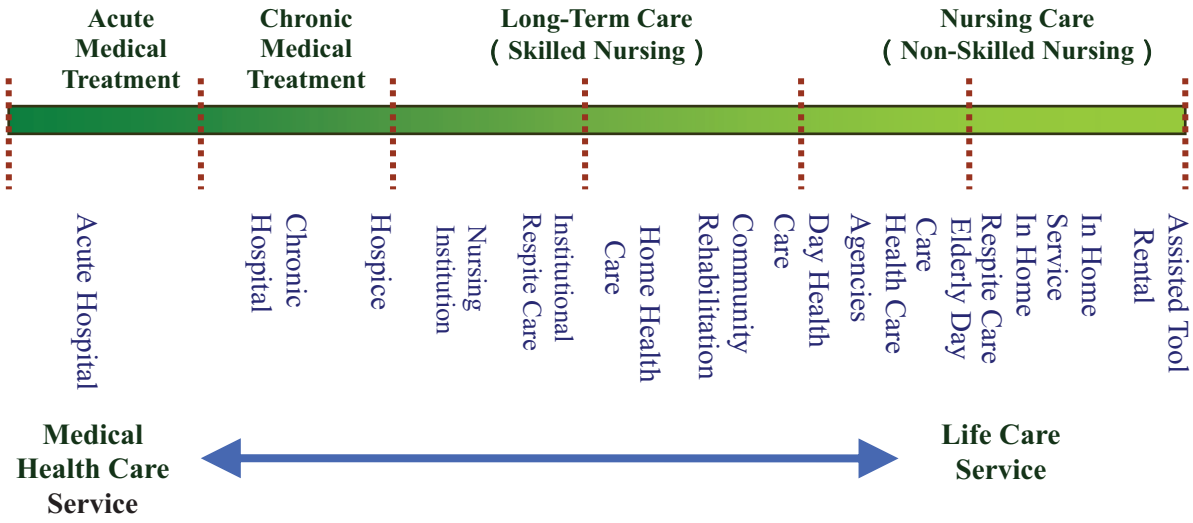

Chart 1. Medical Health Care Classification

Source：Legislative Yuan CEPD (2004)

Current medical care situation of the elderly

There are five major providers of long term nursing care services: (Yu-Mei Ruan et al. 2001):

(1) Home based care：Family members or relatives are responsible for the care. This is the major source of care labor in Taiwan.

(2) Unofficial community care：Unofficial means unlicensed nursing care institutions in a community. It provides major 24hrs accommodations in Taiwan.

(3) Veteran system from the military

(4) Social welfare system

(5) Medical service system

According to Senior Citizens' Welfare Act, domestic nursing care institutions, depending on the level of care required, can be classified into 3 major categories:

(1) Nursing home: Mostly medical, partly social functions.

(2) Nursing care institution: Mostly maintain residents' health, partly social functions.

(3) Care institution: Mostly social, partly maintaining residents' health functions.

The last two categories are often mixed under one institution, which is normally called "nursing care institution". (Hsio Chin Shen, et at. 2003). Taiwan's welfare policy for the elderly covers a wide range of areas, including their life and health, psychological and social needs. However, government resources are divided and the applicable regulations are not uniform. A systematic integration of resources and laws is yet to be developed.

In the last decade, the government has spent much effort on consolidating various governing

agencies of social and medical welfares, but the result has been disappointing. For example, though the standards of setting up nursing homes and elderly long term care institutions are the same, but due to different governing authorities, only one type of business thus one kind of subsidy can be applied. (Tsen Yung Wang, 2000). On the other hand, in terms of human resources, nurses are the major source of labor in nursing institutions, but some not only are having difficulties in employing sufficient nurses, the turnover rate and quality of nurses are also far from ideal. The shortage of care assistant is even worse. (Yu Mei Ruan, 2001). Furthermore, most caregivers are not qualified in giving professional care. So in terms of home care, other than family members, foreign maids are often required to take care of the elderly part time.

Market demand of elderly's medical and nursing care

Current domestic elderly nursing care follows the principles set forth in the Senior Citizens' Welfare Act. Bordy and Masciocchi believe that in order to provide a complete and continuous long term heathcare, the system should include 3 major types of services: family, community, and institution.

Due to natural deterioration of various body functions, many elderly requires the assistance of nursing and medical equipment to sustain their lives. However, medical institutions not only need to take care of elderly's physical health, but also their psychological and social health. Many times, the feeling of respect and mental security are what elderly lacks of. Depending on their body conditions, elderly's nursing cares are divided into two parts: one is the official nursing care system, the other is an unofficial nursing care system. See chart 2 below.

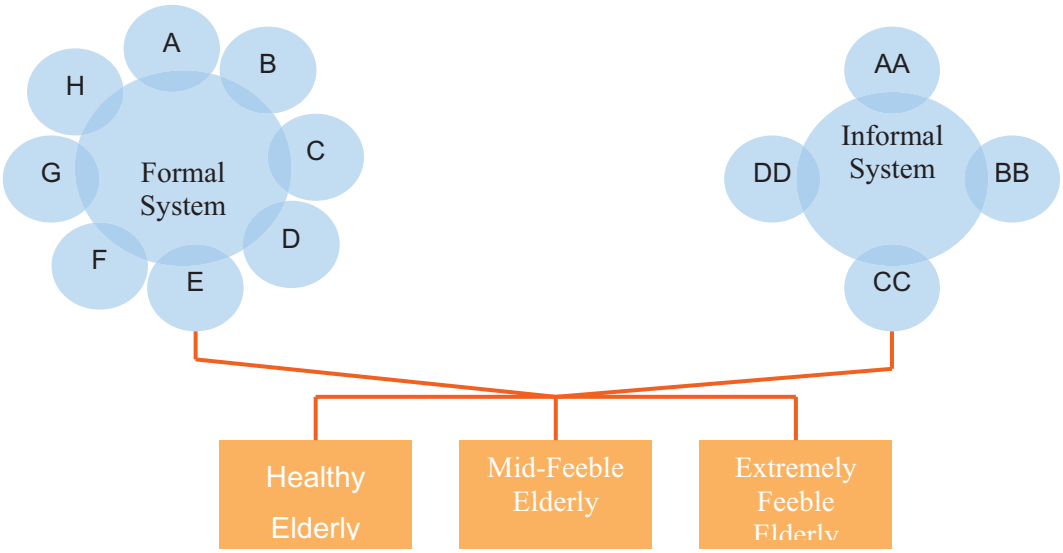

Chart 2. Elderly Care System Classification

A. entertainment B. application assistance C. meal delivery D. chores services
E. health assistant F. transportation service G. consultation service H. odd jobs
AA. emotional support BB. financial management assistance
CC. occasional meal delivery DD. Short-tem assistance

According to Industrial Technology Research Institute (ITRI) Biomedical Department, domestic medical care market will grow from US$24.6 billion in 2001 to US$108.9 billion in year 2025, a growth of 440%. The scope of this market is to provide continuous assistances to those with long term functional disability, like patients with chronic illnesses or handicapped persons, which are services necessary for them to recover or improve their impaired functions. There are 3 dimensions to this market:

(1) provide daily living care services: prepare foods, cleaning, driving, shopping, bathing, etc.,
(2) provide specialized service to reduce functional disabilities: evaluation, rehabilitation, treatment, etc.,
(3) provide environment improvements: environment evaluation and remodeling, assisted equipment, and enhance functional disability's moving ability. (Shu Chung Wu, 1999)

According to a research by Institute for Information Technology in 2005, about 72% of the families with members who were being take care of at home, believed that their members were satisfied with their current cares. And if there are areas to be satisfied, most families believe that medical health examination is what they need. 14.2% of the families consider medical examination to be most desirable, home-based nursing care is next.

Business model

According to the Department of Health's definitions, elderly's medical and nursing cares should be classified by their service locations and service intensity. Basically, they are divided into institutional-based care, community-based care, and home-based care. Among them, community-based care and home-based cares are both classified as home-based cares. (World Health Organization, 2000) In the following table, long term cares are classified according to their service types and subjects:

Table 3. Long term care services operation model

Type	Service targets	Service provided
Home-based	Elderly with low income or physically handicapped or unable to manage oneself and are not taken care of by others	• Care takers: in house service, emotional support, living care, and home based nursing • Automated equipment: provide basic medical equipment services
Institutional-Based	Elderly who need to be taken care of on a long time basis because they are critically ill or highly unindependent or without family nursing resources, or with chronic diseases	• Care taker: professional nurses provide medical services, rehabilitation services, and nursing services. • Automated equipment: use machinery to treat and help patients rehabilitate. Operation models include independently run, or run by hospitals, or by funds.
Community-based	Elderly whose family members need to work. The purpose is to share wage earners' nursing loadings so their incomes activities are not disrupted.	• Care takers：day care, regular phone calls, meal delivery, short-term or temporary nursing care, and transportation services. • Automated equipment: provide basic medical equipment services

However, institutional-based care, community-based care, and home-based care are the 3 major dimensions of healthcare and must be covered by the operation scope of a business model. In addition, medical organization is another dimension that should also be included in the picture. That way, emergent illness and other professional medical treatment can also be provided to the elderly. In the actual operations, there are 3 areas that should be included:

1. Daily living care: provide food, cleaning, transportation, shopping, bathing, toilet using, feeding, moving services.
2. Functional disability service: provide evaluation, rehabilitation, nursing, treatment services.
3. Environment improvement solution: provide solutions to increase the activeness of elderly through environment evaluation and remodeling and assisting tools (Shu Chung Wu, 1999)

RESEARCH FRAMEWORK

After studying the current market conditions of elderly's healthcare, and combine it with government policies, relevant literatures, and in-depth expert interviews, this research has developed a business model, which integrate medical and nursing care management with information technology application for elderly's care. This model's conceptual framework is as follows:

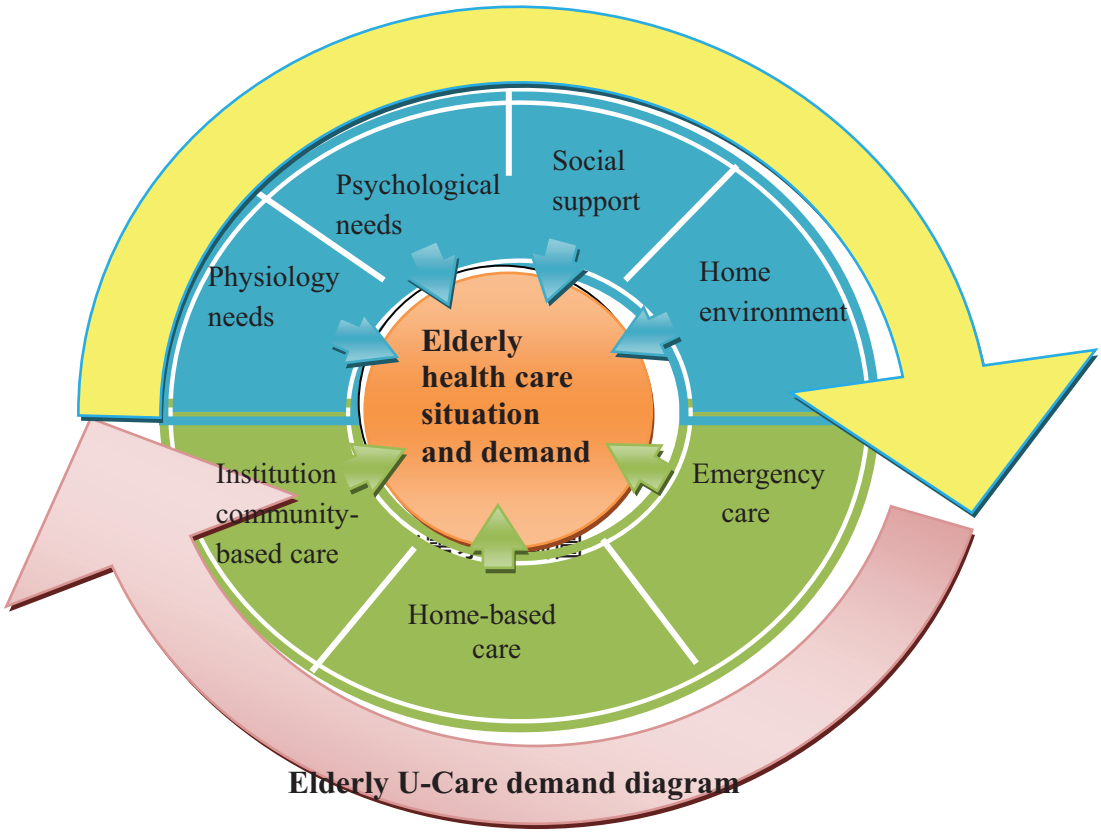

Chart 3. Elderly Care Diagram

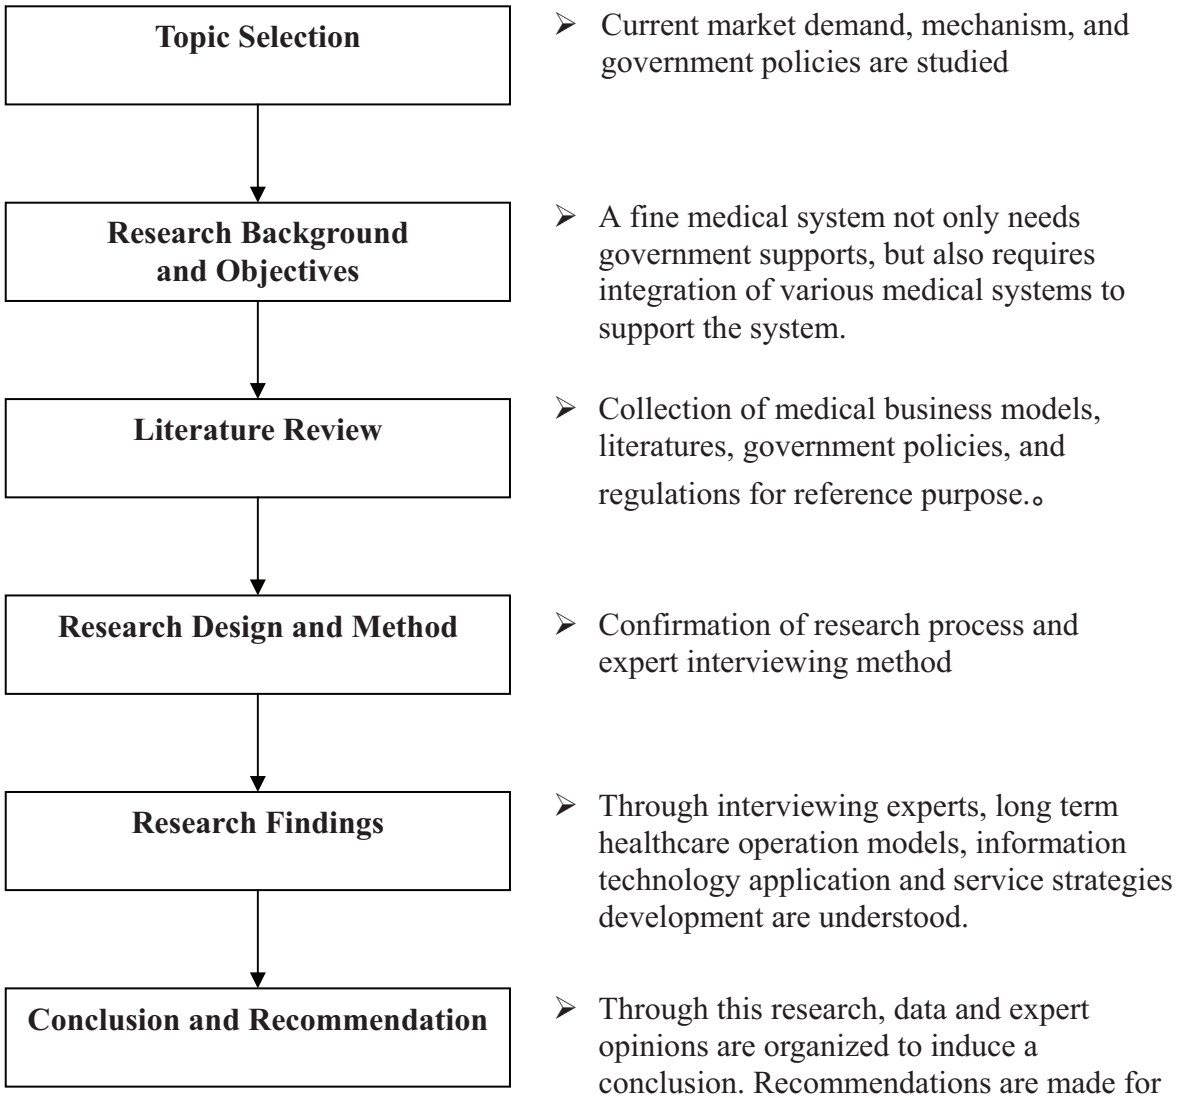
Research Flow



Graph 5. Research Diagram

Research methodology

(1) Expert interviews
Experts who understand and have practical experiences with the long term medical and nursing care markets were interviewed. Business models, technology applications, and service strategies were extracted from the interviews.

(2) Interview's background
Two field experts were interviewed. The topics of the interview included home-based care, institution-based care, and hospital-based care. The future development of each was also discussed. From interviewing field experts, this research hopes to truly reflect the directions actual practice is moving, and provide future operation model, technology application, and strategy suggestions.

(3) Interview questions design
Through qualitative questionnaire designs, consensuses were reached among fields experts. There are 2 major parts:

- **First part:**

This portion is about how elderly's long term caring needs are affected by their physiological and psychological conditions, social support, and living environment as a basis for questionnaire evaluation design. This is to make sure that all facets concerning elderly's needs are systematically discussed.

- **Second part:**

Elderly's U-Care flagship plan which includes dimensions like institutional and community based cares, home-based care, and emergency care are the focus of this part. Elderly's demands of these three business models are individually discussed and sources of satisfaction located. Hopefully, an integrative business model can be proposed to uncover the potential of the medical and nursing industry.

CONCLUSION

Demand drives innovation. Current medical care system also has been driven by the demand to develop various long term care information system. However, many problems remain unsolved. If the problem cannot be treated objectively or seen from a broader perspective, elderly's problems will never be resolved effectively. Through in-depth interviews with field experts, this research has uncovered various weaknesses in the long term care nursing care system and would like to make the following recommendations:

,

Employed full time experts to help manage the nursing care information system

Currently long term nursing care systems of the Department of the Interior and the Department of Health are not operated by full time staff. Information systems not only need specialized professionals to operate, but also need to work closely with staff on the first line. Appropriate medical information should be collected on a case by case basis to meet the requirement of the decision units. Adjustments can be made as required.

Personal feelings outweigh cold machine

Elderly who are being taken care of can be anyone's senior relatives or friends. They are humans with feelings like everyone, and need to be treated like a real person and not just a number or subject. Their feelings are more important than readings from body sensors or medical equipment, and need to be treated with sympathy. Understanding elderly's religions, interests, and hobbies and provide corresponding personalize services is also essential to their health.

Develop caring service network via new technologies

The focus of future home based care is to combine resources from medical treatment, self–care, and preventive medicine. In the future, cooperation with other supporting industries can assist home care industry to provide more versatile services. Home based nursing care should be more than just providing medical treatment, but with the help of RFID technology, elderly's physical health information can be efficiently and easily exchanged between different medical units. And in case of emergency, doctors can get a hold of patients' past body conditions immediately.

Automated inflexible management is not suitable

From interviewing elderly who needs care, this research has found that short visits by medical staff cannot really understand elderly's actual needs. Professional medical personnel should take the initiation to care and understanding elderly's real needs or interests. Professional medical opinions or regulations may not be the best way for locating and servicing elderly.

Set up emergency hot lines for community nursing care

From the interviews this research has also uncovered another deficiency: emergency connection hotlines between community nursing care institutions and the hospitals are not responsive enough, causing medical treatment delays. This paper recommends that a community should leverage its number of residents and set up a health examination station with professional staffs to regularly evaluate and store elderly's medical information. Therefore, in time of emergency, elderly can be sent to an appropriate hospital with complete medical records.

Nursing care at home meets the need of the domestic market

Most elderly would prefer home nursing care over hospital or institutional cares. From the interviews, this research has found that most elderly prefer home-based care much higher than the care given by foreign caregivers. There are two dimensions to this phenomenon. From the perspectives of the elderly's children, reasons include: 1. elderly dislike foreign maids, 2. domestic maids are easier to communicate, 3. most families are not qualified to apply for foreign maids. From the perspectives of the elderly, reasons include: 1. language barrier, 2. feel foreign caretakers are not trustworthy due to culture barrier, 3. do not like a foreigner living in the house. Due to the above, domestic care givers are always consumers' number one choice.

Application of Information Technologies on Nursing Industry

A complete long term care system needs to combine medical, information, and internet technologies. Applying information technologies on the nursing industry can satisfy administration, management, and nursing decision needs. Information technologies are being applied in many industries, including the medical profession. Currently, many advance countries are already applying information technologies on the medical industry, and slowly extend the use into the nursing care. In Taiwan, the application of information technologies is mostly on elderly's long term nursing care, security, and emergency notification services. To conclude, utilizing technologies to meet the needs of various service demands not only can greatly reduce the burdens of relevant parties, but also highly increase the quality of the entire nursing system. In other words, integrating information technologies into the industry is the main stream of the entire global medical industry trend.

ABSTRACT

The concept of strategic alignment rooted in the contingency theory tradition and refers to the match between (or among) a set for theoretical dimensions, has served as the central idea to the development of theory in many management disciplines. With the emerging of operations management area, operations activities have been strongly emphasized and treated as a strategic weapon for decades. Facing an extremely turbulent environment, manufacturers are dealing with a situation needed to be highlighted profoundly. Up to now, operations strategy has been proved that it has significant impact on organizations performance. Meanwhile, across a wide spectrum of areas, IS strategy is transcending its typical image of "supporting role" and is evolving toward a "strategic" role with the potential not only to support business strategy, but also to shape a new business strategy. Business strategy could be viewed as one of strategies top in an organization, which gives a rough picture for every unit in its organization to fulfill step by step. The general purpose of this study is to build up a conceptual model for the further research related to operations strategy strategic alignment. All in all, there are reasons to believe that each of them should fit together and have positive impact on organization's performance.

Keywords: Strategic alignment, Operations strategy, Information system strategy, Business strategy

INTRODUCTION

Research Background

The concept of strategic alignment, rooted in the contingency theory tradition, has served as the central idea to the development of theories in many management disciplines (Van de Ven, 1979). Moreover, it is well known and discussed in managerial behavior and organizational

analysis (Delery and Doty, 1996; Miles and Snow, 1984). It provides researchers with a broader view to identify the four components of strategy, namely market opportunity, corporate competences and resources, personal values and aspirations, and acknowledged obligations to segments of society other than stockholders (Andrews, 1980; Venkatraman, 1990). For contingency theorists, they believe strategy should be fixed, changed, reformed, or even canceled under different scenarios due to the dramatically changing environment. Especially, it's a huge breakthrough after Venkrataman's (1989) study suggests six methods to measure the degree of strategic alignment. Since then, researchers could explore the relationship between different strategic domains with six approaches. Consequently, although there are researchers calling for papers, little attention has been devoted to academic filed and industry.

With the emerging of operations management area, it's gradually invoking scholars' and practitioners' attentions that how to use operations activities to enhance or even maximize organization performance. Therefore, operations activities have been strongly emphasized and treated as a strategic weapon for decades (Skinner, 1969). Besides, facing an extremely turbulent environment, firms, especially manufacturers, are dealing with a situation needed to be highlighted profoundly. Hence, the priority in researchers' and practitioners' mind has been shifted to how to adopt an appropriate operations strategy instead of simply increasing productivity. Additionally, from a strategic perspective, people in this filed are looking for a way to obtain so-called "competitive advantages". Until now, operations strategy has been proved that it has significant impact on organizations performance (Skinner, 1969; Smith and Reece, 1999; Sun & Hungs, 2002).

Meanwhile, it's just similar with the development of operations strategy that information system strategy (IS strategy) has gradually drawn researchers' and practitioners' attentions. Across a wide spectrum of areas, IS strategy is transcending its typical image of "support role" and is evolving toward a "strategic" role with the potential not only to support business strategy, but also to shape a new business strategy (Henderson & Venkatraman, 1999). Practical speaking, for manufacturers, when they're conducting operations strategy or operations activities, cooperating with their information systems is one thing need to take into account(Sambamurthy & Zmud, 1999; Reich and Benbasat, 2000; Cao & Schniederjans, 2004). Therefore, the important role IS strategy plays is not only cooperating with operations strategy, but also strongly link to business strategy.

Advantages are determined, at least in part, by how effectively and efficiently the firm's business strategy is implemented (Walker and Ruekert, 1987). Thus, business strategy could be viewed as one of strategies top in an organization, which gives a rough picture for every

unit in this organization to fulfill step by step. Undoubtedly, the importance of business strategy is undeniable, because it is the direction for other functional strategies (e.g., operations strategy and IS strategy) to go forward, if they co-align well (Sambamurthy & Zmud, 1999; Smith & Reece, 1999; Sung and Houg, 2002; Cao & Schniederjans, 2004).

The issue of alternative resource alignment has been one of the primary concerns of executives and senior managers, in general, since the mid-1980s (Luftman *et al*., 1996; Watson *et al*., 1997). Doty *et al*. (1993), reviewing their own research, indicate that increased organizational effectiveness is driven by the internal consistency or 'fit' between the various patterns of relevant contextual, structural, and strategic factors. Powell (1992) also suggests that the alignment between organizational processes and strategic decisions makes a major contribution to competitive advantage.

The importance of IS in strategic alignment also is acknowledged (Henderson and Venkatraman, 1993; Reich and Benbasat, 2000). A recent study, conducted by Lee *et al.* (2004), demonstrated that contingency and fit (alignment) theory were among the top five frequently-used theoretical framework categories out of the 31 listed among the 993 studies in the MIS field. Researchers have come to realize that an absence of strategic alignment probably can cause organizations to be incapable of realizing sufficient value from their IT investments (Henderson and Venkatraman, 1993; Woolfe, 1993). Alignment has been found not only to make a great contribution to the potential capabilities of an organization's IT infrastructure; it also exerts a significant direct positive effect on organizational performance (Azab, 2005). Conversely, misalignment in organizations results in redundancy and inefficiency in IT functions, and in an increase in costs and delays (Gold *et al*., 2001). More seriously, it can be one of the critical reasons that an organization's performance declines (Chan *et al*., 1997; Luftman and Brier, 1999).

Consistent with the vein, it's obviously that the crucial roles this three strategies play, respectively, partially determined an organizational performance. However, no matter how each one of them contributes to an organization individually, it lacks the consideration of strategic alignment among pertinent strategies. In other words, there is a necessity to evaluate whether these strategies could fit together well and levering the performance.

Research Motivation and Purpose

Over the last couple of decades, many researchers, consultants and practitioners have developed frameworks that attempt to identify the inter-correlations between IS strategy and business strategy (Marchand *et al*., 2001). However, there are still certain issues needed to be

further discussed. For example, what are the relationships among operation strategy, business strategy, and IS strategy? How do organizations truly deploy their operation strategy with business strategy and IS strategy at the same time? Furthermore, though there are numerous studies addressing the strategic alignment between operations strategy and IS strategy, operations strategy and business strategy. But, currently, there is no empirical study focusing on a holistic point of view; that is why operations strategy, business strategy, and IS strategy should fit.

Therefore, the general purpose of this study is to contribute to the academia and practice relating to operations strategy strategic alignment by pursuing two specific objectives. First, we are devoted to shedding more light on operations strategy alignment research to reflect the simultaneous and holistic pattern of inter-linkages among operations strategy and other strategies that influence operations activities. Second, it intends to provide further insights into performance implications within the broad conceptualization of strategic alignment among operations strategy, IS strategy, and business strategy.

LITERATURE REVIEW

Strategic Alignment

In general, Strategic alignment (also termed consistency, contingency, coalignment, harmony, or fit) refers to the match between (or among) a set for theoretical dimensions, however alignment is emerging as an important organizing concept in organization research (Aldrich, 1979; Fry and Smith, 1987; Van de Ven and Drazn, 1985) and strategy management filed (Miles and Snow, 1978; Venkatraman and Camillus, 1984). In spite of many terminologies was used, the meaning of alignment can be defined as the "fit" between strategy and its context—whether it is the external environment or organizational characteristics (Venkatraman and Prescott, 1990). Though this concept has been discussed many times in the past studies, a more definite definition has just emerged through the findings of Van de Ven and Drazin (1985) and Venkatraman's (1989) researches on the concept of alignment. The former defined alignment as three approaches: selection, interaction, and systems approaches and the latter used six different aspects to exam the degree of alignment which are matching, moderation, mediation, gestalts, covariation, and profile deviation. In the following paragraphs, these six methods will be discussed in order.

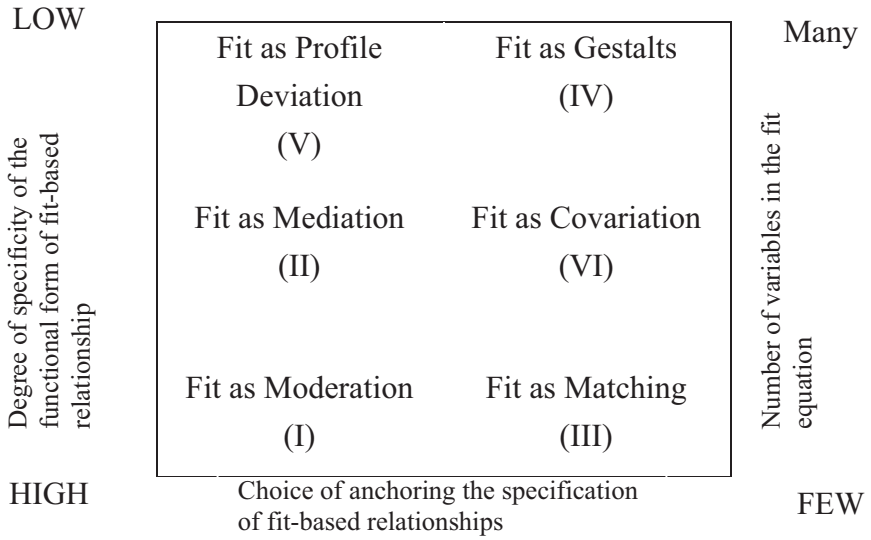

Figure 1. A classificatory framework of fit (adopted from Venkatraman, 1989)

Fit as moderation

Based on contingency theory, there is no universally superior strategy; different strategy is adopted depends on environmental or organizational context. Venkatraman(1989) said "According to the moderation perspective, the impact that a predictor variable has on a criterion variable is dependent on the level of a third variable, termed here as moderator." In another word, in this criterion-specific perspective, it is similar to Van de Ven and Drazin's (1985) definition of alignment as interaction which means alignment is the interaction between two predictor variables. To verify the alignment, analysis of variance (ANOVA), moderator regression analysis, and subgroup analysis are commonly used.

Fit as mediation

This criterion-specific perspective adopts a conceptualization based on an intervening mechanism between an antecedent variable and the consequent variable (Venkatraman, 1989) and basically intervening variable (e.g., structure) has an indirect effect on the antecedent variable (e.g., strategy) and direct effect on the consequent variable (e.g., performance). The degree of specificity of the functional form of the relationship is not as high as in the fit as moderation perspective, especially when more than two variables are incorporated in the model. Path analysis is commonly thought a suitable technique to exam the alignment as mediation.

Fit as matching

To a certain degree, fit as matching is conceptually close to the concept of selection approach

Van de Ven and Drazin proposed (1985) which alignment is the product of selection. According to Venkatraman, the fit as matching perspective is a "major point of departure from the previous two perspectives because fit is specified without reference to a criterion variable, although, subsequently, its effect on a set of criterion variables could be theoretically defined match between tow variables". Venkatraman identifies three analytical schemes for supporting the matching perspective: deviation score analysis, residual analysis and analysis of variance.

Fit as gestalts

Fit as gestalts is corresponding to Vand de Ven and Drazin's (1985) system approach oriented from the system theory that organizations must be a holistic patterns of interdependencies. From gestalts' point of view, researchers should be looking for frequently recurring clusters of attributes or gestalts; that is, the way gestalts view alignment is from a broader perspective, namely, it can be used to test multivariable (Miller, 1981). Venkatraman adopted the definition proposed by Miller and Friesen (1977) and Miller (1981) who conceptualized fit as "a set of relationships which are in a temporary state of balance" (Miller and Friesen, 1977, p.264, as cited by Venkatraman, 1989, p.432). Several taxonomical techniques are appropriate for examining this perspective of alignment such as cluster analysis and q-factor analysis.

Fit as covariation

This perspective defines fit as "a pattern of covariation or internal consistency among a set of underlying theoretically related variables" (Venkatraman, 1989). This perspective is similar to gestalts but they are different in the degree of specification of the functional form. Gestalts consider alignment as the outcome of cluster analysis, however fit as covariation is the process of factor analysis, grouping of attributes based on a set of observations (Venkatraman, 1989). It was noted in Venkatraman's study that in order to perform a rigor research, the confirmatory factor analysis (CFA) is superior to exploratory factor analysis (EFA), although both of them can be used to test this perspective of fit.

Fit as profile Deviation

Fit as profile deviation belongs to the systems approach defined by Drazin and Van de Ven (1985), namely the internal consistency of multiple contingencies. In this context, an ideal profile is assumed, and the deviation from this ideal profile expresses the degree of alignment, that is to say the more organizations' score are resemble to the ideal profile, the higher the degree of alignment organizations attain. The calculation of deviation as a Euclidean distance in an n-dimensional space is the proper analytical method for testing this perspective of fit.

Operations Strategy and Strategic Alignment Model

To retrace the definition of operations strategy, it was stated by Skinner (1969) as a company's competitive strategy at a given time places particular demands on its manufacturing function, and, conversely, that the company's manufacturing posture and operations should be specifically designed to fulfill the tasks demanded by strategic plans. In Anderson et al.'s research, the notion of operations strategy was defined as an activity which integrated business strategy, strategic production policy, and operations life-cycle. On the other hand, to address this issue, distinct typologies of operations strategy are essential. Operations strategy was divided into cost-driven strategy, market-driven strategy, and technology-driven strategy by Stobaugh & Telesio (1983). It's been gradually emphasized Sweeny's (1991) typology, including Caretaker, Marketeer, Reorganizer and Innovator. Furthermore, a convergent concept was reached, especially the one, caretaker, marketer, and innovator (Miller & Roth, 1994).

In the early stage, operations activities was not treated as important as other functional strategy, since it was argued that operations strategy can distribute a lot to business performance and operations activities begun to be put to a posture of strategy—the operations strategy (Skinner, 1969). Operations strategy has regarded as the manner in which the business units deploy its resources (Hayes and wheelwright, 1984). In fact, there are several studies interested in the operations strategy impact on business performance. For example, Wheelwright (1984) defined four competitive priorities of operations which distinctly articulate how operations can support a business performance or Smith and Reece (1999) proved that operations strategy had a positive impact on business performance. Since then, several works contribute to relationship between operations strategy and other functional strategies. Marucheck et al. (1990) concluded that operations strategy was perceived to be reactive and subordinated to business strategy. Recently, in the finding of Sun & Hung's study (2002), it mentioned the alignment of operations strategy and business strategy positively influences the improvement of business performances. The role operations strategy plays in an organization is the linkage between business strategy and internal and technological basis and to play this role, operations strategy must be in alignment with business strategy. The operations strategy research models originate with the development of a conceptual framework for operations strategy research by Skinner (1969) shown in Figure 2. As shown in Figure 2, it links a firm's operations strategy and logistic integration approach to organization performance.

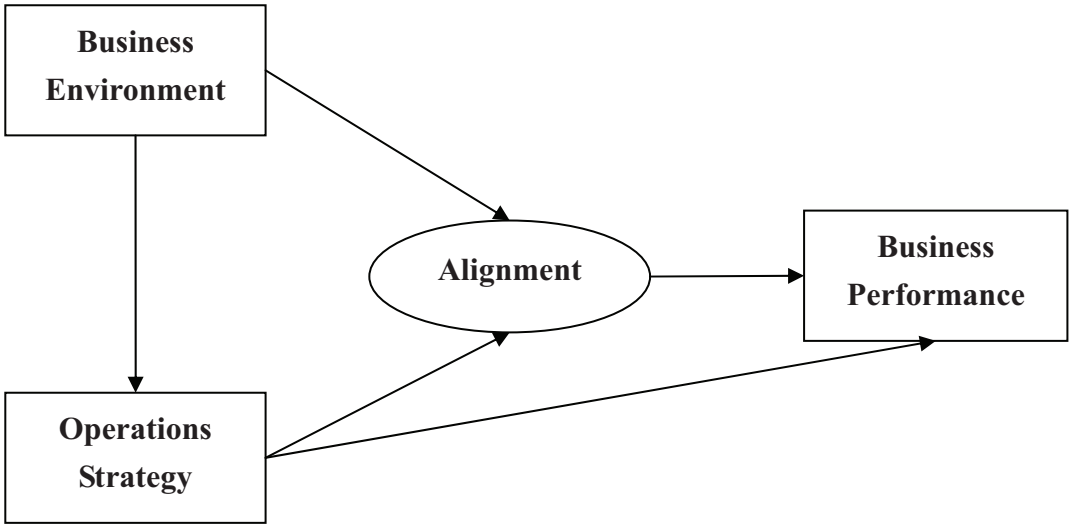

Figure 2 Skinner's (1969) Operations Strategy model.

Information System Strategy and Strategic Alignment Model

As the field of strategic management had expanded, strategic researchers and practitioners have been gradually interesting in how IS strategy works with, or even supports and shapes business strategy. In the earlier work, Venkatraman (1990) has focused particularly on the "coalignment between the strategic context and the IT infrastructure of a business" as a driver of successful exploitation of IT.

In recent years, information system has become a critical tool for the execution of business strategy and a driver of business strategy (Venkatraman, 1989). Furthermore, some conventional information systems become strategic when used in an innovated way (Wiseman, 1988). The relation of IS strategy to business strategy and the attainment of competitive advantage has been the focus of much discussion during the past two decade. In the past decade, there were some studies discussed the link between business strategy and IS strategy. (e.g. Bakos and Treacy 1986, Henderson and Venkatraman 1992, King 1978, McFarlan 1984, Parsons 1983, Rockart and Scott Morton 1984). These studies showed that there are positive relationship between IS strategy and business performance.

Besides, there are numerous frameworks and models proposed by MIS researchers. In 1991, it was proposed by Scoot Morton that a framework including five dimensions, namely structure, strategy, management process, technology and individuals and roles. (see Figure 3). In 1997, Chan et al.'s work provided a model to better understand the relationships between business strategy, IS strategic orientation and Business performance. (see Figure 4).

Business Strategy and Strategic Alignment Model

Venkatraman (1985, 1989) defined the "strategic orientation of business enterprises" (STROBE) as:

> …the general pattern of various means employed to achieve the business goals, with a particular emphasis on the business-unit level of the organizational hierarchy. (Venkatraman 1985, p.52)

Thus, business strategy can be viewed as a set of means how firms compete in an industry or market (Varadarajan and Clark 1994; Ruekert and Walker 1987). In other word, business strategy is an integrated and coordinated set of commitments and actions the firm uses to gain a competitive advantage by exploiting core competencies in specific product markets, nevertheless, it is also a difficult-to-measure construct (Hambrick, 1980) that can differ from competitor within the same industry (Harrigan, 1980).

The two dominant frameworks of business strategy (Hambrick 2003) are the Miles and Snow (1978) typology, which focuses on intended rate of product-market change, and the Porter (1980) typology, which focuses on customers and competitors. Except typology,

Based on Miles and Snow's (1978) well-established typology of business strategy, including Defenders, Analyzers, and Prospectors, business strategy could be characterized as an outward technological profile contributes to organization performance directly. In a study on strategic management, Miller (1987) found a positive association between strategy and performance under various conditions. It definitely describes how an organization gains its own competitive advantage which plays a unique role in organization's performance. At the same time, it represents as the operations direction of a business toward the organization's goal. When formulating business strategy, for instance, Ansoff (1965) and Andrews (1980) emphasized the importance of aligning the organization's strategy with and internal appraisal of the firm and external assessment of environmental opportunities and threats. Therefore, alignment is important not only in developing strategies but also in their implementation.

A Holistic Perspective

As noted before, from strategic alignment perspectives, the factors influencing organization performance should be more than one single aspect. Therefore, it implies strategies somehow should fit together to create synergy in order to better perform in organizations. (Venkatraman, 1984)

Traditionally, as one of functional strategies, operations strategy was not paid enough attention; however, since it was uncovered that the important role operations strategy played in organization, there were numerous researchers devoting them to studying its impact on business performance. It, as well as, was argued operations strategy is a critical element within an organization (Skinner, 1969) and it's the linkage to corporate strategy. In addition,

since then, it has been widely believed that to a certain degree, operations strategy has not been only supporting business strategy but working with business strategy and creating synergy on performance. (Smith & Reece, 1999; Sung & Hong, 2002)

It is without questions that the importance of IS strategy on business performance has increased noticeably during past decades (Bergeron & Raymond, 1995; Henderson & Venkatraman, 1999; Porter & Millar, 1985). In addition, the manufacturing-business alignment positively influences the manufacturing contribution to the improvement of business performance. It's proved that the high-performing organizations are based on the alignment between operations strategy and IS strategy and it has positive impact on performance (Cao & Schniederjans, 2004). The framework proposed by Cao and Schniederjans is shown as Figure 5.

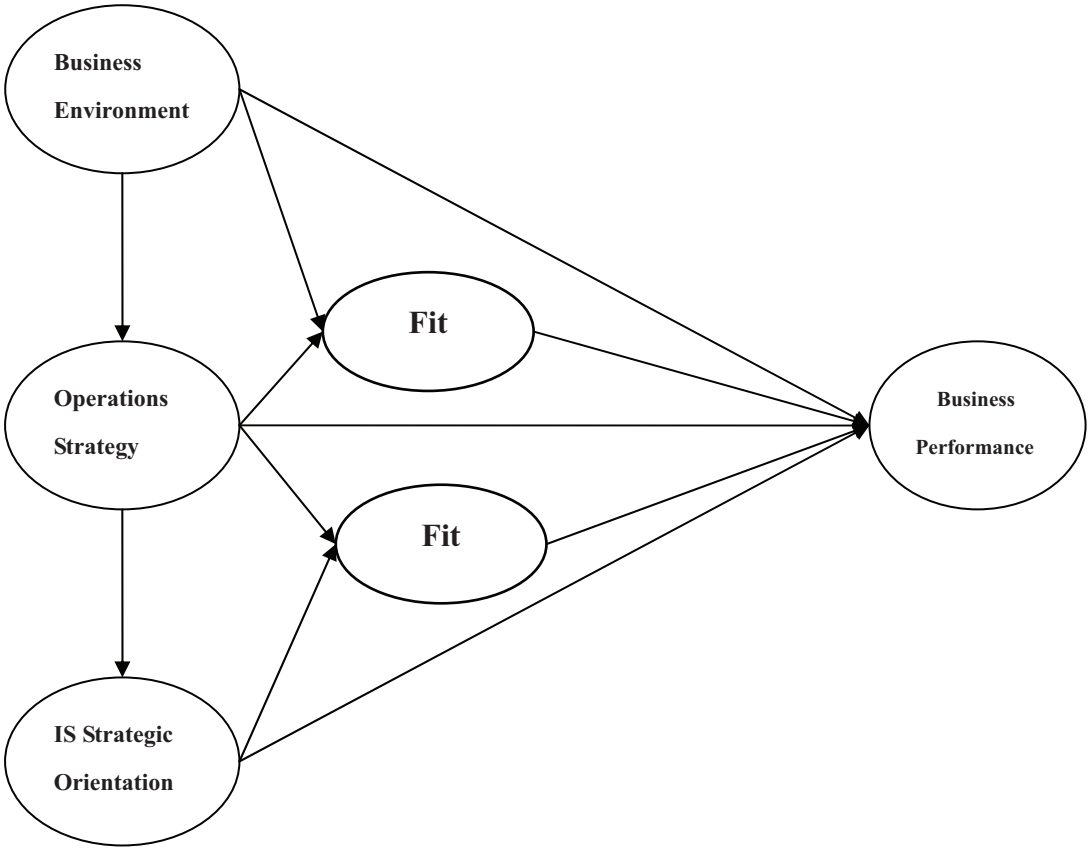

Figure 5 Cao and Schniederjans' conceptual model (adapted from Cao & Schniederjans, 2004)

RESEARCH PROPOSITION AND RESEARCH MODEL

To inherit the vein abovementioned, operations strategy, IS strategy, and business strategy occupy an important part in an organization, respectively; furthermore, they work together to

contribute toward an organization's performance. All in all, there are reasons to believe that each of them should fit together and have positive impact on organization's performance. The following proposition and an ideal framework, Figure 6, are proposed.

P1: The strategic alignment among operations strategy, business strategy, and IS strategy has a significant positive direct effect on business performance

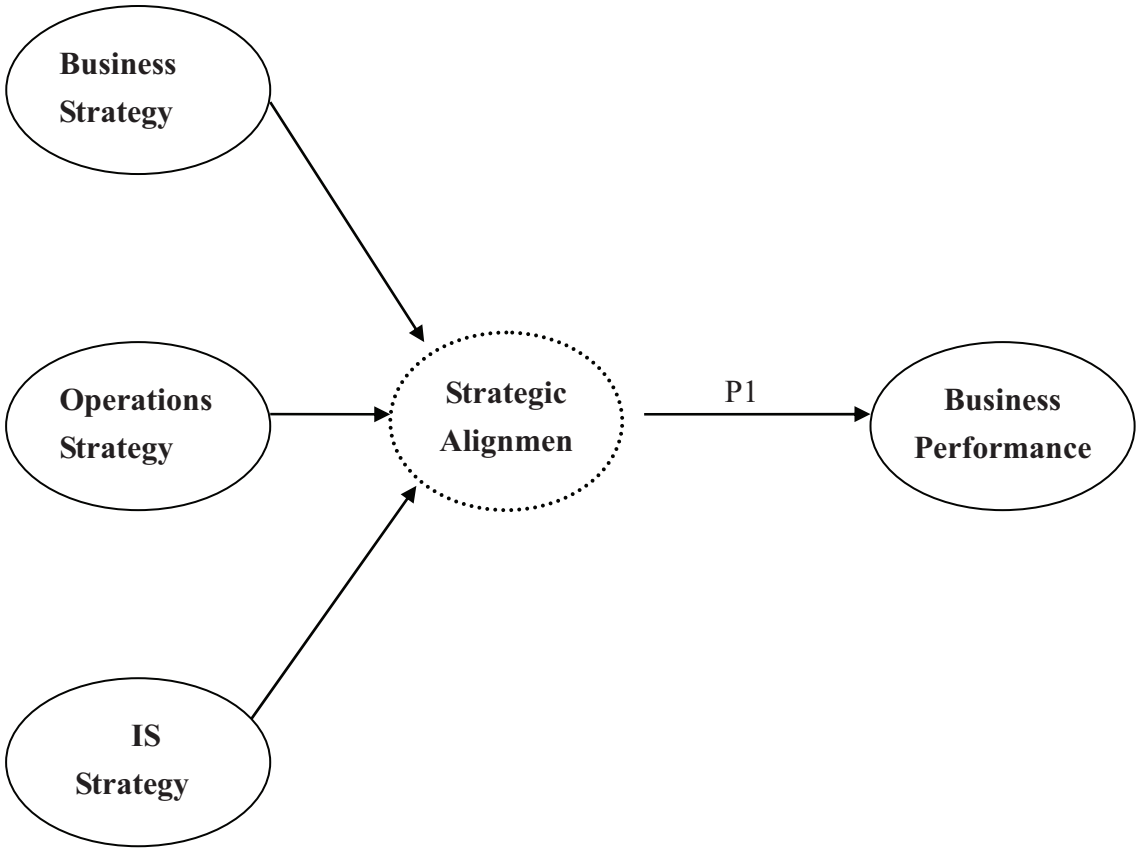

Figure 6. Research Conceptual Model

CONCLUSION

To sum up, no matter for academic filed or practitioners, there is a necessity to clarify and better understand meaning of the strategic alignment among strategies based on the reasons as follows: (1) Since each of them has significant effect on performance and even every two of them do too, should it also has an impact on performance from a broader perspective? (2) Strategic alignment view is comparatively rare discussed by researchers, not to mention being assessed via a system approach in operations filed; this conceptual model provides a well-structured starting point for future research. (3) If it does has an impact on performance,

how to define well-fitted strategies mix (or poorly-fitted) would be another interesting topic

Extension of this study would be applied with empirical data to asses this model. Through examining with statistical methods, a crystal definition of well-fitted strategic alignment mix in operations filed is expected. The outcome will definitely benefit academic research and operations practice.

ABSTRACT

It is noted that marketing, manufacturing and administrative– the first two reflect two important functional spheres, namely, operations and selling, while the third collectively reflect a general conceptualization of the "value-chain" of a business. Which implies three constituents of how business works – marketing strategy, manufacturing strategy, and strategic orientation. Yet to the best of our knowledge, little work has been done to exam the interrelationships from a holistic perspective. This paper tends to deepen the knowledge of performance implication of the fit among the three constituents mentioned above from a holistic perspective. We contend that this strategic alignment may contribution to business performance.

Keywords: Fit, Manufacturing Strategy, Marketing strategy, Strategic orientation

INTRODUCTION

Research background

As every parts of the world being tied together more closely, so is the business competition become more aggressive. One thing about the organization is that marketing is like the Achilles' heel to many prosperous organizations, which makes marketing too important for any organization to do without. What is marketing exactly? American Marketing Association offers the following formal definition: "Marketing is the activity, set of institutions, and processes for creating, communicating, delivering, and exchanging offerings that have value for customers, clients, partners, and society at large" (AMA, 2007). As Kotler (1983) pointed out that the selling activities teemed in our daily life is just a "tip of the marketing iceberg". As an independent intellectual inquiry, marketing has evolved for decades. One of the great milestones of marketing chronicle delivered by Borden(1965) was "Marketing mix", an essential concept later being grouped into four categories by McCarthy known as four Ps of marketing today(McCarthy, 1996). "Product Life Cycle" is another well known work of

Levitt (Levitt, 1965). Another milestone being proposed by Boston Consulting Group in 1970s is the concept of "Strategic Marketing" and its famous BCG product portfolio matrix. By 1981, Kotler and Singh applied principles of military strategies to business situations and proposed "Marketing warfare" (Kotler & Singh, 1981). Marketing usually acts as the channel of communication between the marketing environment and customer preference and usually deals with revenue maximization, whereas manufacturing usually responsible for receiving the design for production and cost minimization (Brooksbank, 1991; Lilien & Weinstein, 1984). Though marketing and manufacturing are organizationally separate in most firms (Karmarka & Lele, 1989), without effective co-ordination of those two functional entities could potentially jeopardize organization's survival in the marketplace (Mukhopadhyay, 1998). Therefore, the strategic alignment between marketing and manufacturing strategy is a crucial issue for academic and empirical practice.

Few would argue that the most crucial problem an organization could get into today is the management of change. However, how to formulate an overall strategy that exploiting synergy from different functional entities within an organization is still difficult to achieve yet so far. To cope with volatile market situations, organizations have been examining decision making for decades from various facets. AS Schendel and Hofer (1979) point out that the manner which a firm position itself competitively, whereas Porter stated "A corporate should seek to respond to the external environment effectively to gain competitive advantages or the competitive forces" (Porter, 1990). Though the definition varies, all of them served the same interest - focusing on how to better deal with competition and maintain competitive advantages simultaneously (Milosevic & Srivannaboon, 2006). Among all the typologies proposed, Miles and Snow (1978) and Porter (1980) typologies, which are being called "business strategy" have been considered two dominant categories of business strategy.

A fact in most companies is that the great bulk of the asset used - the capital invested, the people employed, and management time - are in the operation side of the business. This is true of both manufacturing and service organizations, in both the private and public sector of our economy (Hayes & Schmenner, 1978). It is apparent that the manufacturing is an indispensable constituent to the success of an organization as a whole. Ever since Skinner's famous work back in 1969, manufacturing strategy have been getting spotlight from researchers in related fields. The definition of manufacturing strategy was stated by Skinner as "a company's competitive strategy at a given time and places particular demands on its manufacturing function, and, conversely, that the company's manufacturing posture and operation should be specifically designed to fulfill the tasks demanded by strategic plans" (Skinner, 1969). As he pointed out in his another work in 1974 that no company can perform well on every yardstick. An organization can only outperform its competitor by focuses on a

narrow product mix for a particular market niche with the premises that each of its key functional area (e.g. marketing, manufacturing, sales…etc) in operation activities must have the same objective (Skinner, 1974), in addition, the type of manufacturing strategy of a firm used must be complied with its chosen competitive strategy (Amoako-Gyampah & Acquaah, 2008; Sun & Hong, 2002). Consequently strategic orientation of a business should be in line with manufacturing and marketing strategy.

It is widely recognized that the use of contingency theory is a strategy that most organizations adopt toward the competitive environment which varies in a minute basis. Strategic alignment (or fit) is considered as the central thrust in many management disciplines, especially in strategic management field (Delery and Doty, 1996; Venkatraman, 1984). Doty et al. (1993), reviewing their own research, indicate that increased organizational effectiveness is driven by the internal consistency or 'fit' between the various patterns of relevant contextual, structural, and strategic factors. Usually organization's performance is determined by how effective the organizational structure is being implemented, and that depends on how the functional entities are being organized (Mintzberg, 1979; Ward et al.1996). In other words, through coordinating subsystems within the organization with a variety of different strategies, superior organizational performance can be achieved (Venkatraman, 1990).

Problem statements

Strategy is rooted as a concept to match or align organizational resources with environmental opportunities and threats on an ongoing basis (Venkatraman, 1984). As many studies have either implicitly or explicitly employed the concept of fit, it occupied a central role in many strategic management fields (Venkatraman, 1984). Though theories vary widely in subject matter, they share the common proposition that an organizational outcome is the consequence of a strategic alignment between two or more factors or dimensions (Van de ven & Drazin, 1985).

According to Venktraman (1990), marketing, and Manufacturing reflect two important functional spheres, namely, operations and selling, while the strategic orientation captures the "generic typologies" of organizations. An effective strategy of a business is the one that collectively reflects consistency or coherence among these three dimensions mentioned above. Moreover, due to the concept of strategic alignment has not been adequately clarified when employed in the various social science streams (Venkatraman, 1984), the above mentioned strategic alignment of the three constructs is in the need.

Research Motivation and Purpose

Consequently, the general purpose of this study is to contribute to the academia and practice relating to strategic alignment by pursuing several specific objectives. First, this study tend to shed new light on marketing strategic alignment research to reflect the simultaneous and holistic pattern of inter-linkages between Marketing strategy and other strategies, which refers to Manufacturing strategy and Strategic Orientation. Second, it intends to provide further insights into performance implications within the broad conceptualization of strategic alignment among Marketing strategy, Manufacturing strategy, and Strategic orientation.

LITERATURE REVIEW

Strategic alignment

The basic theme of alignment is generally understood in its metaphoric form and it is common for theorist to postulate relationships using words and phrases such as matched with, contingent upon, consistent with, congruence, fit, or alignment (Venkatraman, 1989). The concept of fit has served as an important building block for theory construction in several areas of research (Aldrich, 1979; Fry& Smith, 1987; Van de Ven & Drazin, 1985). In general, the idea is the efficient alignment of organizational resources and capabilities with environmental opportunities and threats (Andrews, 1980; Bourgeois, 1980; Schendel and Hofer, 1979), it is a match between (or among) a set of theoretical dimensions (Venkatraman, 1990). It is important from two perspectives in the organizational theory literature—descriptive and normative. The descriptive perspective specifies the existence of relationships among a set of theoretically-related variables without any explicit linkage to performance. The normative perspective develops an explicit link between coalignment and performance (Venkatraman, 1990). Venkatraman and Camillus (1984) made an initial attempt to distinguish between the 'content of fit' and the 'pattern of interactions' in 1984. Coalignment is between strategy and one or more relevant constructs in former perspective. The invocation of fit is external to the definition and operationalization of strategy. The latter perspective possessed that strategy is not viewed as a concept that is separable from the conceptualization of fit, coalignment is intrinsic to the conceptualization and operationalization of strategy itself.

Grant and King (1982) proposed that strategy is a timed sequence of internally consistent allocation of resources to achieve an organization's objectives (Venkatraman, 1982); internal consistency refers to the coalignment among decisions in key areas of operations and functions. Gupta's research in 1984 also proposed basic propositions that link strategy and managerial characteristics with explicit linkages to performance. In 1989, Venkatraman has identified six perspectives of fit as follow: fit as moderation, fit as mediation, fit as matching, fit as gestalts, fit as profile deviation, and fit as covariation (Venkatraman, 1989). A

conceptual framework is attached as follow in the Figure 1.

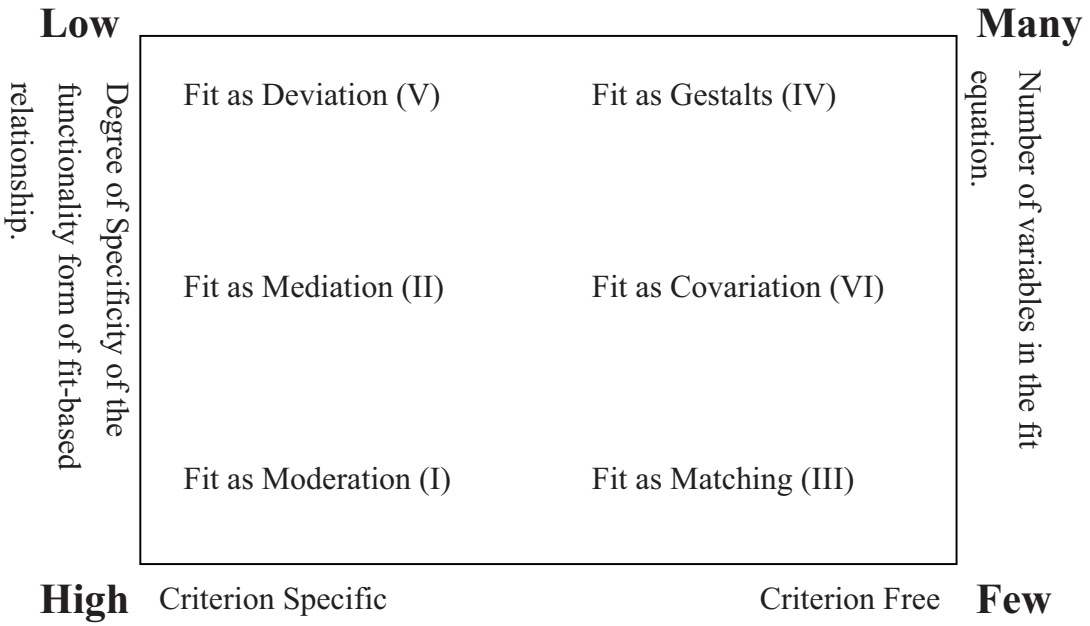

Figure 1. Conceptual framework of strategic alignment

Fit as Moderation

As investigators hold a contingency perspective, the impact that a predictor variable has on a criterion variable is dependent on a third variable, termed as moderator (Venkatraman, 1989). Fit as moderation is criterion-specific, and is conceptualized as the interaction between two variables. The impact a predictor variable has on a criterion variable is dependent on the level of a third variable. In other words, the moderator can be viewed either categorically or characteristically, and it will influence the direction and strength of the link between Independent Variable and Dependent Variable.

Fit as Mediation

While moderation specifies varying moderating effects of moderator to the relationship of IV - DV, this mediating perspective focus on the existence of a significant intervening mechanism between antecedent variable and the consequent variable. The relationship is not as high as the fit as moderation, especially when more than two variables are incorporated in the model. The distinction between complete versus partial mediation has important theoretical implication on managerial perspective.

Fit as Matching

Fit is considered a theoretically defined match between two related variables. The major departure of this perspective is that fit is specified without reference to a criterion variable.

The measure of fit between two variables is developed independent of any performance anchor. The fit as matching model is attached as Figure 2.

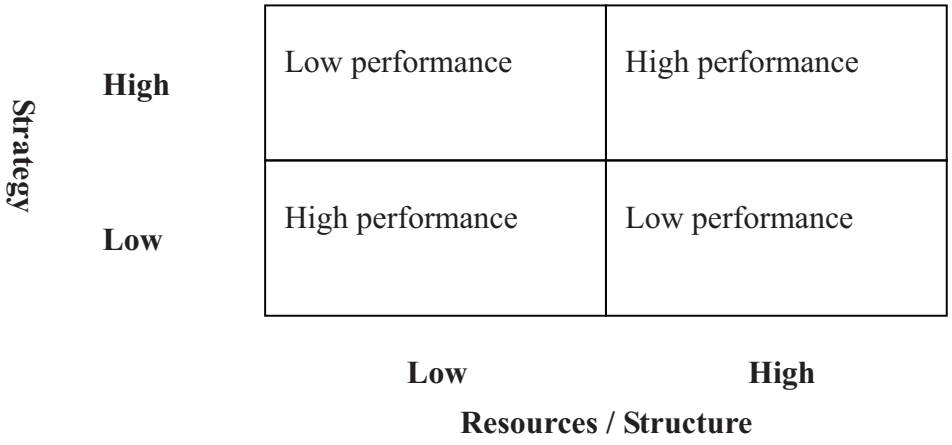

Figure 2. fit as matching model

Fit as Gestalts

Miller describes the role of gestalts as "Instead of looking at a few variables or at linear associations among such variables we should be trying to find frequently recurring clusters of attributes or gestalts".

Fit as Deviation

Similar to Van de Ven and Drazin's patter analysis, fit as deviation refers to the degree of adherence to an externally specified profile with anchoring to a certain criterion. Assumed an ideal profile, and lower performance should result from deviation from the ideal profile.

Fit as Covariation

The concept of fit as covariation is akin to Mintzberg's megastrategy, which means to make an effective strategies, it requires consistent attention to all areas of a strategy. Only focus on any one area is insufficient.

Manufacturing strategy

As academics gradually picked up interest on the importance of manufacturing strategies, researches in the field has increased significantly over the past decades. Research stream in manufacturing strategies has focus on the alignment of strategic priorities and its impact on performance, let along the importance of the alignment between strategies. The strategic

view of manufacturing strategy dates back to Harvard in the 1940s and 1950s where researchers observed different ways companies chose to compete within different industries (Voss,1995). With Skinner's contribution in "Manufacturing— missing link in corporate strategy" and "The focused factory" which not only set out the importance of explicit linkages between manufacturing choices, firm's environment, and corporate strategy, but also developed the concept of focus and of internal and external consistency (Voss,1995). Later Wheelwright also support that the manufacturing strategy should be in alignment with business strategy (Wheelwright, 1984).

Manufacturing strategy process, content and implementation determine how resources and capabilities are to be deployed within organizations to complement the business strategy (Hayes and Wheelwright, 1984). The major benefit of manufacturing strategy is that it provides a means for focusing the attention of corporate management on manufacturing concerns (Leong and Ward, 1994). Manufacturing strategy content embodies the choices of the most beneficial set of manufacturing capabilities for a business unit and the investments needed to build that set of capabilities (Ward, Bickford and Leong, 1996). Manufacturing capabilities are best conceived as stocks of strategic assets which are accumulated through a pattern of investment over time and cannot be easily imitated or acquired by trade, nor can good substitutes be found (Ward, 1996). Manufacturing strategy provides a competitive weapon in the organization's strategic planning if utilized properly (Skinner, 1969).

Marketing strategy

According to the definition of marketing proposed by Philip Kotler's: "marketing is the analysis, planning, implementation of carefully formulated programs designed to bring about voluntary exchanges of values with target markets for the purpose of achieving organizational objective" (Kotler, 1983). Marketing strategy is a set of integrated decisions and actions (Day, 1990) by which a business expects to achieve its marketing objectives and meet the value requirements of its customers (Cravens, 1999). As organizations only have limited resources, market segmentation and targeting is a necessity for firms to commit limited resources only to satisfy certain particular customer group. Marketing Orientation (MO) is considered by many as a measure of the behaviors and activities that reflect the marketing concept (Hunt & Lambe, 2000). However, marketing is not only a strategy or a concept, but a philosophy that is a cornerstone of successful firm's cultures (Hunt & Lambe, 2000). A concept that could lead firms to better understand and meet the needs of their target customer group by putting customers in the center of the firm's operation and strategy formulation (Deshpande & Webster,1989).

Strategic Orientation

There can be little doubt about that, by developing a business strategy, the organization determines how a strategic business unit (SBUs) support organizational goals, competitive direction, its scope, and how it will seek competitive advantages (Garvin, 1993). Business strategy represents the way that a business positions itself to its competitors, and how it confronts with the future challenges. Without a strategy, organization might find itself in a dilemmatic situation of conflict its short-term decisions with long-term goals (St John and Young, 1992). Business strategy is the outcome of a complex processes of decisions made to guide an organization with respect to the environment, structure and processes that influence its organizational performance (Croteau and Bergeron, 2001). Miles and Snow (1978) identified four archetypes of how firm address in market domains and construct structures and processes to achieve success. Prospectors continuously seeks to locate and exploit new product and market opportunities while Defenders attempt to seal off a portion of the total market to create a stable set of products and customers. Analyzers occupy an intermediate position between the two extremes by combining the strengths of both the Prospector and Defender to cautiously follow Prospectors into new product. The Reactor, does not have a consistent response to the entrepreneurial problem.

Strategic Alignment Models

Through 1990s, a number of prior researches have focused on logistics practices and internal congruence. By 2000, Stock et al. proposed a framework that links a firm's supply chain structure and logistics integration approach to organizational performance as showed in Figure 3.

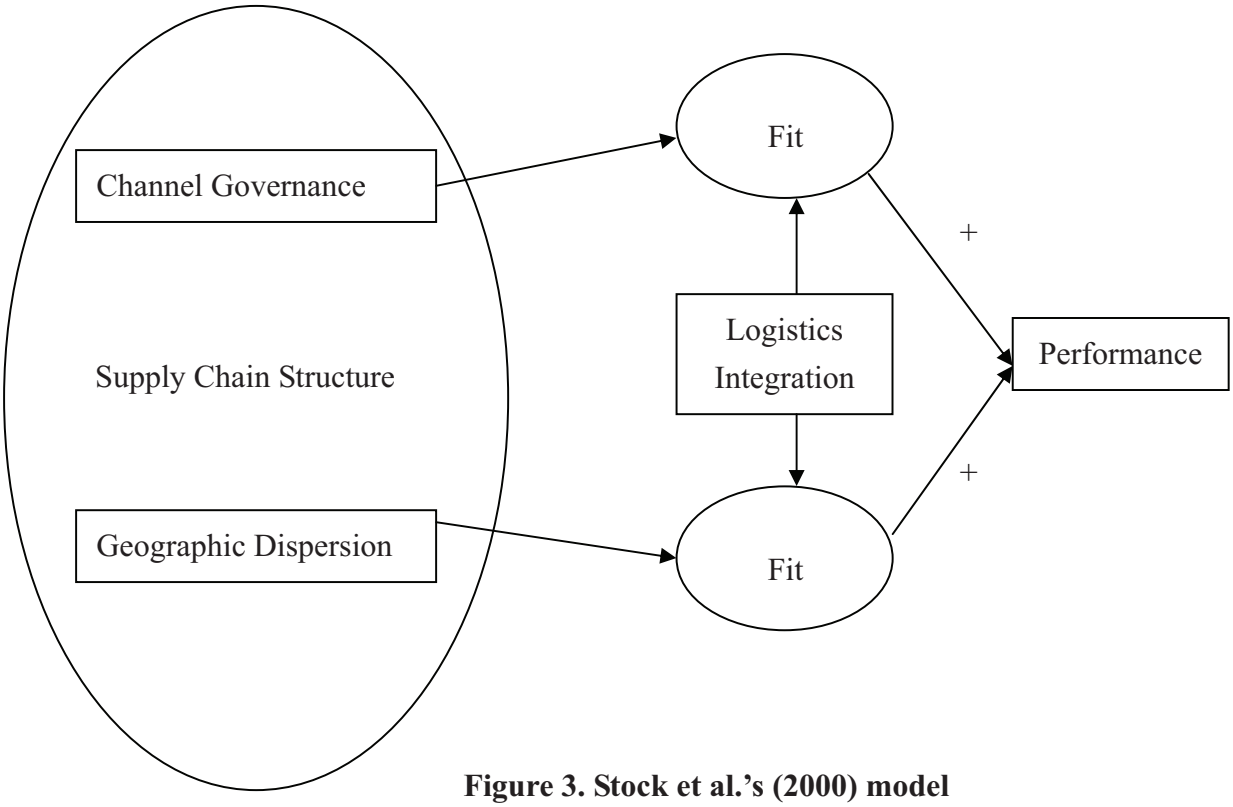

Figure 3. Stock et al.'s (2000) model

Sun (2002) articulated that the alignment of manufacturing strategy and business strategy positively influences the improvement of business performances, and the manufacturing-business alignment also positively influences the manufacturing contribution to the improvement of business performances in his research, which focus on the alignment between manufacturing strategy and business strategy on business performance and the contribution of manufacturing performance to business performance. The concept framework is shown as Figure 4.

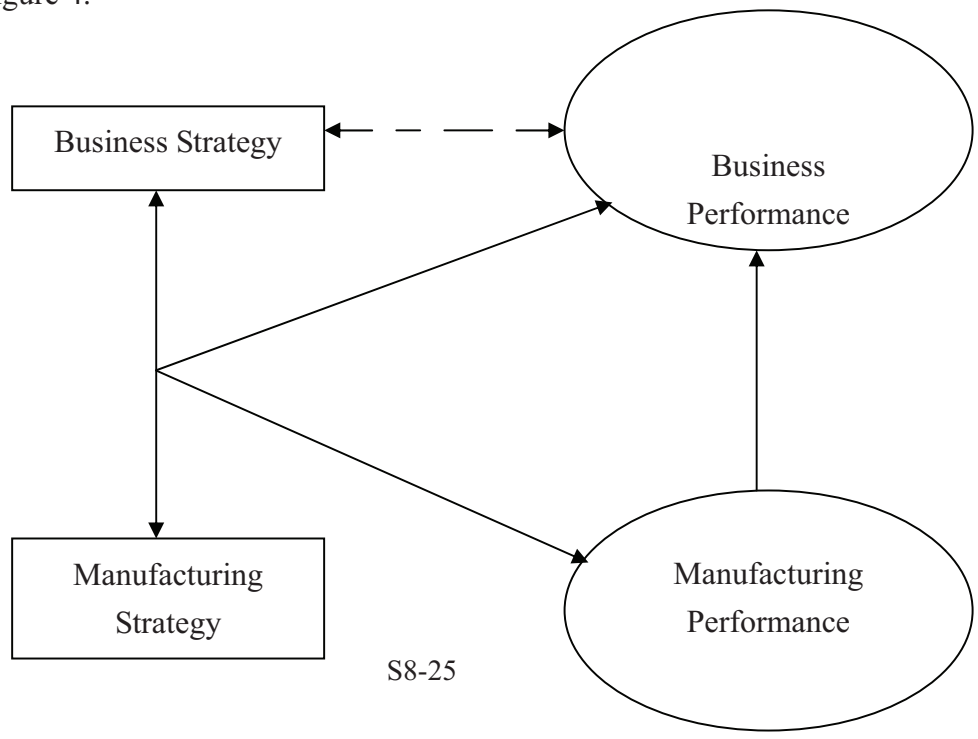

Figure.4 Sun's (2002) model

In 2005, Steven exemplified the existence of fit between the strategies followed by firms and the manufacturing technologies they employed, and proven the quality of the linkage was shown to relate to financial performance. The proposed figure is shown in Figure 5.

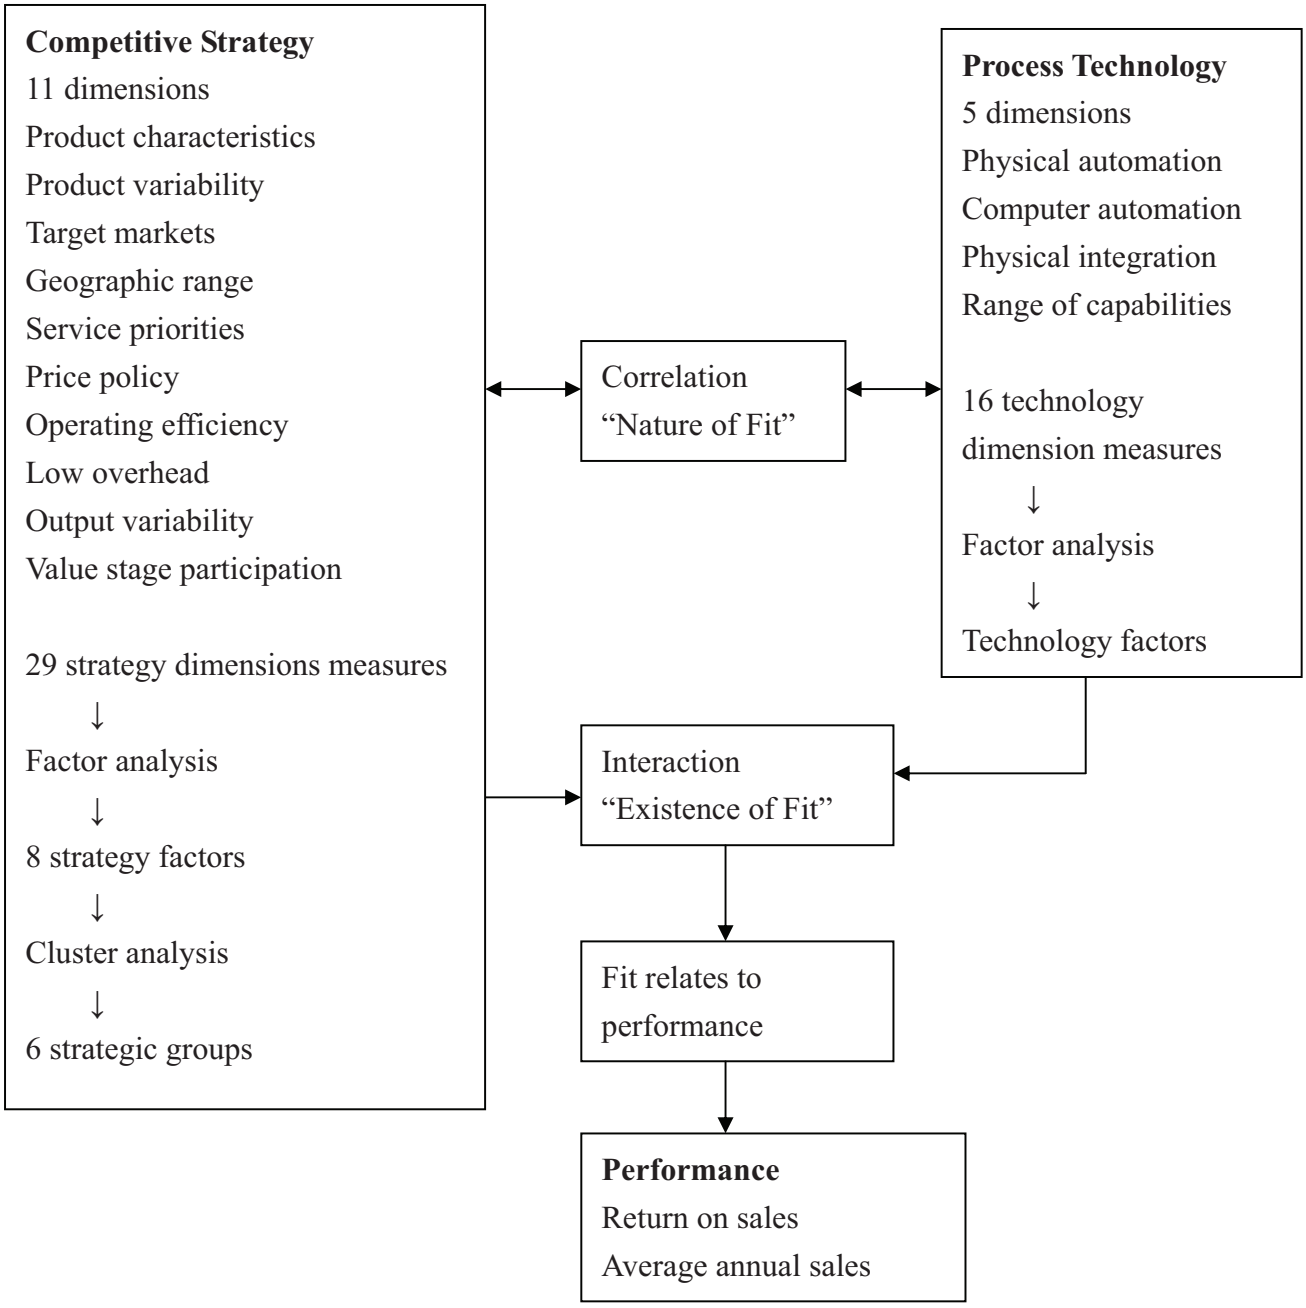

Figure.5 Steven's (2005) model

As indicated by Varadarajan' (1999), marketing plays an important role in the strategy formulation process and the determination of strategy content at the business and corporate

levels, rather than just being responsible for the content, process, and implementation of marketing strategy at the product-maker level (Varadarajan, 1999). Another research conducted by Slater in 2001 also exemplified that marketing strategy should not be considered independently of their business strategy. The implementation of business strategy addressed how marketing activities are accomplished (Slater & Olson, 2001).

An empirical research conducted by Berry et al. (1999) articulate that lack of alignment in marketing and manufacturing could leads to failure in achieving their strategic business objectives (Berry et al., 1999). The proposed framework is shown in Figure 6.

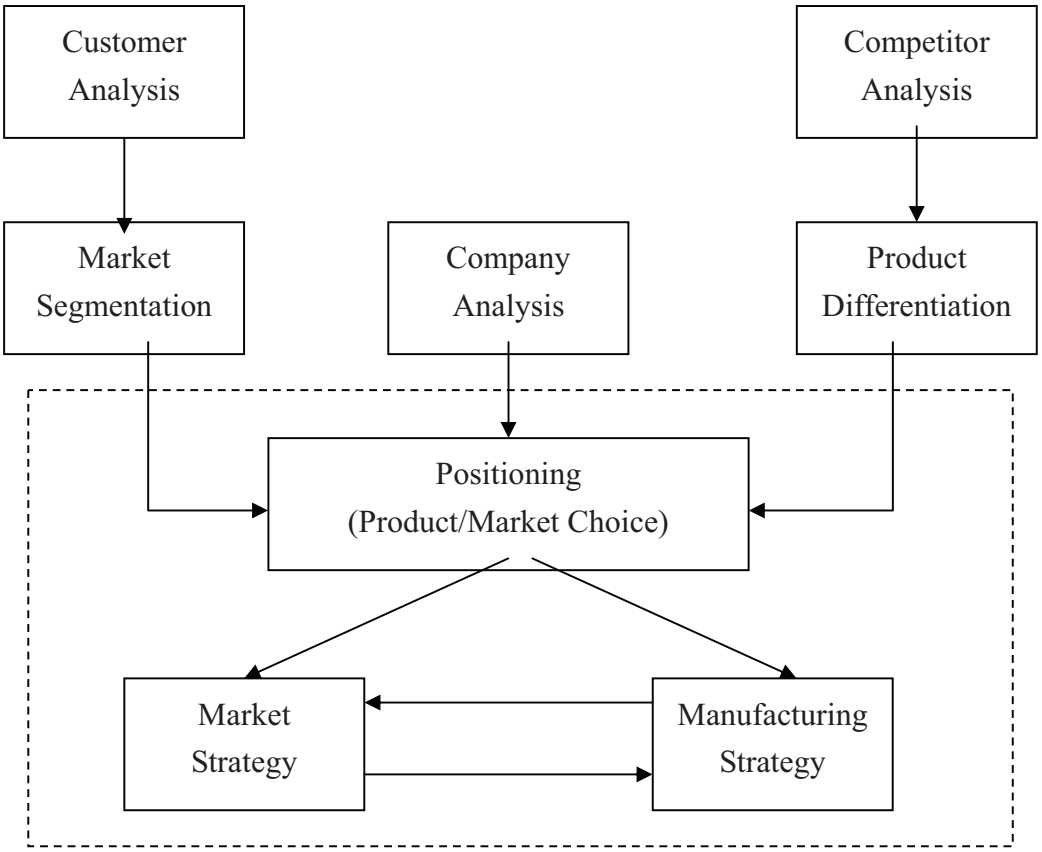

Figure. 6 Berry et al.'s (1999) model

METHODOLOGY

As the discipline and practice of marketing has been undergoing a period of metamorphosis over the last four decades (Varadarajan, 1999). As theory is developed, knowledge enhances and spawns new questions requiring different explanations demanding even greater advances in knowledge; the role of marketing nowadays has become one of the key functional entities within the firm. For more than forty years, the marketing concept has been considered the cornerstone of marketing, which is highly strategic in nature (Hunt & Lambe, 2000).

Jaworski and Kohli (1993) also pointed out that the marketing concept was an important antecedent of business strategic success. The contributions of modern business strategy have come from a broad range of disciplines, and manufacturing is an indispensable part. Sun (2002) has generated the result that only when the manufacturing strategy and business strategy are fit, can manufacturing contribute to the improvement of business performance and business objectives can be achieved. Consequently, this leads to research assumes that the various patterns of marketing strategy, manufacturing strategy and strategic orientation must be in line with each other to optimize the organizational outcome. The following preposition is proposed:

P1: Fit among manufacturing strategy, marketing strategy, and strategic orientation has a significant and positive direct effect upon business performance, in terms of growth and profitability.

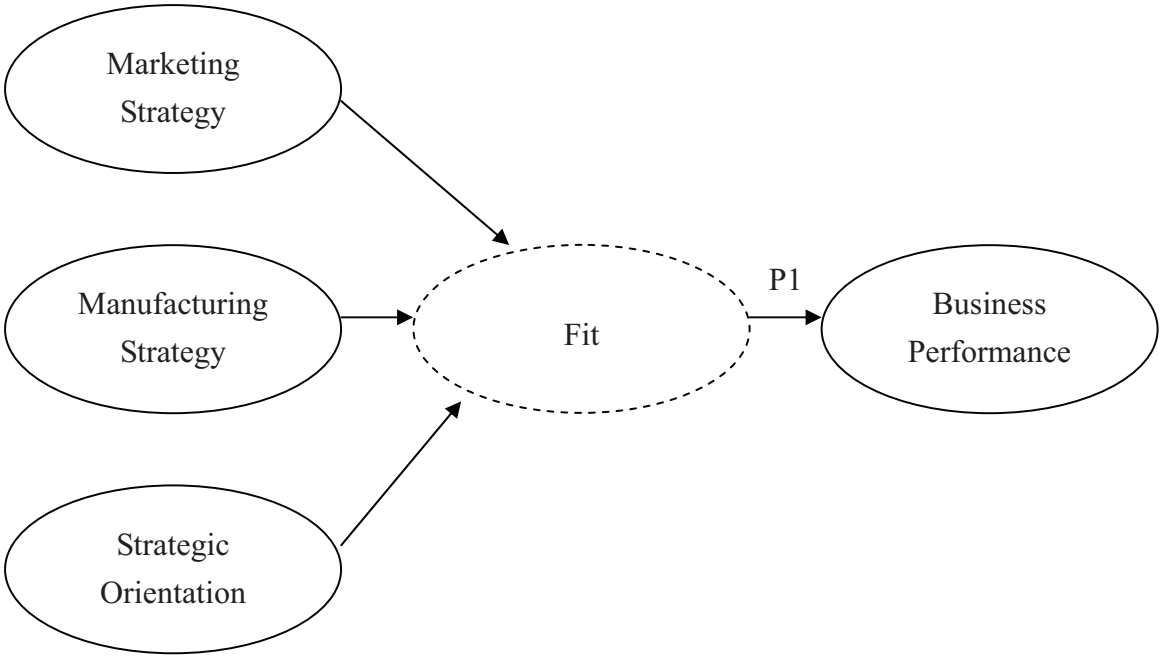

Figure 6. Strategic Alignment Model– Holistic perspective

Therefore, a fit model that articulates the combination of manufacturing strategy, marketing strategy, and strategic orientation is proposed.

CONCLUSION

Understanding the requirement of a successful fit among strategies is of interest to both practitioners and academics, yet the field of strategic alignment is still in its infancy. The

overall picture emerging from this study highlights the performance implication of fit among three aspects, namely Manufacturing strategy, Marketing strategy, and Strategic orientation, from a holistic perspective.

To our knowledge, this is the first study offering performance implication of fit among those three dimensions from a holistic perspective. Yet further empirical study is required to exemplify the correctness of this model and by conducting alternative perspective of fit with statistic analysis, it is possible to find a more proper fit that has more significant effect on performance implication.

ELEMENTS OF STRATEGIC MANAGEMENT OF TECHNOLOGY IN HIGH-TECH SME PRACTISE

***Kari Sahlman, Nokia Siemens Networks, Finland**
kari.sahlman@nsn.com
Harri Haapasalo, University of Oulu, Finland
harri.haapasalo@oulu.fi

ABSTRACT

Strategic management of technology is a necessity for wealth creation in society, but also in corporations as members of that society. Emergence of new economical order enabled by global competition and proliferation of information involves increasingly rapid changes in technologies which causes major competitive challenges to enterprises to manage their technological capabilities. Effective and efficient management of technology practises are crucial especially for small and medium-sized enterprises at all life-stages due to critical role of technology in the companies. In the absence of commonly agreed management of technology frameworks this study discovers perceptions and current state of management of technology in high-tech SMEs. Theoretical background of this study is based on a conceptual framework of strategic management of technology originating from large enterprise practices. The elements are classified with respect to structures, objectives and company internal and external impacts. Companies in this research unanimously consider management of technology important for competiveness and business success. Conceptually entire field is perceived to be complex and there is contingency and immaturity in practises deployment in SMEs. As a conclusion it is suggested that SMEs should consciously develop management of technology practises, and the presented structures elements of strategic management of technology framework would provide a frame of reference when constructing the practises in enterprises. It is also proposed that strategic management of technology should be evolved as a distinguishing functional and managerial domain that enhances the management paradigm of multifunctional strategic orientation in enterprises.

Keywords: Strategic management, management of technology, MoT, technology management framework, element, SME, enterprise, enterprise development.

INTRODUCTION

Enterprise competitiveness and value creation is in the long-term enabled by successful execution of company's strategy in which technology is a critical resource. Competitive environment is involving increasingly rapid changes in technological, social and economical circumstances. Effective and efficient technology management practises are especially important for small and medium-sized enterprises (SMEs) during all life-stages of an enterprise due to the critical role of technology in entrepreneurial activities and lack of possibilities to miss. Capability of strategic management of technology is an imperative for sustained competiveness and performance of an enterprise (e.g. 18, 26). Complexity of the subject and missing comprehensive frameworks give rise to managerial challenges for practitioners. Therefore a consistent framework with substantial insights on what are the elements of strategic management of technology is needed. Absence of commonly agreed theoretical frameworks leads into introduction of diverse empirical solutions (19), which do

not properly address environmental, economical and social aspects either (5). According to Drejer (9) common perceptions of technology and management of technology are not well suited for coping with the complexity, and SMEs have to face similar problems as large enterprises even with more limited resources (23). The practical problem for enterprises is to define what elements are needed for strategic management of technology in order to establish or improve the practises in a company. There is also an identifiable separation between technology management and business planning in the small high tech firms (3) which may lead into competitive disadvantage. For smaller companies it is somehow difficult to imagine the technological cycles and continuity of technologies.

The purpose of this research is to study perceptions of management of technology and current state and importance of the structures elements of strategic management of technology framework in small and medium-sized high-tech enterprises. The research problem is formulated as the following research questions:

RQ 1: *What is the perception of management of technology in SMEs?*
RQ 2: *What is the current state and importance of the structures elements of strategic management of technology in SMEs?*

In this paper first the context of management of technology and the strategic management of technology framework is presented. The framework for strategic management of technology has been developed based on conceptions of large enterprise representatives. The framework is based on literature, integrated management theory (4) and large enterprise practises, and it describes elements of strategic management of technology as classified to structures, objectives and impacts. This study is performed in order to increase theoretical and practical validity of the framework in different enterprise scope. It was expected that SMEs are strategically focused enterprises and concentrating on the most essential activities for the company's success, therefore findings on technology management activities among SMEs would reveal the most important ones. The empirical study was carried through in Small and Medium-sized Enterprises to study what is the importance and current state of the elements of strategic management of technology structures in SMEs, and what is the perception of management of technology in those companies.

CONTEXT AND CONCEPTUAL FRAMEWORK OF STRATEGIC MANAGEMENT OF TECHNOLOGY

Strategic management of technology in context of enterprise management

Strategic management of technology within a company contains aspects of explicitly linking business strategy with products and required technologies. Technologies develop and operational environment of an enterprise changes even at an accelerating speed due intensified competition. Thus efficient and effective management approach is needed for management of technology which is more complicated than traditional management of research and development due its dynamics and fundamental impacts on company's strategy, products, competitiveness and people's knowledge. Strategic management of technology in form of processes and practices shape capabilities of a company internally and with respect to its socio-economic environment, therefore it is practically intertwined with all management activities and operations of an enterprise. Views to enterprise management are presented in figure 1 to outline the context of strategic management of technology.

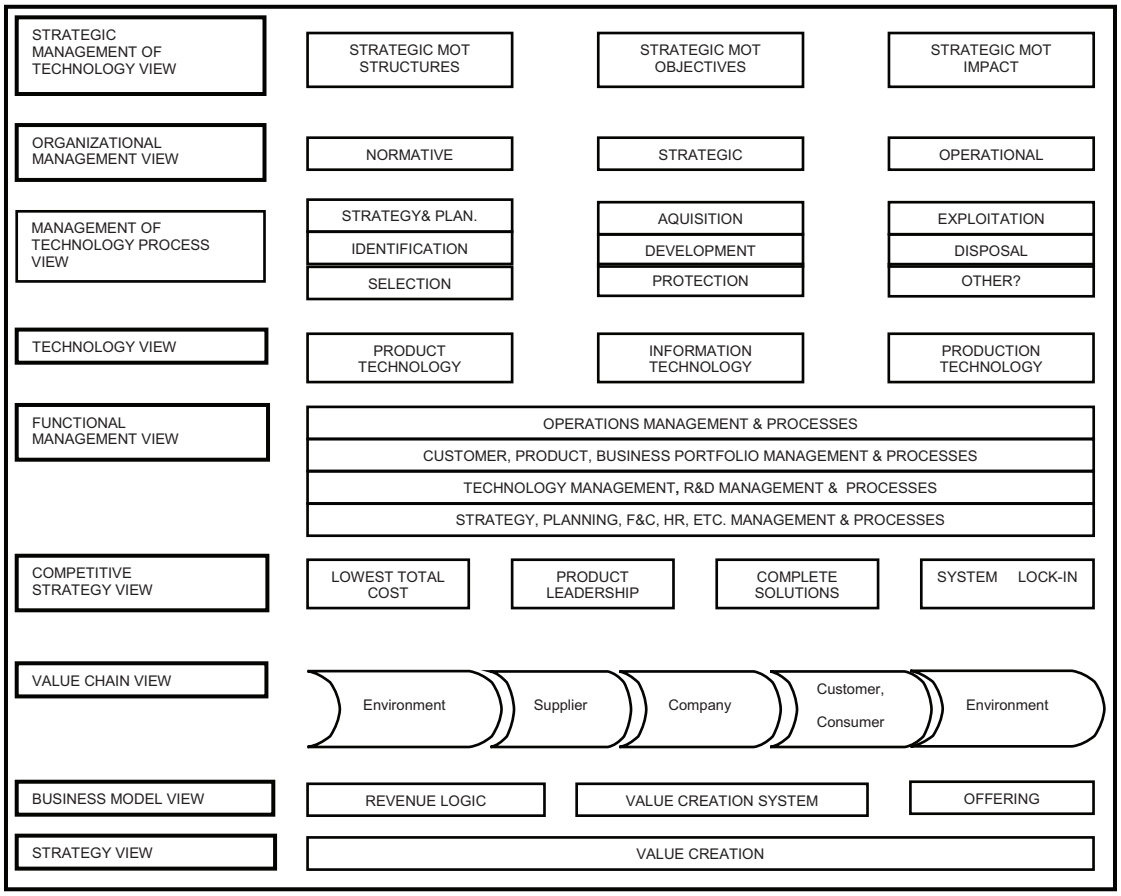

Figure 1: Views to enterprise management in context of strategic management of technology

As classically defined, strategic management concerns company's initiatives taken by management to create, enhance and sustain its capabilities regarding to its environment and to reach company's objectives (1). From strategic management perspective the mission of an enterprise is to create value for owners, personnel, customers, suppliers and society (e.g. 13). To create value a company has to determine and structure its position in the value chain through defined strategies and operationalized actions that execute the strategy. Objects to be created and managed to accomplish company's mission and to place it in a value system are defined by a business model view. It consists of offering, value creation system and revenue logic (25). Offering defines what physical, information or service composition is pursued. Value system describes the value creation structures and networks that are needed to capture the value. It includes relationships to customers, suppliers, collaborators and competitors. Pre-requisite to value capture, cost structures and competitive strategies of the company is set by the revenue logic. Value system can be viewed next as a value chain and network of actors (e.g. 12, 16), including environment as a source for raw-materials and as an object coming in for disposal and waste management of the products. Different types of technologies are involved in enterprise value chain activities and thus need to be managed for fulfilling customer needs (20).

Strategic management of technology covers technology aspects of company's offering, value creation system and revenue model, which are determined by which business company is in and by what competitive strategy a company is driving for. Lowest cost, product leadership,

total solutions offering and system lock-in strategies set different requirements for the technologies and capabilities a company should develop and possess (13). Offensive, defensive, imitative, dependent or opportunist technology strategies require different policies for technological investments and mix of technology portfolio (8).

For creation of value a company can be structured according to perspectives of customer, financial, internal and learning processes (13) which are intended to be executed as cross-functional and cross-organizational processes. Depending on the organizational structure of a company, from view point of functional management enterprise may have operations management, customer, product and business portfolio management, R&D management, strategy management, human resources, financial, accounting and other support types of management functions and corresponding organizations. Typically technology management is not organized as its own function or organization but it is often embodied in R&D function. Strategic management of technology imposes a major paradigm change on organizing it as a distinguishing function in an enterprise.

Technology can be categorized to product technology, manufacturing technology and information technology (24) and it is embodied in people or systems as explicit artefacts or tacit knowledge (6, 14). Technology management can be seen as activities being involved from research to development of technology for products throughout to commercialisation and abolishment of the products. Activities of identification, selection, acquisition, protection and exploitation (11) and technology strategy creation, technology development and disposal (22) cover management of technology activities. Integrated management theory model (4) defines normative, strategic and operational areas of an enterprise management. They all have structural, objectives oriented and behavioural elements. And finally, management is planning, organizing, leading and controlling activities completed through people (21). Within this context, as presented in figure 1, elements of strategic management of technology structures, objectives and impacts form a framework for strategic management of technology.

In this research definition of strategic management of technology is derived from definitions of technology, strategy and management and it is defined as:

> *"Strategic management of technology is management of technological activities interacting with company's technology infrastructure and socio-economic environment to contribute to formulation and execution of company's strategy."*

In the longer form where the terms management, technology infrastructure and strategy have been opened, strategic management of technology is defined as:

> *"Strategic management of technology is planning, organising, leading and controlling of technological activities interacting with company's skills to apply knowledge, structures, resources and socio-economic environment to contribute to formulation and execution of company's basic, long-term goals and objectives, and adoption of courses of action and the allocation of resources necessary for those goals."*

Strategic management of technology framework

Strategic management of technology framework is presented in figure 2. It defines elements of technology infrastructure that consists of internal and external structures, resources and capabilities, objectives and internal and external impacts within the company and towards its environment. The framework is building on studies of Luggen and Tschirky (17), and the framework is applied and amended by Sahlman and Haapasalo (22) to comprise sub-

structures and to consider company internal objectives, structures and impacts to external industry environment. In the following is presented key principles of the framework.

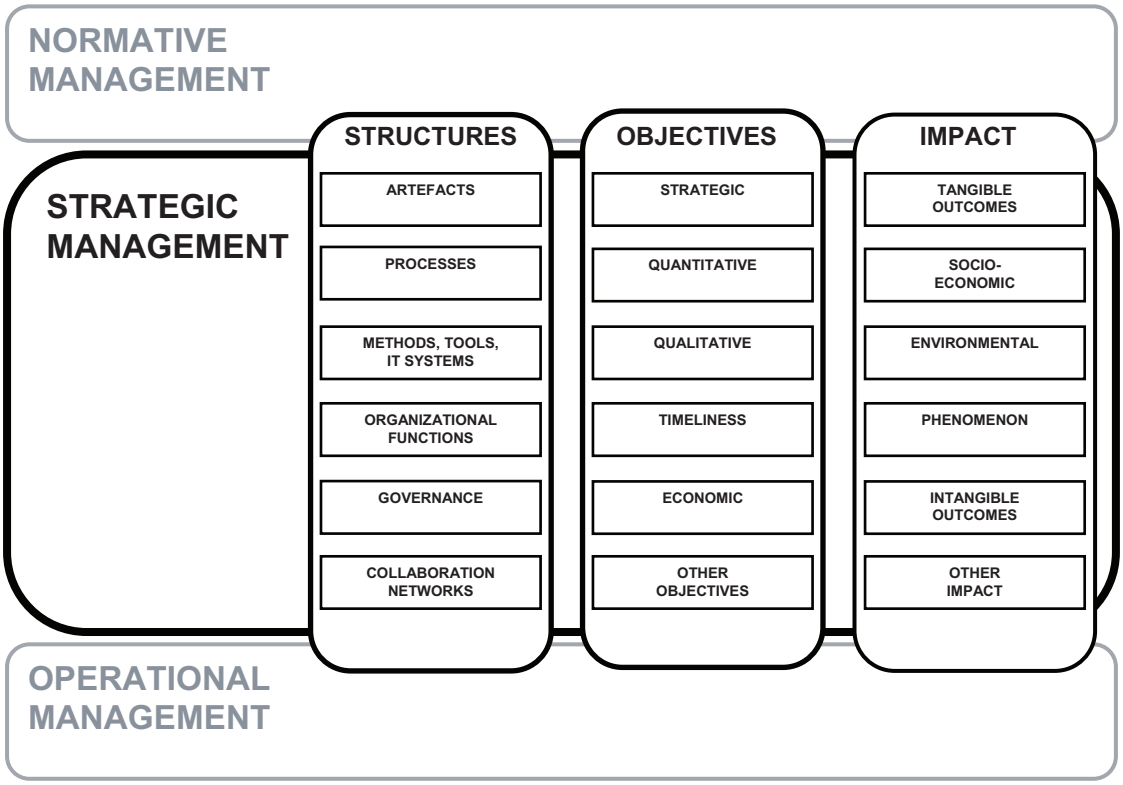

Figure 2: Strategic management of technology framework

The framework is a conceptual model that describes hierarchical structure of the elements in an open system. Each column represents categories that constitute elements of strategic management of technology. Major categories are structures, objectives and impacts. They can be classified into sub-categories that contain the elements at the next level of detail, and theoretically structures, objectives and outcomes are the classified key viewpoints to technology management. The conceptual model describes what the elements of strategic management of technology are, but the framework does not describe how the elements function. Actual implementation of management of technology practises depend on the company mission, business, size, maturity and environment it operates in.

Operational activities using processes, practises and methods produce documents, intangible and concrete outcomes. These activities form and shape the company's technology infrastructure or are manifested as outcomes that are delivered externally. Objectives of strategic management of technology are classified to strategic, qualitative, quantitative, economical and timeliness. Objectives need to conform to company's strategic objectives and to contribute on definition, execution and shaping of the strategy. Impacts of strategic management of technology can be divided into tangible and intangible outcomes, which consequently through operational activities have impact to company internal capabilities and to its external socio-economic environment. In the following the structures elements part of the framework is described in more details and the proposed classification is presented in table 1. Classification is not asserted to be exhaustive.

In the framework the major categorization of technology management processes contains processes of technology strategy creation, planning, identification, selection, acquisition, protection, development, exploitation and disposal of technology. Each of the processes typically can have several sub-process or practises e.g. identification of technologies consists of practises for technology scanning, scouting, monitoring and forecasting. Artefacts, as classified in the framework, are the typical and major outcomes of the operative technology management activities that are using the processes. All the artifacts need to be included in the technology infrastructure of the company and be strategically managed. Creation and utilization of the artefacts requires appropriate methods, tools and IT systems for data and knowledge management. Methods, especially for collection and analysis of information, are needed for operational activities and planning methods are needed for managerial tasks. Engineering methods and tools are required for research, selection, creation and development of technologies. Data and knowledge management systems form the IT backbone of the technology infrastructure and are used for storing and co-ordination of the planning and exploitation of technological assets of the company.

Organizational structure for technology management functions depend on the business, size, traditions and principal decisions about the degree of centralization and de-centralization of the business units and other functions in an organization. Technology management is seldom recognized as a discipline of its own, whereas functions like research, product development, product management and business management and human resources management are organized as separate entities. Processes of strategic management of technology require corresponding management organization and personnel for planning and operative execution of strategic management of technology objectives. Company needs also to manage related operational activities like research, technology development, intellectual property and collaboration management. Governance structure, principle models and criteria are for decision making to communicate and co-ordinate execution of the technology strategy and for prioritization of strategic actions.

Different types of alliances, coalitions and agreements form basic structures for strategic management of technology collaboration and networks which constitute of institutes, sub-contractors, suppliers, industry analysts, regulatory bodies, customers and even competitors. As a summary the suggested categorization for strategic structures is: processes, artefacts, methods and tools, organizational management functions, governance and collaboration networks.

Table 1: Structures elements of strategic management of technology framework

Structures of Strategic Management of Technology	
Artefacts	**Processes (continued)**
Technology strategy	Deployment
Technology forecasts, trajectories	Technology roadmapping
Technology map	Technology portfolio planning
Technology roadmap	Technology assets accounting
Architectures	Lifecycle planning
Architecture roadmaps	Technology insertion, refresh
Research portfolio	Technology retirement
Technology portfolio	Technology licencing
Technology portfolio development plan	Disposal
Technology portfolio deployment plan	End of life/disposal planning
Technology portfolio repository	**Tools, methods, IT systems**
Internal/external technical guidelines	Data management methods&tools
Internal/external technical standards	Knowledge manag. methods&tools
Supplier&collaborator base	Analysis&planning methods & tools
Processes	Engineering methods & tools
Technology strategy & planning	**Governance**
Technology outlook analysis	Decision making structure
Technology SWOT analysis	Decision making points
Technology planning	Decision making subjects
Identification	Decision making metrics
Technology scanning, scouting	Decision making criteria
Technology monitoring	Tech. guidelines governance
Technology intelligence	**Organizational management functions**
Technology forecasting	Technology management
Technology research	Tech. strategy management
Selection	Tech. planning management
Technology evaluation	Tech. portfolio management
Technology benchmarking	Tech. architecture management
Technology feasibility analysis	Tech. assets management
Tech. cost capability analysis	Tech. quideline/stds management
Technology performance analysis	Research management
Supplier evaluation	Product. dev. management
Supplier cost capability analysis	Tech. dev. management
Competitor analysis	IPR management
Acquisition	Standardization management
Due diligence,procurement	Supplier base management
Technology in-licencing	Collaboration management
Early supplier engagement	**Collaboration networks**
Technology creation	Research collaborators, institutes
Development	Technology collaborators
Technology improvement	Technology sub-contractors
Technology re-architecting	Standardization collaborators
Technology platform creation	Industry alliances
Protection	Strategic suppliers
Patenting, trademarks, copyrights	Competitors
License management	Customers
Encryption	Regulatory authorities
Standardization	Industry analysts

RESEARCH METHOD

Scope of the empirical research

Due to practical reasons, but compliant to requirements of qualitative research, the geographical scope is limited to enterprises having premises and personnel in Oulu region to ensure availability of interviewees and efficient use of research resources (see 27). Type of companies was not specifically limited to any industry. Most of the companies have global market, customers, competition and operations. Companies are designing, manufacturing and providing electronics, mechanical, medical instruments and software products, solutions and services. Decisive factor to involve a company in the research was interest and availability of company representatives for the interviews (see 27). Around 30 companies were contacted for asking their interest, and 22 interviews were carried through in companies in Oulu region in Finland.

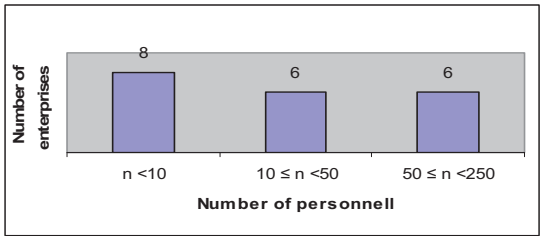
The informants for interviews were persons responsible on functions that are dealing with topics of technology management i.e. business, product, technology and R&D management, typically company founders and senior managers. The job titles of the 25 interviewed persons included CEO, COO, CTO, Site Manager, Engineering Manager, Director, Factory Director, Country Manager, Business Development Manager, Founder, Partner, SW Architect and Senior Specialist. Average working experience of the interviewees was over 15 years.

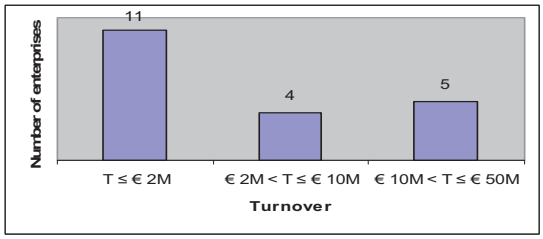
According to definition of commission of European Union in year 2005 (10), SMEs are classified as presented in the table 2. Based on the number of personnel and turnover of the interviewed companies, there are 6 medium-sized enterprises and 14 small enterprises participating in this research. By definition 8 of the companies are micro companies from personnel point of view and 11 according to turnover. Number of companies participating in this research as classified according to the number of personnel and turnover is presented in table 3. Eleven of the companies are less than 6 years old.

Table 2: Classification of Micro-, Small- and Medium-sized Enterprises in EU.

Classification	Number of personnel	AND	Turnover	OR	Balance sheet
Medium	< 250		≤ € 50M		≤ € 43M
Small	< 50		≤ € 10M		≤ € 10M
Micro	< 10		≤ € 2M		≤ € 2M

Table 3: Number of companies in the research as classified according to number of personnel and turnover.





Implementation of the research and evolvement of the theoretical framework

Research method for developing the framework is abductive in which the initial framework, derived from literature and practitioner workshop findings, describes the proposition which is expanded on and validated through results of subsequent research. The logic how empirical data is connected to the proposition is based on comparing and amending the developed initial framework with the analysis of the results of quantitative and qualitative research in SMEs. Thus information is gathered from multiple sources and inference is sought to find best possible description of the framework. It is expected that results support contents of the initial theoretical framework and increase its validity and enables generalization of the initial proposition.

The empirical research was conducted as interviews in 22 SME companies in Oulu region during November 2008. Two of the interview results were omitted from this analysis due number of personnel and turnover exceeding the definition of SME. The overview of the proceeding of the research and evolvement of the theoretical framework is presented in the figure 3. The initial framework was developed during year 2007 and early 2008, thus that research is not in the scope of this paper.

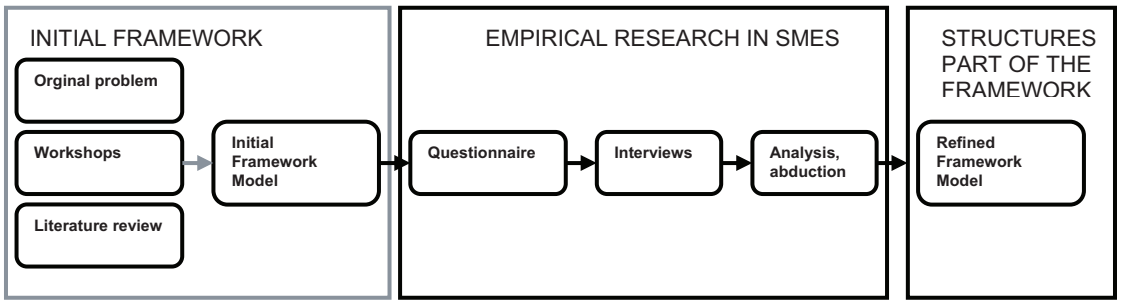


Figure 3: Proceeding of the research

The structural questionnaire consists of open qualitative questions and closed questions to be quantitatively evaluated by the interviewees during the interview. A pilot interview relieved that the number of questions were too extensive for conducting an interview within limited time. Thus in the final questionnaire the number of questions was reduced to 12 qualitative and 18 quantitative questions. Quantitative question evaluation scale was 1 to 5 to evaluate importance (not important, somewhat important, quite important, very important or extremely important) and current state (not practised, occasionally practised, developing practise, practised, well established practise) of the issue. Also the answering alternative “not applicable” was available. Open qualitative questions were asked first. The purpose of the questions was to elicit perceptions of the interviewees to management of technology in free form to avoid expression of preconception by researchers to the subject. Closed quantitative questions reflect to the elements of strategic management of technology framework, and they provide for interviewees a frame of reference to let the interviewees identify an element of management of technology, regardless whether it is familiar to the interviewee in advance or not. The interviews were recorded and lettered in the interview language that was Finnish. Lettered interviews were summarized and grouped according to interpreted similarities in answers to the quantitative questions.

PERCEPTION AND STATE OF THE PRACTISE OF MOT IN SMES

Perceptions of the interviewees on technology management are presented as condensed standpoints based on the qualitative questions of the interviews. All interviewees have their own viewpoint to Management of Technology (MoT) when asked using open questions. Many aspects are covered individually, but none of the respondents consider all of them. Quotations in the following are adapted from the interviews.

Definition and purpose of management of technology

"Management of technology is about knowing capabilities that technology provides for development of products, and about deploying technology for business."

Definition of Management of Technology is felt quite difficult as a comprehensive concept. It is understood to be an important base for products and product creation, and it is affected by the development stage of company and business environment in which the company operates. Starting point and purpose for MoT is fulfilling customer needs that lead into business opportunity and to identification, selection, acquisition or development of technology to be used in products. Essential is that right technologies are available for business goals, and that technology provides competitive advantage.

Management of technology is mostly seen as an implicit activity intertwining with company's business and product management and product development. Basis for MoT is assumed by the interviewees to be derived from company strategy and customer needs. Typically MoT is practised unconsciously and it is not systematically exercised. Thus knowledge of individuals on technology is utilized in defining company's business and product strategy especially at early stages of company development. Technology management is connected to follow-up of trends and to evaluation and selection of technology and platforms. Technology has to be positioned with regards to business and market development and technologies that competitors are using. Accordingly new possibilities need to be researched for creation of new products and improving competitiveness and performance of the existing ones. Scope of MoT is perceived to be people, knowledge, competence, acquiring best tools and methods, software, IT systems, architecture and products.

Key practices on management of technology

"You have to follow your time. People have built-in creativity and curiosity which need to be fostered through openness and trust in order to create innovations."

Key practises on management of technology are mentioned to be focusing on follow-up of trends and collecting information on new and available technologies. Most important sources for information are Internet, journals, news, fairs and people networks. Responsibility areas for technology follow-up are often defined for individuals, and product development people work together with product management and marketing to identify gaps and needs for technologies. Knowledge and competence of personnel is recognized to be important and being developed and maintained. Highlighted is also importance of fostering of innovative culture and open atmosphere of the company as means to manage technological and innovative capability of the company.

Feasibility studies and evaluations are made on identified promising technologies and trialled through prototyping, testing and piloting of products. Benchmarking and assessments are made to study performance and weaknesses of the products to find out improvement needs. Existing product platforms are utilized for development and verification of new products and

applications. Development of technology is mentioned as a systematic product development type of practise in a few companies. Platform decisions are also seen elementary for management of technology. Some of the companies make own research or are involved in research projects with suppliers and research institutes and universities. Also patent publications are followed to some extent.

The practises result in reports on competitor analysis, technology benchmarking and reviews, evaluation and testing. Also concept proposals and comprehensive technical and commercial study reports are mentioned by some of the interviewees. Other outcomes or documents mentioned being key to management of technology are company strategy, business and product plans, customer feature requests, product roadmaps, technology roadmaps, technology forecasts, lists of technology portfolio and links to information references in Internet. Many of the companies mention specifically that there are no systematic processes or formal practices defined for management of technology. Existing formal processes are typically identified to be related to quality management and product development and production. Road mapping is mentioned in a few companies. Some of the companies state that used technologies depend on diffusion of technologies used by end-users or industry standards and agreed policies state what technologies to use. Technology and platform decisions are mentioned to be documented as part of applicable management meeting minutes.

Decision making and governance of MoT

"Technology decisions are made as a part of leadership team work."

Decisions on technology are usually made on basic principles, guidelines and policies that are derived from business and product strategy. Decision making is influencing and related to all activities of the company, especially to products and applications development fulfilling customer needs. Planning of the technology management activities is happening as part of the business and product planning and budgeting, which may take place annually or when new opportunities or customer needs have been identified. In some cases company's vision, business strategy or explicit technology strategy is mentioned to set goals for technology management activities. New initiatives are handled and steered by leadership teams or in meetings where representatives of different functions are participating. Make, buy and collaboration decisions are made, as well decisions on what technologies are used for product creation. Decisions are concerned with product platforms, technology blocks, modules and components, interfaces, tools, methods, investments, costs, roadmaps and timing.

The bodies making decisions are often CEO or board of the company for major decisions. Various types of decision making bodies like leadership teams, product development management teams, steering teams and product council are mentioned. In some cases personnel is taking autonomous decisions on what technologies to use, and in some companies customers and even suppliers influence and steer technology selections. Decisions are made regularly when the above mentioned decision making bodies have their meetings i.e. annually, quarterly, bi-monthly, monthly, weekly or flexibly when necessary especially is small companies.

Objectives and impacts of MoT to competitiveness

"Customers expect usability, features and quality on our products. Objective is to make best commercial solutions based on available technologies."

Cleary technology have to satisfy customer and product requirements in terms of features, quality, usability, performance, reliability, security and energy efficiency, to name a few. Importance of complete solutions satisfying customer needs is also highlighted. Products are preferred to be based on open standards and have to comply with regulatory requirements and de facto conventions of the business area. A few companies seek for product differentiation, technology leadership or market leadership. Important is time to market and timing of product releases for example with respect to market seasons. Fundamentally availability of good enough technology is sufficient for most of the companies since differentiation comes through application of technologies to fulfil customer needs and through knowledge and expertise on customer's problems and processes.

Product cost and productivity enabled by right technology choices, tools and methods is emphasized. Also ability for flexible and adaptive production is mentioned, as well capability to enhance functionality and expansion of the products over the life-time. Right technology selections are seen as the most important to company's competitive advantages. Technology has to satisfy customer needs and to provide excellent productivity as effectiveness and efficiency in production and product development in terms of used technology, methods, tools and speed and flexibility to react on customer requirements.

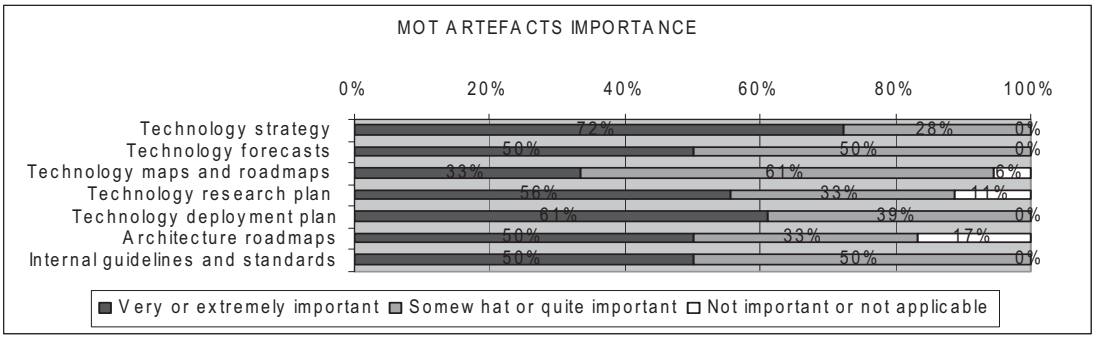
In order to make the right technology selections forecasting, assessment, evaluation and proof-of-concept methods are seen to have big impact on competitiveness. Also ability to identify new opportunities and areas for applications is noted. Improving capability of decision making based on formal data and with consideration of product life-cycle aspects is brought up. Companies also rely extensively on people's knowledge on technologies and on their inherent innovativeness.

Importance and current state of management of technology practises in SMEs

In the following in tables 4 to 7 is presented the frequencies of 18 company evaluations on importance and current state of management of technology artefacts and activities. Also a potential explanation to response patterns found form the results is given. Only frequency analysis is used due to relatively low number of companies evaluating the quantitative questions.

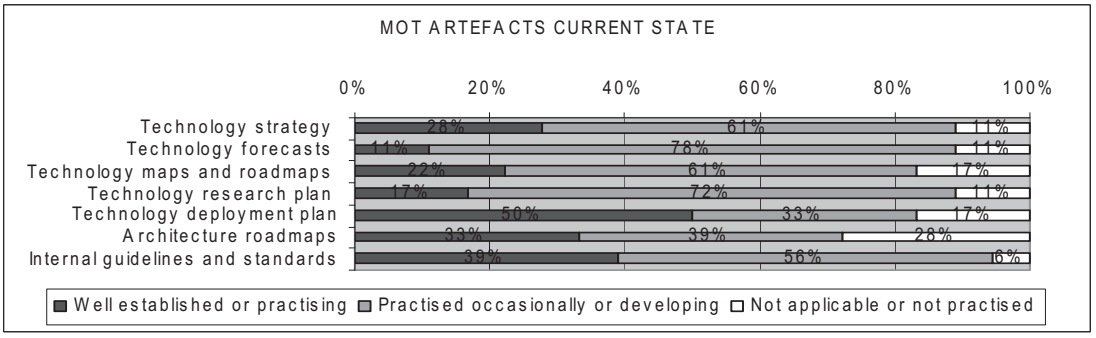
According to the evaluation results in table 4 all artefacts are seen at least somewhat important by over 80% of the companies. Technology strategy is seen as the most important artefact, which appears quite regular opinion for any company. Similarly technology deployment plan and internal guidelines seem to be normative for all companies. Importance of technology forecasts gets high evaluation, obviously due to the uncertainty of the business and technology environment. Technology maps and roadmaps are seen by 84% of interviewees important, but only one third see it very or extremely important. This seems to be related to the size and life-stage of the companies i.e. how many and for how long time products have been in the market. Typically larger and older companies see road mapping more important. Same applies for architecture roadmaps but three companies do not see it important or applicable at all. Two companies do not see research planning important or applicable for them because they are providing services or are in embryonic phase still. Technology research plan was seen important by all except two start-up phase companies.

Table 4: Importance of MoT artefacts



Although technology strategy is seen as the most important artefact, less than one third of the companies have technology strategy properly practised as presented in table 5. Only one company says it is well established, two companies say that they do not have technology strategy, the rest as a majority is developing the practise or have strategy occasionally existing. Best practised is technology deployment plan although only 50% evaluate that they do have a plan practised or well established. In SMEs internal guidelines and standards seem to be easy to agree as they are practised by 95% of the companies. Architecture roadmaps have most distribution in responses, about 1/3 has it practised, 1/3 is not practising and 1/3 is in between these ends. Only two (11%) of the companies say that they have technology forecasts properly practised which may indicate that forecasting is the most difficult activity to perform amongst day to day business practises. Technology maps and roadmaps are practised by one fifth of the companies, and three companies are not practising road mapping at all. This indicates that product and technology planning span is relatively short in SMEs. Technology research planning is practised by less than 20% of the companies which is also indicating short term product and business priorities in R&D activities.

Table 5: Current state of MoT artefacts



Distribution of the evaluated importance of activities is presented in table 6 and current state of the activities is presented in table 7. Highest ranking in evaluation of importance and current state of the activities are technology evaluation and linking technology plans with product plans, which is natural priority for a high-tech company. Companies also must concentrate on their own core, which is indicated by importance and current state of collaboration and supplier engagement, and can be seen as consequent importance of supplier and technology cost capability analysis. Another important activity is decision making on what technologies to use. One third of the companies evaluate that they are making systematic decisions on technologies and 90% is practising it at least occasionally.

Table 6: Importance of MoT activities

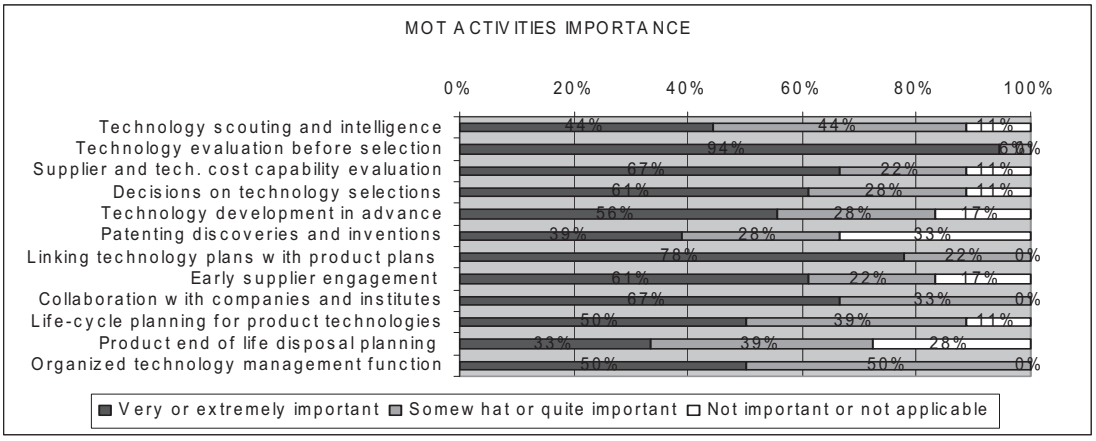


Table 7: Current state of MoT activities

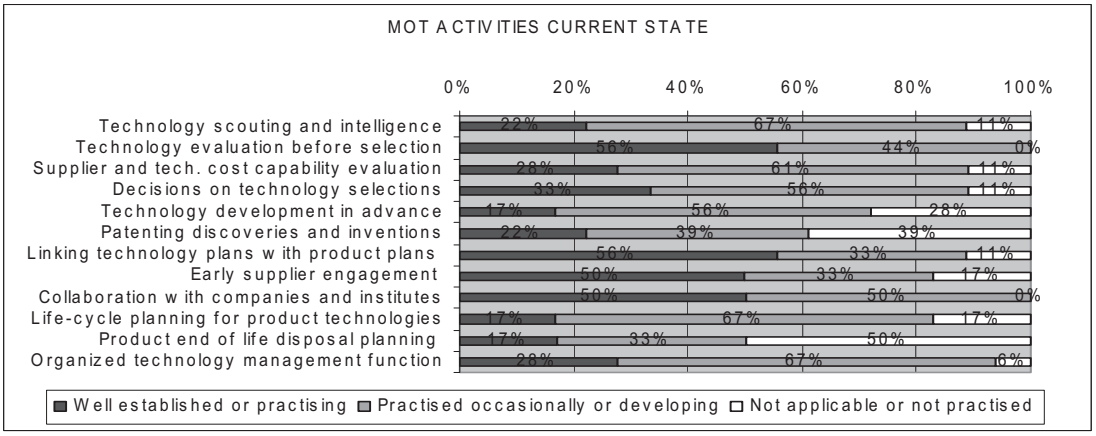

Technology development in advance is seen quite or extremely important by majority of the companies, whereas less than half see technology intelligence that much important, which is reflected by low current state of these front-end activities. High-tech SMEs typically have focus on getting into market therefore product technology life-cycle planning and end of life disposal are seen very or extremely important by 50% and 33% of the companies, but practised only by 17% of the companies. One third of the companies do not see patenting applicable or important at all for them. Another 33% do see only some importance on patenting for them, whereas one third sees patenting extremely important. Based on interviews most SME companies do not have resources on expensive and time consuming patenting. Almost 40% of the companies are not doing patenting. Some do not see it necessary due to the business they are in. Although current state of practises is quite diverse all companies see organized technology management to have at least some importance for them, and all except one is practising it at least occasionally.

MANAGERIAL IMPLICATIONS

Management of technology is relative young discipline compared to strategic management, marketing and product management. Strategic management of technology has been researched by scholars increasingly some 30 years. Companies have converged since 1960's from single-function orientation to multifunctional strategic orientation due to continuing and

accelerating turbulence and complexity in the marketplace (2). In such business environment strategic management of technology is crucial for large and small companies to manage technology evolution and deployment as the essence of the company's capabilities and offering. Still management of technology is not clearly distinguishing as a function amongst other management disciplines.

The purpose of this study was to find out perceptions of management of technology and current state of practises in SMEs. Results and findings of the study confirmed that the field of MoT is complicated and somewhat confused among practitioners. From the responses it becomes clear that the companies have to prioritize activities which are securing short-term business goals, while hoping to have made right technology choices, and making the best out of the resources and available technologies. This is valid especially in the early stages in enterprise development when getting products to the market is the most critical activity.

Role of technology is seen as a key for effective product development and to knowledge on applying technology on customer's problems and processes. According to interviewees technologies have to offer right quality, performance and cost level of the developed products with right features over the product life-time. This imposes challenges to companies in terms of resource utilization for technology follow-up, evaluation, testing and technology development prior to product development. Right technology choices and availability of good enough technology is high-lighted, especially in the early stages in enterprise development when getting products to the market is the most critical activity.

Systematic decision making as an end to the means that MoT practises provide to fulfil customer needs and to reach enterprise business goals is crucial. Technology selections, tools and methods have major impact on company's internal processes and thus to productivity. The companies understand the role of platform selections and importance of technology selections to achieve business objectives. Used technologies are linked to product plans and before entry into the market, major challenge is to assess cost capability, maintenance and life-time costs of the selected technology for the company. Product disposal, end-of-life aspects and technology and product life-cycle planning are seen also challenging, although not being the first priority. Importance of managing life-cycles of products and technology is emphasized due to the need to identify technology risks early and due to the long-term impact on investments and on competitiveness that technology choices have.

Product and technology life-cycle management, technology scouting and road mapping are areas which are diversely practised. This may be due to the stage and sizes of the respondent companies i.e. young micro-companies do not pay much attention to anything else than making the fundamental business idea to succeed in the first place. In addition role of creating patents have diverse significance to the interviewed companies. Patenting is seen to be costly, time and resources consuming activity which has also been confirmed in research by Kitching and Blackburn (15).

Evaluation response frequencies to current state and importance of the practises indicate that MoT is seen important as a concept but in reality there is little evidence that practises are systematic or properly integrated into day to day operations. Berry and Taggart (3) state that formality increases along company's growth and development. It seems that medium-sized companies are more aware about the need for systematic MoT practises which may indicate

that they have to consider company's transformation from technology orientation to strategic or market orientation.

Regarding to the presented strategic management of technology framework the structures of the framework are in general recognized by the interviewees as important, but they are being practised variably in SMEs. From MoT generic processes point of view technology selection, development and protection are the most familiar activities, although also diversely practised. Technology management is governed and organized implicitly as part of other business management and product development management practises. Best practised areas are systematic technology evaluation before selection and objective of clearly defined product or services cost position. Also supplier engagement and collaboration networks are well identified and commonly practised i.e. companies have defined their core competence and technology, thus companies tend to have policies which parts of the products or activities are sourced or collaborated. Largest gaps are in technology strategy creation, forecasting, systematic decision making, life-cycle management and advance development. These all indicate lack of time and material resources to plan, research and develop technologies to be deployed in products.

Enterprises are not alike, but importance of strategic management of technology is uniformly similar for development of technological capabilities and sustained competitiveness in large and small companies. They all need to surmount within the same changing environment. Enterprises should look management of technology as a distinguishly organized and managed function that has interrelations to other functions and management disciplines in organization. A view to functional management of an enterprise is presented in figure 4.

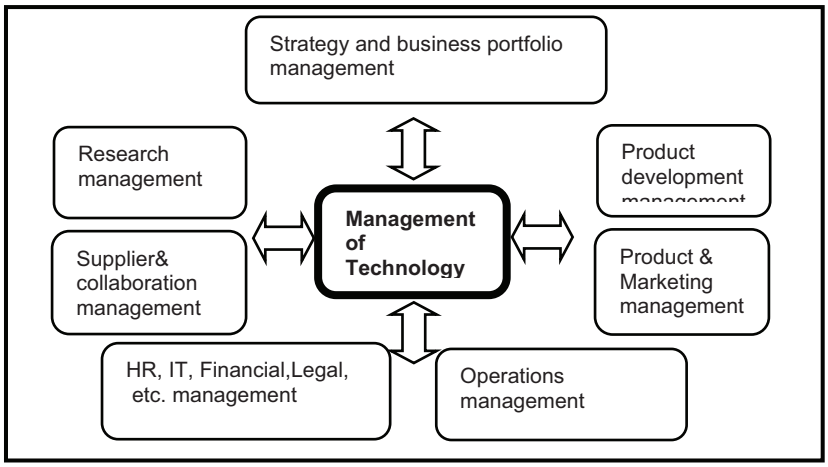

Figure 4: Functional management view to technology management in enterprise.

Strategic management of technology have implications to SMEs also especially on how to efficiently and effectively organize MoT activities i.e. what to do in practise and how, how systematic activities are, and how much resources are concretely allocated to the activities. SMEs do not have or need similar management practises or resources as large organizations (7, 23) and therefore MoT practises cannot be seen as downscaled from large enterprises. Another question is what management of technology activities to perform explicitly, what is done implicitly, and how to integrate those with company's decision making and other processes. All of the MoT practises involve specific skills and they need to be planned, organized, executed and monitored appropriately.

CONCLUSION

As a concise answer to the RQ1 and RQ2 it can be summarized that in the interviewed SMEs perception of the purpose and importance of management of technology is like-minded. Nevertheless every company have their specific problem areas due to the business and company life-stage, and they are struggling to formulate a comprehensive view and scope to management of technology. Currently management of technology is diversely practised as embedded activity integrated into company's business and product management and product development.

Characteristic for the companies participating in this study is that management of technology is contained in entrepreneurship as knowledge and experience of key individuals of the company, and that MoT is mostly practised implicitly. Starting point is to understand and predict customer needs and satisfying those as effectively and efficiently as possible within enterprise resources. Need for explicit technology strategy and systematic MoT practises become more evident as company grows, and consequently technology and management of technology becomes critical for the enterprise success. Aligned business and technology strategies are needed to enable communication and co-ordination of the execution of company's technology strategy through systematic technology management activities over the product life-cycle.

This research concentrated to find out perceptions on what is management of technology and importance and current state on what is practised. This study does not reveal on how practises are implemented and what is their maturity, effectiveness and efficiency, which all would be interesting for further study. Another area to study is methodologies and best practises across companies, evaluation of maturity of the practises and the impact of MoT to company's success and competitiveness. A problem is also how to organize and integrate MoT with company's other processes and management disciplines. All these topics would call for further research both in large and small enterprises.

Implementing management of technology knowingly for business benefits requires competence and rational effort. Intuitively companies may take the right steps, anyhow intensifying competition and pace of technological changes call for conscious improvement on management of technology practises in SMEs. As a whole there is still a lot of contingency in concepts and practises of strategic management of technology. Therefore consistent framework with clear definitions on elements of strategic management of technology is needed with insights and discussion of best practises to implement MoT in enterprises for sustained competitiveness.

Extend and need for systematic MoT practises change over time depending on the life stage and size of the company. As company matures and grows, management of technology practises can be assumed to develop accordingly through stages of initial, contingent, developed, advanced and established. In established stage practises are part of the organizational culture, and the scope and objectives of strategic management of technology is comprehensively understood. The proposed framework presented in this paper provides premise for theory development, and it is suggested to be applicable as a frame of reference for designing MoT practises in enterprises. As conclusion it is also suggested that strategic management of technology should be perceived and evolved in enterprises as a distinguishing

function and management discipline enhancing management paradigm of multifunctional strategic orientation.

ABSTRACT

Porter's five forces model has been one of the most influential frameworks for strategic management. In contrast to its importance as a centerpiece of textbooks, however, it has attracted less attention from both academic researchers and practicing managers. This is due to its difficulty in operationalization. The vital requisites for operationalizing the five forces model are to deal with it as a complex system composed of interrelated forces and their sub-forces, and to prioritize them with consideration of their interdependency. This study proposes an analytic network process (ANP) approach to fulfill the requisites. The ANP, which is a generalization of the analytic hierarchy process (AHP), produces priorities of elements in a complex network model with consideration of interdependency among elements. The five forces model is transformed into a network model of the ANP. The ANP procedure is then carried out to obtain the priority weights of the forces. Combining the derived weights and ratings on the forces produces the state-of-industry-competition index (SICI) values that represent the overall competitive condition of a given industry. The proposed approach is expected to expand the five forces model into a workable system of analysis by improving its analytical power.

Keywords: Five forces model; Analytic network process; Competitive analysis; Strategic management.

INTRODUCTION

Porter (1980)'s five forces model has been one of the most influential frameworks for strategic management (Hax and Wilde II, 2001). It has been considered a standard tool for analyzing industry attractiveness, building upon the assumption that the state of competition in an industry is determined by the five competitive forces. In contrast to its importance as a centerpiece of textbooks on business strategy and strategic management, however, the five forces model has attracted less attention from both academic researchers and practicing managers (Grundy, 2006). The most plausible reason is due to its difficulty in operationalization; that is, its analytical power is limited in that the overall competitive condition as well as the degree of each force cannot be quantified. The vital requisites for operationalizing the five forces model are to deal with it as a complex system composed of interrelated forces and their sub-forces, and to prioritize them with consideration of their

interdependency.
The tenet of this study is the requisites can be achieved through the analytic network process (ANP). The ANP proposed by Saaty (1996) is a generalization of the analytic hierarchy process (AHP) which is one of the most widely used multiple criteria decision making method (MCDM). It produces priorities or relative importance of elements in a complex network model with consideration of interdependency among elements. Although the ANP was originally developed for selection and prioritization of alternatives as a MCDM method, it has widely been employed and proved to be effective for quantification of existing frameworks by prioritizing elements that are interrelated with each other such as balanced scorecard (BSC) (Leung et al., 2006), strategic management concept (SMC) (Asan and Soyer, 2008), and SWOT analysis (Yuksel and Dagdeviren, 2007). This study also proposes an ANP approach to operationalization of the five forces model.

The remainder of this paper is organized as follows. Section 2 briefly outlines the underlying methodology of this study, the ANP. The proposed approach is explained in Section 3. The paper ends with conclusions in Section 4.

ANALYTIC NETWORK PROCESS

The ANP is a generalization of the AHP (Saaty, 1996). The AHP, also developed by Saaty (1980), is one of the most widely used MCDM methods. The AHP decomposes a problem into several levels making up a hierarchy in which each decision element is considered to be independent. The ANP extends the AHP to problems with dependence and feedback. The ANP allows for more complex interrelationships among decision elements by replacing the hierarchy in the AHP with a network.

The process of the ANP is comprised of the following four major steps (Saaty, 1996; Lee et al., 2009).
(i) Step 1 (model construction): A problem is decomposed into a network in which nodes corresponds to components. The elements in a component can interact with some or all of the elements of another component. Also, relationships among elements in the same component can exist. These relationships are represented by arcs with directions.
(ii) Step 2 (pairwise comparisons and local priority vectors): The elements are compared pairwisely with respect to their impacts on other elements. The way of conducting pairwise comparisons and obtaining priority vectors is the same as in the AHP. The relative importance values are determined on a scale of 1–9, where a score of 1 indicates equal importance between the two elements and 9 represents the extreme importance of one element compared with the other one. A reciprocal value is assigned to the inverse comparison; that is, $a_{ji} = 1 / a_{ij}$ where a_{ij} denotes the importance of the ith element compared with the jth element. Also, $a_{ii} = 1$ is preserved in the pairwise comparison matrix. Then, the eigenvector method is employed to obtain the local priority vectors for each pairwise comparison matrix.
(iii) Step 3 (supermatrix formation and transformation): The local priority vectors are entered into the appropriate columns of a supermatrix, which is a partitioned matrix where each segment represents a relationship between two components. The supermatrix of a system of N components is denoted as the following:

$$
\mathbf{W} = \begin{array}{c|c|c|

The conceptual framework of the five forces model presented is transformed into a network model of the ANP in a way by which clusters in the network model corresponds to the five forces, and elements in a cluster are equivalent to sub-forces in a force. The interrelationships between forces are represented by arcs with directions. Since the interdependencies among forces are implicitly only given in Porter's original work and other textbooks, they have been defined based on the previous studies explicitly specifying them (Chen et al., 2001; Grundy, 2006).

Figure 1 shows the constructed ANP network of the five forces model. The detailed descriptions of the sub-forces are summarized in Table 1 with their abbreviations and types. Some of the sub-forces give a rise to the intensity of competition when the degree is high while the others do when they are low. The formers are classified as positive (+), and the latter is denoted as negative (-).

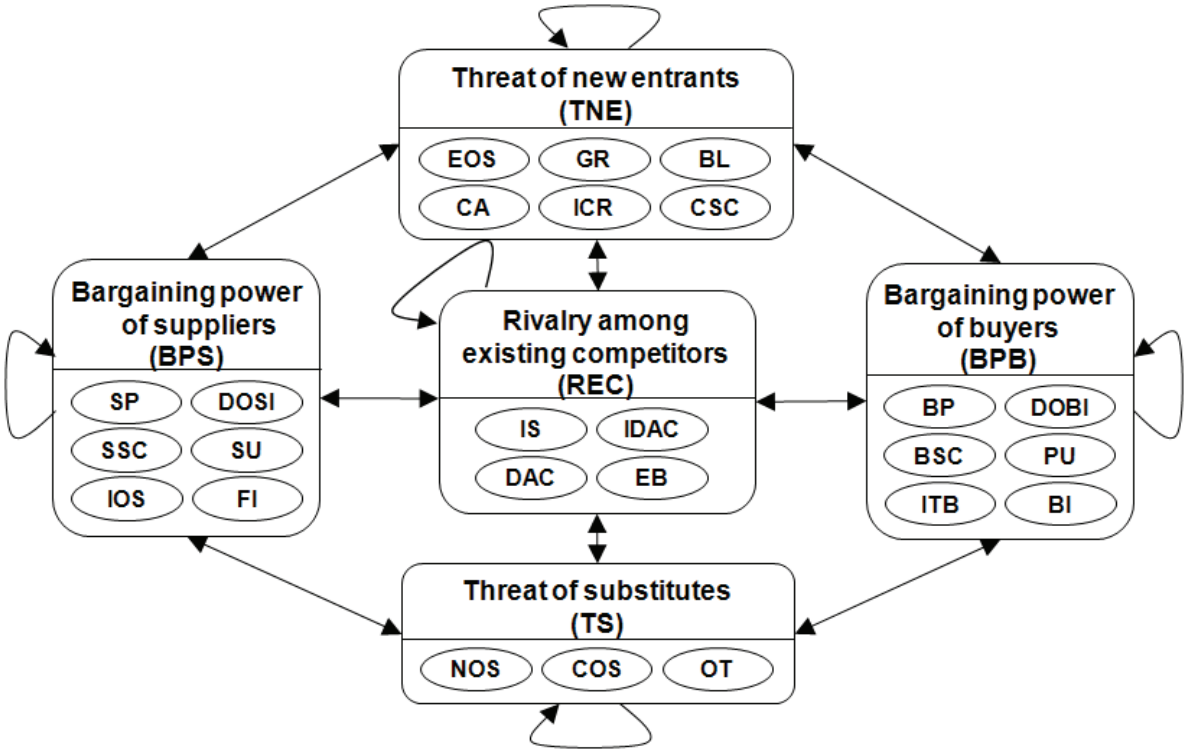

Figure 1. The ANP network of the five forces model

Table 1. Forces and sub-forces

Forces	Sub-forces	+/-
Threat of new entrants (TNE)	Economies of scale (EOS)	-
	Government regulation (GR)	-
	Brand loyalty (BL)	-

	Dependence on supplier industry (DOSI)	+
	Supplier switching costs (SSC)	+
	Supplier uniqueness (SU)	+

	Importance of suppliers (IOS)	+
	Forward integration (FI)	+
Bargaining power of buyers (BPB)	Supplier portfolio (SP)	+
	Dependence on supplier industry (DOSI)	+
	Supplier switching costs (SSC)	+
	Supplier uniqueness (SU)	+
	Importance of suppliers (IOS)	+
	Forward integration (FI)	+
Threat of substitutes (TS)	Number of substitutes (NOS)	+
	Closeness of substitutes (COS)	+
	Other technologies (OT)	+
Rivalry among existing competitors (REC)	Industry structure (IS)	+
	Industry demand and capacity (IDAC)	+
	Differentiation among companies (DAC)	-
	Exit barriers (EB)	+

Procedure

The proposed approach consists of the three stages. Figure 2 shows the overall procedure of the proposed approach.

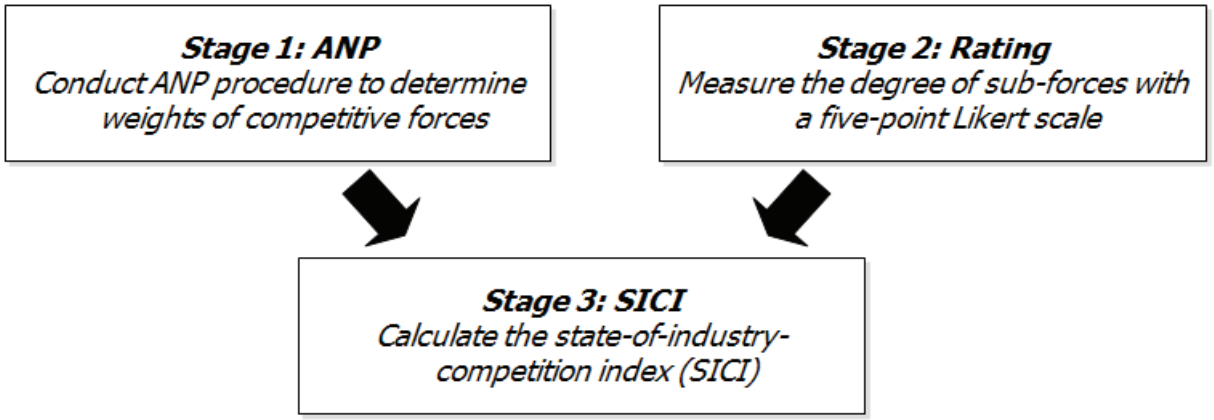

Figure 2. Overall procedure of the proposed approach

Firstly, the ANP procedure is then conducted to produce priority weights of the forces and sub-force at Stage 1. Pairwise comparisons are made among the forces and sub-forces based on their interrelationships. The supermatrix is constructed with the local priority vectors obtained from pairwise comparisons. The corresponding form of the supermatrix to the network model in Figure 2 is as the following:

$$\mathbf{W} = \begin{array}{c} \\ \\ C_1 \\ \\ \vdots \\ \\ C_k \\ \\ \vdots \\ \\ C_N \\ \\ \end{array} \begin{array}{c} \begin{array}{cccccc} C_1 & & \cdots & C_k & & \cdots \end{array} \quad C_N \\ \begin{array}{cccccc} e_{11}\cdots e_{1n_1} & & \cdots & e_{k1}\cdots e_{kn_k} & & \cdots \end{array} \quad e_{N1}\cdots e_{Nn_N} \\ \begin{array}{c} e_{11} \\ \vdots \\ e_{1n_1} \end{array} \\ \begin{array}{c} \vdots \\ e_{k1} \\ \vdots \\ e_{kn_k} \end{array} \\ \begin{array}{c} \vdots \\ e_{N1} \\ \vdots \\ e_{Nn_N} \end{array} \end{array} \begin{pmatrix} \mathbf{W}_{11} & \cdots & \mathbf{W}_{1k} & \cdots & \mathbf{W}_{1N} \\ \vdots & & \vdots & \ddots & \vdots \\ \mathbf{W}_{k1} & \cdots & \mathbf{W}_{kk} & \cdots & \mathbf{W}_{kN} \\ \vdots & & \vdots & \ddots & \vdots \\ \mathbf{W}_{N1} & \cdots & \mathbf{W}_{Nk} & \cdots & \mathbf{W}_{NN} \end{pmatrix}$$

The supermatrix is then transformed into the weighted supermatrix and the limit supermatrix. The converged column of the limit supermatrix contains global priority weights of each sub-force.

In stage 2, industry experts give ratings on the degree of the sub-forces with a five-point Likert scale from 1 (very low) to 7 (very high). In the case of negative items, the reverse value is assigned for measurement to be consistent.

Stage 3 measures the state-of-industry-competition index (SICI). It is calculated as the weighted sum of global priority weights of the sub-forces and corresponding ratings:

$$SICI = \sum_{k=1}^{5} \sum_{j=1}^{n_k} w_{kj}^{g} r_{kj}$$

where n_k is the number of elements in the kth cluster, w_{kj}^{g} is global weight of the jth element of the kth cluster, and r_{kj} is the rating on the jth element of the kth cluster. The SICI represents the overall competitive condition of an industry. The higher the value of SICI, the more intense the industry competition and the less attractive the industry. The SICI of each force can also be obtained by using the local weights normalized by each cluster. It is defined as the following:

$$SICI_k = \sum_{j=1}^{n_k} w_{kj}^{l} r_{kj}$$

where w_{kj}^{l} is the local weight of the jth element of the kth cluster. The pattern of changes in the competitive condition of an industry can be observed by conducting the same analysis for multiple time points. Figure 2 shows an example of the final output of analysis, competitive dynamics of an industry.

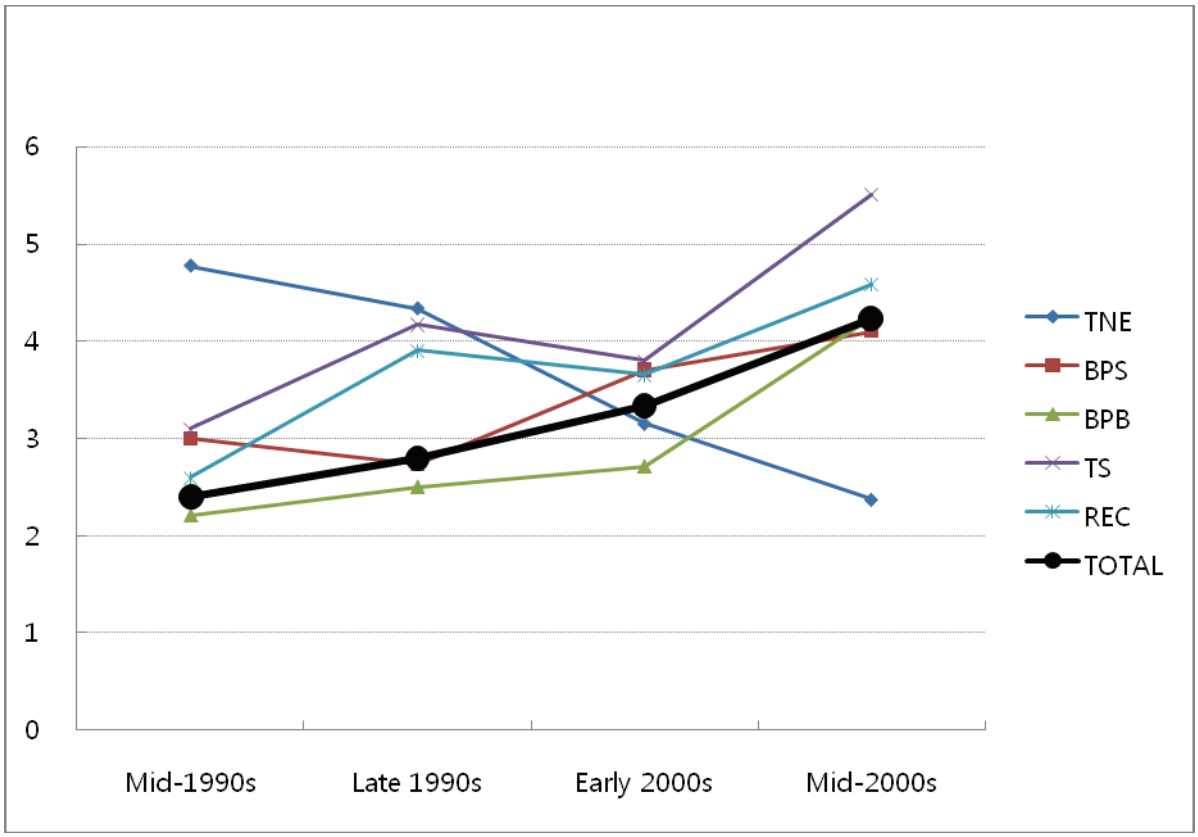

Figure 2. Changes in SICI

CONCLUSIONS

This study proposed an ANP approach to operationalization of the five forces model. The five forces model was transformed into a network model of the ANP. The ANP procedure was then carried out to obtain the priority weights of the sub-forces. Combining the derived weights and ratings on the sub-forces produces the SICI values that represent the overall competitive condition of a given industry.

Since the ANP produces priorities of elements in a complex network model with consideration of interdependency among elements, it can fulfill the requisites for operationalization of the five forces model, prioritization of the forces with consideration of their interdependency. The proposed approach is expected to expand the five forces model into a workable system of analysis by improving its analytical power.

The clusters and elements of the ANP model are by no means exhaustive or fixed. Although the model was constructed based on the Porter's original work, it can be variant depending on the industry or strategic context. The irrelevant sub-forces can be ignored, and additional sub-forces considered important can be added. The sixth forces such as complementers (Hill & Jones, 2004) and government regulations (Rugman & Verbeke, 2000) can also be included in the model. The major task to be conducted in future research is to apply the proposed ANP approach to a real case.

A NEW MODEL FOR MANAGERS USED FOR POSITIONING THEIR ORGANIZATIONS IN MARKET PLACE

Ahmadreza Shekarchizadeh, University Technology Malaysia, Malaysia
Ahmad_shekar2@hotmail.com

ABSTRACT

Diagnosing position of an organization for top managers in the competitive environment is vital for making strategies to grow firm. The purpose of this paper is finding a model for managers to diagnose position of their organization in the market place. Managers usually are too busy to study complicated strategic models, so the aim of this paper is offering a model without usual complexity for top managers. Top manager who uses this model is like the captain who uses his map to realize his situation and the rout to his destination.

Keywords: marketing, quality, position

INTRODUCTION

The variety of firms in the service industry makes generality regarding strategy difficult. A scheme is presented to classify service organizations in a way that provide strategic insight and transcend narrow industry boundaries. This scheme can be used to think about the choices being made to position the service in relation to its competitors. According to (Fitzsimmons & Fitzsimmons, 1994), Positioning is a marketing term used to describe the process of establishing and maintaining a unique place in the market.

A BRIEF HISTORY

After reviewing the literature, author realized that there isn't a model without usual complications for managers in order to position their organization in market place. One of the most well known classification schemes developed by Christopher Lovelock (C. H. Lovelock, 1983) that are regarding possible strategic dimensions which transcend industry boundaries. He has classified the services for strategic insights referring nature of the service act, relationship with customers, customization and judgment, nature of demand and supply, and method of service delivery. In the following, the first one has been explained.

The service act can be deliberate across two dimensions: extent of tangibility nature of the service and who or what is the direct receiver of the service (Figure 1). Accordingly services can be classified to four classes: (1) tangible actions directed to the customer, for instance restaurants and hospitals; (2) tangible actions directed to the customer's possessions, for instance laundry and industrial equipment repair; (3)intangible actions directed at the customer mentality, such as museums and cinemas; and(4) intangible actions acted on customer's assets, for instance accounting.

Nature of the Service	Direct Recipient of the Service: People	Direct Recipient of the Service: Things
Tangible actions	*Services directed at peoples bodies*: Passenger transportation ▪ Health care ▪ Exercise clinics ▪ Haircutting	*Services directed at goods and other Physical possessions:* ▪ Laundry and dry cleaning ▪ Freight transportation ▪ Veterinary care
Intangible actions	*Services directed at people's minds:* ▪ Education ▪ Broadcasting ▪ Theaters	*Services directed at intangible assets:* ▪ Accounting ▪ Securities ▪ Banking

Figure 1: Lovelock (1983)

Next, (Chase & Hayes, Fall, 1991) proposed an operations-oriented framework. By this framework, service performers are grouped into four levels: loser, nonentity, professional, and leader.

The model that will be discussed is a new one which has based on the satisfaction literature in marketing. This model tries to classify organizations based on their performance. One of the most important advantages of this model is its implications in the field of marketing, operations, and human resources. With using this model, organizations can be classified to four categories. In the other words, this model is a grid for managers to diagnose weaknesses and strengths of their organization.

A NEW MODEL

After measuring perception and expectation of customer in the field of dimensions of quality in organization, managers could calculate mean of them. Mean of the dimensions (for example, according to items of SERVQUAL model offered by (Parasuraman, Zeithaml, & Berry, 1988b)for perception and expectation, indicate in which position organization will be. Chart 1 shows this model. There are four positions:

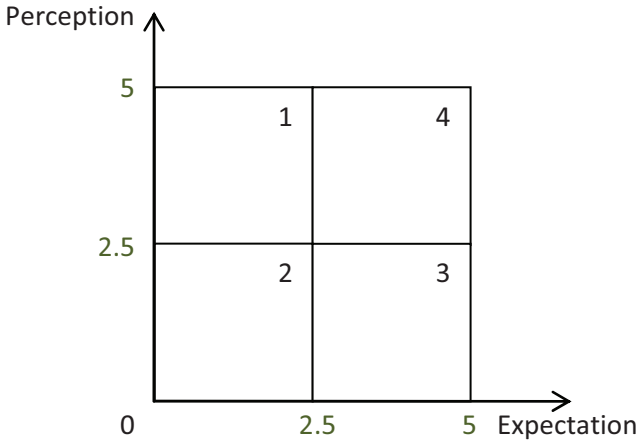

Chart 1: A model for classification of organizations

1. 2.5< Perception < 5
0< Expectation < 2.5 ⇒ Position 1

Organizations in position 1, perception of their customer is much more from their expectations.

- **Marketing Function specifications**: These organizations raise customer expectations to new levels and continuously improve their quality. Also, these organizations usually are leader in their industry. According to Chase and Hayes in (C. Lovelock, Wirtz, & Chew, 2008), these are main leader in special segments, recognized for marketing skills; brand name of their services; conduct sophisticated analysis of relational databases as inputs to one-to-one marketing and proactive account management. From competitive appeal point of view, company's name is synonymous with service excellence; its ability to delight customers raises expectations to levels that competitors can't meet. Concept testing, observation, and contacts with lead customers are used in the development of new services that respond to previously unrecognized needs.

Furthermore, from competition perspective firm is well known for its service excellence. In these organizations, customers usually are delighted by delight programs that usually competitors couldn't offer. According to (Rust & Oliver, 2000), delight programs are probable to be profitable if customer satisfaction can be maintained at the higher expectation levels caused by assimilated levels of delight. This is true both for the firm's customers and those converted from competitors. Moreover, satisfaction with higher levels of quality as perceived by current customers will attract more customers from other firms as a result of decreasing level of satisfaction with the competitors' lower quality. Another distinctive of these companies is their selected customers. Customers are selected and preserved based on

their potential value to the firm, including their potential for new service occasions and their capability to inspire novelty.

- **Operation Function specifications**: They use progressive techniques; use theory testing; use of head customers as inputs to new-service growth and have enlightened Customer Relationship Management (CRM) systems. Business experts work with technology leaders around the world to expand new applications that will create a first mover advantage. Consequently, the company can achieve at levels that competitors cannot hope to attain for a long time.
- **Human Resources Function specifications**: Clear standard processes in the organization help employees to follow them, and this facilitates the work of them. Top management consider quality of their employees as an important competitive advantage. There is a culture of service-oriented in the firm that has developed by human resource managers, who create a superior working environment that attracts and retain the best people. The stuff are committed in the firm's values and aims. Employees propose new ideas because they are involved, empowered and quick to adapt change.

2. $0 < \text{Perception} < 2.5$
$0 < \text{Expectation} < 2.5$ ⇒ Position 2

- **Marketing Function specifications**: Organizations in position 2, meet some customer expectations and are consistent on one or two key dimensions, however they fail to be reliable in all dimensions. According to Chase and Hayes in (C. Lovelock et al., 2008), these organizations uses mix of selling and mass communication, using simple segmentation strategy and make selective use of price discounts and promotions. They might use price discounts to try to attract new customers. Also, these institutions usually conduct and tabulate basic satisfaction surveys. Customers usually neither seek nor avoid the firm. Managers may talk about improving quality and other aims, however they fail to set clear priorities, to have a clear direction, nor gain the respect and commitment of their employees.
- **Operation Function specifications**: From perspective of management function in principal line, they create and deliver service, focuses on standardization as key to productivity. Quality in these institutions is defined from internal perspective. Also they run each step in delivery service independently. One of their main weaknesses is that support stuff is unfamiliar with customers. They also reward for keeping costs below budget and stick to traditions.
- **Human Resources Function specifications**: Their policy for human resources is recruiting and training employees who can perform competently. Workers follow

procedure but aren't motivated and turnover usually is high. Managers in front line control workers.

In these organizations, although there are a lot of rooms for improvement, their position is better of organization in location 3, that have the worst features. A few organizations may compete in this way and it is difficult to tell one from the other.

3. 0 < Perception < 2.5

2.5 < Expectation < 5

- **Marketing Function specifications**: These firms are at the bottom. They are unsuccessful in marketing, operations, and human resource management. They are highly variable from service quality perspective, usually unsatisfactory. These firms are subservient to operations priorities. According to Chase and Hayes in (C. Lovelock et al., 2008), role of marketing managers is limited to tactical role. In addition, advertising and promotions lack focus and no involvement in product or pricing decision. Also role of frontline managers is limited to control workers.

Customers utilize these firms for reasons other than performance. These firms have unspecified customers and serve a mass market at a minimum cost. Customers buy from them because there is usually no other option. This is the reason why these companies continue to survive.

- **Operation Function specifications**: Operations in these organizations are reactive and cost oriented. Also, locations and schedules are unrelated to preferences of customers, who their needs usually are ignored. Backstage operations are separately from front-stage and productivity is usually undefined. In this direction, managers are punished for failing to bond within budget.

According to Rogers in (Rasli, Arshad, Talib, Ramli, & Senin, 2008), stages in the technology life-cycled can be identified based on the relative percentage of customers, to five stages. The organizations in position three are at last stage in Rogers model, who are late adopter and Rogers identified them as Laggards. They use new technology when it is necessary for survival.

- **Human Resources Function specifications**: From human resource point of view, these organizations are involved in the employee cycle of failure and customer cycle of failure(C. Lovelock et al., 2008). The employee cycle of failure begins with a tight design of jobs for low skill levels. There is an emphasis on rules rather than delivering service, and the use of technology to control quality. Management supplies low-cost employee who meet minimum skill requirements for the job. Employees are not interest, have negative constraint, poor performance, disloyal and do not care. Accordingly, they lack the ability to respond to customer

problems. Then they become dissatisfied and expand a poor service attitude. This result for the organization low service quality and high employee turnover. Because of low profit margins, the cycle repeats itself with the hiring of more low-paid employees to work in the same manner. Some service organizations can reach such low levels of staff drive that frontline workers engage in service damage rather than deliver service excellent.

The customer cycle of failure begins with emphasizing on attracting new customers. Because employees are dissatisfied, the customers become dissatisfied with employee performance. High employee turnover means that consumers are always served by new faces, so there is no continuity. This in turn causes customers fail to be loyal to the firm. This cycle repeat it by requiring firm an ongoing search for new customers to maintain sales volume.

4. 2.5 < Perception < 5
2.5 < Expectation < 5 → Position 4

- **Marketing Function specifications**: These organizations consistently meet or exceed customer expectations across multiple dimensions. According to Chase and Robert (C. Lovelock et al., 2008), these organizations have clear positioning strategy against competition, use focused communications with distinctive appeals to clarify promises and educate customers. Their policy for pricing is based on value, and they monitor customer usage and operate loyalty programs. Furthermore, they use a variety of research techniques to measure customer satisfaction and obtain ideas for service enhancements. Marketing managers work with operations to introduce new delivery systems. Customers look for the firm, based on its continued character for meeting customer expectations.
- **Operation Function specifications**: In these organizations operations have a strategic role in competitive strategy. Operations managers recognize tradeoff between productivity and quality. Operations and marketing managers' work together to introduce new delivery systems. Also they willing to outsource and monitor competing operations for ideas or threats. Service delivery in front line is driven by customer satisfaction, not tradition. Front line always willing to customize, accept new approaches and emphasis on promptness, convenience and comfortable.

From point of view supporting operations, there are clear links between backstage and front line activities. Also they consider their role as serving internal customer, who in turn serves external customers. Top managers in these organizations focus on reengineering backstage processes and avoid productivity improvement that will degrade customers' service experience. Additionally they continually refine processes for efficiency. According to (Rogers, 1995), when a new technology is created, these organizations are early adopters, who are primarily concerned with the underlying technology and its performance. Especially,

when IT promises to enhance service for customers and provides a competitive edge, these organizations quickly approve it.

- **Human Resources Function specifications**: Human resource managers in these organizations, invest in selective recruiting, ongoing training. They also keep close relationships to employees, promote upward mobility and try to enhance quality of working life. Consequently, employees are motivated, hard working, and allowed some discretion in choice of procedures. Top managers usually encourage staff to recommend, hence workforce offers many suggestions. Frontline managers listen to customers, coach and facilitate workers.

CONCLUSION

A new classification of organizations presented in this article, provides a tool for managers to understand position of their organization and lead their firms in order to grow up levels of service performance. This model also has implications from perspectives of marketing, operations and human resources. Managers in organizations should try to shift their organization to position 1.

THE ROLE OF HUMAN RESOURCES MANAGEMENT AS A STRATEGIC PARTNER

Ravee Phoewhawm, Chiang Mai University, Thailand
rtcm999@yahoo.com

ABSTRACT

The human resources management profession is under pressure from their C.E.O's to bring more value for their organization. Professor David Ulrich, of Michigan University, has done extensive work on trying to make Human Resources Management (HRM) a strategic partner. Despite providing good theoretical concepts most of the profession has been viewed in the eyes of their organization as being neither strategic nor adding much value for their organization. This study focuses on converting this line of work from an administrative position into a strategic role. The work is aimed at gaining insight on the attitude and working behavior to see what is the cause that is preventing or failing to make HRM on becoming a strategic partner. Five open-ended questions were constructed to ask human resources manager working at manufacturing industry and regular workers from other fields for data collection. The findings revealed that HRM has inserted itself into a position for ensuring that all of the energies, behaviors, and efforts of the workers comply to the operational output with efficiency. Workers in general see the profession of HRM providing very little positive impact to their organization. Some knowledge management theories have been proposed as a rational guideline for making the human resources profession mindset to assume the strategic role.

Keywords: systems thinking, decision-making, customer focus, human resources strategy.

INTRODUCTION

With globalization causing an unpredictable and rippling effect in the economic cycle of the world it's time for the staff and title holders of human resources management to heed to the signals and take proactive measures in order to justify their position within their own organization. Scholarly literature and strong requests from chief executive officers for making HR a strategic partner cannot be taken with a lukewarm reception. For the HR profession in this age knowing what to do does not transmit enough credibility when the demand is asking for knowing how to do it. The former task performs within the system while the latter is based on producing values and benefits for the organization. Ever since Professor David Ulrich, from the University of Michigan, sent out the message to the world of Human Resources Management on becoming more of a business partner there has been many ideas and interesting models for the practitioners of HR to follow. Professor Ulrich (1997) has stressed that:

- the HR function needs to become **strategically proactive**,
- that HR needs to go **beyond administrative expertise** and

- ☐ be an **expert in strategic business partnership, change management, and employee advocacy**.

Despite the urge and scholarly effort by Ulrich for HR to modernize its position, there has been a lack of initiative to do so. Works gathered from other profession studies reveal the information as followed:

1. HR's working relationship with their line managers tend to be emphasized on the rules and policies over the final production. This leads to HR and the line managers always being in a state of disagreement. (*Workforce,* August 1999, Vol. 78., No. 8, pp. 32-38.)

2. The Chief Executive Officers see their HR people focusing only on their general function to fulfill the quantitative assignments. Hiring a certain number of new staff in order to fill the quota is a good example. HR's concentration on their functions makes their C.E.Os believe that HR is unresponsive to the rapid changes in the business world. (*Joe Wert,* Copyright 2002 The Segal Company (Eastern States), Inc.)

3. When it comes to business goals, HR remains conservative while other business units have taken a strategic role during the period of business turbulence. It just seems that they are unwilling to learn in making their business grow. (*Workforce,* January 2003, pp. 26-30 By Shari Caudron)

4. The HR staff themselves execute on familiar tasks and duties that complies to the basic administration of human resources management. This clearly shows that they are failing to convince top management of becoming a strategic business partner. (Lawler, Edward E., Mohrman, Susan A. Human Resource Planning • Sept, 2003)

David Ulrich proposed four role models (2005) for HR. This contributed to the movement of HR from a functional orientated standpoint to a more partnership-centered one for their organization. Ulrich defines the recommended roles as followed:

Proposed Role	**Characterization**
Strategic Partner	Alignment of human resources activities and initiatives with the global business strategy.
Change Agent	Supporting the change and transition of the business in the area of the human capital in the organization.
Employee Champion	Attending to the interest of employees and installing confidence during the process of the change in the organization.
Administrative Expert	Searching for an opportunity of providing quality service with efficiency for the organization.

However, the progress for HR has been limited. According to Kiger, only 23% of the HR departments have taken part in corporate strategy and made a significant impact on operating results. *(Patrick J. Kiger, May 29, 2007)* Overall, HR departments are still not considered a valuable strategic asset. The findings by Suri (Nishchae Suri, Business Head,

Consulting Analytics, Asia-Pacific, Hewitt Associates 2008) states that the majority of HR executives remain, to all extent and purposes, neither strategic nor leaders.

This paper is aimed at leading HR to take a mental approach into becoming a strategic business partner to their organization. So much work and seminar have been constructed to actually make HR go beyond their role. The so called knowledge economy has called for HR to assume the leading role in bringing out the best in talent, expertise, performance, and intelligence for making their organizations highly competitive. The workshops and educational documents from the HR gurus and mavens may have entertained the sight and sound of these professional. But in the end, the thoughts and behavior have portrayed the opposite direction in being a strategic partner. The question raised is "*What are the obstacles that are preventing HR from becoming a strategic partner?"* Therefore, this paper offers a new point of method for HR to become this idealistic role. The new way is targeted at the mind of HR. It is the belief that the frame of mind is the potential weapon that can either help HR advance or decline in their quest to become that valuable cohort. By changing the mind, the attitude and behavior will follow with the changes. The driving force for this study stems from the opportunity to revamp the image of HR to be more devoted to the human side.

The structure of the paper is outline in the following. First, strategic theories and approaches have been analyzed for literary discussion to see if there is crucial information that leads to a path for HR in taking on strategic role. Second, the answers to the research question on "*What are the obstacles that are preventing HR from becoming a strategic partner"* have been provided by analyzing the data collected. For the third part, an approach using Peter Senge's "systems thinking" as a knowledge management tool along with business case studies and professional analogy have been designed as the framework for HR to inherit a new outlook. In theory, it is hope that this will serve as the basis for HR to finally see that they actually can become a strategic partner after all.

1. Literature Review.

Aughton (2005) suggests that HR needs to frame a new mental model that will make others take notice and listen to the profound and sustainable benefits HR brings to organisations in the new economy. Such a mental model must form the strategic framework that provides HR professionals with the evidence that HR is truly adding value to key stakeholders. Aughton tells us that "as societies shift from the old industrial era to new service/knowledge economies the more valuable HR deliverables will become in creating a competitive advantage for organizations. He claims that the market values of companies that are largely determined by the intangibles; if they're not managed properly they can have a negative impact on the shareholders' value. Aughton points out to how intangibles such as leadership, governance, R&D, innovation, reputation, brand strength, tacit knowledge, plant flexibility, speed and quality of service, customer and employee loyalty, and informal processes and trusted networks are the essential factors that build the future growth expectation of investors. What's really good for HR is that, as Aughton describes, it presents tremendous opportunities for this type of profession because the only way these intangibles can be achieved is through people. Since HR deals with people, the new mental model that Aughton proposed is to think systematically. Aughton advises HR to mind-frame their organization operating within its environment and to be a competent in using state-of-the-art systematic tools and concepts designed for adding value to stakeholders. He feels that this idea will enable HR to see their organization from a different view. This will lead HR to act

on the important strategic business matters that other managers might have overlooked. While Aughton recommends this mental model it doesn't quite strike up the nerve for HR to make this proactive movement.

Price (2008) cites work from other studies on making HR positioned in a strategic role. Price reports on Gubman's 'HR Strategy and Planning: From Birth to Business Results' study of having the focus as their financial colleagues: return and growth. Therefore, 'HR-things' can only create economic value from three sources:

- Employee turnover and retention
- Productivity - revenue against employee costs
- Expenditure on the HR function and related activities

Price also informs that this work by Gubman relates to three familiar HR goals:

1. Attracting, developing and retaining staff
2. Aligning, engaging, measuring and rewarding performance
3. Controlling or reducing HR costs

Price then alludes to the study done by Tamkin who used a set of criteria described as the '4A model' (Access, Ability, Attitudes, Application). From the study of almost 3000 British organizations, it was discovered that the use of 'bundles' of HR practices produced improved performance and profitability. A number of issues were suggested for HR managers to focus on:

- Access The quality of the recruitment process: putting serious effort into attracting high quality applicants; using policies and practices that 'ensures the ongoing movement of the best people through the organization'.
- Ability Effective, long-term development plans focused on the needs of employees and the business. These plans should be constantly monitored to ensure their effectiveness. The researchers also highlight the need for a high workforce quality, e.g. possession of degrees.
- Attitudes Aligning employees to the objectives of the organization - 'vital in terms of capturing discretionary effort'. They emphasize one-to-ones, appraisals and reward strategies related to organizational performance.
- Application Encouraging autonomy, empowerment and generation of ideas.

And finally, Price refers to Weiss's argument that HR managers must demonstrate the ability to provide stimulating ideas and challenge decisions that do not have business value. Most importantly, they need to wear a 'business hat' rather than a 'HR hat' otherwise they will be relegated to the traditional administrative or tactical (second-level) role that has be-devilled the human resource function for decades. Weiss considers that HR managers need to demonstrate the following to show their ability to add value:

- Broad understanding of the business, thus helping the human resource function to contribute to the overall direction of the company.
- Knowledge of how all activities needs to be aligned, thus enabling the company to maximize the success of its strategic initiatives.

- Professionalism in investing in human capital and HR processes, allowing HR to help guide employees and the organization's decision making.
- A unique perspective, allowing the HR function to become an 'ideas merchant' so that people and the outcomes of organizational processes can be made into strategic advantages.

These studies mainly offer a practical guideline of approaches on how HR can assume a strategic role. There are many more scholarly and commercial articles that provide useful advice for HR to become beyond their position. These implications do stimulate motivation for HR and perhaps the CEOs in allowing HR to transform into a value strategic business partner and player. But time and time again, not many of these HR practitioners will be able to rise like a Phoenix out of the ashes. Whether it's due to the political culture or the will of HR themselves this paper calls for an alternative approach to make HR become that desirable profession. Since HR is after all human the mind must be shaped to think differently in order to embrace these professional advices from some of the best HR gurus and mavens.

2. "What are the Obstacles that are Preventing HR from Becoming a Strategic Partner"?

To answer this research question, an open-end question form questions were asked to HR managers working at an industrial organization that are product-centered. The companies that these HR managers worked for were owned by the U.S., Japanese, British, German, and French based in the Lamphun province of Thailand. Twelve questions were sent out and nine responded back. The names of these companies that the HR managers represented were the SMV company, Keihin, Abbeycrest, Hana Microelectronics, Lanna Products, Thai-Sakae Lace, Bluechips Microhouse, Murata Electronics, and Label Bank Asia. These same questions were also asked to general individuals who were working as top managers and regular staff members at organizations that were non-product centered. The questions were structured as followed:

1. What is the role of Human Resources Management?
2. How does HRM add value (for an organization)?
3. Does HRM contribute in making the organization effective?
4. Where can HRM improve in developing an organization?
5. How important is HRM to an organization?

These questions asked to the participants were aimed to find out what the HR staff is currently doing to be viewed as a strategic partner and to gather the perception of non-HR staff in how they see this profession implementing the practice.

Analytical Insight to the Response of HR

1. HR defines their **role** by the function that they do on a weekly basis. The functional role of recruitment, compensation & benefit, training & development, employee relation, performance evaluation, and retaining employees is to make sure that they are all aimed (catering) towards meeting the organizational objectives. One of the main objectives is to ensure efficiency by directing the labour to be productive in meeting the demands of the organization's clients, reducing unnecessary expenses and

expenditure. HR enforces the rules and regulations to ensure that working operations are running on a smooth basis.

2. HR **adds value** by coordinating the working conditions and systems to direct the behavior and skills of the organizational staff to meet the objectives with efficiency. The focus is on safety and security of staff as this is believed to generate motivation on the part of the workers. HR has to focus on keeping the company at a subsistent level by making sure that they have competent people; in theory competency eliminates damage to the work operation.
3. HR **contributes in making their organization effective** by identifying and detecting any mistakes that might cause the work production to slow down. HR claims accomplishment to organizational effectiveness by measuring their company's profit sheet and the number of staff participating in activities. HR designs the policies and procedures for reducing wastage of resources, time, and energy as well as improving the work system that results in productivity.
4. HR can **improve** by getting their staff to see how their job is connected to the organization's mission and values; they will feel more motivated and get a clear picture of their role. HR has to find a better way of making the financial statement to be a lot more positive than negative; the bottom line (finished product up-to-standard) must be maintained.
5. HR shows its **importance** by re-shaping policies, process, and procedure to meet the objectives. HR upholds their organization competitiveness by targeting skilled people for recruitment. Gaps in skills are quickly identified and training is arranged for the purpose of keeping the work performance on track to maintain the organization to stay competitive in the long run. HR devises the working system to obtain results.

Analytical Insight to the Response of non-HR personnel

1. They administer work policies and procedures. HR recruits new staff, evaluate work performance, providing training, deal with working relations, handling compensation & benefits of the staff.
2. There wasn't much elaboration for HR adding value to the organization. HR perceives to add value when they select the right person for the job and provide residency assistance for newcomers.
3. In terms of contributing to organizational effectiveness, there was not much to say. As long as HR is able to retain qualified staff then they've done their job.
4. In their opinion, HR needs to improve in helping to make the financial sheet look good. Better training programs and learning opportunities should be designed to meet the needs of staff and to make them effective in their job role.
5. ** HR is important in a sense of providing information and support of the work system. However the organization can survive temporarily without them.*

Criteria	Human Resources	Regular Staff
Role	• General/administrative function (recruiting, training, compensation + benefits, performance evaluation) • Ensure efficiency by directing the labour to be productive in meeting the demands of the organization's clients, reducing unnecessary expenses and expenditure • Enforces the rules and regulations to ensure that working operations are running on a smooth basis	• administrate work policies and procedures. • HR recruits new staff, evaluate work performance, providing training, deal with working relations, handling compensation & benefits of the staff.
Adding-Value	• Coordinating working conditions and systems to direct behavior and skills of staff to meet the objectives with efficiency. • Focus on safety and security of staff to generate motivation and morale of the workers. • Concentrate on keeping the company at a subsistent level by making sure that they have competent people; in theory competency eliminates damage to the work operation.	• Not much elaboration. • When they select the right person for the job, support learning opportunities and build a positive working environment.
Contribution to Organizational Effectiveness	• Identifying and detecting any mistakes that might cause the work production to slow down. • Accomplishment by measuring their company's profit sheet and the number of staff participating in activities. • Policies and procedures for reducing wastage of resources, time, and energy as well as improving the work system that results in productivity. Only workers who perform efficiently will be retained.	• Not so much information. • As long as HR is able to retain qualified staff then they've done their job.
Area for Improvement	• Getting staff to see how their job is connected to the organization's mission and values; they will feel more motivated and get a clear picture of their role. • HR has to find a better way of making the financial statement to be a lot more positive than negative; the bottom line (finished product up-to-standard) must be maintained. • HR needs to develop a career path for their staff, identify the skills and abilities required for the job, and build up the competencies of line management; need to create a learning environment.	• Helping to make the financial sheet look good. • Better training programs and learning opportunities to meet the needs of staff and to make them effective in their job role.
Importance	• Re-shaping policies, process, and procedure to meet the objectives. • Gaps in skills are quickly identified and training is arranged for the purpose of keeping the work performance on track to maintain the organization to stay competitive in the long run. • Planning the work system to obtain results. All functional tasks and practice of retaining workers, creating positive work conditions, and good relations are driven towards the company's existence and goals.	• ** Important in a sense of just providing information and support for the work system. However the organization can survive without HR for a temporary period of time.*

This chart depicts how HR see themselves and how regular working staff view HR from five different principles.

Findings from the data

We see that HR has not really transformed its role to be what Ulrich has recommended. The general function and administrative tasks of HR has labeled the profession to be viewed by themselves and others of what they do rather than what they could really do – it's the term "what you see is what you get".

The practice of HR, in an industry where it is product-centered, demands that the role provides a strong support in making their organization highly competitive and has a prolonging existence in the market. The attitude and opportunity to be a strategic business partner, change agent, employee champion, and administrative expert have been diminished due to the pressures of meeting the financial objectives and needs of the corporation.

Rather than seeing HR practice its profession to be more innovative and lenient towards the human side it is clearly seen that HR has converted itself into being a police officer within their organization. HR has to make sure that the systems and policies are complied to. Any signs of defect or deceleration of productivity must be immediately addressed in order to ensure that the financial and profit statement shows a high positive rate of return. Any staff being seen as unproductive is subjected to immediate training or reprimanding. HR must perform in a clockwork fashion because efficiency rules over effectiveness. They carry out their roles as the proctor of an exam; detecting and monitoring any signs of errors or resistance towards the operational system. The numbers are more important than what people feel or think.

Even if HR tries to demonstrate the human side of their function (retaining, motivating, and creating a positive working environment) it would be considered as a desperate attempt to feed the objectives of being more efficient in the workplace. HR works on a practical theory approach where the system is fine. The procedure is considered correct overall and should not be changed. The system needs to run its course even if it means running over others who do not agree. According to HR it is the people who need to be changed in order to fit into the modus operandi like a box.

Therefore, it's no wonder that HR is looked upon more as a traffic officer by non-HR staff. From the views of other, HR is seen as a mere profession that can be done by anyone. Thus it answers the question on *"the obstacles preventing HR from becoming a strategic partner"*.

The call is for HR to stop relying on the system and start to think more like entrepreneurs who see people as a customer and client to be served with dignity and respect. HR needs to go beyond its current functional task and become part of a leader where people truly matter.

3. An HR Framework for a New Outlook.

It was mentioned in the literature review that Aughton (2005) suggested that HR needs to frame a new mental model that will make others take notice and listen to the profound and sustainable benefits HR brings to organizations in the new economy. He advises HR to mind-frame their organization operating within its environment and to be a competent in using state-of-the-art systematic tools and concepts designed for adding value to stakeholders. He feels that this idea will enable HR to see their organization from a different

view. Leadership expert, John C. Maxwell (2003), tells us that "we are either the masters or the victims of our attitudes". At times, the mind perceives thing to be as is and hardly view how things could be. This research proposed that HR develops the mindset before moving on to the mental model. Edward De Bono has introduced an innovative way for the mind to make sense of things. Coined as the phrase "parallel thinking" De Bono mentioned this idea as a way for both individuals thinking in congruence. In theory, these individuals will think co-operatively and in a coordinated fashion while going in the same direction. The direction itself can be changed in order to give a full scan of the situation. But at every moment each thinker is thinking in parallel with all the other thinkers. There does not have to be an agreement. Statements or thoughts which are indeed contradictory are not argued out but laid down in parallel. In the final stage, the way forward is 'designed' from the parallel thought that have been laid out. In general parallel thinking is a further development of the well known lateral thinking processes, focusing even more on explorations — looking for what can be rather than for what is. (De Bono, 1999) In his work for helping to develop a learning organization, Peter Senge offers another way that can shape HR's attitude. This would not only overcome doubt and impossibilities but also see how things are interconnected and where they can truly make a contribution towards organizational values. In its most eloquent meaning, Senge describes systems thinking as a discipline for seeing the whole…."seeing the structures that underlie complex situations, and for discerning high from low leverage change…All are concerned with a shift of mind from seeing parts to seeing wholes, from seeing people as helpless reactors to seeing them as active participants in shaping their reality, from reacting to the present to creating the future." (Senge, pg. 69, 1990) With this information HR can see that they are not really a lone unit that monitors the working procedure free from lawsuits, conflict of interests, and other political deceptions. Instead, HR should see itself as a business partner that is aimed towards enhancing the performance of others so that they can create prosperity within their organization. Senge (pg.73, 1990) also states that the essence of the discipline of systems thinking lies in a shift of mind:

- Seeing interrelationships rather than linear cause-effect chains, and
- Seeing processes of change rather than snapshots

By means of De Bono's parallel thinking concept and Senge's systems thinking, when we compare the general functions between HR and Marketing we find that they are very much similar in content. What HR and Marketing do have in common is that they deal with people. Their craft of dealing with people are the means for developing an interpersonal relationship. Cobb, Samuels, and Weston (1998) believe that HR can reap additional benefits by learning more about the marketing of services including the marketing of their own services to their internal customers. They feel that the skills and knowledge of HR should also flow to marketing. To support this study, they cite the work from Berry on the importance of treating employees as customers. The suggestion is for companies approaching their employees with the same empathy and concern for satisfying their needs as the employees themselves are expected to display when dealing with external customers. It is the belief that employees respond to company policies and practices in ways similar to customers; customer retention and employee retention should be examined together. The next part of this research shows the similarities between the tasks and functions of HR and marketing.

Recruitment & Selection/Segmentation, Targeting, & Positioning

When HR has to recruit a person for a certain job position they look for individuals who have good qualifications or high potentials otherwise known as a candidate or prospect. Of course HR doesn't go all over the planet to find the prospect. They have to find out where that prospect is located so that they can implement the right method for persuading that person to join HR's organization. If we use the U.S. Army recruiting method as an example we see that they already have the right person or people in mind to join their organization. Gathering intelligence on the typical profile of their prospect the U.S. Army quickly mobilizes in carrying out a plan of convincing these individuals to enlist for the armed services. With a target number set, these recruiters have to decide very carefully on the best economic situation of getting the most with the least amount of resources. Communication is the best reliable tactic for getting into the minds and hoping to persuade these individuals to enlist. Despite the challenges and obstacles of recruiting to meet the target numbers the U.S. Army's no surrender attitude has spawn some innovative ways to get a handful of new recruits. Entertaining events such as sports and music concerts are the perfect ground to sign up young and energetic people. However, it's even more effective to get closer to the prospects if the event was sponsored; and this is what the U.S. Army did. To make it more effective the U.S. Army would bring in a sports celebrity into the event and provide the message about opportunities, a future, and personal development. The recipients of this message are the young men and women who are considered most likely to warm-up to the "sales pitch". The recruiting strategy on the part of the U.S. Army is to target mostly the younger generation. These are the selected groups that fit with the Army's profile of: the physically fit, the inexperienced but hopeful minded, the promising example that would remain with the service, and most importantly the ones that would exemplify leadership for the armed service organization. It's important that the U.S. Army recruits these people so that they sustain the organization's ideas and accomplish the stated mission as well as objectives.
