The employees of DIEM took care of all the match-making meetings and exhibiting in general on behalf of the CEO. Since the CEO could not take part in the match-making meetings, five on-site visits were arranged for the next day. The visited companies are SMEs headquartered in Chengdu and were the same ones that joined the match-making meetings. All the meetings followed somewhat the same procedure. First, the participants gave general introduction of their companies. After the introductions, potential cooperation model and some technical issues regarding their technologies were discussed. A general concern in the end of the meetings was how to communicate with each others in the future since no common language existed. Immediate results were generated only with one company, although several contacts were found interesting. Since the company was having problems with piracy, they were hoping for more secure protection and the codecs of Hitmedia could be the solution. A problem is that the company should first create an account but there is only Finnish version of the registration page.

Case 4: Micropolis

Micropolis is a technology centre focusing on micro- and nanotechnologies as well as environmental applications. The company has built a network of other companies from the focus areas and acts as an umbrella organisation for these companies. Micropolis guides and supports its network companies to many collaborative projects which are partially funded by the European Union and its seventh framework program (FP7). Trade fairs are a significant part of Micropolis' marketing strategy. Besides marketing its network companies, it aims to enlarge its relationship networks through trade fairs as well. The network companies of Micropolis are interested of China as potential market area, but China has

remained uncovered for many of those companies. The goal of the participation was thus to gain information about the Chinese business environment. In addition, the company aimed for promoting the company network and finding partners for its projects, FP7-projects particularly.

Micropolis took part in the event exceptionally without its network companies. Booth exhibiting was again secondary compared to match-making meetings. The most interesting booth discussions Micropolis had with some other European companies that were also exhibiting in the fair. Match-making meetings were held five of which two were for Micropolis and others for the network companies. Micropolis had no problems with the arrangements, but conducting business with Chinese was seen a bit complicated. They had problems related to trust since experience with the Chinese was zero and it was thus creating strong prejudices. Because most of the international experience has developed with the Germans, whose culture is close to Finnish one, making business with the Chinese was seen completely differently than with the Germans.

Micropolis joined DIEM delegation to visit one Finnish and three Chinese high-tech corporations, all of them operating in Chengdu. The visits were seen really beneficial because of the insights that they could offer about work conditions, organisation culture and other operational issues essential in Chinese context. Micropolis was also arranged a visit to one of the universities that researches micro- and nanotechnologies. Their goal was to get known to their research topics and results, and make some connections to the university. As already mentioned, the Chinese companies could not offer interesting cooperation opportunities, and results for Micropolis were lame in this sense. They did manage to establish some connections to European companies and non-profitable organisations, though. However, the best cooperation opportunity would probably be with EUPIC, since its already focusing on Sino-EU collaboration.

Summary of the cases

Some of the essential key data of the case companies is summarised in table 1. Almost all the case companies have some international experience. Only Hitmedia is lacking that kind of experience because of recently started business, but the CEO of the company is experienced in international business. In some sense Flowman has the most developed internationalisation process because 50% of its business comes from China, which is culturally a very distant place. International business of the other companies is mainly located in Northern and Central Europe.

Table 1: Summary of the key empirical data.

	Akkuser	Flowman	Hitmedia	Micropolis
International business	Northern Europe, less than 50% of the revenue	50% of the revenue from China, cooperation started in 2007	None	Frequent collaboration with European companies
Trade fair experience	Participates yearly three fairs	Four in Central Europe	Two in Finland	Numerous of participations around Europe
Objectives of the fair	Establishing relationships, increasing understanding of the business environment	Establishing relationships, increasing understanding of the business environment	To find at least one supplier	Increasing understanding of the business environment, promoting Micropolis and its partners
Key actions	Booth exhibiting, match-making meetings	Visiting the Chamber of Commerce and Chinese companies, match-making meetings	Match-making meetings, visiting the potential partners on-site	Visiting the Chamber of Commerce and Chinese companies, match-making meetings
The number of adequate leads	5-6	3	3-4	3-4

Besides sales effect, the companies have understood the possibilities of trade fairs for marketing and networking purposes in their previous participations. It was the same case this time; the objectives of the fair related greatly to establishing new relationships and increasing understanding of the business environment. Hitmedia named a more concrete objective of finding at least one supplier, but it has also the same objectives in the background. One of the key measures that were asked in the interviews is the number of adequate leads. Although it does not tell the whole picture of the fair results and it does not match with all the objectives, it does give some kind of idea of the benefits the fair brought with it. Most of the leads were generated during the match-making meetings.

DISCUSSION

RQ1: What kind of results was gained from the fair activities?

Based on the literature review and on the interviews, the objectives of a fair participant are simplified and classified in four most significant categories in the figure 2. All the categories are practically interconnected to each others in some level, but this fact is now ignored. Depending on the company some objectives are more essential than others, but there are also other factors independent of the company such as the nature of a trade fair that have impact on the potential objectives. The objectives, i.e. preferred results, can be seen as actualised results. The whole procedure in the figure goes actually in objective-action-result sequence, or in other words preferred results-actions-actual results sequence. Even though objectives should affect what actions to choose, the case companies did not have any chance to change the options. They were told that if they join the delegation, they can

utilise the activities depicted in the figure. On the other hand, the options were quite wide so in case of failing to reach the objectives, the lack of activities cannot be accused.

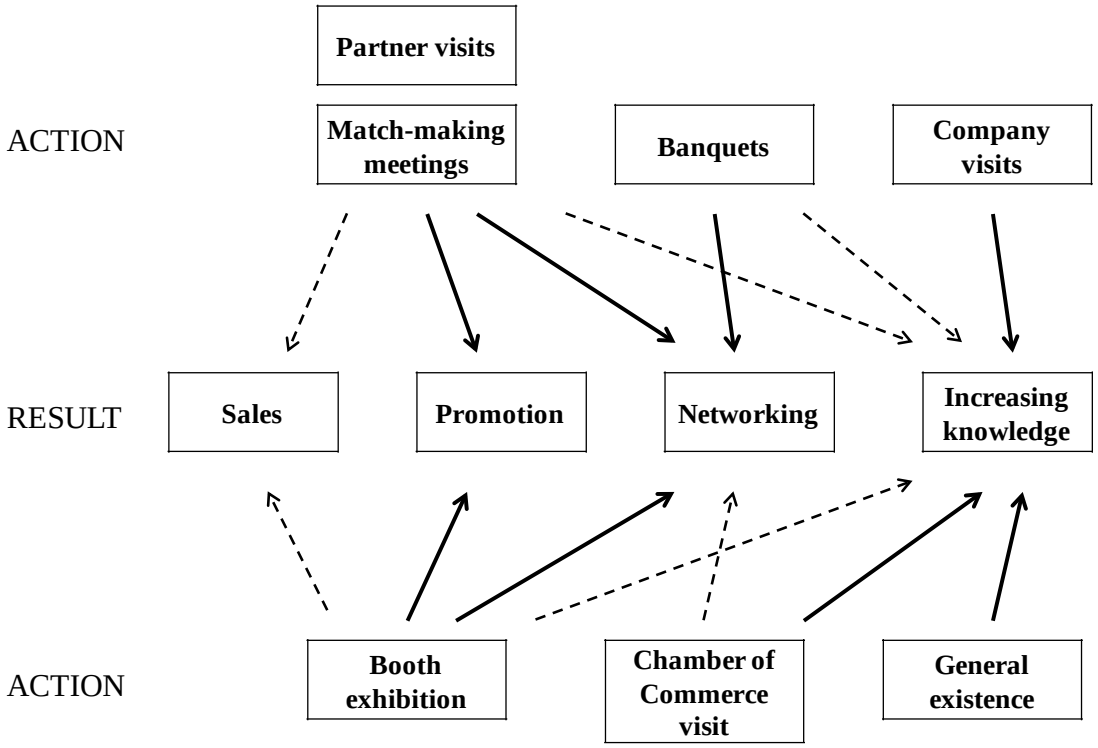

Figure 2: Potential strength of actions to affect the preferred results in the EUPIC fair.

Increasing sales is one of the traditional objectives, but it is usually related to short-term interests. Promotion, in turn, has more long-term impacts. Whether it is promotion about the exhibiting company in general or its products, it may take months or even years before it impacts sales of the company. Networking follows the same pattern, but its most important features relate to getting access to external resources instead of having direct effect on sales. The fourth common objective is increasing the knowledge and understanding of business environment. It asks for understanding the players, i.e. potential customers, suppliers, competitors, public organisations and in general all the players that may have some kind of influence on the focus company, and their connections to each other and to the focus company. Moreover, for example the rules of the environment, i.e. legislation, and processes of the system must also be understood.

The figure 2 depicts the relation of actions and potential results in the fair event, and in this case all the support activities are also included, not just exhibiting. The thickness of arrows corresponds with the relative strength of each action on the results. However, it has to be noted that some of the results are more preferred than others. Therefore the figure is like a mix of theoretical outcome of a situation where all the results are equally preferred and of practice which takes account the nature of the companies and the fair affecting the objectives. For example, because the case companies overlooked the sales objective and its relevance was not high in the theoretical part, its importance is minimised also in this figure. In some other circumstances and with some other companies it would have got more attention.

The figure is mainly based on the researchers' observation during the fair but the interviews of the case study are also utilised. Next, a detailed analysis is conducted about the actions and results, and their relation to the factors introduced in the synthesis of the literature review. Because the objectives of the case companies and their actions were very similar, the analysis proceeds action by action, not case by case. However, some notes are raised from the cases as well if they bring additional value for the analysis.

As the case companies have somewhat long-term objectives for the fair, promotion is generally ranked before sales in importance. Match-making meetings impact thus mostly on promotion and networking; sales may have some kind of effect in the future. Partner on-site visits are seen to have same kind of effects on results as match-making meetings. The meetings and partner visits were quite long, from 30 to 90 minutes, so there is enough time to make initial steps in establishing a relationship and plan future collaboration. The meetings also increase knowledge and understanding of the business environment because of familiarising with the players and learning how they operate in the environment. They could actually have even stronger impact, if the objectives are favouring this matter. For example, Flowman had the on-site visit with one of the companies from the match-making meetings, and the only objective of the visit was to gain information about the media industry in China and find out how it is possible to make business with them.

Two banquets were held during the fair: a cocktail party in the first evening and a gala-dinner in the last day of exhibiting. The banquets were organised by EUPIC and only the European participants and their hosts could join the events. No significant result was gained except for Micropolis who could familiarise with some European companies and non-profitable organisations. Again, the results are very dependable on the exhibitors, and what objectives they set and how strongly they pursue for them. Anyway, an increased network is a probable outcome after a banquet. It can be said that banquets yield also knowledge but it is particularly because of the increased network that acts as a source of information.

Besides Hitmedia's visits to its match-making partners, the whole delegation visited three Chinese companies which were all large corporations in the high-tech industry. These companies and the case companies did not have any interest to make business with each others, but the purpose of the visits was to get known to their success stories, best practices, factory arrangements, etc. As they have years of experience of successful business, they certainly could provide hints how to exploit the huge size of China's domestic market and wide variety of suppliers. The visits were generally found interesting, probably due to their uniqueness as most of the visitors had not visited Chinese companies before, and due to the insight information they offered.

In addition to the Chinese companies, one Finnish company was visited. This visit was a bit disappointment since the Finnish executive manager could not host the delegation as was planned. He was supposed to enlighten especially the challenges the company has encountered in its operations in China. The delegation made also a visit to the chamber of commerce, which gave general introduction about the province and about China's investment policy regarding its western parts, including Chengdu.

The trade fair was quite poor as an exhibition since it could not provide enough visitors. Low traffic was a consequence of the cancellation of another, remarkably bigger trade fair, and the EUPIC event had to act on its own. If the number of visitors had been greater, definitely better results would have gained since several other factors supported this fact. For example, the booth worked well for promotional purposes and part of the case companies raised serious interests at least in relation to the low number of visitors. Flowman is an exception in this sense, because the features of its industry set certain challenges to conduct business in China. Besides promotional results, booth exhibiting could have impacted severely on networking as well, considering again the greater number of visitors. On the other hand, the companies could give much time for their few visitors. The three sub-processes of relationship learning, information sharing, joint sense-making and relationship-specific memories, by Li (2006), can thus be actively advanced, even though all the contacts are new ones. Moreover, as all kind of communication and common activities with the Chinese creates knowledge about the business environment, booth exhibiting cannot be without affecting this matter. Booth exhibiting may also have direct influence on sales in addition to three above mentioned indirect ways: promotion, networking and increase in knowledge. As a conclusion, the role of booth exhibiting as the most versatile tool of trade fairs is valid even if the number of visitors remains low.

During the trip the participants saw and heard things about the Chinese culture and the business environment that improve their awareness and enable them to conclude why certain matters occur in a certain way. Thus the whole trip itself enhances experiential knowledge and diminishes psychical distance to China. Knowledge can be acquired about companies, the city, the country etc. Therefore just by being there company managers can discover new business opportunities or get new ideas for their operations. For example, the vast population of China is often discussed topic in Finland. But when you actually see the masses of people or the technological advances in Chinese cities, it is possible to truly understand the whole potential of Chinese markets. In the end, all the information accelerates the internationalisation process that companies are planning to follow.

RQ2: How the participation could have been improved?

The general idea of the participation was that DIEM takes care of the practical arrangements and consults the companies about their needs and wants if necessary. After the fair DIEM would handle the follow-up if necessary. Figure 3 represents activity of DIEM and an average case company to the whole participation process as the researcher sees it. Only minor differences were discovered in the case companies' activity. The actual, occurred processes are depicted with the solid line and the target processes with the dash line. The participation process is divided in three phases: preparations, trade fair and follow-up. The biggest problems relate to preparation and follow-up phases. Each phase is separately discussed below.

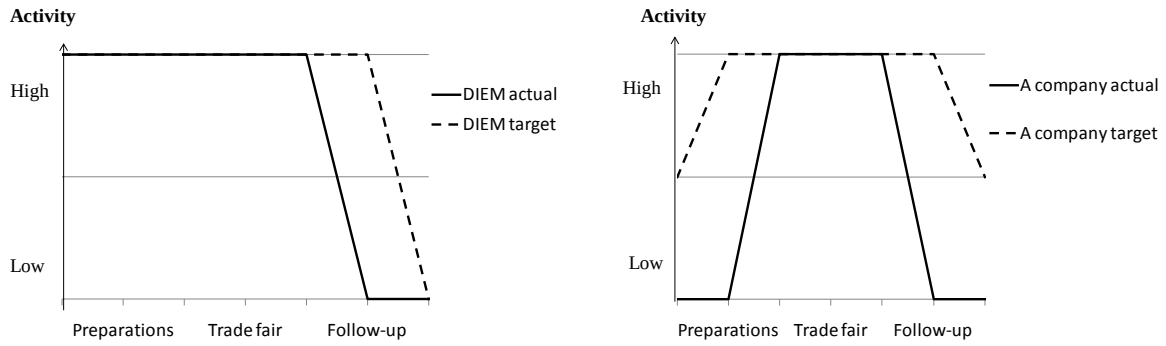

Figure 3: Actual and target activity of DIEM and an average case company during the participation process

The preparation phase

A fundamental problem during the preparation phase was that it was too much on DIEM's responsibility. This was due to the facts that the trade fair event was already familiar to DIEM from the previous year and preparations become most efficient when centrally conducted. Furthermore, the case companies were SMEs, and therefore did not have many resources to be allocated. Managerial time is perhaps the best factor to depict the low commitment but also the participation price, which barely covered the transportation costs, made the participation supposedly too effortless. The reason why commitment of the participating companies should be increased is not that DIEM needs more help with in the preparation phase. Instead, if the companies are planning to continue their business in China, they should consider the learning possibilities that the whole participation process, not just the fair itself, provides. Someday, they may have to arrange the whole participation by themselves. Hence, DIEM should somehow increase duties of the participating companies if this kind of delegation will be organised again in the future. The suggested activity increase during preparation phase can be seen in the figure 3.

In conclusion, there are several conditions for the actions the companies should conduct. First, the actions should enhance learning experience. Second, only small amount of resources can be allocated. And third, the efficiency of arrangements should not be remarkably affected. On the other hand, the learning experience must be absolutely higher with bigger amount of resources allocated.

Eventually, the above mentioned problem is actually finding a balance between learning experience and the allocated resources, still paying attention to the third point and to the fact DIEM's preparation actions made the joining quite trouble-free. All the case companies and their managers in the fair have participated fairs before. Consequently, training concerning trade fair participation in general is not the top priority even though it was mentioned in the theoretical part. Instead, as part of the managers have only little experience of the Chinese people or culture, training in this regard is necessary. It allows the managers to focus on essential issues during the fair and make observation on things that they know may yield long-term benefits as form of experiential knowledge. DIEM could easily take care of the training as it already is somewhat experienced trade fair visitor (altogether second participation in this fair) and has knowledge about the Chinese business

environment. Another trainer party could be companies that have already conducted some business in China. These companies could be exploited as mentors to share some detailed hints and experiences of challenges and opportunities in China.

The database provided by EUPIC could be another tool to increase companies' efforts during the preparation phase. The database included potential match-making partners, but it was utilised only in small scale. Although the case companies gave their preferences of the partners they wanted to meet, it would have been significantly more efficient if the companies had looked them thoroughly through. Further, they would have familiarised themselves with the partners they are going to meet.

As the database listed Chinese companies based on their industrial segment, it could offer further business opportunities. The database consists of companies seeking European partners for customers, suppliers, R&D collaboration etc. Thus, Finnish companies could also take partners from their supply chain to exhibit in China. In a big picture, companies or clusters that can provide complete solutions are highly valued in China. If the Finnish companies realise the synergies that a cluster could bring, their chances to succeed are naturally higher. Finding synergies for the participating companies is a topic worth to pursue also for DIEM. This time, the case companies were all from different industrial segments.

Before participating in trade fairs companies should prepare themselves for international business, unless they are participating purely for experiential and informational reasons. In general, the companies should find out how far their internationalisation process is and decide if a trade fair can benefit the company in its current state. Accordingly the companies should devise strategies and business models for international business. Whether they have the strategy or it is still open, the objectives of the fair should follow these matters. For example, Akkuser had not decided its business model for Chinese markets, and therefore its objectives related to finding out information that may help to determine the model. Knowing the Chinese, the fastest, and maybe the most risky, way to get truly functioning business collaboration is to establish a representative office or even a production facility. They are great ways to denote commitment, which is a key to a long-term relationship.

The participating companies should also mind their facade, i.e. web pages, marketing material etc. Hitmedia is a good example of the problems that may occur, if web pages are not finished. As mentioned in the empirical part, Hitmedia did not have Chinese web pages (the same situation with all the case companies), nor it has English version of the registration page so that the Chinese partner could upload content to the web pages. Creating Chinese web pages does not ask for lots of effort, but they may have huge impact on the credibility of a Finnish company and on getting business immediately started. As the web pages are often the first thing to check from the company and English is still poorly understood in China, Chinese web pages are almost a necessity for successful business in China. At least they can remarkably accelerate the business.

Trade fair phase

No significant problems, which could have been avoided, occurred during the fair. For example, Akkuser did not have a representative, but it was unavoidable. The following

improvement suggestions may gain significant results, depending on the company and the fair it is participating. The suggestions are considered bearing in mind the "impact-resource"-ratio, i.e. producing efficiently as high results as possible with minimal resources.

Each case company utilised some kind of support material, often their own PowerPoint presentations, during the booth discussion and the meetings. They affected positively the fluency of the discussions and meetings as they could send a clear and consistent message for the counterpart. In addition, the interpreter's work was eased with the presentations. Interaction in general was quite smooth although there were concerns in Akkuser's and Hitmedia's case that how credible representative DIEM, as a university, would be.

A major disadvantage was the missing CEO of Akkuser. The discussions and the meetings went reasonably smoothly even without the CEO, but the problem lies in the fact that the learning effect was quite minimal inside the company. Some notes have been sent to Akkuser to transfer experience and gained knowledge, but the knowledge transfer process can never be wholly completed. However, Akkuser has already some experience of the Chinese business environment due to the fairs it has been participating in China. The minimal learning effect is thus not that critical.

The missing CEO has more remarkable impacts on the relationships to the Chinese leads, though. Currently, the relationships are established between the DIEM employees and the leads. If the leads are still satisfying, relationships should also be established between the CEO and the leads. The trade fair would have been a great platform for this purpose since it enables information sharing, joint sense-making and developing relationship-specific memories, the key issues in relationship learning. Now the DIEM employees experienced these issues, but this kind of experience is rather difficult to transfer. There have been plans that DIEM takes care of the follow-up for Akkuser since the leads are already familiar and Chinese language is needed in the communication.

Visitor classification is one of the important topics emphasised in the theory. None of the case companies practiced concrete classification, where they qualify their leads in some kind of lead form. However, as the number of leads remained low for all the case companies, the absence of classification system does not have a major impact on the coming follow-up work. Anyway, creating some kind of lead classification system requires only little effort, but may become essential if the number of visitors is expected to be greater. Simply put, leads could be qualified based on money and time factors, as discussed in the theoretical part.

Follow-up phase

Figure 3 notes that there is much to improve in the follow-up process. A key notion is to recognise that there is no planned and systematic follow-up-process. A few leads were contacted immediately after the fair, but only by DIEM. Follow-up was not on DIEM's responsibility but contacting the leads was seen to happen most conveniently in this way since DIEM already knew the leads and there was no language barrier between DIEM and the leads. DIEM and the participating companies should decide already in the preparation phase about the follow-up so that the transition to follow-up phase would be fluent and

immediate. Moreover, if a company has implemented a lead classification system, it can help to focus on the most important leads immediately after the fair.

DIEM could compile a follow-up manual of guidelines and best practices during the follow-up phase, no matter if it is DIEM or the participating companies that manage the follow-up process. If there is a language barrier between Finnish companies and leads, DIEM could take care of the follow-up phase. However, the companies should be involved in some level already in the beginning and gradually increase their responsibility so that after a while it is actually greater than DIEM's (figure 3). This is because of the same reasons why Akkuser would have benefitted more if their CEO had participated: the learning effect and established relationships. All kind of communication and collaboration with the Chinese enhance learning about conducting business in China. Later, it is easier to start business and no intermediates are needed. Furthermore, follow-up is a way to deepen relationships and if DIEM continuously contacts the leads, there is a danger that no relationship will be established between the Finnish companies and the leads. The follow-up phase should include continuous contacting with the leads, not just in the beginning. Contacting the leads for any purpose is recommended because it is a way to tell that the company still exists and is willing to collaborate with the lead.

Summary of the research question 2

Figure 4 summarises problems that occurred during the whole participation process. The problems are categorised based on their severity and how easy they are to fix with scarce resources. In the upper right corner are the problems that should undoubtedly get attention. The upper left and lower right corners are also essential. The problem in lower left corner refers to the low number of visitors. It is not very severe since the event provided so versatile side activities and the low number was just an exception because of force majeure reasons. On the other hand, the fair could be changed to some other one, but the good relationship to EUPIC remains the inputs of participation quite low. It is thus difficult to find a more efficient fair especially if the objectives of the case companies relate to promotional and networking matters. A participating company should always find out if its objectives match with the opportunities provided by a fair.

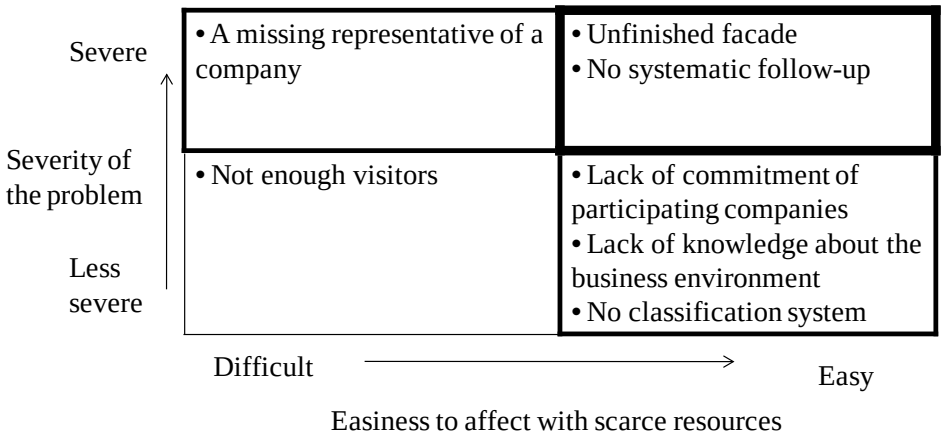

Figure 4: Problems during the participation process

Based on the previous figure, table 2 summarises the tools and actions that should be carried out to solve the problems occurring during the participation. The table presumes that DIEM will organise another delegation to Chengdu, and therefore part of the actions are on its responsibility. Nonetheless, most of the actions can be applied also to companies that are participating in a fair just by themselves.

Table 2: Summary of the improvement tools and actions

Problem	Tool/Action	Accountable
lack of commitment of participating companies	training about the Chinese business environment	DIEM
	finding out match-making partners	companies
lack of knowledge about the business environment	mentoring help in Finland or in Chengdu	DIEM, companies
	cultural training	DIEM
unfinished facade	Chinese web pages	DIEM, companies
	translating other marketing material in Chinese	DIEM, companies
a missing representative of a company	knowledge transfer	DIEM
	involving the company during follow-up	DIEM
no classification system	creating classification system	companies
no systematic follow-up	follow-up manual	DIEM, companies
	starting plannig already before the fair	DIEM, companies
not enough visitors	checking the objectives vs. fair opportunities	companies

Limitations and topics for further research

The case study includes matters concerning only Finnish SMEs. Therefore, it is not straightforward to apply the findings of the paper in companies from different countries. However, as the study was mainly carried out in international stage, the findings can be estimated to be applicable for foreign companies as well, at least for western ones. Next, applying findings in multinational enterprises that already have established their position in the international market is also somewhat precarious. A third limitation is the small amount of the case companies which constrains the generalisation of the findings. And finally, since the Chinese business environment differs significantly from the western one, findings from a Chinese trade fair can differ compared with findings from a western trade fair as well.

As generalisation is a problem in this study, findings are more like guidelines due to the explanatory study. Further studies in similar conditions are needed to verify the results of the study. A study with the same companies is not rational, though, since the situation would not be unique anymore. Figure 1 could also be an initial step for further studies, although similar kinds of studies have already been made. It should be found out that which internationalisation approach' managerial implications fit best for the Chinese context and the effect of internal and external factors on entry mode. For example, international new ventures are one of the newest approaches but they partially ignore psychical distance which is an important determinant in the Uppsala model.

ABSTRACT

The paper analyzes five Finnish case companies to study the sourcing process from China. A framework of a six-stage sourcing process is developed which include finding and choosing supplier, making contract and orders, production and quality control, logistics, purchasing inspection and the development of supply chain management. Each stage describes the activities from the channels of seeking suppliers to the cooperative areas for further development. The case study illustrates the practices of sourcing from China are actually quite similar with the sourcing process in other countries. The study highlights that quality control is the core issue in the process of sourcing from China. Moreover, the difference in understanding of sustainable quality affects the activities of supplier screening and quality control. Close cooperation on quality control is the key activity to manage supply chain in order to increase the competitive advantage through sourcing in China.

Keywords: sourcing process, Chinese supplier, case study

INTRODUCTION

Managing the purchasing task in the supply chain has been a challenge in the last decade for many corporations (Karpak et al. 2001) Supply chain management is not just a domestic phenomenon. Supply chain transcends national boundaries, imposing the challenges of globalization on managers who design supply chains for existing and the new product lines (Meixell & Gargeya 2005). The catalyst for global sourcing has been the worldwide competitive pressure forcing firms to reduce costs and to improve quality and responsiveness (Gelderman & Semeijn 2006). Global supply chains are more difficult to manage than domestic supply chains. Substantial geographical distances in these global situations not only increase transportation costs, but complicate decisions because of inventory cost tradeoffs due to increased lead-time in the supply chain (Pennanen et al. 2011).

Interest in China has soared in recent years because of the booming economy (Pyke et al. 2000). Due to economic growth of China and the increasingly global competition, China is gradually becoming an attractive sourcing destination rather than merely a market for many foreign companies (Campbell et al. 2004), especially in the case of manufactured products and components (Enderwick 2009). Moving the sourcing activities to China is a challenge for the foreign companies because of various difficulties, such as intellectual property infringements, customs delay, poor communication between headquarters and suppliers (Campbell et al. 2004); quality fade ((Enderwick 2009); unpredictable inflation rates, problems of government intervention (Mentzer 2001); and long geographic distance and increased delivery time (Fredriksson & Jonsson 2009). Although low cost is main motivation for sourcing in China (Salmi 2006), the degree of cost advantage is also a concern (e.g. Salmi 2006) when decreased delivery precision may increase costs in terms of expedited freight, unfulfilled demands, extra inventory, and managerial time spent on "fire-fighting" (Fredriksson & Jonsson 2009).

Although many hurdles are in sourcing from China, well organized procurement practices is a source of competitive advantage when the foreign companies have strong ties to supplier in China and adopt best practices that cut operating costs and improve lead time (Campbell et al. 2004). Therefore, mapping a good sourcing process is an important concern for the foreign companies when moving sourcing activities to China. The question of "how to start and operate" is usually proposed by many practitioners taking advantage of cost competitiveness.

Zhang & Goffin (2001) summarize that research focuses of supply management are in the areas of supplier selection and evaluation; sourcing strategy; developing relationships with suppliers; contextual issues influencing supplier management; and supplier management in Chinese IJVs. The study of Zeng (2003) shows that there are very limited studies on sourcing process design and management. This paper focuses on the sourcing process of supply chain management (SCM) with Chinese suppliers. The research questions are how to develop sourcing activities with Chinese supplier and what the activities of the sourcing process from China are. The scope of the study covers from the channels of finding suppliers to the interactions in the sourcing process. The objective of the research is to develop a framework of sourcing process based on the experience of Finnish case companies with Chinese suppliers. The purpose of the study is to facilitate the sourcing process of supply chain management.

The rest of the paper is organized as below. The part of literature review presents some studies on sourcing process. The section of research design introduces the selection of research methodology, the collection and analysis of data. Then, cross-case analysis is discussed after the empirical study describes the practices of five Finnish case companies sourcing from China. The final part consists of the concluding remarks, research limitations and further study.

LITERATURE REVIEW

Supply chain management is the integration of key business processes from end-users through original suppliers that provide products, services, and information and add value for customers and other stakeholders (Min & Zhou 2002; Cooper et al. 1997). SCM is the process of managing relationships, information, and materials flow across enterprise borders to deliver enhanced customer service and economic value through synchronized management of the flow of physical goods and associated information from sourcing to consumption (Mentzer 2001). Purchasing is one of the strategic functions with the highest potential impact on a firm's long term profitability (Quintens et al. 2006). Van Weele (2005) defines purchasing as "the management of the company's external resources in such a way that the supply of all goods, services, capabilities and knowledge which are necessary for running, maintaining and managing the company's primary and support activities is secured at the most favorable conditions". The scope of purchasing has increased from buying operations to supply management (Salmi 2006).

Referring to Van Weele (2005), procurement, purchasing, sourcing and supply management can be used interchangeably. Therefore, the terms are homogenous in this paper.

Quintens et al. (2006) conceptualized the purchasing process, and defined four phases: (1) the investigation of purchase markets and the screening of potential suppliers, (2) the selection of supplies, (3) the negotiation and contraction, and (4) supplier evaluation and follow-up. Coordination of purchasing encompasses the creation of purchasing synergies from economies of scale, scope, process, and learning.

Van Weele (2005) illustrates the main activities within the purchasing function and the purchasing process model (Figure 2). These activities aim at (Van Weele 2005):

- Determining the specification of purchasing goods and services in terms of required quality and quantities.
- Selecting the best potential supplier and developing mechanism to be able to do this.
- Preparing and conducting negotiations with the supplier in order to achieve an agreement and the legal contract.
- Placing the order with the selected supplier or to develop efficient purchase order and handling routines.
- Monitoring and control of the order to secure delivery.
- Follow-up and evaluation on the elements of setting claims, keeping product and supplier files up-to-date, supplier rating and supplier ranking.

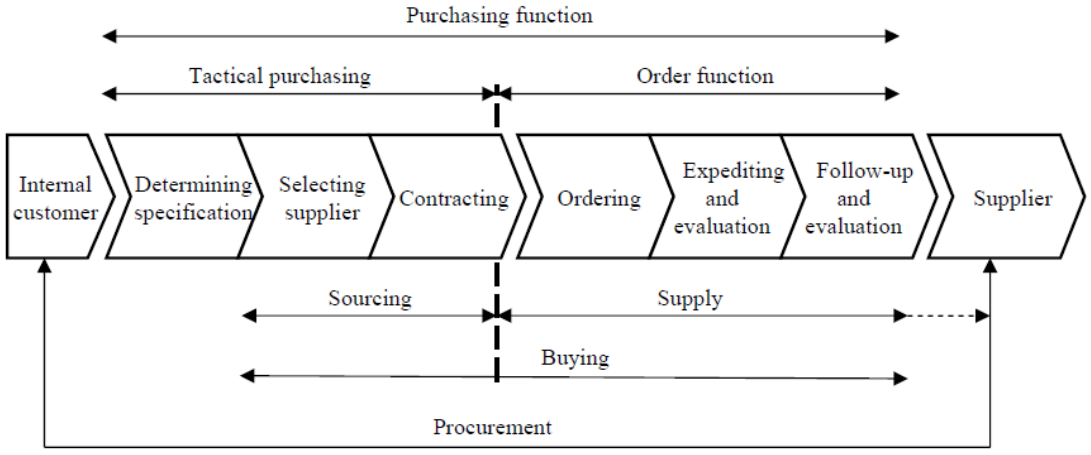

Figure 1: Purchasing process model (Van Weele 2005).

Zeng (2003) summarizes some studies on the sourcing process to form a five-stage sourcing process, which includes investigation and tendering; evaluation, supplier selection & development; implementation and performance measurement & continuous improvement. Figure 1 lists the activities in each stage of the sourcing process.

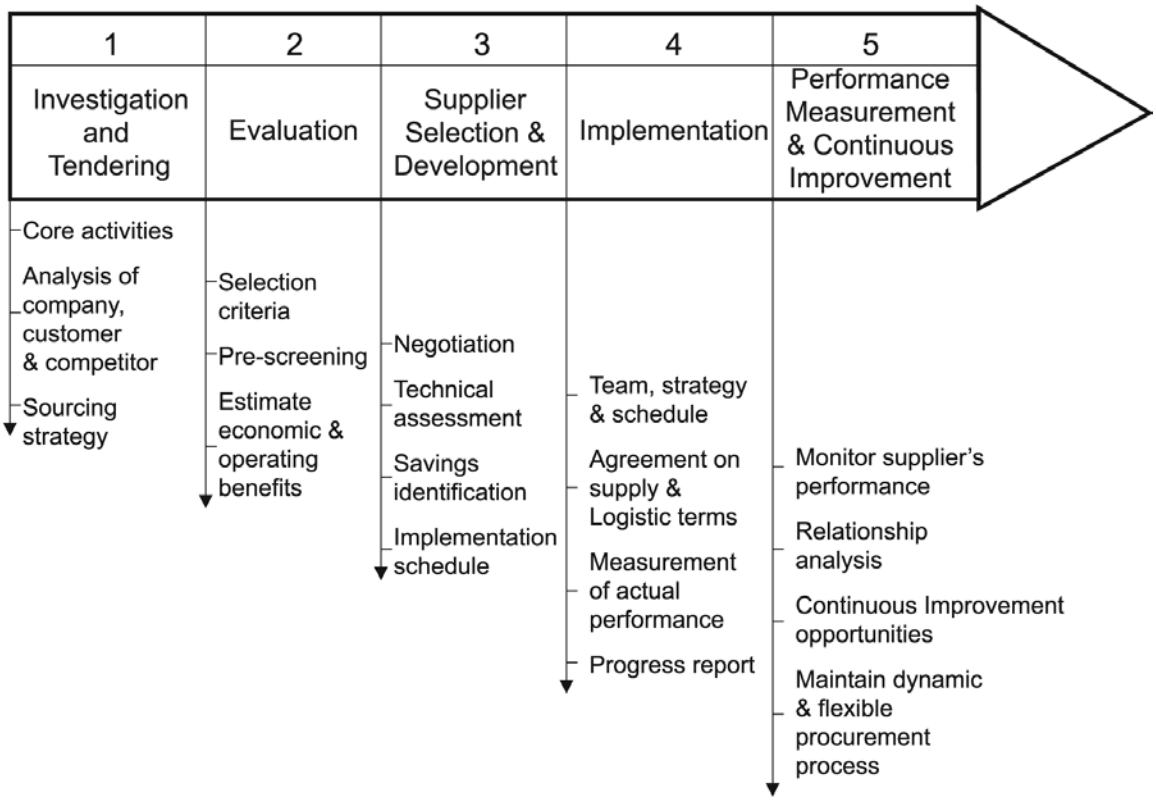

Figure 2: A generalized five-stage sourcing process (Zeng 2003).

Trowbridge (2006) identify eight optimal stages of sourcing process, which include preparing for strategic sourcing, profiling the category, developing category sourcing strategy, generating supplier portfolio, competitive selection or supplier development, selecting competitive suppliers and negotiate, implementation and continuous improvement. Trowbridge (2006) lists a set of activities in each stage which are believed to progress a solid sourcing process. Table 1 lists the activities of each stage.

Table 1: The stages and activities of sourcing process (Trowbridge 2006).

Stages	Activities	
Preparing for Strategic Sourcing	• Do we have a sourcing project? • Selling early procurement involvement • Internal customer needs – a comparison of needs • Internal customer relationship management • Common procurement myths	• Developing a marketing plan • Internal customer marketing support tools • Establish steering committee & sponsor team • Establish cross-functional team • Project plan preparation
Profiling The Category	• Getting started with the strategic sourcing process • Defining the sourcing category • Identify basic category characteristics • Collect and analyze basic information • Expenditure analysis • Request for information (RFI) • Stakeholder interviews	• Process review and mapping • Total cost of ownership identification • Cost reduction/opportunity development • Market analysis • Market segmentation identification • Defining balance of power in the supply market • Sourcing category evolution
Developing Category Sourcing Strategy	• Definition of sourcing strategy • Category positioning matrix • Factors determining buyer power and category criticality	• Opportunities for creating value from strategic sourcing • Strategic sourcing approach • Positioning the sourcing category
Generating Supplier Portfolio	• Supplier portfolio generation • Developing the candidate supplier list • Supplier types • Supplier capabilities • Source location • Supplier profile • Identification of potential suppliers	• Developing the short list of prequalified suppliers • Evaluation criteria and methods • Data collection • Request for information • Supplier evaluation summary • Stakeholder “buy-in”
Competitive Selection or Supplier Development	• Selection of implementation path • Identification of preferred supplier(s) • Supplier development and the strategic sourcing process	• Supplier development constraints • Negotiation strategy – competitive vs. collaborative
Selecting Competitive Supplier(s) and Negotiate	• Preliminary strategy formulation • Proposal generation • Developing the request-for-proposal (RFP) • Proposal solicitation and evaluation • Potential post-bid problems • Post-bid strategies	• Negotiations overview • Negotiation goals • Negotiation strategies and methods • Preparing for negotiations • Negotiation tools • Negotiation process
Implementation	• Key implementation activities • Key implementation factors • Cross functional team roles and responsibilities • Communication needs	• Cost savings calculation and tracking • Savings spend baselines • Cost savings tracking key elements • Savings calculation methodologies • Utilizing the market basket approach

	• Communication methods • New process implementation	• Baseline savings reporting approaches
Continuous Improvement	• Continuous improvement activities • Continuous improvement monitoring • Key contract administration players • Tips for pro-active contracting • Monitor performance – benchmarks	• Progression in supplier relationships • Supplier performance rating system • Supplier performance criteria • Supplier performance reporting • Benchmarking

Literature review shows that the studies classify the stages in the sourcing process (e.g. Quintens et al. 2006, Zeng 2003, Van Weele 2005) and identify the activities in each stage (e.g. Trowbridge 2006). The major stages of the sourcing process include supplier selection, purchasing implementation, performance of supplier measurement and further development. Trowbridge (2006) provides a detailed check list of sourcing process on the practical level. The stage identified by Trowbridge (2006) comprises more preparation activities on strategic level and an in-depth analysis of internal sourcing management.

RESEARCH DESIGN

Research methodology

The paper proposes "how" question to study the supply chain management of the Finnish companies when using Chinese suppliers. The research intends to reveal descriptive and exploratory information in order to understand the practices and process of the supply chain. The research purpose leads to choose qualitative method first to better understand the phenomenon remaining unknown; second, to gain new perspectives on matters already well known; and third, to gain more in-depth information that may be difficult to convey by quantitative means (Strauss and Corbin 1998).

Case study is a typical qualitative method to conduct on "how" or "why" questions, especially when the investigator has little control over the events or, when boundaries between studied phenomenon and real-life context are not clear cut (Yin 1994). In the study, a multiple-case approach is utilized. The purpose to using multiple cases is to produce analytical generations of the findings (Yin 1994).

Case companies

There are five case companies from Finland in the study. Four are located in Vaasa region and one in Vantaa. The case companies are contacted by two authors of the paper. The case companies in Vaasa region were selected only on the condition that the case company conducts sourcing activities from China without any own subsidiary in China. The case company in Vantaa was from a project work to study the internationalization process of Finnish company to China. The case study found that the company mainly conduct sourcing activities from Chinese suppliers. A representative office was established in China after 17 years sourcing from China. The company has sourcing experience from China for about 20 years. The four case companies

in Vaasa are SMEs. The one in Vantaa is a group company. All the case companies are in manufacturing industry (Table 2).

Data collection

The data are collected through interviews with the management personnel or the owner of the case companies. Table 2 lists the relevant information of the case companies and the interviewees. The names of the case companies and the interviewees are not disclosed in the paper.

Table 2: Case companies and interviewees.

Case company	Business area	Souring items	Interviewee
Case A	Sports clothes	All tailor-made clothes	One of the owners
Case B	Plastic components	Moulding production	Project manager
Case C	Product development service	Semi products, cables, parts and connectors	The owner of the firm
Case D	Cabin of agrimotor	Metals, glasses, tire products, coupling gears, steering wheels, lights etc.	Purchasing manager
Case E	Machine building	Tailored products and standard products	Managing director

Two questionnaires were used in the data collection. One questionnaire was used for four case companies in Vaasa region. The other questionnaire was used for the case company in Vantaa. The reason was mainly due to the researchers had focused on different aspects of project tasks at the moment of conducting the interviews. Despite the different means, the paper utilised the five cases as they arrived the same end to reveal the practices of sourcing process with the Chinese suppliers. All the interviews were conducted in the companies' premises in 2010.

Data analysis

The paper is a part of project and a combination of a Master thesis work and the project work. The four case companies in Vaasa region were analyzed through a theoretical framework in the Master thesis developed by one of the authors. The Master thesis is regarded as a report of case study as it provided detail description of the case companies and their practices of sourcing from China. The analysis of the case company in Vantaa was follow the same analysis framework of the other four case companies in order to keep construct validity by establishing chain of evidence and having key information from the interview transcription (Yin 1994). This paper focuses on the practices of sourcing process of the case companies. The theoretical part of the paper is developed based on the specified topic.

EMPIRICAL STUDY

Case A

Case A is a Finnish company that specializes in clothes that are especially adapted to fit the customers' needs of training and competing. The company works closely with different athletes and sports clubs in order to make custom made training- and racing clothes. It makes design work according to the customer needs. The company purchases all sporting clothes designed for the customers. So far, it has five suppliers in China.

Originally, the company purchased sporting clothes from Estonia in 1999. The price level started to grow very quickly after Estonia became member of EU (European Union). The company started to swift supplier from Estonia to China because of the low labor costs, material costs and Chinese know-how of garment industry.

One owner of the company had a friend working in China. Choosing the supplier was quite easy because the friend in China was familiar with the culture and had connections to the Chinese supplier in garment industry. The company started the collaboration with Chinese supplier in 2004. According to the company, it is good to have a local partner because they usually know how to do business with Chinese. The best way to find trustworthy supplier is by creating contacts with Chinese people. In Chinese culture, relationships are highly respected. Local people may know someone, and that person knows someone who might be important person in finding a decent supplier. Local people may have really strong ties with centrally placed actors in that specific industry. Also a good way to find a supplier is to go through different fairs and, for instance local website, (www.alibaba.com), where all the suppliers are listed.

Even though the cooperation with Chinese suppliers has been success, there are still quite much complexities and problems. Chinese people are not so assertive as compared to Western people, especially Finnish, and they don't always keep their promises. The company takes care of quality control itself. The company has one employee in China who visiting once in a week in the factory. He makes sure that the clothes have the right quality. The finished clothes are not leaving from the factory without quality control.

Delivery reliability is a problem all the time. Deliveries are usually late, and then company and the supplier have to decide who is paying the cost by delay. Clothes that are delivered to sports clubs goes first to Helsinki and then to customers. Those clothes are not going through the company. Clothes that are delivered to retailers go first to the warehouse of the company and further to customers after the quality control. The company takes care of research and development. It does not have collaboration with supplier in that area.

The company has two market segments – sports clubs and retailers. Sports clubs' orders are usually easier to handle, and the order to the supplier is done via email. The delivery time is approximately two months. More complexities are including in the retailers orders. Retailers are usually sports stores and they want to sell their own inventory first before they are

willingness to order more. This causes problems to the company because they should know as early as possible the retailers' orders. The order should come at least nine months before the delivery, but usually the company receives the order six months earlier than the desired delivery time. Therefore, it is quite complex to make the orders on-time.

Several things that could develop the supply chain between Chinese suppliers were found by the company. Automation is one of these. It was hoped that in the future the company could control the manufacturing process. It would clarify how the process is going further and when the delivery is going to be late. At this moment it is not possible and usually the late delivery is informed too late. Information goes via email and the company doesn't have an access to suppliers' databases. It takes a lot of time and effort to maintain good relationships with suppliers but it is worth it. The company is planning to build up an own factory and own brand store but these are only in the planning phase.

Case B

Case B is a manufacturer offering injection and reaction injection moulded plastic parts from single products to part assemblies. The company purchases moulds of ready for the production from China. They also purchase different raw materials and so on, but mostly the focus is on moulds.

The cooperation with Chinese suppliers started because of the growing competition. The company needed to be cost effective as well when competitors were purchasing cheaper from China. At the same time, the volumes started to grow; outsourcing has been very effective way to handle the situation so that the company has been able to concentrate on service, product changes and product development.

Originally the company had purchasing activities from other countries, but nowadays all these activities are focused on China. Motivation for purchasing from China was based on costs, the lack of suppliers in other countries, delivery reliability, precise culture, Chinese huge efforts of their way of working and knowledge of technology. The Company participated in industry fairs in China. They also searched suitable suppliers from the internet, and in that way they found the most qualified suppliers. Nowadays the company has wide connections to China but only couple of key suppliers, mostly in Shenzhen.

The company has only positive experiences of cooperation with Chinese suppliers. They have long-term relationships with suppliers and the cooperation is working smoothly. The company believes that it is important to visit in China and see the suppliers face to face. The most important factors when doing business with Chinese companies are quality, price and the fluency of cooperation. According to the company, working with Chinese is fluency, flexible and organized. Chinese are also taking care of documentation coordination and that is very effective and well organized. That is especially useful when something needs to be checked. The amount of suppliers has grown but the company still has, more or less, cooperation with all its suppliers.

Even though company has key suppliers, it is purchasing every now and then from other suppliers to keep the cooperation alive. The purchasing process starts from customer's order. First the company discusses with customer and finds out customer's needs. This is an impulse that needs to happen before purchasing activities from China can start. Delivery times are usually more than five weeks, but with the most complex parts the delivery time can be eight to nine weeks. The company hasn't had any problems with delivery times and the deliveries happen when they are supposed to happen. Company receives the report on weekly basis from the suppliers about the progress of manufacturing process and usually the company knows when the delivery is going to happen. Information sharing is handled via email or Skype. That is the easiest and the cheapest way to communicate. It is also easier for Chinese to use email, because their written English is much better than the spoken one. Every key supplier has own contact person who is speaking English and Mandarin, and who can translate all the needed information. That person is also acting as a link to the technical personnel.

The company is taking care of logistics and they are using both sea transport and air transport. The way of transportation is choosing according to the weight and size. The bigger parts are transported by shipping, because it is much cheaper than flying. Logistic decisions are made by case-by-case. The cost of the transportation varies according to who is booking the transportation. Usually it is cheaper when the booker is Chinese. They are not using couriers but they are booking straight from the shipping company. This means that they also have to take care of taxes and customs. Chinese suppliers are delivering products to the harbor but after that the responsibility transfers to the case company. The company and its suppliers have no access to each other's databases, and the impulse to the purchasing comes from customers' order. The company is doing collaboration with Chinese suppliers in R&D. the case company is sending raw materials to China for testing. After testing, Chinese suppliers are sending these test parts back to Finland with testing reports. In Finland, moulds are having another test drive before the implementation and transferring to the production.

The case company has specified the quality strategies for all its suppliers and how they should work to fulfill the quality requirements. Suppliers are sending different kind of quality documents to the company when needed. The case company is taking care of quality controlling when the products are arriving to Finland. For the ready products the case company is doing different kind of quality measurements, for example hardness measurements. The case company is very satisfied to the cooperation with Chinese. They don't have any specific development areas in mind, but one suggestion would be recruiting own employee to China but that is only development proposal.

Case C

Case company C offers product development services primarily for companies that design and manufacture electrical equipment. Additionally, the company produces and sells its own ergonomic and energy efficient products. The company purchases different kind of semi products, cables, parts and connectors. Purchasing part of net sales is approximately 3000 Euros and China's part of this is 500 Euros. Western firms are not offering qualified suppliers

and that's why the company had started to find suppliers from Chinese markets. The company has searched suppliers from the internet and has contacted the companies that would be the most qualified. Contact has happened via email. Because the amounts of orders are not so significant, the company feels no need to visit in China. Email is the best way to communicate with Chinese and they are very active in that field. The case company has now only one supplier. It uses couriers for logistics. Couriers are taking care of taxes and customs and they are transporting products from door to door.

The case company is now developing and producing its own products and has a lot of ideas for the future. The company has now purchased USB-cables from China and the production is going to start in Finland. The company has a stockpile because it is easier to purchase larger batches at the same time. According to the company, it is very important for Chinese to visit in China and see the supplier face-to-face. Now when there has only been one supply from this supplier, it is not yet necessary to go and visit in China but if the cooperation continues it would be the next step in the development of cooperation. The company just trusts that the supplier can handle its work. Quality control takes place in Finland when the components have arrived. The company does not have an employee in China who could take care of quality control. It has just buyer-supplier relationship with its supplier and they are not doing more collaboration.

The biggest problem in collaboration with Chinese is communication. Chinese people are not speaking English very well and they are not so willing to take advices from another people. Quality, price and Chinese active way of working are still the biggest reasons to choose Chinese supplier. Chinese people are also very friendly and it is nice to collaborate with them. The case company hasn't had any problems with delivery times with its supplier.

Case D

Case company D is a manufacturer to produce cabins for tractors. The company purchases metals, glasses, tire products, coupling gears, steering wheels, lights etc. from China. Approximately 50 percent of purchasing comes from abroad and China's part of this is 17 percent. The company started first purchasing from China in 2004 through one European company who had relationships to Chinese suppliers. The company has found their own suppliers by visiting in fairs, and by using different contacts. Usually someone knows someone who could be a qualified supplier. Chinese business people have some much contact, so it is easier to search suppliers with the help of local people.

Price has been the main reason for purchasing from China. However, the company has not chosen the cheapest suppliers because they also require a good quality. The company is doing cooperation with every supplier. Changing the supplier usually takes from one to two years. It takes time and energy to develop long-term and trustworthy relationship with new supplier. This is the reason why the case company has chosen their suppliers very carefully in the first place. The company really wants to have long-term and close relationship with every supplier.

In general, the case company hasn't had any problems with its suppliers. The only problem was with one supplier who had financial problems and which led to its bankruptcy. In transportation, the case company uses DDU (delivered duty unpaid) Hampurg and DDU Mäntyluoto. This means that Chinese supplier pays all the costs until the product is delivered to the destination. The case company pays all the taxes and customs of the destination country. When the products are delivered, the company has a purchase inspection. If there are nonconformities in the product, next incoming delivery will go through different measurements.

The case company has four suppliers and three material controllers. They have production management system which is producing different kind of purchasing proposals. However, purchase orders are not transferred automatically to suppliers' database but the orders are being made manually. The company is doing the orders and Chinese suppliers do not have the access to the production management database. Cooperation with Chinese is different only because of the long distance. The process is the same as with Finnish or European suppliers. The company is just doing orders little bit earlier to China than to European suppliers. The company has two weeks stockpile for the products ordered from European countries and one month stockpile for Chinese products.

Communication happens mainly via email. The purchasing manager of the company travels regularly to China and spends two weeks there. The company is doing collaboration in R&D with its suppliers. It gives specific requirements for products and defines also customer's requirements. Chinese are designing products according to these guidelines and produces the final products for the case company. Planning work is done in Finland and designing in China. In the future the goal is to have closer relationship with suppliers. Both Finnish and especially Chinese respect to long-term relationship. The case company would like to have more cooperation in R&D and they are going to put a lot of effort on that.

The case company hasn't been any problems and the supply chain works between Finland and China the same way as with Finnish suppliers. The case company has been very satisfied to its suppliers. The suppliers were chosen very carefully and vendors' know-how is in excellent level. Chinese work moral is very high which has affected to the level of satisfaction. Chinese are also very committed and accurate. They really respect their customers and are willing to do more for satisfied customers. For Chinese, the most important issues are customer satisfaction and value adding. The case company prefers to choose all their suppliers from Asia, if the distances would be shorter. The case company has been very satisfied for the fluent supply chain, and they don't see any reason for changing anything crucial. One thing to approve would be the storage, because it is causing a lot of costs. The case company expects that suppliers should take more care of warehousing, and in that way they could share the costs of warehousing more effectively.

Case E

Case company E is a group company to provide individual components, semi-finished products, assemblies and demanding equipment in the machine building industry. The company has been sourcing components from China for about 20 years.

The company is searching potential suppliers from China. It has gone through around 500 of them around China. The company seeks for the Chinese through many ways such as fairs, internet, customers and Finnish intermediaries. The starting point is through its Chinese personnel and their friendship networks. The company used a principle of 'word of mouth' to find out the trustable supplier. Quality and price are absolutely the two important factors when seeking for the suppliers. The company pays attention to the quality standard of the suppliers using in order to evaluate the reasonable quality level of the supplier. Especially, the company would learn and evaluate the quality in the future based on the quality standard.

The company audited potential suppliers and ordered test series and model series. The company is negotiating with the Finnish customers about the types of products would being source from China and what are the customer needs. Then the case company takes care of sourcing and the quality of the items.

The company believes there is no problem in the communication as the company has many Chinese and Chinese speaking personnel. On the other hand, the company also has found also persons capable of speaking English in the sourcing process.

The case company highlights some differences from their intensive sourcing activities in China. First, the challenges have been related to the understanding of the specifications as Chinese technical standards are so different. It causes some problems to the company when explain these specifications to the Finnish customers. In the cases if the company is not able to test the quality of materials internally, it will utilize some intermediary organization such as VTT (Technical Research Centre of Finland) to make the test. The second problem is related to payment processes. The company is usually asked to pay in advance so that the Chinese suppliers are able to buy raw material and produce the product. Thirdly, the company notices that there are differences on the understanding of the importance of quality. The case company states that test product is ordered from Europe, it is considered as how the final product can be produced at the top level of the supplier. In some cases Chinese suppliers take the test products as a kind of the draft of the desired product. The case company has just thought that this supplier is not capable of producing what they want as the test products are bad. However, later on when the supplier finds out that the company really wants to order these, it was fully capable of producing what the company wants. On the other end, in some case the first products received are exactly as the quality requirements, but the Chinese supplier has started to think that also some other kind of quality is good as well. Thus, the supplier would use other type of steel when some specified materials are not available right now. The shortcuts have been made and then the quality of the products has not lasted for long in this cold environment of Finland. The case company believes that some Chinese suppliers do

not understand the importance of sustainable, continuous quality as the quality culture is not well developed. Although the quality level is progressing with high speed in China, the company still finds these opportunistic suppliers who want to make extra money in a short term by making shortcuts. It is the reason that the case company makes close audit on quality assurance on-site in China. It always audit the way of functioning in Chinese companies beforehand. If quality is evaluated sufficient, the company continues to follow closely the level of price development.

The case company expects the improvements in the sourcing from China should be focused on on-time delivery and continuous quality.

CROSS-CASE DISCUSSION

The case study illustrates the practices of Finnish companies in the sourcing process from China. The main tools to find out the potential suppliers are internet, personal contacts, and trade fairs. The case companies have used internet to find information of suppliers. Google is good way to find information and website www.alibaba.com where all the suppliers are listed. Visiting in Chinese fairs is a good way to find contacts and qualified suppliers. It is good to have a local contact because usually they have even more contacts. Chinese are respecting meeting face to face so it is also important, every now and then, to visit in China. The development of personal trust is highly important in China. Guanxi is highly emphasized in China and it means personal relations. Also deep trust is important for successful business relations in China. Regular visits to the country help to create a friendly and cooperative atmosphere, which in turn facilitates the exchange of information, the building of mutual trust and the efficient management of quality control and other supervisory activities. The tighter the links to Chinese partners, the more explicitly relations can be managed.

The orders are made via email. Because of the long distance, companies are usually preparing for longer delivery times and that's why they are doing the orders little bit earlier than the European orders. Email is the easiest way to communicate with suppliers. Chinese people usually write English better than speak it. Chinese suppliers are sending different reports and documents in different manufacturing phases and usually companies know when the suppliers are going to deliver the products. All the companies are doing orders manually, and supplier has not the access to company's database. Orders are not going to suppliers automatically. Logistics is usually handled through couriers or with suppliers. Supplier usually pays costs until the product is delivered to its destination. The buyer pays destination country's customs and taxes. Delivery times have been accurate in three interviewed companies but only one company has had problems with delivery times.

Quality is the central issue when sourcing from China. Purchase inspection happens both in Finland and in China. Some companies work closely to audit the quality of products on-site in China before the suppliers deliver the products to Finland. The other companies are doing the quality control when the products are delivered to Finland. After the inspection, products are delivered to the customers or they are moved to the production line. If a problem occurs, they

are being informed to the supplier, and compensations are going to be made. Only little reclamation is being made, because Chinese products have good quality and they are properly made.

Two of the five case companies are doing cooperation with suppliers in R&D at the current stage. In the future the two companies really expect to further development the R&D cooperation. The other companies may develop the cooperation with suppliers and expand it to R&D. Chinese know-how is in so high level that companies are outsourcing their design pleasingly to Chinese.

The main reasons to choose Chinese supplier are price, quality, know-how and also Chinese high working moral and their perseverance. Due to the increasing competition globally, the companies are subject to be more cost effective. Even though the logistics distances are long, purchasing from China is still cheaper than from the Europe. China also offers a large scale of suppliers when comparing to European countries. Price is tempting, but usually companies are not choosing the cheapest supplier. Quality and price are making a strong combination which is affecting mostly to the choosing of supplier. Good cooperation is also affecting to the satisfaction and continuous of collaboration.

In general, the case companies have been very satisfied to cooperation with Chinese suppliers and also to the fluency of the supply chain. Chinese were described as faithful, friendly, precise, efficient, competent, and organized and they really respect their customers. Besides the communication problem because of language barrier, the case companies illustrate the central problems of on-time delivery and sustainable quality control, especially the differences on the understanding of quality (e.g. case E).

The case study illustrates the practices of Finnish companies in the sourcing process from China. Figure 3 summarizes the stages and activities of the sourcing process.

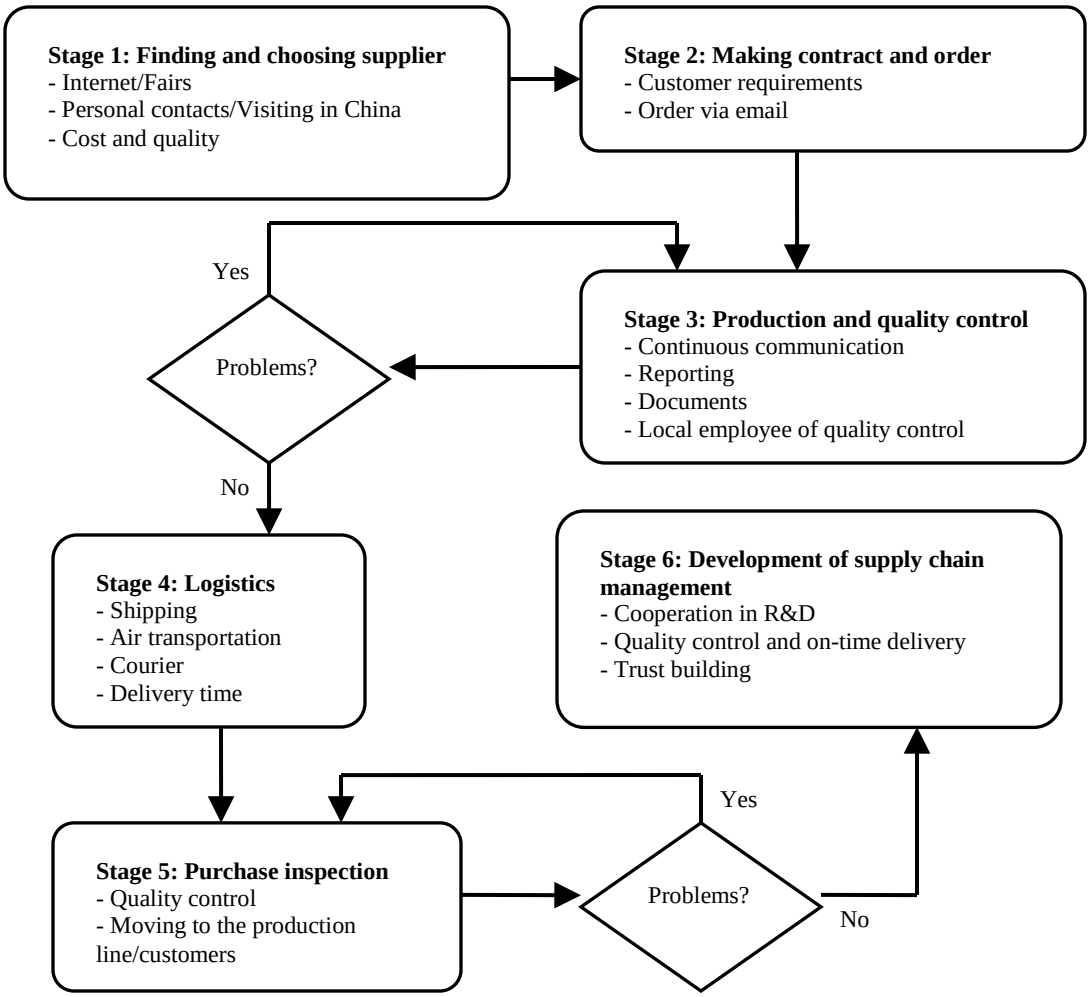

Figure 3: Sourcing process of Finnish companies in China.

CONCLUSIONS

The paper studies the sourcing process of supply chain management through learning the practices of Finnish companies sourcing from China. There are six stages of souring from China in the cases – finding and choosing suppliers; making contract and orders; production and quality control; logistics purchasing inspection and development of supply chain management. The Finnish case companies seek for the potential suppliers through internet, trade fairs, network and a local visiting. Cost and quality are the two main factors to select a qualified supplier. The communication with Chinese suppliers is mainly through email to exchange the quality specification and the information of orders. Quality control is the central issue in the sourcing process. The Finnish companies attempt many ways to guarantee the quality by checking the quality standards of the Chinese suppliers, asking the production report and documentation, and using a local employee for quality control. The problem in logistics focuses on the on-time delivery, although some companies have not suffered the problem of delayed delivery. The case companies make a double check when the products arrive in Finland. The

experiences of the case companies with Chinese suppliers are positive. Both the case companies and Chinese suppliers expect to establish a long-term cooperative relationship in the areas of R&D activities, quality control and on-time delivery. A framework of the sourcing process is developed in the paper (Figure 3).

Theoretically, the case study does not illustrate that the process of sourcing from China is quite different with the sourcing process from the other countries (e.g. Zeng 2003, Van Weele 2005). The major stages of sourcing process are similarity. Compare the study of Trowbridge (2006), the case study also does not reveal many activities on the preparation stage. One explanation can be the case companies already identified China as the sourcing destination. The other explanation is the organizational structure is simple as most of the case companies are SMEs. However, the case study highlights the core activity of sourcing from China is quality control. One more phase focuses on the quality control in the process of sourcing from China. Especially in case E, the company emphasizes there are differences on the understanding of sustainable quality between Finnish company and Chinese supplier. The difference can affect the supplier screening and quality control. The study generates managerial implications that sourcing from China is more or less a continuous process of quality supervision and improvement. In this sense, it is important that a long-term relationship with trustable supplier is built in the process of sourcing from China so that the companies can achieve cost advantage.

There are some methodology limitations in the research. First, all the case companies involved in the study show a very satisfactory sourcing experiences with the Chinese suppliers. From the methodology perspective, the five companies are successful cases. The failure cases are not available in the process of selecting case companies as they do not have any business relationship with Chinese suppliers. Therefore, the sourcing practices may not exhausted reveal all challenges in other situation. Secondly, the findings of the study mainly focus on the sourcing practices when the companies do not have own physical facilities in China. The research results may not be directly applied to the sourcing process of those companies with local production premises in China. For further study, it is worth to exploring the detail study on quality control with the Chinese suppliers. Furthermore, the research is supposed to highly improve the practices of sourcing from China when the companies expect to achieve cost competitiveness.

ACKNOWLEDGEMENTS

The authors are grateful for the project funding supporting by the Finnish Centres for Economic Development, Transport and the Environment (ELY-Keskus) and the European Regional Development Fund. We highly appreciate the companies involved in the study to share their experiences. We also thank the comments from two blind-reviewers to develop the paper.

ABSTRACT

The aim of this study is to describe the experiences of Finnish SMEs (Small and Medium - sized Enterprises) sourcing from China. The study is made as part of CHISU -project (Building an internationalization process for Chinese markets) funded by European Regional Development Fund (ERDF). SMEs are expected to face challenges in international sourcing due to their limited resources and experience in the international business. Moreover, the Finnish SMEs are expected to face context-specific challenges due to their geographical and cultural distance to the market.

This case study seeks to find answers to the following research questions: What are the drivers for Finnish SMEs to start sourcing from China? What kinds of challenges were faced in sourcing from China? These research questions are answered through eight case studies in the Finnish SMEs in which sourcing from China plays a significant role.

As a result of this study, the main drivers and challenges related to the process were analysed and evaluated. SMEs analysed here faced special drivers and challenges related to sourcing from China – more drivers than challenges were pointed out. SMEs could strongly benefit from external support tailored for their context specific needs. The results of this analysis are mainly applicable to the SMEs in Finnish context.

Keywords: international sourcing, internationalization, small and medium sized enterprises, China

INTRODUCTION

This study is part of the CHISU project funded by European Regional Development Fund (ERDF). Economic growth has increased rapidly for many decades and China offers a lot of possibilities for both large and small companies. China is a world's fastest growing economy,

and its economy has grown already almost 30 years (Kettunen et al. 2008). China is the second largest economy in the world after the United States, and it accounts for 7.5 % of the world's total economic activity. This study focuses on sourcing from China. The intention is to support SMEs planning to start collaboration with Chinese suppliers. The focus is on Finnish SMEs.

Multinational corporations have become increasingly interested in Chinese market for goods and services. In China, western firms face a business environment that differs from their home market. However, these firms can to learn about this market and improve sourcing accordingly. International sourcing refers to the purchasing of materials, components, and finished products from foreign suppliers. It thrives from globalization, communication technology, and transport system development, as well as the reduction of international trade boundaries. (Carlsson et al. 2005) These issues have developed rapidly in the Chinese market within the recent history, making it one of the most attractive sourcing markets. Since most big retailers are now sourcing from China, smaller ones typically wonder whether they should do the same, but are often put off by the complexities of getting started. China is the third largest exporter in the world, so there are plenty of serious and high quality suppliers.

SMEs are considered to be an important and integral part of every country's economy, the fastest growing sector of many economies, more flexible and adaptable in terms of structure and having a faster speed of response than larger organizations. (Tagliavini et al., 2001). SMEs are often associated with a higher economic growth of nations (See i.e. Reynolds 1997, Robson & Bennett 2000). According to Beck et al. (2005) the share of SME employment in total manufacturing employment is associated with higher rates of gross domestic product (GDP) per capita growth. The existence of a large SME sector should rather be considered as one characteristic of successful economies. However, in a relatively recent study, Ayyagari et al. (2007) analysed the relationship between the relative size of the SME sector to total employment in manufacturing and GDP across 76 countries. By presenting comprehensive statistics utilising a cut-off of 250 employees, Ayyagari et al. (2007) show that on the average in these countries, SMEs' contribution to the labour force constitute 54% of the economy. The impact of SMEs on employment is significant. On the other hand, compared to large enterprises, SMEs typically have fewer financial resources, lower technical expertise, and more limited management skills (Blili & Raymond 1993). Therefore, it is increasingly important to study SME perspectives to Chinese market. Growth (See i.e. Muhos et al. 2010) is a critical issue for long-term survival of SMEs and development towards large scale companies and sourcing from China may provide opportunities for speeding up this complicated process.

The aim of this study is to learn from the companies that have experience on sourcing from China, and to provide practical guidelines for SMEs. This study may help SMEs to function more effectively and efficiently in Chinese market. More information is needed of how to source from China and what needs to be taken into account. Further, this study aims to clarify the management of sourcing process from Finnish SME's perspective. There are still a lot of complexities in international sourcing. For example long lead times, environmental uncertainty, lower levels of quality, extension of supply lines, delivery risk, cultural differences and sourcing professionals' lack of skills and capabilities are among the biggest

impediments in global sourcing. Sourcing from China may be important to a firm's competitive position as a means to access raw materials, improve quality, lower cost, or access technology.

The research questions of this study can be articulated as follows:

1. What are the drivers for Finnish SMEs to start sourcing from China?
2. What kind of challenges and advantages were faced in sourcing from China?

In this study, the case study was selected as a potential strategy to answer the main research questions. According to Yin (1989, p. 23) *'a case study is an empirical inquiry that: investigates a contemporary phenomenon within its real-life context; when the boundaries between phenomenon and context are not clearly evident; and in which multiple sources of evidence are used.'* Eight case companies located in Northern Finland were interviewed and analysed.

This study consists of five parts. In the introduction the background, motivation, research problem and research questions are presented. In the second, theoretical part of this study, the short introduction to Chinese market, the sourcing perspective, and the most potential drivers and challenges related to sourcing are presented. Third the method of this study is described. Fourth, through description and analysis of eight case studies, the answers to the research questions are provided. Finally, in the discussion part the main results, limitations, and further research topics are covered.

SOURCING FROM CHINA – PERSPECTIVES

China is a world's fastest growing economy, and its economy has grown already almost 30 years (Kettunen et al. 2008). The economic growth started in early 1980s when China opened its markets and after that, many Western companies have been interested in Chinese markets. China is the third largest economy in the world after the United States and Japan, and it accounts for 7.5 % of the world's total economic activity. The Chinese market has grown very fast and it has affected its economy in many ways. The personal income levels have become higher in China, and the competition has grown. China finds it challenging to train and develop its human resources. Consumers are more demanding and they insist high quality products. Foreign investors have become more interested in China's market – usually expanding markets and low labour costs are the main factors why Western companies want to invest in China. Also Finnish companies have started to pay attention to Chinese markets and in 1990's the large companies moved to China, followed by SMEs in 2000's. China has maintained its position in sixth largest trade partner of Finland, and China is also Finland's largest trade partner in Asia.

Chinese market

China constitutes an important country for sourcing and in today's global economy China is increasingly seen as a key area for international sourcing. (Salmi 2006.) Finnish companies started to do business in China already in 1950's. Large companies started to move to China

gradually in 1980's, but big wave of investments happened in 1990's, when subcontractors and contract manufacturers were forced to follow their customers. SME's moved to China mainly in 2000's.

As China has opened up its economy to foreign investors, transnational corporations have become interested in China's enormous market for goods and services (Roy et al. 2001). China and its reforming markets have increasingly attracted the attention of Western companies, because of its expanding markets and low labour costs. China constitutes an important country for sourcing and in today's global economy China is increasingly seen as a key area for international sourcing. According to Nassimbeni & Sartor (2006), China's success does not only drive from its low labour cost. It is the result of strategic planning, the outcome of a logistic system that, if not perfect, is better by far than any other system existing in developing countries. China means strong internal competition, pride and the ambition to become the strongest economy in the world. (Salmi 2006.) However, it must be remembered, that unforeseen events, surprises, risks and delays are possible. The lure of enormous markets and profits in China comes entangled with sources of risks and uncertainties.

To succeed in China, a Chinese partner plays a key role. Specifically, foreign firms making their initial entry into China's market have found it almost impossible to succeed without a Chinese partner. (Wong & Maher 1997.) Guanxi is a key concept for understanding social behaviour in China, especially the linkage between interpersonal relations and the attainment of desirable resources, and entails a strong social obligation to do favours for another person. The development of personal trust is highly important in China. (Björkman & Kock 1995.) Business environment in China is differs from environment of Western firms and creates different challenges. One way to learn about Chinese markets is to be present in China and acquire knowledge of the Chinese market. There are two different ways to manage cultural distance; either the company uses a trustworthy partner familiar with Chinese business culture (intermediaries, an agent) or the company itself invests in building and nurturing long-term business relations. The way for Western companies to ensure and increase commitment from the Chinese side is to build up personal relations. Personal relations are also important for overcoming barriers in communication.

Sourcing perspectives

Managing the sourcing task in the supply chain is a challenge many corporations (Karpak et al. 2001). In an increasingly competitive business world, global competition puts high demand on the flexibility of industrial companies. As a result of worldwide competition, firms are combining domestic and international sourcing as a means of achieving a sustainable competitive advantage. Organizations have realized that a world-class global supply base is required in order to meet world-class competition. The catalyst for global sourcing has been the worldwide competitive pressure forcing firms to reduce costs and to improve quality and responsiveness. (Gelderman & Semeijn 2006.) The need to gain a global competitive edge on the supply side has increased substantially. Particularly for companies who spend a high percentage of their sales revenue on parts and material supplies, and whose material costs represent a larger portion of total costs, savings from supplies are of particular importance. Moreover, the emphasis on quality and timely delivery in today's

globally competitive marketplace adds a new level of complexity to outsourcing and supplier selection decisions. Many companies attempt to streamline the number of suppliers from which they source. (Karpak et al. 2001.) Purchasing is the key intermediary between members of the supply chain. It is essential that purchasing serve an integral, if not a primary role, in the management of the supply chain. (Carr & Smeltzer 1999.)

Quintens et al. (2006), conceptualized the sourcing process, and defined four phases: (1) the investigation of purchase markets and the screening of potential suppliers, (2) the selection of supplies, (3) the negotiation and contraction, and (4) supplier evaluation and follow-up. Coordination of purchasing encompasses the creation of synergies from economies of scale, scope, process, and learning.

Companies have changed their focus from short term transactional sourcing concept to supply chain management approach where they concentrated on developing long-term relations with suppliers including forming partnerships that resulted in improved coordination of supplier networks (Karpak et al. 2001). Supplier relationships connect the company's internal configuration of supply to the external resources of its suppliers. Therefore, interaction in relationships and, for instance, the skills of the interacting personnel come to play a critical role in ensuring efficient supply. Indeed, attention on the supply side has shifted from product features to external issues: supply management increasingly stresses, for example, a process focus and a market focus. (Salmi 2006.)

The drivers for international (or global) sourcing can be, for example, decreasing tariffs, improving transportation, communications and information technology, globalization of products, services and markets, global competition, and economic regionalism (See i.e. Pennanen et al. 2011). International competition has increased and now the services and products are available worldwide. Firms have to offer greater product and service quality at lower cost in order to remain competitive. Moreover, companies need to work more closely with its suppliers and customers.

In international sourcing, buyer–supplier relationships take time to establish. During this process, a key issue firms must address is effective management of the supplier network, including identification of supplier selection criteria, supplier selection decisions, and monitoring of supplier performance. Supplier selection decisions determine the number and identity of vendors that should be selected as supply sources and how order quantities should be allocated among the selected vendors. Vendor selection is inherently a complex decision. The decision process involves more than one criterion, products have many attributes such as price, quality, service, and more, and members of sourcing committees bring diverse criteria to sourcing decisions that are driven by their departmental interests such as cost, reliability, and delivery. These factors are affecting to the selection complexity (See Karpak et al. 2001)

Potential challenges in global sourcing have been mentioned by several authors (See i.e. Mentzer 2001, Fredriksson & Jonsson 2009, Salmi 2006):

Table 1: Potential challenges in sourcing from China.

Internal challenges	External challenges
- Weak international sourcing skills and capability - Lack of international sourcing management skills and capability - Lack of international sourcing strategy - Lack of information technology fit for international sourcing - Language skills and capabilities - Cultural skills and capabilities	- Extended supply chain and long lead times - Uncertainty of business environment and unpredictable inflation and exchange rates - High levels of government intervention - Quality challenges and delivery challenges - Geographic distance and different time zone - High logistics and transaction costs - Cultural distance

As presented in the Table 1, there are many complexities in global sourcing. Long lead times, extension of supply chain, environmental uncertainty, lower levels of quality, delivery risk, cultural differences and sourcing professionals' lack of skills and capabilities required to manage globally are among the biggest impediments in global sourcing. Global sourcing may be important to a firm's competitive position as a means to access raw materials, improve quality, lower cost, or access technology. Pursuing a global procurement strategy successfully requires that a firm possess a supply chain orientation and the skills to deal with the complexities and uncertainties of the global environment.

THE METHOD

This is a multiple case study with holistic strategy. The case study followed the process presented in figure 1:

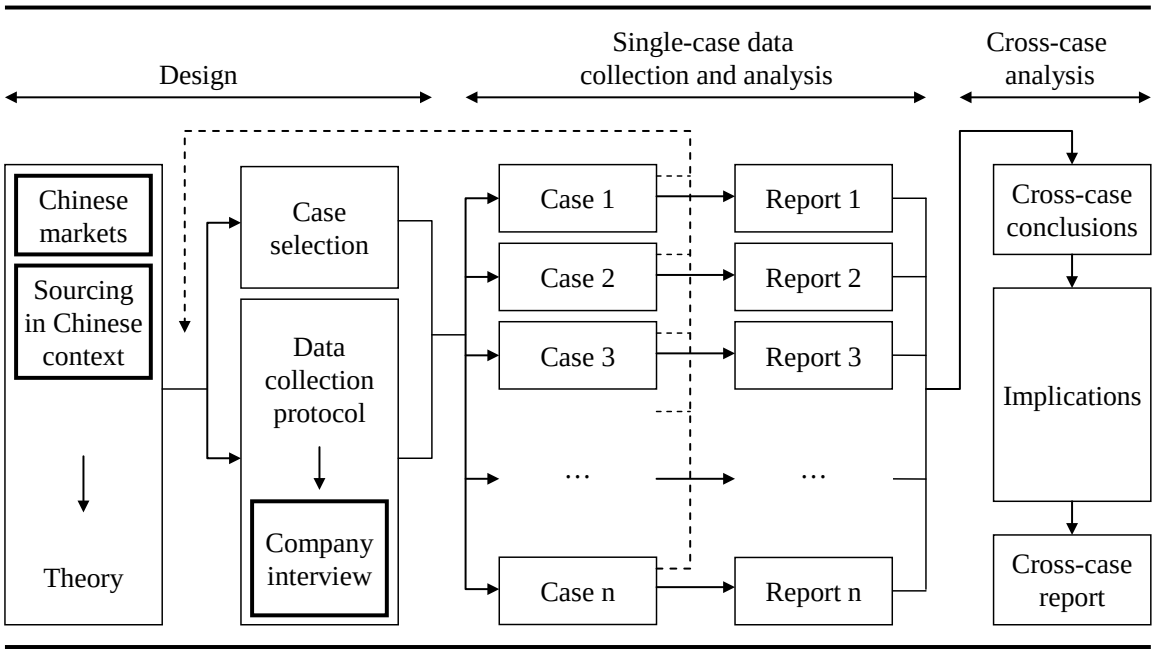

Figure 1: The research process (Modified from Yin 1989).

The unit of analysis in this study is the SMEs with experience on sourcing from China. The definition of an SME is different in different contexts. The US context, for example, offers many definitions of SME depending on the industry. For example, in some industries, SME is a company having less than 500 employees. In the European context, the SME is a company having less than 250 employees. This difference on definitions needs to be taken into account when studying the SME related literature. The variance in defining the SME causes some confusion in the field of SME research. Ayyagari et al. (2007) covers this topic in his globally focused, statistical study on SMEs (p. 416): *The term SME covers a wide range of definitions and measures, varying from country to country and varying between sources reporting SME statistics. Some of the commonly used criteria are the number of employees, total net assets, sales, and investment level. However, the most common basis for definition is employment, and here again, there is variation in defining the upper and lower size limit of an SME. Despite this variance a large number of sources define an SME to have a cut-off of 250 employees.* (Ayyagari et al. 2007). Because of the case context, the European definition is utilised. Within the SME category, the European Union defines medium sized firms as having 50-249 employees, small firms as having 10-49 employees, and micro-firms as having 0-9 employees. (Storey 2003).

The case study evidence was collected by two graduate students as part of their Master's Theses (See Karjalainen et al. 2010, Pennanen et al. 2010) in the first and the second quarters of 2010. The Theses were conducted using similar research process and questionnaires. The case study evidence is further analysed synthesized through this analysis.

THE CASE STUDIES – PERSPECTIVES FROM FINNISH SMES

The case study was carried out in eight SMEs located in Northern Finland. The basic information of the case companies is presented in the following table:

Table 2: The case companies – basic information.

Case	SME category	Industry	Sales (year 2009)
A	Small company	Business-to-business wholesale trade	10 million €
B	Medium-sized company	Mechanical industry – steel and aluminium products	35 million €
C	Medium-sized company	Wholesale trade and import of non-eatable products	50 million €
D	Small company	Manufacturing of metal products	2 million €
E	Small company	Custom made training and racing clothes	3 million €
F	Medium-sized company	Injection moulding and mould manufacturing	15 million €
G	Micro company	Contract manufacturing and design for high-end technology leaders	30 thousand €
H	Medium-sized company	Manufacturing of safety cabins	55 million €

Case A started sourcing from China in early 1990's. The main focus is on sourcing of bearings which are the main product of the company. In the beginning, the drivers for starting sourcing from china were pressure to lower prices, lowered product origin sensitivity among customers, willingness to respond to customer needs, and open-mindedness of the company. The advantages of the Chinese market have been low costs of products, low labour cost, fast response, fast delivery, sufficient quality, customer service attitude, resources available for product development, and location near to customers who have also moved functions to China. Based on the experiences of the company A, some challenges were faced. Among these challenges were some quality problems, long physical distance and different time zone.

Case B started sourcing from China in 2007. The main focus is on sourcing of steel products, components and plastic products. The main drivers for starting sourcing from China were low costs of products, tools, labour, and raw material, high prises of domestic suppliers, typically fast response to orders, and positive earlier China experiences of managers. Based on the experiences of company B, there were a couple of challenges related to sourcing. Among the challenges were quality challenges, long delivery times, problems in delivery management, grown inventories, constricted communication interface. It has been a significant challenge that Chinese supplier have not been willing to shorten delivery time.

Case C started sourcing from China already in 1960's. First experiences were related to Hong Kong and then the sourcing was extended to the mainland China. The main focus has been all the way sourcing of wholesale products. The main drivers for starting sourcing from China were low cost of the product, sufficient quality, competitive price-quality ratio, and sufficient logistics (compared to some other countries). Based on the experiences of company C, there were a couple of challenges related to sourcing. Among these challenges were unexpected government intervention (tax refund restriction), bureaucracy in Finland and EU (i.e. protectionist taxes), sudden closure of supplier, IPR-problems, agreement problems, and language barrier.

Case D started sourcing from China in 2001. The main focus is sourcing of specific hard metal products. The main drivers for starting sourcing from china were managers strong experience on international sourcing, manager's strong experience on selection of product sourced, favourable exchange rates, low cost of raw material, low cost of product, low cost of tools, availability of raw material, sufficient quality of product, fast delivery, improved reliability of delivery, flexibility in tailored products, and good motivation for collaboration. Based on the experiences of company C, there were a couple of challenges related to sourcing. Among these challenges were risk of becoming short-changed, risk of bypassing in supply chain, extra resources tied to quality control, and complicated methods of payment.

Case E started sourcing from China in 2004. The main focus is the sourcing of customised training and racing clothes. The main drivers for starting sourcing from china were raising costs of earlier suppliers, good connections of owner to Chinese suppliers, low labour cost, low material cost, availability of material, and good industry specific knowledge of Chinese supplier. Based on the experiences of company E, there were a couple of challenges related to sourcing. Among these challenges were problems in keeping promises, extra resources tied to quality control, quality problems, poor delivery reliability, and long delivery time.

Case F started sourcing from China mainly in 1990's. The main focus is the outsourcing of moulds. However, also other types of sourcing, such as sourcing of raw materials is needed. The main drivers for starting sourcing from china were need to respond to increasing price competition, competitors sourcing from China, need to increase volumes, lack of suppliers in other countries, delivery reliability, precise culture, Chinese high morale in working, and high-level technology knowledge and potential resources for product development. Based on the experiences of company F, there were a couple of challenges related to sourcing. Among these challenges were long physical distance, variable costs of logistics, and constricted communication interface.

Case G started sourcing from China soon after establishment (year 2004). The main focus of the case G is on sourcing of electrical semi-products, cables, parts, and connectors. The main drivers for starting sourcing from china were manager's earlier experience in business with Chinese companies, sufficient quality, low price of the product, Chinese active way of working and very rapid response in communication. Based on the experiences of company G, there were some challenges related to sourcing. Among these challenges were poor English language skills in China and culture-related communication challenges especially situations where advice is needed.

Case H started sourcing from China in 2004. The focus is on sourcing of metals, glasses, tire products, coupling gears, steering wheels, lights etc. The main drivers for starting sourcing from china were low price of the product, quality of operations, high work moral of Chinese people, high commitment, excellent level technical know-how, respect towards customers, and accuracy. Based on the experiences of company G, there were some challenges related to sourcing. Among these challenges were time consuming trust and relationship building, sudden closure of supplier (and loss of moulds), long physical distance and costs of grown inventories.

On one hand, the case companies had many drivers for starting sourcing from China and keeping that option also in the longer run. The main drivers towards sourcing from China are presented in the following table 3:

Table 3: Drivers for sourcing from China.

Internal drivers (Cases)	External drivers (Cases)
- Willingness to respond to customer needs (A)	- Low costs of product (A, B, C, G, H)
- Open-mindedness of the company (A)	- Low labour costs (A, B)
- Lowered sensitivity to product origin (A)	- Production near to customers (A)
- Positive China-experiences of managers (B, G)	- Fast delivery (A, D)
- Managers strong experience on international sourcing (D)	- Fast response in communication (A, B, G)
- Manager's strong experience on selection of product sourced (D)	- Sufficient quality (A, C, D, G)
- Need to increase volumes (F)	- Customer service attitude/motivation (A, D, G, H)
	- Resources for product development (A, F)
	- Low cost of tools (B, D)
	- Low raw material cost (B, D)

	- High-cost domestic suppliers (B) - Price-quality ratio (C) - Sufficient logistics (C) - Favourable exchange rates (D) - Availability of raw material (D) - Improved reliability of delivery (D) - Flexibility in tailored products (D) - Increasing price competition (F) - Competitors sourcing from China (F) - Lack of suppliers in other countries (F) - Delivery reliability (F) - Precise culture (F, H) - Chinese high morale in working (F, G, H) - High-level technology knowledge (F, H) - Quality of operations (H) - High commitment of Chinese suppliers (H)

On the other hand, many challenges and complexities were faced. The challenges faced in sourcing from China are presented in the following table 4:

Table 4: Challenges faced when sourcing from China.

Internal challenges (Cases)	External challenges (Cases)
- Problems in delivery management (B) - Grown inventories (B, H) - Extra resources tied to quality control (D)	- Quality problems (A, B, E) - Long physical distance (A, F, H) - Different time zone (A) - Long delivery time (B, E) - Constricted communication interface (B, F) - Unexpected government intervention (C) - Bureaucracy in Finland and EU (C) - Unexpected closure of supplier (C, H) - IPR-problems (C) - Agreement problems (C) - Language barrier (C) - Risk of becoming short-changed (D) - Risk of bypassing in supply chain (D) - Complicated methods of payment (D) - Problems in keeping promises (E) - Extra resources tied to quality control (E) - Poor delivery reliability (E) - Changing costs of logistics (F) - Cultural distance (G) - Communication problems (G) - Time consuming trust and relationship building (H)

As a conclusion of the empirical part, it can be said that Finnish SMEs faced both strong drivers for sourcing from China as well as many challenges on the way to build successful supply chain from Chinese market to Finland.

DISCUSSION

The aim of this study was to describe the experiences of Finnish SMEs sourcing from China. Eight cases located in northern Finland were studied in order to point out the common drivers towards sourcing as well as the common headaches. As a result of this study, the main drivers and challenges related to the process were analysed and evaluated. The answers to the research questions 1 and 2 can be condensed into a table of common drivers and challenges:

Table 5: The drivers and challenges in Finnish SMEs sourcing from China.

The main drivers	Cases	The main challenges	Cases
Low costs of product	5	Quality problems	3
Sufficient quality	4	Long physical distance	3
Respect of customers	4	Long delivery time	2
High work morale	3	Poor communication interface	2
Fast response in communication	3	Unexpected closure of supplier	2
Fast delivery	2	Grown inventories	2
Precise culture	2		
Low cost of tools	2		
Low labour costs	2		
Low raw material cost	2		
Positive experience of managers	2		
Product development resource	2		
High technology knowledge	2		

The managers of the Finnish SMEs recognised more drivers than challenges as they described their approach to the establishment of a sourcing channel between China and Finland.

The clearly most common group of drivers was related to low costs. Not only the low costs of a product sourced but also the labour-, tool- and raw material costs. Sufficient quality played an important role as well – without a sufficient quality of products the investment would not have paid for itself. It should be noted that sufficient quality meant different things for different cases – however, no one of the companies seemed to be willing to pay for 'over-quality'. Respect for customers and high work morale were important drivers as well and were backed up with the earlier positive experiences of managers in some cases. Fast response and fast delivery times were pointed out by some of the managers – these drivers seemed to fit with the precise culture mentioned in two cases. Finally, the high technological know-how of Chinese suppliers was found a positive driver – this notion was supported with the notion that two managers saw a Chinese supplier as an important resource for product development collaboration.

A couple of challenges were noted in more than one of the cases. Quality problems were noted as an important challenge – this notion was supported with the notion of extra resources tied to quality control. This seems to conflict with the 'sufficient quality' -driver. Long physical distance was seen as an important challenge as well – partly because of the fact that some cases suffered longer than expected delivery times. This led in some companies to overgrown inventories and extra costs. Two companies faced unexpected closure of a supplier, which practically meant the loss of resources invested in these suppliers. Finally, the communication interface between partners was seen as poor and constricted by technological or human barriers.

This analysis may support for the managers of Finnish SMEs considering sourcing from China in their critical decision. The viewpoints pointed out by the managers with experience on sourcing may shed light to the factors that need to be taken into account prior the decision and during the development of a sourcing process between China and Finland. The results of this analysis represent the viewpoint of SME functioning with fewer financial resources, lower technical expertise, and more limited management skills – this viewpoint is often different from a viewpoint of large enterprises.

This analysis is based on a limited number of cases. A construct validity of the study is based on a research plan that has worked as a road map through the study. The case study used multiple sources of evidence. The synergy between quantitative and qualitative data was used. The chain of evidence was preliminarily defined in a research plan to strengthen construct validity. The internal validity of the study relies on the research design. In theoretical part, the theoretical background was presented and in empirical part the data was shown to enable analysis. The test of external validity shows that the findings of the study cannot be widely generalised because of the uniqueness of the cases. The research findings depend on the point in time when data is collected. Evaluation of the reliability highlights the following points. Reproducing the same case study in the same environment later would change some of the findings. A case itself has a significant role when the case study research method is used. In addition, researchers' own paradigm or point of view inevitably affects the findings.

In the future studies it would be interesting to open more cases with more similar industrial backgrounds. The SMEs analysed differed from each other in many ways which weakens the applicability of the results. It would be interesting to compare the results of similar analysis made in SMEs located in other European countries or in US. The role of intermediaries in the support of SMEs in this challenging area requires closer look.

ACKOWLEDGEMENT

The authors are grateful for the project funding supporting by the Finnish Centres for Economic Development, Transport and the Environment (ELY-Keskus) and the European Regional Development Fund. We highly appreciate the companies involved in the study to share their experiences. We also thank the comments from two blind-reviewers to develop the paper.

CONCEPTULIZING ERP APPLICATION FOR SOCCER INDUSTRY

Farshad Salimi, www.reprocess.co
farshad@reprocess.co

ABSTRACT

The purpose of this conceptual research paper is primarily to investigate the opportunities in restructuring in entertainment industry with the focus on soccer clubs. The reason is the rapid advances in operational units and project management of restructuring processes, the new technology integration in new economy, e-business, which has no barrier in ERP application. A clear example of this development is Football Club (FC) Manchester United (MU) in soccer industry.

While soccer clubs (e.g. Real Madrid, Barcelona, Manchester United) appear to be simple enterprises, the complexity of their organizational processes provide opportunities in optimization through benchmarking with ERP applications in service industry.

From the literature, we learnt that a number of business processes at professional soccer clubs are compatible with the business processes at service industry. This has been the basis for a conceptual study on application of ERP (enterprise resource planning) business processes.

Keywords: Conceptualization, ERP Applications, Business Processes, Soccer Industry, Restructuring.

LITERATURE REVIEW

The literature study shows that English premiership clubs have been trying to understand the business processes for some time. In fact this is the area that we address as peculiar and different to any other ongoing research studies in ERP implementation at various organisations. From literature it does not appear to be a comprehensive research study in logistics of soccer clubs.

The current emphasis in pursuing success lies on the possession of top talents and trainer(s) in the team. Of course, there are some exceptions. A successful team can exist without a successful financial position. For example, Rayo Vallecano and Alaves in Spanish leagues moved from the 2nd division to UEFA Cup finals in late 90s. This paper investigates for factors other than financial position and consequently the presence of the top players in a team that can also contribute significantly to the success of a major soccer club in international leagues.
Davies (1995) used England and Wales Football premier leagues dataset on season-by-season team performance and gate revenue for the period between the 1946-7 and 1993-4 seasons. He concluded that; the use of revenue data offers two advantages over attendance.

First of all, there is an easier access to financial resources which grant clubs to attract better players so as to improve performance, and then revenue is a more appropriate measure of financial strength than attendance.

From the point of view of managing any organization it is important to establish the relationship between the inputs used in production and their relative contributions to output.
Sports' teams are similar to other enterprises in this respect attempting to provide a 'product', referring to a victory, by employing and combining various inputs (i.e. the skills and various team competencies).

A production function can serve as a basis to determine players' salaries, as well as helping to identify those areas in which a team's opportunities for improvement lie, including the type of player that should be acquired to strengthen and improve the team and similarly the current players that need to be shed. All these sports' team decisions are made, albeit informally, in the context of a production function.
The context of production function is practiced in the form of OPTA index in the English premiership football. This index breaks down the performance of the team to the performance of individual players.
Statistical tools in evaluation of the players and predictions of team success played a major role in previous research studies on team success and team performance.
OPTA Index is the matches' observations data in ball-oriented system on shots at goals, passes, tackles and clearances, dribbles and runs with the ball & free-kicks awarded, it provides extensive data for statistical analysis generating production function models and coaching efficiency models (Thomas, 2000).

Club Performance, Revenues and Economic Results

The evidence for the relationship between sports performance and revenue appear clear in English football (Barajas, A, 2005). For the economic results, it is worth observing the effect of sports performance on revenues and the relationship of these revenues with costs. Although both turnover and expenses depend on managerial skills, the expenses are more easily controlled than turnover because income relates to the consumer demand.

Deloitte and Touche (1999) carry out analogous studies comparing, by means of a non linear regression, the total incomes of Spanish football clubs in the first division with their ranking at the end of league championships in seasons 1996/1997, 97/98, and 98/99. In Scottish Premier League the relationship between economic results and sports performance is less direct and more complex than we might expect. In analysis of relegation, Deloitte and Touche suggests that the levels of attendance and states, without a solid base, that in the season which follows relegation fans continue to attend matches through force of habit.

Pricing, Habitual Attendance, and Revenues

Spenner and Fenn (2004) applied the model of Becker et al. (1994) to National Football League and found that the sports league is a habit forming product. Conceptually, fan loyalty may create habitual behaviour, leading to a dynamic model specification of attendance demand (Won, D.C., 2008). Using the two-period model, Ahn and Lee (2007) showed that inelastic pricing is consistent with team owners' profit maximization decision if attending sports games is habit-forming and if the inter-temporal elasticity of substitution (IES) in the attendance at sports games is small. Using both linear and non linear models with respect to the infinite horizon, Won and Young (2008) derived a stationary attendance level and price, as well as the paths of optimal prices and attendance preceding the stationary point. Then they compared these results with those of a static model that assumes the absence of habit formation.

Our theoretical finding and simulation results imply that; i) inelastic pricing is consistent with lifetime profit maximization (the confirmation of Ahn and Lee, 2007); ii) in the presence of attendance habit formation, both the long run equilibrium price and the level of attendance are greater than the corresponding static profit maximizing price and attendance; iii) the dynamic equilibrium paths indicate that a team owner lowers price during early periods, to induce greater present and future attendance; and raises it in the long run to take advantage of habit persistence in attendance; and (iv) while the dynamic price path for the case of strong habit formation begins below that for weak or absent habit formation, it increases rapidly and eventually terminates in a higher price.

Team Success Based on Players' Income

The economics of English league soccer bear some resemblance to the economics of the team sports in U.S. In other words, the method of analysis can be benchmarked for similar sports in the same industry. In a survey established for 39 premiership clubs, a performance and club wage bill (1978-1993) indicate that players earn wages that reflect their talents, and club expenditure on players is a fairly reliable indicator of talent and club performance, i.e. average league rank as a team in the premiership.

Assuming the players' income factor is constant; the same study shows that major clubs with a higher number of black players have a higher ranking Premiership league (Szymansky, 2000).

Production function models estimate aggregate team performance or the success over a season in the English premiership league.

The relation between team performance & revenue was investigated using co-integration & causality tests. The selection criterion for the test was the unbroken league membership between 1946 and 1994 (Dobson, 1998).

The dependence of performance on revenue seems to be greater for the smaller clubs than for the larger clubs. The empirical results support the fact that team success is concentrated for rather wealthy clubs at premiership leagues in England.

The revenue as a full context does not represent the successful performance of a club. The length of the club life time in business is part of the selection criteria for the test.

The influence of the lagged revenue on current performance is greater than the influence of lagged performance on current revenue (Audas, 1994).

The cost breakdown by a major Scottish premiership club shows approx 70% on players' salaries and that of staff and 30% on any other overhead expenses.

The data show the importance of revenues from media rights, sponsors, tickets as well as the contemporary changes in soccer business with the important role of management team, supply chain and commercialization process (Cain, 1987/2000).

A major sponsor, Vodafone, financed approx. 6% of the total Manchester United market value (GBP 500 millions) on the London stock exchange over four years while Orange financed the Formula I team for double the amount over three years.

Tottenham Hotspur was the first major club to float in the stock market in 1983 followed by Manchester United in 1991 (Szymanski, 2000).

Real Madrid with a market value of GBP 105.2 millions, second after Manchester United, and indebted for over US $ 110 millions, spent US $ 60 millions to buy Luis Figo from FC Barcelona in 2000.

On the basis of Manchester United Business characteristics as an entity, some dependent measurable indicators in club success can be drawn as; Revenues, Profits, Number of fans, Franchising capacities and Sponsorship.

For other sports in U.S. in particular, there are studies on production function, performance evaluation, and correlation analysis.

Similar studies took place on the performance evaluation, production function and coaching efficiency of the top teams at English premiership league.

In a study performed by the University of Chicago a logarithmic chart of average league ranks versus wage expenditure relative to average (logarithm) showed a direct relation between the players' incomes and the ranking of the soccer club in the English Premiership leagues.

In the English premiership, the injuries cost the clubs GBP 40 millions while statistics showed 10% of a club's squad were unable to play at any time. This figure indicated what a club would require to compensate from its allocated budget.

Under the new EC legislation, players' wages will rocket as clubs use the money they would have spent on transfer fees to induce players to stay, wages increased by 30% a season in the

UK and wage packets of GBP 100000 a week were inevitable, say football analysts at Deloitte & Touche.

Any club at the top of the premiership league is paying two third of their turnover in total wages.
The managerial efficiency scores were used as covariate in an estimated managers' survival function in which the duration of survival was found to be positively related to managerial efficiency.

One element of team performance that was completely beyond the soccer managerial control is the quality of the playing squad that could be inherited at the start of his spell.

To control for that element, the difference between the team's current league position and its initial position when the manager first took charge is included as a covariate in the hazard function.

With this formulation, the quality of squad inherited was reflected in the initial league position, and the manager was assumed to take either full credit or blame for any subsequent positional improvement or deterioration.

Possible criticisms for this formulation is the fact that;
First if the outgoing manager is underperforming at the time of termination, the initial league position may undervalue the strength of the playing squad inherited by the incoming manager. The latter, however, still faces the task and (if successful) takes the credit for reorganising and restoring confidence or motivation to a squad that was previously underachieving.

Furthermore, formulation does not control for the extent to which different manager could have access to funds to spend on players' wages and in the transfer market, other than those generated internally through the impact of team performance on gate revenues.
The manager's ability to control match and league outcomes is surely constrained by chronic unpredictability surrounding; fitness, performance and interactions of the players.

The process that determines the team productivity is opaque while results are transparent.
Each match is a zero-sum game and the results are ranking in the league. Promotions and relegations between divisions also create substantial and lasting rewards and penalties for success and failure, respectively.

For each club as a firm, the typical consequences of inadequate performance are not the loss of customers, internal reorganization, liquidation, or acquisition by competitors. All clubs retain a base of highly regular spectators.

Constraints to Restructuring Soccer Clubs

The rigid technology associated with the soccer club's main product tends to impose similar uniformity upon the club's organization and structure.

Despite what is generally perceived to be a very high and price inelastic demand for the services of professional football teams, the clubs themselves seldom make money.

Modelling team Success and Club Success in Professional Soccer

The team strength scores are used as covariate in an estimated team success function, wherein the team success is proved to be positively related to management quality.

Causal empiricism suggest that a run of poor results over a relatively short period within a season can have a far more damaging impact on the manager's survival prospects than would be suggested by its full season win ratio or efficiency score.

Organizational Performance & Managerial Turnover period 1972-1997 (Audas, 1999)

Short term fluctuations in performance strongly influence the involuntary termination hazard.

The latter is also heavily dependent on the team's current league position relative to its position when the manager took charge, and on the win ratio over the entire pull.

The match-level data set allows identifying the link between very short term fluctuations in team performance and managerial survival.

The effect of a change of manager on organizational performance is a well-researched topic, despite constraints on availability of suitable data and the difficulties encountered in defining unambiguous measure of inputs and outputs.

In this context, Lieberson & O'Connor (1972) established a prototype for much subsequent work on managerial succession effects, by investigating the links between changes of chief executive officer and subsequent movements in performance indicators, such as sales profits.

CONCEPTUAL MODEL

We define two types of success defined in this conceptual study; successful soccer club and successful soccer team. Although these two types of successes are interrelated, in modern soccer they are recognized from each other in terms of business and sport. A successful soccer club can provide the grounds for a successful soccer team. The club has to be primarily financially successful as an entity. This criterion of financial strength, or capability, is almost a prerequisite to the formation of a successful team. This criterion brings the operation management, structure and logistics of processes in a major soccer club in picture.

For example, Real Madrid makes a distinguished exception in this regard. FC Real Madrid as the most indebted soccer club of the world in late 90s, was financially supported by other institutes rather than successfully running a profitable business. The same situation applied to FC Valencia and other soccer clubs in Spain. Later, Real Madrid as an entity with a high debt to equity ratio succeeded in generating substantial revenues from national and international leagues.

We built two constructions for the two independent hypotheses and one integrated hypothesis; Team Success & Club Success, and Management Quality.

The independent measurable indicators from these two constructions are listed in the scenarios I to IV.

The medical team (i.e. selected by the management team as support and advising staff), the audience (fans), the season (weather), sponsors (e.g. their financial contribution), culture (e.g. measured with the fans) and the environment (e.g. the pitch, fans and the weather) are among the dependent indicators.

The purchase of famous players and trainers by clubs counts also as a form of publicity. The source and size of revenues of a club are related to the success of its team (e.g. in a national and champion leagues). This is generated in principle from the public media, ticket sales and the sale of the players.

The model consists of the management team professional knowledge described as technical director, coach (his history and his references) and president director (e.g. business network, supply chain, procurement skills, and etc). And the proposed model represents the management of a typical major successful club in Europe.
The barometers in management quality, players' talent and degree of success of a soccer club (e.g. ranking in national and international leagues) will be indicated using a scale of 1 - 10.

Club Success = f (number of participations in the international leagues over the period of five years, e.g. Manchester United, financial position of the club and its value ranking in the entertainment industry, e.g. Manchester United is ranked as number one in generating revenues.)

Management Quality = f (technical director (e.g. full time years in physiology with a no. of years' experience in other professional clubs, trainer (e.g. cooperation with technical director and an international proof record of success in coaching, president (e.g. negotiations skills with network capacities)

Team Success = ƒ (sum of the quality individual players, no. of years of service with professional leagues on the same position, top 10 % and bottom 10 % of the national leagues)

Team Strength = ƒ (no. of core players over the three years period, no. of top talent players with transfer fees above GBP 20 million, No. of injuries over the period of three years, No. of the coaches over the three years period, no. of nationalities over the three years period)

In order to design the score models for the two constructs, the indicators are given values (weight factor), i.e. one to ten score models.

Team Success Based on Coaching Quality

We take the coach/players and situations/games as two opposite poles wherein these two poles have to get together in order to make a successful team.

Thus training situations should be as close as the actual game situations. Equally the understanding and the relation between the coach and the players should be as close to each other as possible.

Most literatures showed that major focus of both research and commercial efforts were on players' income as the team key success factor.

The club success is directly related to possession of top players in the team, in which the players' talents are rewarded with their incomes.

The impact of players' talents, players' salaries and the coaching performance in team success and its ranking is empirically correlated in various literatures.

The emphasis of this conceptual study is on the operation of management team and related business processes in a major soccer club. The purpose is to find the optimal operation for a major soccer club to boost its performance as an entity and as a team in national and international leagues.

The models derived in this study suggest that both team success and club success as independent constructs are related to the management quality.

For the measurement of management quality, we can suggest that the index is weighted equally by three decision making organs; president, technical director, and the soccer coach.

Each organ has a 30% share in the success and failure of the team and/or club success.
The independent variables in this model of team success are related to players' performance in this model.

Club & Team Success Performance Concept;

Regression Analysis

Club Success:
Revenue of clubs, γ; Wages, χ

Team Success:
Club Ratings, γ; Management Quality, χ

This study proposes a methodology based on regression analysis of the independent variables against dependent variables.

The measurement of management quality can be related to the dollar value of the coach in the market. Then a correlation coefficient for regression lines can be drawn.

Hypotheses

Hypothesis 1

Team Success

The management team is defined by the management team (technical director + coach and the president) of the soccer club.

The hypothesis of team success is evidenced by a higher proportion of the variation in league performance which is attributed to the management quality and team strength.

Team success is characterised by ranking at national and international leagues which is directly dependent on the team strength. Team strength is in turn based on measurable indicators on players' talents and team formation.

The combination of the two elements can result in successful and unsuccessful scenarios in the following forms;

Successful Team

- Moderate team strength and high management quality
- High team strength and high management quality
- High team strength and low management quality

Unsuccessful Team

- Moderate team strength and low management quality

Management
Quality

High

Successful I	Successful II
Unsuccessful III	Successful IV

Low

Moderate Average High

Team Success

Hypothesis 2

Club Success

The hypothesis of club success is evidenced by a higher proportion of the variation in club performance which is attributed primarily to management quality and players' qualities (players' talents).
The combination of the two elements can result in successful club in the following forms;

Successful Club

- High club success and high management quality

Unsuccessful Club

- Low management quality and moderate club success
- Low management quality and high club success
- High management quality and moderate club success

Management
Quality

High	Unsuccessful I	Successful II
Average	Unsuccessful III	Unsuccessful IV

Low

Moderate Average High

Club Success

Hypothesis 3

Club Success and Team Success

Thus the combination of the hypotheses 1 and 2 results in the hypothesis 3, i.e. the implication of success in both as a club and as a team is only attributed to high management quality and high team strength and high financial strength.

The hypothesis 3 is supported by the evidence of clubs (e.g. FC MU) a leading edge in sport industry worldwide. This fact is owed to its top quality management and team strength providing a sustainable team success and club success at national and international leagues.

CONCLUSION

We reviewed major part of literatures on; players' salaries versus team performance, the importance of sponsorship, marketing and advertising, commercialization of soccer teams, necessary contemporary changes in soccer business, i.e. recognition of the business processes such as procurement, marketing and management skills, the role of management in success or failure of the team and the club, the empirical correlation of team production function, coaching efficiency and team success, estimating the demand for professional team sports, trying to identify the objective function of professional clubs, and a few papers attempt to link the analysis of supply and demand conditions.

In this conceptual study, we defined the management quality as key success factor in team club success. We also defined the management quality as integration of performance by management team. Optimization of business processes at a soccer club is a tool in improving management quality. The hypothesis of club success is evidenced by a higher proportion of the variation in the club performance which is attributed primarily to quality of management and quality of players.

ABSTRACT

With the rapid development of information technology and progress of the Internet in recent years, labor division has become more and more specialized all over the world; therefore, enterprises not only nurture local human resources but can also successfully introduce overseas technologies. In view of this, to acquire technology advantage and competence, an enterprise must be truly globalized to maintain its competitive edge among other competitors. Facing such change, a R&D institute also expands its business to procure technologies and resources overseas, thereby leading to R&D globalization. Thus, how to evaluate an optimal R&D center to minimize R&D costs and risk has become a major concern for enterprises. In order to help enterprise evaluate an optimal R&D center, this study develops a R&D center ranking methodology to identify the optimal R&D center using AHP approach. At last, this study employs an industrial computer development project as a case study for explanation and verification of practical contributions and efficiency of the methodology proposed in this study.

Keywords: R&D center, Analytical Hierarchy Procedure (AHP), R&D costs and risk

INTRODUCTION

As customer needs change fast and new products roll out quickly, enterprises have to speed up its product development and cut the time to market. Besides, the advance of information technology and required R&D resources scattered across the world have resulted in distributed product development, a company, in order to fully leverage on its advantages in technologies and resources, should develop itself as a multinational" R&D task force. Meanwhile, a R&D institute also sets up overseas R&D centers, which therefore catches up

the trend of R&D globalization. According to von Zedtwitzp and Gassmann (2002), companies in European countries launch approximately 30% of R&D globalization, among which only a few companies are engaged in over 90% of R&D globalization. From this trend, we may find that previous R&D projects, which were simple, independent and tactical, have evolved into interdependent overseas R&D activities with global coordination and strategic missions. In addition, with increased R&D globalization, enterprises can make the best use of foreign human resources and technologies to lower R&D costs, move closer to the market, understand market demands and make full use of local creative (Terpstra, 1977). To address the current environment of R&D globalization, enterprises should integrate R&D technologies and resources throughout the world to select an optimal R&D center for new product development. For this reason, how to select the optimal R&D center from those worldwide to minimize R&D labor and facility costs and to effectively mitigate the risk of timely completion of R&D missions and cost control has become a critical issue. To develop a ranking methodology of a R&D center, this study first creates a R&D center selection hierarchical structure, which is divided into two dimensions, namely cost and risk. The cost dimension includes R&D labor force expected cost and R&D facility expected cost, while the risk dimension consists of risk of timely completion and risk of cost control for R&D missions. Next, we calculate criteria weights in the dimensions using the Analytical Hierarchy Procedure (AHP) and apply the criteria weights to rank R&D center. In this way we may create a R&D center order preference to help enterprises select the optimal R&D center so that these enterprises can consolidate their competitive capacity by taking full advantage of global technologies and resources. At last this study employs an industrial computer development project as a case study for explanation and verification of the proposed methodology and its benefits.

The study's structure is described as follows. In Part II, we will summarize the criteria for evaluating R&D centers and the methodology; in Part III, we will depict the application of the AHP to develop a R&D center performance assessment model and the ranking methodology; in Part IV, we use an industrial computer development project as a case study for explanation; and in the last part, we elaborate the benefits of the proposed methodology.

LITERATURE REVIEW

Reddy (1997) proposes that a low R&D labor cost is a key factor for selection of a R&D center. John et al. (2006) suggest 39 factors associated with selection of a R&D center, including R&D personnel's technology capacity, know-how, tax and interest rate, etc.; they also identify relative importance of respective factors through questionnaire survey. Kumar

(2001) argues there are seven major evaluation criteria that attract multinational firms to establish R&D centers, including market scale (Agarwal and Ramaswami 1992; Brouthers and Brouthers 2000), R&D personnel's labor cost (Reddy 1997), technology specialization, government policy (Delios & Beamish 1999; Gomes-Casseres 1989), intellectual property protection and liberalization of trade. Sarkis and Sundarraj (2002) consider several criteria such as cost, time, R&D labor resource and risk to determine the location of a R&D center.

In terms of selection of alternatives, Saaty (1980) proposes the AHP, which may take both qualitative and quantitative criteria into account and calculate relative weights of each criteria and relative performance of each decision option, through an evaluation criteria hierarchical structure and pairwise comparison, to evaluate the optimal alternative. Today, the AHP has been widely used as a method for multicriteria decision-making (Dey and Gupta 2001; Mian and Christine, 1999; Loch and Kavadias 2002; Eugene and Dey 2005). Brenner (1994) uses an AHP to evaluate a R&D project and, depending on four criteria relating to customers and markets, groups R&D projects and selects the optimal one for investment. Crowe et al. (1998) propose an AHP-based methodology; they develop an ISO 9000 certified criteria and a hierarchical structure to help decision-makers measure performance of costs and benefits for ISO 9000.

From these literature reviews given above, few papers involved discussion about selection of a R&D center. This study therefore summarizes and creates a R&D center evaluation criteria structure and employs an AHP to develop a R&D center performance assessment model and a ranking methodology for enterprises to identify the optimal R&D center. With an industrial computer development project as a case study, we verify the feasibility of the proposed methodology in the last part.

METHODOLOGY

This study creates a R&D center performance assessment model and a ranking methodology and, by AHP, selects the optimal R&D center, such that each cost and risk of the R&D mission can be minimized. AT first, we summarize literature reports related to selection of a R&D center to identify important consideration criteria and then calculate criteria weights through AHP. This study divides evaluation criteria into cost dimension and risk dimension; the cost dimension includes R&D labor force expected cost and R&D facility expected cost, while the risk dimension consists of risk of timely completion and risk of cost control for R&D missions. Next, we integrate criteria weights into the AHP performance assessment model. With this approach, an order preference of R&D center can be created to help senior executives identify the optimal R&D center. Figure 1 shows the study's analysis process

structure.

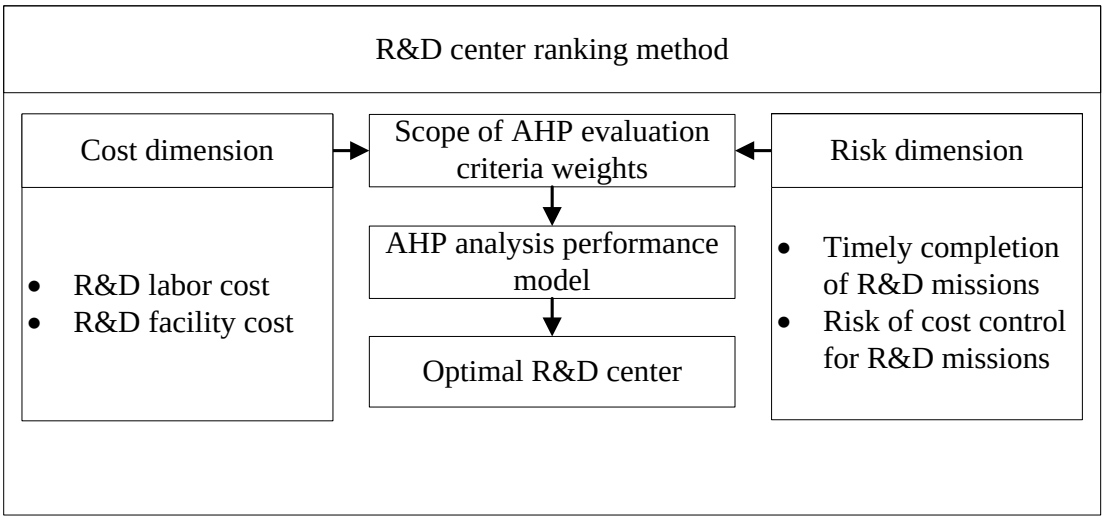

Figure 1: Analysis process of the methodology.

To examine relative weights of criteria for the selection dimension, this study employs the AHP proposed by Saaty (1980) to calculate relative weights of criteria. First, we use the nine-interval Likert scale to express the relative importance between Criteria *i* and Criteria *j*, as shown in Table 2, such that we can develop a pairwise comparison matrix [a_{ij}] as indicated in Formula (1).

Table 1: Nine-interval Likert scale.

Score	Linguistic variable
1	Equal importance
3	Moderate importance
5	Strong importance
7	Very strong importance
9	Absolute importance
2、4、6、8	Ranging between 1.3.5.7.9

Next, we use geometric mean to calculate the relative weight of Criteria *i*, as shown in Formula (2). Because the comparison of criteria relative importance is a subjective judgment, we should ensure consistency of the pairwise comparison matrix. According to Saaty (1980), if the consistence index (CI) of the matrix [a_{ij}] is less than 0.1, it suggests that the pairwise comparison matrix [a_{ij}] meets the consistency. Formula (3) shows a CI qualifying equation. To integrate various opinions from different decision-makers, this study uses geometric mean to acquire the final weights of respective criteria. Finally we integrate criteria weights into the AHP performance assessment model and calculate R&D center score (C_i^*), as shown

in Formula (4). This analysis result will be helpful to a company in selecting the optimal R&D center.

$$A=\left[a_{ij}\right]=\begin{bmatrix} a_{11} & a_{12} & \cdots\cdots & a_{1n} \\ a_{21} & a_{22} & \cdots\cdots & a_{2n} \\ & & & \\ a_{n1} & a_{n2} & \cdots\cdots & a_{nn} \end{bmatrix} \quad (1)$$

$$w_i=\left[\alpha_{i1}\otimes\cdots\otimes\alpha_{in}\right]^{1/n},\forall i \quad (2)$$

$$CI=\frac{\lambda_{\max}-n}{n-1}, \text{ where } \lambda_{\max}=(1/n)\left(\frac{w_1'}{w_1}+\frac{w_2'}{w_2}+\cdots+\frac{w_n'}{w_n}\right) \quad (3)$$

$$W'=AW$$

$$C_i^*=\sum_{j=1}^{m}a_{ij}b_j \quad i=1\cdots n \quad (4)$$

CASE STUDY

This study employs an industrial computer development project as a case study. The R&D project comprises three modules, namely software module, mechanism module, and electronic module. With assistance to top executives in evaluating the mechanism module of industrial computer R&D projects as an example, this study is intended to explain and verify the feasibility of the proposed methodology to minimize each R&D cost and risk.

To rank the performance of R&D centers, this study employs an AHP approach to integrate opinions from various experts and derive evaluation criteria weights with Formula (1)~(3) and ultimately obtain evaluation criteria weights through a consistency test. Table 2 shows weights of R&D center evaluation criteria. Subsequently, we apply criteria weights obtained with an AHP method to rating matrix by formulae (4), use the index C_i^* as a basis for making an order preference in this study, and determine the order preference of performance based on the C_i^* value. If the R&D center has the highest score, it is rated the ideal R&D center in this case. Table 3~6 shows the pairwise comparison matrix of R&D center in terms of the criterion. Table 7 shows the results of the order preference of R&D centers. Finally it is found that No.5 R&D center has highest $C_i^*=0.329$ value; thus No.1 R&D center is rated the ideal R&D center in this case. It is therefore suggested that the proposed methodology is helpful to an enterprise in selecting the optimal R&D center.

Table 2: The weights of R&D center evaluation criteria.

Dimension	Criteria	Codes	Weight
Cost	R&D labor cost (C1)	C1	0.509
	R&D facility cost (C2)	C2	0.309
Risk	Timely completion of R&D missions (R1)	R1	0.08
	Risk of cost control for R&D missions (R2)	R2	0.102

Table 3: The pairwise comparison matrix of R&D centers for the R&D labor cost.

C1 / R&D centers	1	2	3	4	5	Weight
1	1	2	4	1/2	1/4	0.159
2	1/2	1	2	1/2	1/4	0.105
3	1/4	1/2	1	1/4	1/5	0.058
4	2	2	4	1	1/2	0.241
5	4	4	5	2	1	0.438

Table 4: The pairwise comparison matrix of R&D centers for the R&D facility cost.

C2 / R&D centers	1	2	3	4	5	Weight
1	1	1/2	1/2	1/5	1/6	0.057
2	2	1	1	1/5	1/4	0.094
3	4	2	1	1/4	1/2	0.113
4	5	5	4	1	4	0.492
5	6	4	2	1/4	1	0.244

Table 5: The pairwise comparison matrix of R&D centers for timely completion of R&D missions.

R1 / R&D centers	1	2	3	4	5	Weight
1	1	1/8	1/2	1/2	1/5	0.050
2	8	1	7	5	2	0.485
3	2	1/7	1	1/2	1/5	0.067
4	2	1/5	2	1	1/4	0.099
5	5	1/2	5	4	1	0.300

Table 6: The pairwise comparison matrix of R&D centers for the risk of cost control for R&D missions.

R2 / R&D centers	1	2	3	4	5	Weight
1	1	6	1/2	4	5	0.314
2	1/6	1	1/5	1/4	1/2	0.046
3	2	5	1	5	7	0.447
4	1/4	4	1/5	1	4	0.133
5	1/5	2	1/7	1/4	1	0.059

Table 7: The order preference of R&D centers.

The number of R&D center	Criteria				Final score C_i^*	Rank
	C1	C2	R1	R2		
	0.509	0.309	0.080	0.102		
1	0.159	0.057	0.050	0.314	0.134	3
2	0.105	0.094	0.485	0.046	0.126	4

4	0.241	0.492	0.099	0.133	0.296	2
5	0.438	0.244	0.300	0..059	0.329	1

CONCLUSIONS

From the ongoing trend of R&D globalization, previous R&D projects, which were simple, independent and tactical, have evolved into interdependent overseas R&D activities with global coordination and strategic missions. Since an enterprise has to integrate R&D technologies and resources scattered throughout the world, how to select the optimal R&D center in such R&D circumstances has become a major concern. To address the problem, enterprises should use scientific decision analysis approaches to identify an optimal R&D center to accomplish their R&D missions and alleviate their R&D costs and risk as well. For this reason, this study proposes a R&D center performance assessment model and a ranking methodology; we develop a R&D center performance assessment model and a ranking methodology by AHP, aiming to help enterprises rank their R&D centers and select the optimal R&D center for integration of existing R&D technologies and resources, such that enterprises may minimize each R&D cost and risk. In the final part, this study employs an industrial computer development project as a case study for explanation and verification of practical contributions and feasibility of the proposed methodology.

ABSTRACT

The focus of the paper is on analyzing the innovation activities and related resource development strategies in shaping the evolutionary path of a small software firm. We have carried out a qualitative study of an entrepreneurial venture and interviewed entrepreneur and key personnel adopting the critical incident technique. We find that the role of the entrepreneur is significant during the early stages of innovation activities following technological changes. We also find evidence of the distributed agency perspective advocated by Garud & Karnoe (2003).

Keywords: bricolage, technology entrepreneurship, opportunity development, technological change, product line strategy

INTRODUCTION

It is widely acknowledged that in most high technology industries, innovation and knowledge creation are critical for firm growth (Nambisan 2002; Francis and Bessant 2005). Software industry can be considered as prototypical high technology industry characterized by innovation-driven market growth, rapidly shrinking product and technology life cycles, high knowledge intensity, and global markets. In a firm operating in this industry the nature and rate of innovation often shape its evolutionary path as well as its future growth. (Nambisan 2002, 141-145.) This paper is based on a research project that aims at a better understanding of the growth path of small software firms. The focus of the paper is on analyzing the innovation activities – identification, development and exploitation of opportunities – and related resource development strategies in shaping the evolutionary path of a small software firm. The research questions we address are: How were opportunities for innovation identified? Who participated in the development and exploitation activities, in which way, and what where the outcomes? In this paper we contrast entrepreneur-centered and distributed agency views on technology entrepreneurship.

THEORETICAL GROUNDING

Innovation is commonly considered a complex activity in which new knowledge is applied for commercial ends. Part of this knowledge reaches the firm from external sources. Studies have shown that for example customers have important information and that many innovations originate in the user domain. (von Hippel 2005; Chesbrough 2003.) According to Francis and Bessant (2005), in spite of its importance, innovation is often described narrowly: it is applied to changes to what a firm offers (product/service innovation) and to the ways it creates and delivers those offerings (process innovation). The authors point out that this definition is insufficient, as it does not take into account business models and market position, two of the areas where innovation is possible.

In essence the purpose of products and services is to create and deliver value for stakeholders. Ardichvili and colleagues (2003, 105-109) point out that identifying and selecting right opportunities for new businesses are among the most important abilities of a successful entrepreneur. Sensitivity to market needs in addition to ability to spot suboptimal deployment of resources may help an entrepreneur begin to develop an opportunity. Opportunities seen from the perspective of prospective customers represent value sought. Opportunities arising from resources, from technology or other types of proprietary knowledge or abilities may be labeled value creation capability. For example new technology may offer possibilities to value creation even though the precise forms that new value will take may be undefined. Ardichvili, Cardozo and Ray (2003; see also Klofsten 2005) have presented a process model of opportunity identification (Figure 1). The core process includes recognition of an opportunity, its evaluation and development per se. Authors point out that the development process is cyclical and iterative: an entrepreneur is likely to conduct evaluations several times at different stages of development which can lead also to recognition of additional opportunities or adjustment to the initial vision. Five major factors influencing this process include entrepreneurial alertness, information asymmetry and prior knowledge, social networks, personality traits of the entrepreneur (optimism, self-efficacy and creativity) and type of opportunity itself. According to authors the theory is expected to hold in the domain of new business creation and development, both as independent businesses and as new businesses created within existing corporations.

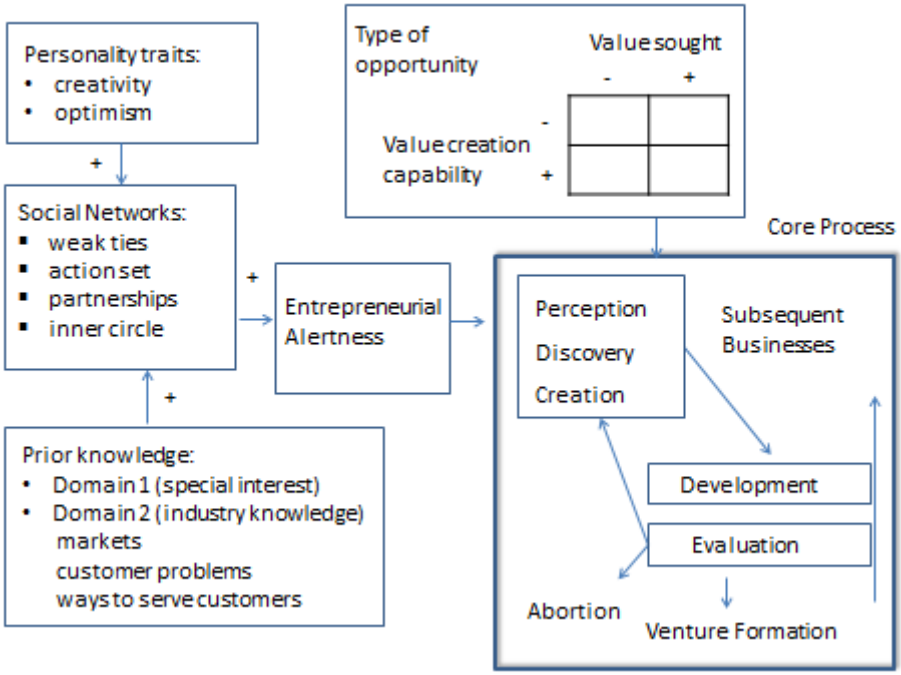

Figure 1: Model of opportunity identification and development (applied Ardichvili et al., 2003).

Ardichvili and colleagues represent the traditional entrepreneurship literature, which according to Garud and Karnøe (2003) primarily attributes the entrepreneurial success and failure to specific individual. In this literature entrepreneurial agency is located in a few individuals who have the full-blown ability to discover, create and exploit opportunities that lie beyond the reach of most. Departing from this conceptualization Garud and Karnøe (2003), who have studied the emergence of wind turbines in Denmark and in United States, suggest that technology entrepreneurship is a larger process that builds upon the efforts of many. According to these authors skills and resources required to take an idea from its inception to commercial use have to be mobilized by drawing upon the generative impulses of actors from multiple domains. In other words, they posit that entrepreneurial agency is distributed across actors each of which possesses "dispersed bits of incomplete and frequently contradictory knowledge". Actors include not only those who create and discover ideas, but also those who develop complementary assets, representatives of institutional forums and customers. Each actor becomes involved with a technology, and in the process, generates inputs that result in the transformation of an emerging technological path. The steady accumulation of inputs (artifacts, tools, practices, rules, knowledge) generates a momentum that enables and constraints the activities of distributed actors.

One source of business opportunity is new technology. Radical technology changes represent a break with past techniques and practice whereas incremental changes build on them. Radical changes introduce new design components combined in a system whose function relies on different knowledge base than previous products. Such changes create also challenges and they can be regarded as competence destroying because firm´s existing knowledge base is of limited relevance at best. A new technology is both physical and conceptual. It consists not only of the actual components and their associated testing and

production tools, but also a set of accumulated knowledge, techniques, and skills that set the agenda for further problem-solving and product refinement. (Jones 2003, 1265-1269.)

Referring to Wheelwright and Clark (1992) Jones (2003, 1269-1270) presents a three-category typology of development projects that characterizes their relationship to earlier projects. It is based upon a project´s level of continuity with existing products and processes. 1) derivative projects; share most with previous projects and their development requires only minor changes to existing products and/or processes, 2) radical projects; involve major change in product and process, often establishing a new product category for a firm and they represent a significant break with the past, 3) platform projects; is an intermediate category, which represents significant change in product or process, or more rarely, both. A platform is a base product that can be leveraged, perhaps successively over a significant time period to produce a family of related derivative products.

The competitive significance of the management of related products and product relationships has been emphasized in strategic managerial and innovation literature. In a technologically dynamic environment, firms must choose when to leverage existing platforms with derivative products and when to develop new platforms and/or replace existing platforms and their related derivatives. The overall result of these choices constitutes a firm´s product line management strategy, which can be characterized by the speed of product development and by the length of time each product is offered for sale. Together these factors reflect the rate at which products are replaced or renewed and the rate at which product lines are expanded. (Jones 2003, 1268-1270.)

Bricolage – assembling the resources to new challenges

According to Van de Ven (1986) to understand the process of innovation is to understand the factors that facilitate and inhibit the development of innovations. Critical challenge in small high-technology firms where technological capabilities determine if a firm can meet their R&D strategy is the problem of constructing resources for growth. Entrepreneurial (small) firms are typically resource and/or time constrained. Faced with these constraints, the standard make-or-buy decision of resource construction may not be relevant. (Banerjee & Campbell 2009; Street & Meister 2004.) Baker and Nelson (2005) have introduced entrepreneurial bricolage as the process by which resource-constraint firms are able to render unique services by recombining elements at hand. Bricolage is defined as a process of resource use and development characterized by using resources at hand, recombining resources and making do (Steffens and Senyard 2009; Baker and Nelson 2005).

According to Newbert (2008) firms need not necessarily possess rare resources and rare capabilities in order to attain a competitive advantage. Common resources can be as essential provided they are paired with other capabilities (or resources) in such a way that the resulting combination in which they are exploited is rare. Therefore firms may be able to build a competitive advantage from the resources and capabilities they already possess. In technology R&D the firm´s key resources that can be reallocated and recombined to address new opportunities are the skills embedded in inventors. (Banerjee & Campbell 2009, 474-475).

Baker and Nelson (2005, 353) point out that when a firm faces new challenges, whether opportunities or problems, without providing new resources it has basically three alternatives; seek new resources, avoid new challenge or engage in bricolage. In their study they find that 9 case firms out of 25 exhibited no discernable evidence of bricolage. These firms for example didn´t undertake offered job opportunity if they weren´t confident of being able to do it "the right way". Authors (2005, 358-359) have in their research utilized a definition by Stevenson and Jarillo (1990) of opportunity as "a future situation which is deemed desirable and feasible". For the firms they observed bricolage shaped both of these dimensions. Authors point out that alertness to resources is as important as alertness to opportunities. For example inventors in a firm will keep improving technology in a context of use until given a new context (Banerjee and Campbell 2009, 475).

Bricolage capabilities may help firms explore and exploit new opportunities that might appear too expensive to pursue through other means. When firms use bricolage more narrowly or temporarily, first rejecting and then enacting environmental resource limitations, they appear to be more likely to grow. This also suggest that firms may differ systematically in their ability to apply bricolage skillfully (Baker & Nelson 2005, 334, 342, 357) According to Duymedjian & Rüling (2010, 148) the distinctive competences of the manager-bricoleur include the capacity to sense (latent) connections, ability to get close to the reality of organized work, and dexterity in manipulating resources.

Ardichvili (2003, 111) and colleagues refer to Kirzner (1973) in their statement that entrepreneurs are selling not just products but rather, their knowledge, the ability to assemble resources, and the resources already available to them. This perspective allows entrepreneurs to move away from analyzing "what is" to discussion of "what is possible", and opens an opportunity for entrepreuneurial discovery. According to Garud and Karnøe´s results (2003, 296) concerning technology entrepreneuship bricolage was a process of moving ahead on the basis of inputs of actors who possessed local knowledge, through interactions, and by gradually transforming emerging paths to higher degrees of functionality. This co-shaping occurred at several interaction points, between designers and shopfloor workers, between producers and users, between external researchers and producers, and between policy makers and the markets that they regulated.

DATA AND METHODS

The focus of the paper is on analyzing the innovation activities – identification, development and exploitation of opportunities – and related resource development strategies in shaping the evolutionary path of a small software firm. To answer the research question, an empirical study using the critical incident technique has been carried out. The critical incident technique is a form of qualitative research that was originally developed by Flanagan. It has become a widely used research method which is utilized across number of diverse disciplines (Butterfield et al. 2005). In this study critical incident refers to an event that has had a significant effect (positive or negative) to the business activities.

The advantage of the CIT is that it can capture both opportunities (potential success) and risks (potential failure factors) and it generates detail descriptions that can identify links between different processes (Kaulio 2003, 196). Further advantages of CIT are for example

that it does not force the respondents into any given framework, it identifies even rare events that might be missed by other methods which only focus on common and everyday events. When looking at disadvantages the method relies on events being remembered by users and will also require the accurate and truthful reporting of them. The method also has a built-in bias towards incidents that happened recently, since these are easier to recall. (Butterfield et al. 2005; Chell 1998.)

Having the research focus on growth and on what kind of resource development strategies can be found "behind" this process, access to growth company was the first key point of the research. The first phase of selection process was based on publicly available information about growth figures (personnel, turnover) of small software firms. The present study was applied as a single case in order to perform a detailed data analysis and understand the case context. Final selection was based on the familiarity with the firm. One of the researchers has worked in the firm for a short period at the beginning of the 2000`s and has since that followed the development of the firm.

The case company is established in 1980`s and it operates in business-to-business niche market. The turnover was approximately 4.9 Million EUR in 2010. The firm consists of two divisions. One is focused on companies own products and the other more in consultant work and tailored products. During the interviews the company had 45 employees. Number of personnel has grown since that. In addition to own personnel the firm has also subcontractors and a growing international partner network, which consists mainly of sales personnel.

The empirical data consists of two pilot thematic interviews (Managing Director, Product Development Manager) done in June 2010 and five CIT based interviews conducted from September - November 2010. The latter ones consist of three individual interviews and two group interviews. The participants are listed in Table 1. Being a mature firm with long history some of the participants had over twenty years of work experience in the firm. The group interview was chosen as a method to help the memorizing of the shared past experiences and thus avoid the bias of reporting only resent incidents. The length of an interview varied between two and three hours. All interviews were tape recorded and later transcribed.

Table 1: Characteristics of the interviews and participants.

Title	Period of employment	Number of interviews	Type of interview
Managing Director	**Founder**	**2**	**individual**
Product Development Manager	**12**	**2**	**individual**
Manager, Consulting Services	**7**	**1**	**individual**
Productization Manager	**21**	**1**	**group 1**
Production Manager	**20**	**1**	**group 1**
Technical Specialist, Project Manager	**25**	**1**	**group 2**
Technical Support & Training	**24**	**1**	**group 2**

Our analytic strategy consists of three steps; identifying incidents, forming and analyzing categories. In analyzing the data we have mainly followed the protocol for credibility checks

introduced by Butterfield and colleagues (2005, 486-490). The checking procedure of the incidents meeting the criterion of inclusion in the study was done by checking the 1) antecedents information, 2) description of the experience itself and 3) the outcome of the incident. In the CIT study the sample size is not determined by the number of participants but by incidents reported. The point of exhaustiveness was achieved in the last interview when no new incidents were found.

At the basis of interviews 70 incidents were identified. Identification was a process done by group of three researchers. After independently identifying the incidents, the agreement level was checked. From each interview differing opinions was found approximately on 2-4 incidents. Final consensus about the 70 incidents was formed after all material was analyzed. Together these incidents form the "big picture" case history which is presented in the next chapter. Next step in analysis was grouping the incidents into categories of critical turning points in growth path of a small firm and finding whether or not regularities can be found. This stage was based on comparative examination – done independently and confirmed by agreement check. In analyzing the R&D related incidents further we have mapped out the actions taken by the entrepreneur and other actors and the outcomes achieved. By adding the details the history could provide a series of R&D "mini-cases".

RESULTS

From sideline job to international player – the development path of the case firm

The case company was founded in 1983 (CE1). Before starting the company, the entrepreneur had worked for three years to obtain customer industry knowledge and to establish customer networks. In the beginning, the entrepreneur continued to work outside the case company and it took two years before he engaged fulltime in developing the firm (CE2). At the same time, first external employees were hired (CE3). At the time, the firm development was slowed down by lack of ICT knowledge; both the entrepreneur and the employees were experts in the substance area, but did not have software development experience. Two years later, in 1987, the firm began to sell also consulting services and tailormade software, which is typical for software firms (CE4).

There were many important changes in operational environment at the coming of new decade. General standardization process of computers and operating systems (CE5) during the late 1980`s made it possible to use same software in different computers. As the need for tailoring diminished it released resources to development work. Case firm had focused from the outset in a niche market in which the use of platform software produced by a major stakeholder in the software industry was growing. Another important technological change was the new interface in this platform software (CE6), which opened up new possibilities for application development. In 1990 though the firm had a good portfolio of own products, the decision was made to start developing a new base product in this platform in cooperation with a partner firm "Alpha" (CE7). At the beginning of 1990´s Finland ended up in deep recession (CE8) but case firm managed to avoid financial decline by making market entry with consulting business in neighbouring market A (CE9).

In 1991 started a long-term (later subcontracting based) cooperation with start-up firm “Beta” (CE10) when a competent applications programmer exited a major industrial stakeholder and started his own firm after developing inside house -software in industry. This cooperation and decision to integrate knowhow complemented case firms coding expertise and helped directing operations to concentrating on chosen programming language (CE11). Year later case company ended the cooperation with firm “Alpha” and bought the source code (CE12). Development work related to new base product continued with firm “Beta” and other stakeholders also in the form of publicly funded development project A (CE13). At the time case firm got membership in developer network organized by platform product producer (CE14). When both offering and personnel were growing internal changes were made in organizational structure by separating the developer team of the new software from consulting team (CE15) in order to manage the information flow. Initial market entry of this new X -base product in domestic market was made 1994 (CE16) which was followed by an internationalization attempt with this own product to market A in trade fair (CE17) later in same year. Though this wasn´t a success concerning sales, initiate contacts with competitor firm “Gamma” and person A representing firm “Delta” about possible cooperation were made. At the time internal changes in the case firm continued as remote office in other city became established (CE18), sales function became professionalized (CE19) and firm joined the retailing network of the platform software (CE20). Exploratory cooperation started in trade fair with firm “Gamma” fizzled out (CE21). Another contact made with the representative of firm “Delta” was more fruitful end result being the establishment of joint venture (CE22) year after the first meeting. Marketing of X –base product in this new market area was boosted by localization of product (CE23).

Changes in operational environment characterize the latter part of the decade. There were signals of changing customer demands in international market. When a new development environment of platform software with better programming possibilities (CE24) was released in 1996 firm started to develop new base product (CE25) with a clean sheet in cooperation with firm “Beta”. Development work was also facilitated by participation in publicly funded development project B (CE26). This new Y -base product was from the beginning directed to international market which was expressed in that the market entry was done in market A instead of domestic market (CE27) in 1998. This was soon followed by initial market entry to market B based on connections made in development project B (CE28) and entering to market C (CE29). Case firm continued strong R&D work and new Y –base product turned into product family with market entry of derivative product 1 (CE30) in 2000. This was followed later by ending the development work of still successful X –base product (CE31) that was widely used in domestic market.

At the beginning of new century changes in business environment ended in tightening competition (CE32). Internationalization continued also in the domestic head office as the number of foreign personnel was growing significantly (CE32). Due to conflicting interests in market A with partner firm “Delta” case firm decided to acquire the ownership of joint venture (CE33). Market position A was further strengthened by major reference transaction (CE34). Internationalization continued by boosting of marketing in market C with new partner (CE35). Case firm continued also growing the product family based on needs of international customers. Year 2002 market entry of derivative product 2 (CE36) enlarged also the domestic clientele by being directed to new customer segment that traditionally

didn´t belong to a domestic target group of firm operating in this niche market. At the same time firm started also the development work with new platform that was used in consulting business (CE37). The offering continued extending when content creation services got more established (CE37) year later. Concerning internal organizational evolution the case firm faced also changes in form of domestic (CE38) and international (CE40) remote teams. New millennium was time of rapid internationalization through networking as the case firm entered market D in cooperation with partner firm "Epsilon"; a contact found through global developer network of the platform software producer (CE41). This was later followed by entering the market F with network connections (CE43) of this new partner firm.

Turbulence in business environment started few years earlier ended in crisis in cooperation with case firm and major stakeholder in the industry (CE44). Due to this turbulence in industry one major competitor exited the market by acquisition of this stakeholder (CE45). Case firm however managed to continue quite successfully in chosen path and proceeded in internationalization by seeking market entry to market G (CE46). Also the Y -product family got new member in the form of market entry of derivative product 3 to this base product (CE47). Year 2005 case firm participated in public development project (CE48) and made important internal development by developing software interface (CE49) and interoperability (CE50). Both crisis in cooperation with major stakeholder (CE51) and internationalization continued as case firm sought market entry to market H (CE52), market I (CE53) and market J (CE54). At the time international sales function become professionalized (CE55) and knowledge management improved (CE56). Marketing of Y – product family in market I and C was boosted by localizations of product (CE57 and CE58). Rapid growth continued both in the form of expanding the offering by making market entry of derivative product 4 (CE59) and by boosting marketing in market B with new partner (CE60).

In 2007 a significant change in operational environment was the release of the new platform software by aforementioned software industry stakeholder (CE61). Next year the case firm started development work of new base product (CE62) in this new platform, which helped also to revive the strategic cooperation (CE63). With growing personnel and offering firm made changes to licensing (CE64), delivery (CE65), knowledge management (CE66, CE67 and CE68) and organization (CE69) at the end of the decade. The market entry of new Z – base product was done in 2010 (CE70). The development of Y –product family is still the main priority and it is expected to continue also in the near future.

To summarize the development path of our case firm we identified 10 categories of incidents – internationalization, internal organization, expansion of offering, R&D, strategic alliance, change in operational environment, focusing of business, remote offices, public development cooperation, crisis in cooperation - that have had a significant (positive or negative) effect to the business activities of the firm. This firm has focused to a certain niche market and due to that and the small size of the domestic market, growth has mainly occurred in a form of internationalization. Essentially the development path of the firm mainly consists of alternation of growth elements (R&D and related expansion of offering, internationalization) and arrangements made in a way the firm operates (internal organization of firm, strategic alliances, focusing).

Entrepreneur -centred or distributed agency?

From the case history four major R&D projects that is “mini-cases” can be found, that have had significant impact to firm´s success (Table 2). Three of which have related strongly to particular technology change, and one to more general changes in technology. The role of the entrepreneur was significant concerning the early stages of innovation activities in every single one of them. It was the entrepreneur who had been alert to sensing the signals from different stakeholders about changing working culture and/or needs through networks and who by utilizing and combining this new information to prior knowledge started to assemble the needed resources to develop the opportunity. Concerning the personality traits of the entrepreneur, as part of the opportunity identification model created by Ardichvili and colleagues, every interviewed employee mentioned that the entrepreneur as a person and his drive to develop things further was the single most important thing for the success of the firm.

“The most important thing is managing director as a person. He has inexhaustible energy to develop things further. And he is also a really good seller. It is absolutely the single most important thing. And in the course of time he has been able to push the right buttons, knew what to do and to which market to enter. His eye for the game has probably been the most valuable thing.”

Table 2: The role and input of different actors in platform –level R&D projects.

Actors	**Technological opportunity 1**	**Technological opportunity 2**	**Technological opportunity 3**	**Technological opportunity 4**
Entrepreneur	identifying opportunity, starting and leading the development process, domestic network	identifying opportunity, starting and leading the development process, nordic network	identifying opportunity and starting the development process, international network	identifying opportunity, starting and leading the development process, international network
Consulting department	indirect input from customer understanding from tailored products	from no input to participation through tailored interoperability issues	learning new technology by doing, derivative services	learning standardized interoperability work by doing
Products department	learning new technology by doing, creating new base product and localization (1)	learning new technology by doing, creating new base product family; derivatives(4) and localizations (2)	learning and creating interoperability by doing	learning new technology by doing, interoperability, creating new base product
Platform software producer	New platform Provider of contacts, information, resources and credibility through developer and retailer networks	New interface Competitor after expanding to application production, exclusion from networks and resources	-	New platform software Partner seeking win-win – situation in application localizations, revival of developer partnership.
Developer partners	"Alfa"- complementary earlier experience on platform software "Beta" ; expert know-	"Beta" – first technical solutions together with entrepreneur, continuing participation in	-	"Beta" - first technical solutions together with entrepreneur, continuing participation in derivatives

	how on programming, first version of new technical solution in joint project, continued participation	derivatives		
Industrial partners and customers	Participation and funding in joint project	Growing importance in customer industry process and interoperability understanding, content creation	Needs to new solutions, partners in improving interoperability within industry, content creation	Growing importance in customer industry process and interoperability understanding, content creation
Substance area related stakeholders	Pioneer firms using the platform product, signals of changing culture in industry	Partners in improving interoperability within industry	-	Partners in improving interoperability within industry
Product customers and users	Contacts provided by domestic lead user led R&D project, cooperation in testing and development after the first released version	Continual cooperation in testing and developing (usability, needs) also with international lead users, needs from international customers for wider offering	Indirect input concerning interoperability needs	Signals from changing needs from international customers
Competitors	International forerunner´s example of possibilities with application to platform	International forerunner´s example of new dimension in applications	-	Benchmark knowledge from international competitors about wider vs. deeper markets
Public partners	Finance to joint project	Finance to joint project	Customer industry	Customer industry

	Customer industry regulations	Customer industry regulations, developer partners	regulations	regulations
Sales partners	National regulations and needs	National regulations and needs	-	National regulations and needs

Klofsten (2005) has analyzed the early process of ideas development in a newly started knowledge intensive firms. His main conclusions are in line with our results in that the technical skills of the founder(s) were decisive for the generation of new ideas and that the early process of idea development was is in many respects technique driven. Results are similar also concerning the first appearance from the data that having an idea seemed to be a random process, "don't remember where the idea came from", and beginning of development work quickly done, though in fact behind these two processes are years of mental work that makes a discovery possible.

All in all the product development work done in case firm has been visionary and the products created have from their own part had an effect also on the working culture of customers. In the late 1990`s the new software first even met resistance in domestic market because users had to renew their way of working. There was no pressure from domestic market to renew the offering at that time. Still the entrepreneur made the decision to stop the development of the old base product and concentrate resources to developing new product family. This is in line with Nambisan´s (2002) results concerning the evolvement of software firms where the author posited that the first prerequisite for a firm to evolve is the positive attitude towards pursuing technology leadership and envisioning a clear technology development path by top management. In the case firm the signs from change in customer industry came from international competitors which were much bigger firms acting on different scale. The created software was however technologically transcendent and the small nameless firm managed to made breakthrough.

When looking at the stage of opportunity exploitation, the pattern of entrepreneur led prototyping done by a small group characterized the way how every major R&D project began. So also this first stage when resources beyond time were used was based on and led by the vision of the entrepreneur. Executing the vision may require also calculated risks because besides offering a business opportunity new technology is also risk by being competence destroying (see Jones 2003; Nambisan 2002). Every four major R&D projects required learning by doing from the employees of the firm. Even when trying to get education it might not be available. Networking and strategic alliances have been the way to complement knowledge base and speed up the development.

"You just have to learn the hard way. We didn´t know how to use it (platform software). We participated to some courses, but both were equally lost. Those courses were quite vapid."

"He was an expert programmer and we were just engineers. He was more competent and we decided to join our forces."

Though the beginning of the innovation process has been strongly in the hands of the entrepreneur, one of the biggest strengths of the firm (or entrepreneur) has been the capability to recognize the importance of different stakeholders and get them to participate in creation of new technology. The substance area is regulated by national standards which guide the work of different customer segments. This meaning that in new market area you have to have knowledge not only about customer needs but also about local regulations, which highlights the need for good partners.

"We just kind of an early stage started export business and this way started to understand the importance of communication. That you really have to be able to interpret the messages the opposite firm is sending, and to understand that things aren´t necessarily as they say. We also have reached an understanding that this line of business consists of many stakeholders. We have to scan the market throughout. It has forced to think quite diverse about things."

When looking at the R&D cases, the number and role of different partners has grown in three major R&D projects related to own products. In 1990`s the firm developed first versions of software together with a small start-up partner firm and later on together with a domestic lead user customer and made first experiments in international market. The next R&D project wasn´t just about usability or new attributes related to certain software, but the important development questions had to do with interoperability concerning whole customer industry. In these later R&D projects the role of major stakeholders comes close to Garud and Karnøe´s (2003) perspective on technology entrepreneurship as involving agency. In questions of improving interoperability the development has been a process that is based on stakeholders having local knowledge about their substance area and providing inputs through interactions to mutual development process where different stakeholders are gradually transforming not only functionality of a certain software product but also common industry way of action.

CONCLUSIONS

The role of the entrepreneur was significant concerning the early stages of innovation activities related to technological changes that opened up new opportunities. Every major R&D event it was the entrepreneur who identified the opportunity, started and (mostly) led the early process. Concerning the personality traits of the entrepreneur every interviewed employee mentioned that the entrepreneur as a person and his drive to develop things further was the single most important thing for the success of the firm. To summarize it can be said that the process model of opportunity identification presented by Ardichvili and colleagues that links the agency to the entrepreneur helped to shed light to question about identifying the right opportunities.

The importance of networks was significant not only as an antecedent of entrepreneurial alertness and opportunity identification as in model created by Ardichvili and colleagues but also in exploiting the opportunities. Though the firm managed several times to rose up to the challenge of using existing resources to new purposes, external networks were critical. At earlier R&D projects these helped not only in understanding market requirements but also in filling critical internal technology gaps. In recent development work the role of these stakeholders has come closer to creating common processes that have impact to evolution of whole industry. From this point of view there are implications that the entrepreneur-centred viewpoint is too narrow concerning innovation activities in the context of technology entrepreneuship.

The interview material didn´t provide much information how the opportunity development proceeded and which actors participated when moving ahead from opportunity identification towards more concrete business opportunity. The details of actions made

before committing other resources than the time of an entrepreneur and other actors are not known. This shortcoming can at least partly be explained by the fact that being a mature firm with a long history it was a challenge both to interviewer and participants to go through the major events that had shaped the evolutionary path of the firm during almost thirty years.

ABSTRACT

The appearance of the Internet in the economy in the 1990s, has let in today's globally competitive environment, a tremendous expansion in technology for business and rapid growth in investments (Skerlavaj and Dimovski, 2006) and assessing the value of technology has never been easy. Then, the aim of this paper is to highlight the importance of different technological aspects of organizations on high technology Spanish firms´ performance. To obtain perfect adaptation of the firm to its environment, it is crucial that managers develop the corporate entrepreneurship to improve high technology sector firms´ performance. The paper shows the important role of top manager's support on technological distinctive competencies and organizational learning. Success in this kind of aspects is of vital importance to the corporate entrepreneurship in the firm.

The studied relationships are empirically confirmed by using a structural equation model to demonstrate our hypotheses. The sample was selected from the database Dun & Bradstreet España in 2005, obtaining 201 Spanish firms. Finally, CEOs were our main informants.
To sum up, the paper seeks to stimulate new lines of research regarding one variable (technological distinctive competencies) and relate it to other constructs, producing new relationships and observing their repercussions for the firm.

Keywords: Technological Distinctive Competencies, Top Management Support, Organizational Learning, Corporate Entrepreneurship, Organizational Performance.

INTRODUCTION

The 1990s might well be considered the beginning of the era called the new or e-economy because of the appearance of the Internet in the economy, which has let in today's globally competitive environmºent, a tremendous expansion in technology for business and rapid growth in investments (Skerlavaj and Dimovski, 2006).

Assessing the value of technology has never been easy. The application of technology throughout the company (Andreu and Ciborra, 1996; Giarratana and Torrisi, 2010; Leonard-Barton, 1992) has increased the importance of Technological Distinctive Competencies

(TDCs), which permit exploitation of the technological opportunities for the development of corporate entrepreneurship, the reduction of costs and the generation of organizational competitive advantage (Alvarez and Barney, 2007; Autio *et al*., 2000; Real *et al*., 2006; Woolley, 2010).

In this research, TDCs represent "the organization's expertise in mobilizing various scientific and technical resources through a series of routines and procedures which allow new products and production processes to be developed and designed" (Real *et al*., 2006, p. 508).

This research contribute to the previous research by joining TDCs to other strategic constructs, such as the necessity of Top Management Support of technology (briefly TMS) to obtain these competencies, or the learning processes needed all over the organization, analyzing globally and empirically their repercussions for the corporate entrepreneurship so as to achieve a higher value firm. Thus, the study seeks first to analyze empirically the influence of TMS on TDCs (e.g., Byrd and Davidson, 2003; Haro *et al.*, 2010). Secondly, we seek to analyze how these TDCs and TMS influence organizational learning (OL) (Alvarez and Barney, 2007; Autio *et al*., 2000; Leonard-Barton, 1992; Shane and Venkataraman, 2000; Teece, 1986; Woolley, 2010). Thirdly, we try to analyze the direct relationships between both TDCs and OL on corporate entrepreneurship (Alvarez and Barney, 2007; Leonard-Barton, 1992; Woolley, 2010). Organizations that engage in entrepreneurial activities achieve higher levels of growth and profitability than organizations that do not, thus also achieving higher organizational performance (Antoncic and Hisrich, 2001). Corporate entrepreneurship involves "extending the firm's domain of competency and corresponding opportunity set through internally generated new resource combinations" (Covin and Slevin, 1991, p. 1). Thus, corporate entrepreneurship refers to ''the process by which firms notice opportunities and act to creatively organize transactions between factors of production so as to create surplus value'' (Jones and Butler, 1992, p. 735).

All of these technological variables demand strong and committed TMS to guide the initiative and develop a working environment that supports technology (Ghosh *et al*., 2001). TMS "reflects, in many ways, the importance that top management executives place on technology" (Byrd and Davidson, 2003, p. 246). For Leonard-Barton and Deschamps (1988, p. 1254), TMS is a "perceived powerful source".

TDCs influence corporate entrepreneurship, improving organizational performance. In addition, TDCs impact corporate entrepreneurship directly because they permit entrepreneurs to earn their status by demonstrating excellence in technological and professional skills and knowledge (Leonard-Barton, 1992). TMS has been closely linked to TDCs (Byrd and Davidson, 2003; Ghosh *et al*., 2001; Leonard-Barton and Deschamps, 1988).

Although corporate entrepreneurship is directly influenced by TDCs, it may well be also influenced through OL (Benitez *et al*., 2010; Chenhall, 2005; González and Nieto, 2005; Leonard-Barton, 1992; Omerzel and Antoncic, 2008; Rerup, 2005), since OL disseminates and uses the learnt knowledge to encourage entrepreneurial behavior (García *et al*., 2006; Senge *et al*., 1994). OL can be considered a process whereby members in an organization are stimulated to strive continually for new approaches and acquire, as well as to share

knowledge consequential to interactions with environments (Argyris, 1993; Nonaka and Takeuchi, 1995).

In the section on hypotheses, we draw on prior research to develop a number of testable hypotheses concerning the influence of TMS on TDCs, the influence of TMS and TDCs on OL, the influence of TDCs and OL on corporate entrepreneurship, and the way corporate entrepreneurship improves organizational performance. That section serves as the theoretical foundation for the paper. The next sections present the research methodology and discuss the results. The final section makes some concluding observations and points out some of the study's limitations and lines for future research.

HYPOTHESES

The influence of TMS on TDCs and OL

TMS has long been recognized as one of the most important factors for ensuring successful implementation of distinctive competencies (Byrd and Davidson, 2003; Ghosh *et al*., 2001; Leonard-Barton and Deschamps, 1988; Petroni and Panciroli, 2002). It reflects the importance that the top management executives place on technology competencies (Byrd and Davidson, 2003).

TMS helps the firm to obtain more TDCs and competitive advantage in key business areas (Byrd and Davidson, 2003). An innovation-supportive culture from top managers can generate higher business value (Petroni and Panciroli, 2002), which is translated into higher TDCs in the firm (Benitez *et al*., 2010).

In the technological innovation literature, management support is seen as an important power-tool to promote TDCs (Kanter, 1984). Zmud (1984) finds that managerial influence is stronger for technological innovations, because they require more skilled individuals who may achieve excellence in technology (Leonard-Barton and Deschamps, 1988).

Torkkeli and Tuominen (2001) found TMS to be seen very advantageous and appropriate to core competency-based technology because it offers many potential benefits for supporting core distinctive competency-based technology, such as skilled technological entrepreneurs (Antoncic, 2007), exceptional skills managers (Leonard-Barton, 1992) and better-trained employees (Andreu and Ciborra, 1996; Torkkeli and Tuominen, 2001).

Such support is vital to obtaining TDCs and the successful implementation of TDC strategies to improve competitiveness, as well as to achieving a sustainable competitive advantage that is truly difficult to imitate (Haro *et al.*, 2010). Then, in the light of the foregoing, the following hypothesis is proposed:

Hypothesis 1: TMS will be positively related to TDCs in technological organizations.

TMS is one of the most important factors of systematic knowledge management and OL. Omerzel and Antoncic (2008) studied TMS in small and medium-sized enterprises and concluded that one person is usually in charge of OL, combining both knowledge ownership

and the managerial function. For them, the main manager is the person who provides employees with a knowledge technological framework by means of an OL process. Fineman (1996) provides insight into the influence of TMS as it plays a key role in shaping the climate for such a learning culture. Managers should understand company culture and values, and they should maintain what is good and promotes knowledge creation through an OL process. This can be achieved if the manager is willing to observe and talk to employees, to recognize obstacles, problems and success, and to train employees (Leonard-Barton, 1992). Top management characteristically requires different knowledge in different growth periods and thus continuously develops its OL process so as to obtain that knowledge (Omerzel and Antoncic, 2008).

Furthermore, expert managerial culture may provide an overarching frame of reference, helping to align employees' behavior who, if implement a technology-supportive culture, will have more precise knowledge of the organizational objectives for innovation and will make a greater effort to achieve these objectives more efficiently, (Andreu and Ciborra, 1996; Leonard-Barton, 1992) provided by top management (Chenhall, 2005). In practice, top management designs OL processes for employees to learn and, consequently, the firm may well be able to obtain a competitive advantage that it would otherwise not achieve (González and Nieto, 2005).

Successful managers develop various practical skills during their work and exert considerable effort on building support systems for disseminating knowledge technological and initiating an OL process to teach it (Andreu and Ciborra, 1996; Leonard-Barton, 1992; Omerzel and Antoncic, 2008).

TMS permits the organization to learn through experimentation, communication, dialogue, personal mastery and the process of organizational knowledge creation in order become an intelligent organization (Leonard-Barton, 1992; Lloréns *et al*., 2005). Consequently, OL needs strong technological commitment and TMS to achieve competitive advantage (Lei *et al*., 1999; Lloréns et al., 2005). Based on this prior literature, we propose the following hypothesis:

Hypothesis 2: TMS will be positively related to OL in technological organizations.

The influence of TDCs on OL and corporate entrepreneurship

Technological competencies are one important element of the core competencies of the firm. Management usually strengthens these TDCs as a means to nurturing strengths in technological knowledge and production routines to exploit potential outcomes, create potential markets and beat potential competition (Banerjee, 2003).

TDCs may become institutionalized over a long period of time and form part of the company's knowledge creation system (Leonard-Barton, 1992). Andreu and Ciborra (1996) share this idea and observe that the development of central competencies (e.g. TDCs) is linked to the process of OL. TDCs constitute the roots of a firm's sustainable competitive advantage, since the competencies comprise patents protected by law, technological

knowledge, and production skills that are valuable and difficult for competitors to imitate (Lee *et al*., 2001). Such competencies are obviously even more central in high-technology firms because they comprise technological knowledge—internal know-how generated by R&D and other technology-specific intellectual capital such as OL (Lee *et al*., 2001). OL programs make possible effective incorporation of the firm's TDCs into the firm's organizational context, making them apparent on all organizational levels and giving them meaning (Andreu and Ciborra, 1996).

Along similar lines, Real *et al*. (2006) state that developing competencies involves OL about how to combine and use resources, as well as the learning already embedded in the organizational routines employed.

An educational system or OL program is required for the entire production staff, involving both classroom education and on-the-job training to exploit technological competencies (Alvarez and Barney, 2007; Leonard-Barton, 1992). Management actions aim at giving learning processes the appropriate direction at any point in time (Argyris, 1993). The goal is for employees to understand TDCs (Real *et al*., 2006) on all levels of the organization so that the organization can obtain a competitive advantage and stand out from its competitors (Real *et al*., 2006). Based on this literature, we propose the following hypothesis:

Hypothesis 3: TDCs will be positively related to OL in technological organizations.

TDCs are typical of entrepreneurs who support the generation of corporate entrepreneurship. These entrepreneurs have exceptional skills or distinctive competencies that enable corporate entrepreneurship by distinguishing the technological competencies. Entrepreneurs are able to invent their way out of difficulties using their technological excellence (Leonard-Barton, 1992). TDCs enable entrepreneurship (Leonard-Barton, 1992; Rerup; 2005).

Technology-intensive firms should be more flexible in order to combine their technology with other complementary assets, such as competencies in exploiting international growth opportunities (Autio *et al*., 2000; Haro *et al.*, 2010). Woolley (2010) applies this insight to technological firms and underscores that TDCs provide opportunities for entrepreneurs in the firm. Technological competencies provide an ownership advantage that enables entrepreneurs to increase the firm's likelihood of survival (Giarratana and Torrisi, 2010).

TDCs are a necessary but not a sufficient condition for generating a sustainable competitive advantage (Giarratana and Torrisi, 2010). Such advantage requires that TDCs be combined with other complementary assets that the firm may or may not be able to develop or acquire and which could have negative consequences for profitability (Teece, 1986).

Thus, the entrepreneur must take existing technological knowledge and assimilate it to obtain TDCs. The entrepreneur must identify potential market opportunities and then act upon them (Woolley, 2010) to obtain an outstanding advantage. TDCs are thus a brilliant way for entrepreneurs in the corporation to demonstrate their technological knowledge. Consequently, we formulate the following hypothesis:

Hypothesis 4: TDCs will be positively related to corporate entrepreneurship in technological organizations.

The influence of OL on corporate entrepreneurship

OL models are usually appropriate for the study of corporate entrepreneurship (García *et al*., 2006; Yang and Rui, 2009). When used strategically, OL and information systems promote entrepreneurial actions by efficiently filtering, sorting, routing, and contextualizing relevant information for senior managers (Simsek *et al*., 2009). Simsek *et al*. (2009) consider OL to be a central mechanism in an organization, a mechanism that is likely to grant the firm an adaptive advantage via corporate entrepreneurship.

Many organizations make considerable efforts to build systems for acquiring and disseminating knowledge, developing OL processes for all employees in the firm so that they may achieve corporate entrepreneurship (Leonard-Barton, 1992; Omerzel and Antoncic, 2008). If an organization wishes to have well-constructed corporate entrepreneurship, entrepreneurs should view the need for different knowledge in different growth periods as characteristic and thus continuously develop OL processes to satisfy their need for knowledge (Omerzel and Antoncic, 2008).

OL is normally analyzed as an antecedent of entrepreneurship, which increases the organization's capability to carry out actions to improve organizational performance (e.g., García *et al*., 2006; Yang and Rui, 2009). In addition, corporate entrepreneurship requires an OL framework that involves search activities such as expending resources on the exploration of alternative possibilities, attempting to understand the relationship between organizational characteristics and outcomes, and determining the viability of organizational change (García *et al*., 2006; Lant and Mezias, 1990). Thus, information flows lead us to know that OL is expected to be positively related to corporate entrepreneurship (Antoncic, 2007; Antoncic and Hisrich, 2001; Yang and Rui, 2009). Based on the previous literature, we formulate the following hypothesis:

Hypothesis 5: OL will be positively related to corporate entrepreneurship in technological organizations.

The influence of corporate entrepreneurship on organizational performance

Corporate entrepreneurship is a strategic variable in successful organizations (Antoncic and Hisrich, 2001; Antoncic and Prodan, 2008; Kanter, 1984). It is positively related to the firm's growth and profitability (Covin and Slevin, 1991; Zahra, 1993). Organizations that engage in entrepreneurial activities achieve higher levels of growth and profitability than organizations that do not (Antoncic and Hisrich, 2001). A study by Zahra and Garvis (2000) shows that international corporate US companies' entrepreneurship was positively associated with the firm's overall profitability and growth, as well as its foreign profitability and growth. Furthermore, corporate entrepreneurship enables organizational performance (Antoncic and Prodan, 2008). Entrepreneurs, who identify their firms' positions in the competitive network of the industry correctly, strengthen and engage new sales, financial capital and important decisions, about alliances and joint projects (Batjargal, 2007). Wood

and McKinley (2010) suggest that entrepreneurs are not simply filters and interpreters of information; rather, they are an integral part of opportunity emergence, as they invent part of what they believe to be viable in order to improve organizational performance (Wood and McKinley, 2010).

Nevertheless, it is not expected that all firms will demonstrate strong corporate entrepreneurship and, then, a higher performance (Lengnick-Hall, 1992). For instance, some organizations avoid responding to the need for change as long as possible (Lengnick-Hall, 1992).

For technological organizations, various current studies indicate a positive relationship between corporate entrepreneurship and organizational performance. Pearce *et al*. (2010) assert that corporate entrepreneurship has a positive effect on commercial organizations, as it leads to a beneficial first-mover advantage. Audretsch *et al*. (2008) show that positive economic performance in high-tech or Information and Communication technology companies depends on entrepreneurship capital, the capacity of a region to support entrepreneurs. Based on previous literature, the following hypothesis is proposed:

> *Hypothesis 6: Corporate entrepreneurship will be positively related to organizational performance in technological organizations*.

METHODOLOGY

Sample and Procedure

The population for this study consisted of technological organizations possessing the greatest turnover in Spain. Technological organizations are firms which put emphasis on an orientation towards R&D, on innovativeness and entrepreneurship and maintain a special pattern of work relations (the corporate culture of technology). These elements describe shared values, beliefs and symbols, and the way things are done in the firm (Grinstein and Goldman, 2006). The sample was selected by means of a stratified sampling with proportional allocation (size and geographical location) from the database Dun & Bradstreet España (2005). Choosing a sample of firms located in a relatively homogeneous geographical, cultural, legal and political space enables us to minimize the impact of the variables that cannot be controlled in the empirical research. The Spanish market is relatively well developed and wholly integrated in the European Union. However, Spain is in a geographical area that has received relatively little attention from organizational researchers in the field of technological competencies.

We developed a structured questionnaire for sending it to CEOs of the organizations. CEOs were our main informants, since they constitute a valuable source for evaluating and molding the different variables under study throughout the organization by determining the types of behavior that are expected and supported (Baer and Frese, 2003).

Surveys were mailed to the 1000 selected organizations along with a cover letter. We used this method because it enabled us to reach a greater number of organizations at a lower cost, to exert less pressure for immediate reply, and to provide the interviewees with a

greater sense of autonomy. The cover letter explained the goal of the study and offered recipients the option of receiving the results once the study was completed. It also explained that all responses obtained in the questionnaires would be used on an aggregate level to prevent the identification of any organization in order to reduce desirability bias.

We mailed each manager who had not yet responded two reminders. 226 valid questionnaires were returned, but because of missing values only 201 questionnaires were included in the research. The response rate was 20.1 % (Table 1) without significant difference between early and late respondents. Characteristics of the responding businesses were compared to those of the non responding businesses to reduce the possibility of non-response bias. The results for return on assets, return on equity, return on sales and number of employees indicated that there was no significant difference among respondents and non respondents. Nor did we find significant differences due to geographical location or size in the variables studied in the different tests, such as the chi-square and t-tests. Since all measures were collected with the same survey instrument, the possibility of common method bias was tested using Harman's one-factor test (Konrad and Linnehan, 1995). A principal components factor analysis of the questionnaire measurement items yielded four factors with eigenvalues greater than 1.0, which accounted for 71 percent of the total variance. A substantial amount of method variance does not appear to be present, since several factors, not just one single factor, were identified and because the first factor did not account for the majority of the variance (Podsakoff and Organ, 1986).

Table 1: Technical details of the research.

Sectors	High-tech services (computer science activities, research and development services, postal and telecommunications services), high-tech manufacturing (chemical industry; aerospace construction; radio, television and communication manufacture; office machinery and computer science equipment; medical instruments, precision optics and watches)
Geographical location	Spain
Methodology	Structured questionnaire
Procedure	Stratified sample with proportional allocation (size)
Universe of population	50,000 firms
Sample (response) size	1000 (201) firms
Sample error	6.9%
Confidence level	95 %, p-q=0.50; Z=1.96
Period of collecting data	From April 2010 to May 2010

Measures

Given that developing new constructs or scales of measurement is a complex task, wherever possible we use pre-tested constructs from past empirical studies to ensure their validity and reliability. Subsequently, we performed an exploratory factor analysis using the method of extraction of principal components with varimax rotation obtaining the five factors of our study clearly framed (Table 2).

Table 2: Exploratory factor analysis.

Items	Factor 1	Factor 2	Factor 3	Factor 4	Factor 5
MANSUP1		0.820			
MANSUP2		0.720			
MANSUP3		0.753			
MANSUP4		0.782			
TECCO1	0.798

TECCO6	0.427				
ORLEAR1			0.783		
ORLEAR2			0.801		
ORLEAR3			0.784		
ORLEAR4			0.662		
COREN1					0.538
COREN2					0.849
COREN3					0.553
COREN4					0.817
PERFO1				0.857	
PERFO2				0.863	
PERFO3				0.875	
PERFO4				0.589	
PERFO5				0.570	

TMS: Using scales established by Byrd and Davidson (2003) and Ray *et al*. (2005), we drew up a four-item scale (Appendix) to reflect TMS. We developed a confirmatory factor analysis to validate our scales (χ^2_2=11.42; NFI=.99; NNFI=.98; GFI=.99; CFI=.99). The scale was one-dimensional and showed high reliability (α=.926).
TDCs: Using scales established by Real *et al*. (2006), we drew up a six-item scale (Appendix) to reflect TDCs in the organization. We developed a confirmatory factor analysis to validate our scales (χ^2_9=19.39; NFI=.99; NNFI=.99; GFI=.99; CFI=.99). The scale was one-dimensional and showed high reliability (α=.917).

OL: We used the scale of four items developed by Aragón *et al*. (2007) and García *et al*. (2006, 2008) to measure OL (Appendix). These items have been duly adapted to the present study. We developed a confirmatory factor analysis to validate the scales (χ^2_2=5.74; NFI=.99; NNFI=.99; GFI=.99; CFI=.99) and showed that the scale was one-dimensional and had adequate validity and reliability (α=.908).

Corporate Entrepreneurship: We used five items developed by Knight (1997) to measure proactiveness, five items developed by Zahra (1993) to measure new business venturing, eight items developed by Zahra (1993) to measure self-renewal, and six items developed by Zahra (1993) to measure organizational innovation. These items have been duly adapted to the present study (Appendix). A 7-point Likert scale (1 '*totally disagree'*, 7 '*totally agree'*) for this and all prior variables allowed managers to express agreement or disagreement. We calculated the arithmetical mean of these items (a high score indicated good level of proactiveness, new business venturing, self-renewal and organizational innovation) and obtained a four-item scale of corporate entrepreneurship. We developed a confirmatory factor analysis to validate the scale of corporate entrepreneurship (χ^2_2=16.39; NFI=.98; NNFI=.95; GFI=.99; CFI=.98) and showed that the scale was unidimensional and had adequate validity and reliability (α=.867).

Organizational Performance: We used the scale of five items developed by Murray and Kotabe (1999). The use of scales for evaluating performance relative to the main competitors is one of the most widely-employed practices in recent studies (e.g., Choi *et al*., 2008). Many researchers have used managers' subjective perceptions to measure beneficial outcomes for firms. Others have preferred objective data, such as return on assets. The literature has established widely that there is a high correlation and concurrent validity between objective and subjective data on performance, which implies that both are valid when calculating a firm's performance (Homburg *et al*., 1999; Venkatraman and Ramanujan, 1986). We included questions involving both types of assessment in the interviews, but the CEOs were more open to offering their general views than to offering precise quantitative data. When possible, we calculated the correlation between objective and subjective data, and these were high and significant. We developed a confirmatory factor analysis to validate the scales (χ^2_5=34.92; NFI=.97; NNFI=.95; GFI=.98; CFI=.97) and showed that the scale was unidimensional and had high reliability (α=.867). We used a Likert-type 7-point scale (1 *"Much worse than my competitors,"* 7 *"Much better than my competitors"*) to ask about the organization's performance as compared with that of its most direct competitors.

Model and analysis

Data were analyzed through a structural equation model (LISREL 8.30 program) to determine the existence of exogenous latent variables (TMS [ξ_1]), first-grade endogenous latent variable (TDCs [η_1] and OL [η_2]), second-grade endogenous latent variables (corporate entrepreneurship [η_3], organizational performance [η_4]) and to establish the causal relationships among these variables. This process allowed us to translate the theoretical constructs into mathematical models so that the constructs could be estimated and evaluated empirically (Jöreskog and Sorbom, 1996). The hypotheses are plotted graphically in the theoretical model presented in Figure 1. We used a recursive non-saturated model. Structural equation modeling takes into account errors in measurement, variables with multiple indicators and multiple-group comparisons.

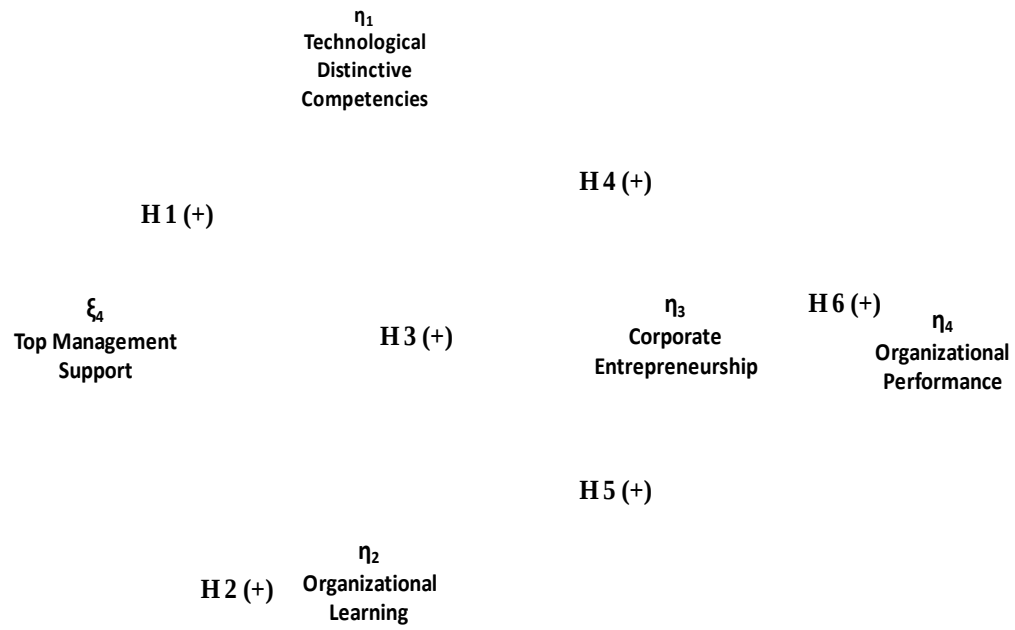

Figure 1*: Hypothesized model*.

RESULTS

In this section, we present the main research results. First, Table 3 shows the means and standard deviations as well as the inter-factor correlation matrix for the study variables. There are significant and positive correlations among TMS, TDCs, OL, corporate entrepreneurship and organizational performance.

Table 3: Means, standard deviations and correlations.

Variable	Mean	S.D.	1	2	3	4	5
1. Top Management Support	4.706	1.438	1.000				
2. Tech. Dist. Competencies	4.664	1.273	.748***	1.000			
3. Organizational Learning	4.791	1.404	.670***	.681***	1.000

Note: *p<.05;**p<.01;***p<.001(two-tailed). n=201

Second, structural equations model was performed to estimate direct and indirect effects using LISREL with the correlation matrix as input. This type of analysis has the advantage of correcting for unreliability of measures and also gives information on the direct and indirect paths between multiple constructs after controlling for potentially confounding variables. Figure 2 shows the standardized structural coefficients. The relative importance of the variables is reflected by the magnitude of the coefficients.

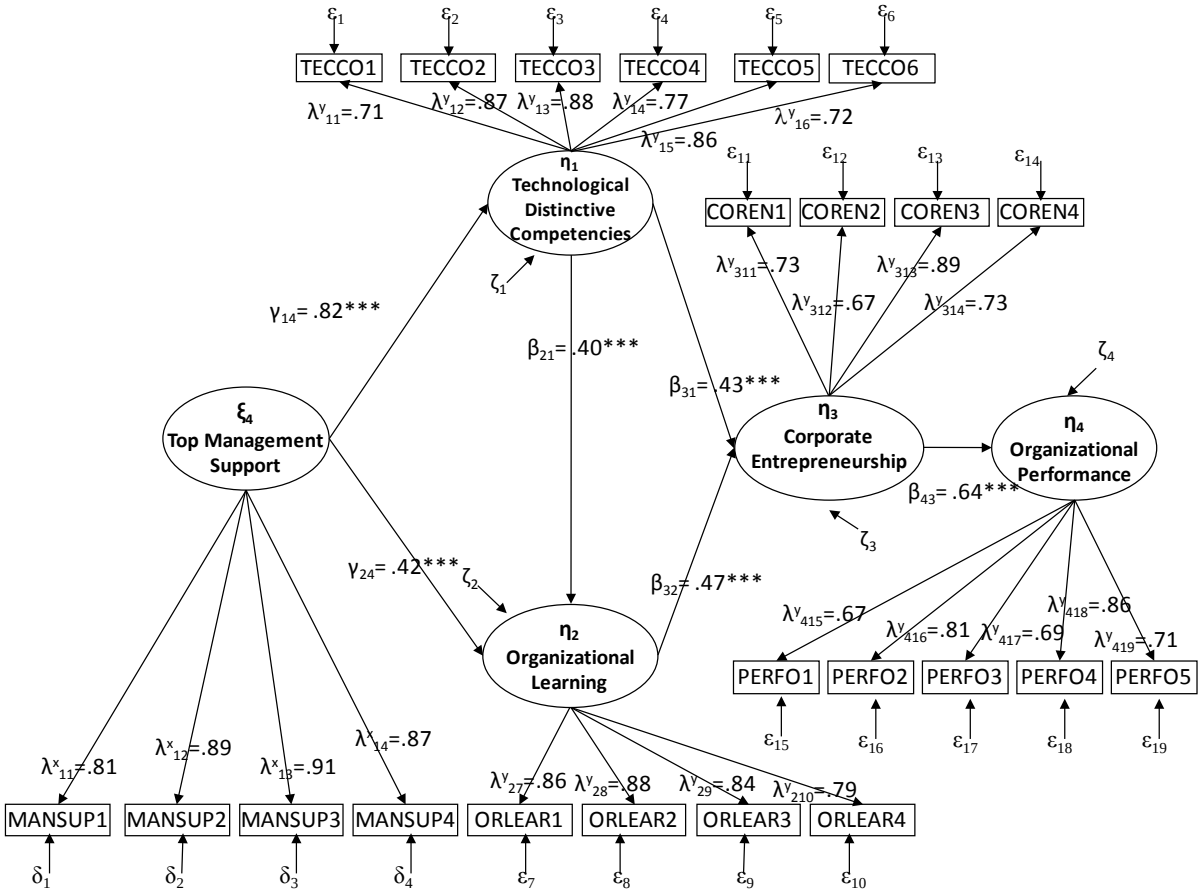

Figure 2*: Results of structural equation model.*

For quality of the measurement model for the sample, the constructs display satisfactory levels of reliability, as indicated by composite reliabilities ranging from 0.84 to 0.92 and shared variance coefficients ranging from 0.57 to 0.87 (Table 4). Convergent validity can be judged by observing both the significance of the factor loadings and the shared variance. The amount of variance shared or captured by a construct should be greater than the amount of measurement error (shared variance>0.50). All of the multi-item constructs meet this criterion, each loading (λ) being significantly related to its underlying factor (t-values>15.55) in support of convergent validity. To assess discriminant validity, we performed a series of chi-square difference tests on the factor correlations among all constructs (Anderson and Gerbing, 1988). We did this for each pair of latent variables by constraining the estimated correlation parameter between them to 1.0 and then performing a chi-square difference test on the values obtained for the constrained and unconstrained models (Anderson and Gerbin, 1988). The resulting significant differences in chi-square indicate that the constructs are not perfectly correlated and that discriminant validity is achieved.

Table 4: Validity, reliability and internal consistency.

Note: λ* = Standardized Structural Coefficient; R^2 = Reliability; α = Alpha Cronbach; C. R. = Compound Reliability; S. V. = Shared Variance; f. p. = fixed parameter; A. M. = Adjustment Measurement; *p < .05; ** p < .01; *** p < .001(two-tailed).

The overall fit measures, multiple squared correlation coefficients of the variables (R^2s), and signs and significance levels of the path coefficients all indicate that the model fits the data well (χ^2_{224}=574.86; p>.001; χ^2_{ratio}=2.56; NFI=.99; NNFI=0.99; GFI=.99; CFI=0.99; IFI=.99; PGFI=.80). The hypothesized model was a significantly better fit than the null model (χ^2_{253}=11984.91; p>.001;Δ χ^2_{29}=11410.05;p>.001). All of the modification indices for the beta pathways between major variables were small, suggesting that adding additional paths would not significantly improve the fit. The residuals of the covariances were also small and centred around zero.

If we examine the standardized parameter estimates (Table 5), the findings show that TMS (γ_{11}=.82; p<.001) is related to and affect TDCs, as predicted in Hypotheses 1. TDCs is explained well by the model (R^2=.67). TMS affects the development of TDCs because human, conceptual, and technological competency are thought to be supported by managerial effectiveness (Benitez *et al*., 2010). TMS also affects OL directly (β_{21}=.42; p<.001). Furthermore, we have shown an indirect effect (.33; p<.001) of TMS on OL by TDCs (.82x.40; see Bollen, 1989 for calculation rules). The global influence of TMS on OL is thus 0.75 (p<.001), supporting Hypothesis 2. TMS encourage OL processes´ development, which let new technological abilities and knowledge be developed (García et al., 2006). TDCs affects OL (γ_{21}=.42; p<.001) supporting Hypothesis 3. TDCs allow increasing an organization's capability to carry out actions and improving OL (Senge *et al*., 1994). Comparing the magnitudes of these effects indicates that the effect of TMS on OL is larger than the effect of TDCs on OL. Globally, OL is explained well by the model (R^2=.61).

Corporate entrepreneurship is influenced by TDCs (β_{31}=.43; p<.001) and OL (β_{32}=.47; p<.001), supporting Hypotheses 4 and 5, respectively. Furthermore, we have shown an indirect effect (.19; p<.001) of TDCs on corporate entrepreneurship by OL (.40x.47). The global influence of TDCs on corporate entrepreneurship is thus 0.62 (p<.001). Comparing

the magnitudes of these effects indicates that the total effect of TDCs on corporate entrepreneurship is larger than the total effect of OL on corporate entrepreneurship. Globally, corporate entrepreneurship is explained well by the model (R^2=.71).

TDCs and OL enhance capacity and knowledge to discover and exploit entrepreneurial opportunities (Omerzel and Antoncic, 2008). Finally, for organizational performance, we find a significant relationship with corporate entrepreneurship (β_{43}=.64; p<.001), supporting Hypothesis 6. Corporate entrepreneurship allows increasing the benefits for the companies (Andreu and Ciborra, 1996; Shane and Venkataraman, 2000). Globally, organizational performance is explained well by the model (R^2=.41). In addition to these effects, we have shown other indirect effects in Table 5.

In testing the theoretical framework, we fit several nested models, each incorporating different assumptions about parameters. Comparisons with reasonable alternative models are recommended as a means of showing that a hypothesized model is the best representation of the data. Comparison is considered to be an important part of assessing model fit (Bollen and Long, 1993). The summary statistics in Table 6 indicate that Model 1 was preferred to the others, supporting the inclusion of a model with these relationships among the analyzed constructs. For example, if we compare the theoretical model (Model 1) to a model that does not consider the relationship between corporate entrepreneurship and organizational performance (Model 6), we can see that the latter has a worse Root Mean Square Error of Approximation (>RMSEA=.008), Expected Cross-Validation Index (>ECVI=.30), Akaike Information Criterion (>AIC=58.92), Consistent Akaike Information Criterion (>CAIC=58.92) and Estimated Non-Centrality Parameter (>NCP=58.92). Hence, results show that corporate entrepreneurship affects organizational performance and that Model 1 was preferred to Model 6 ($\Delta\chi^2$=58.92;Δdf=1). The theoretical model is also preferable to other models formulated (Table 6). Length restrictions prevent a detailed discussion of each model and of other models (a full report is available from the authors). In sum, the proposed theoretical model represents (Figure 2) the preferred, i.e. the most acceptable and parsimonious, model.

CONCLUSIONS AND FUTURE RESEARCH

Discussion

Research´s results have supported the existence of a positive significant relationship between TMS and TDC. TDCs development will be enable if the top managers achieve some fundings y support their development. This support does not have to be only financial support (Petroni and Panciroli, 2002); it must also be educational support, as all the employees in the company should trained to understand and achieve the distinctive competencies on technology (Andreu and Ciborra, 1996; Haro et al., 2010; Leonard-Barton and Deschamps, 1988; Torkkeli and Tuominen, 2001). TMS is also significant positively related to OL. Top managers should motivate learning processes and promote some courses for the employees and lower managers to learn all the knowledge generated by technological competencies in order to become an intelligent organization difficult to imitate (Leonard-Barton, 1992; Lloréns *et al*., 2005). Likewise, the results of the research support that TDC encourage OL. This learning must be produced in all organizational levels in order to achieve excellent technological skills and a specific technological knowledge (Lee *et al*., 2001).

When TDCs and OL are promoted in the firm, some opportunities appear for entrepreneurs in the firm (Woolley, 2010). If technological organizations use their capacity to absolve new technology, or their capacity to generate new advanced technological processes, they will exploit their TDCs and may obtain an outstanding advantage over other firms (Real *et al*., 2006). Likewise, it is shown how corporate entrepreneurship is also promoted by OL, since the higher new knowledge acquired in the organization will increase the autonomy of different parts in the firm, what will allow it to adopt more flexible structures to increase their corporate entrepreneurship and it will also let employees be more creative (Antoncic and Hisrich, 2001; García *et al*., 2006; Knight, 1997). Finally, the results show up that corporate entrepreneurship will increase the benefits in the firm, sales or the market share (Antoncic and Prodan, 2008; Lengnick-Hall, 1992; Murray and Kotabe, 1999). Corporate entrepreneurship is beneficial to the revitalization and performance of large corporations, as well as that of small and medium enterprises (Antoncic and Hisrich, 2001). Organizations that engage in entrepreneurial activities achieve higher levels of growth and profitability than organizations that do not (Antoncic and Hisrich, 2001), thereby obtaining higher performance (Antoncic and Prodan, 2008; Zahra, 1993).

Limitations and future research

The investigation presented exhibits several limitations. First, survey data based on self-reports may be subject to social desirability bias (Podsakoff and Organ, 1986). However, an assurance of anonymity can reduce such bias even when responses are related to sensitive topics (Konrad and Linnehan, 1995). The low risk of social desirability bias in this study was indicated by several managers who commented that it made no sense at all for their companies to go beyond regulatory compliance. Still, the responses are subject to interpretation by individual managers.

Second, the use of the CEOs to responded questions on TMS or corporate entrepreneurship. are valid measures (e.g., García et al., 2008), however, interviewing and administering questionnaires to other organizational members would have been preferable to verify these variables. To confirm the validity provided by the CEO in the research we sent the same questions to members of selected firms. The different results were contrasted with those obtained in the main research survey by means of different tests to confirm that there were no significant differences between the research variables.

Third, although Harman's one-factor test and other method tests did not identify common method variance as a problem, it still might have been (Podsakoff and Organ, 1986; Konrad and Linnehan, 1995). Although Spector (2006) has argued that it is incorrect to assume that the use of a single method automatically introduces systematic bias, we recommend that future research gather measures of independent and dependent variables from different data sources to minimize the effects of any response bias (Podsakoff *et al*., 2003).

Fourth, our data are cross-sectional, making it difficult to examine the evolution of the different variables in our study. This aspect is of particular interest when considering the dynamic nature of some of our variables. Although we tested the most plausible directions for the pathways in our model, longitudinal research is needed to assess the direction of causality of the relationship and to detect possible reciprocal processes. We have tried to temper this limitation through attention to theoretical arguments by rationalizing the relationships analyzed and integrating temporal considerations into measurement of the variables (Hair *et al*., 1999). Fifth, future studies should be based on a larger sample and preferably in more than one country. As this study focuses only on Spanish firms, an empirical research paper could study the same relationship in Europe in order to generalize the results throughout the European economy, and subsequently throughout the world.

Finally, the model only analyzes the relation of TDCs (influenced by TMS), TMS and OL on organizational performance through corporate entrepreneurship. It should be noted that the variables selected explain an acceptable amount of the variance in organizational performance. However, other intermediate constructs could be analyzed, such as absorptive capacity or knowledge management (e.g., García *et al*., 2006; Nonaka and Takeuchi, 1995). The homogeneous geographical context examined here, limits the influence of external factors, but future research might well explicitly integrate the influences of external factors.

APPENDIX.

- **Top Management Support.**

1. Indicate the degree to which you agree or disagree with the following statements about top management support.
   1.1. Top management cultivates technology project champions.
   1.2 Top management ensures adequate funding of technology research and development.
   1.3 Top management restructures work processes to leverage technology opportunities in the organization.
   1.4 Top management facilitates technology transfer throughout the organization.

- **Technological Distinctive Competencies.**

2. Indicate the degree to which you agree or disagree with the following statements about whether the organization has:
   2.1 Capability to obtain information about the status and the progress of science and relevant technologies.
   2.2Capability to generate advanced technological processes.
   2.3 Capability to assimilate new technologies and useful innovations.
   2.4 Capability to attract and retain its qualified scientific-technical staff.
   2.5 Capability to dominate, generate or absorb basic and key technologies of business.
   2.6 Capability to establish efficient programs to develop technology from R&D units, providers and clients.

- **Organizational Learning.**

3. In the last three years:
   3.1 The organization has acquired and shared much new and relevant knowledge that provided competitive advantage.
   3.2 The organization's members have acquired some critical capacities and skills that provided competitive advantage.
   3.3 Organizational improvements have been influenced fundamentally by new knowledge entering the organization (knowledge used).
   3.4 The organization is a learning organization.

- **Corporate Entrepreneurship.**

4. In the last three years.
   4.1. Proactiveness.
      4.1.1. In dealing with competitors, the organization is very often the first business to introduce new products/services, administrative techniques, operating technologies, etc.
      4.1.2. In dealing with competitors, our organization typically adopts a very competitive, undo-the-competitors posture.
      4.1.3. In general, the top managers at our firm have a strong proclivity for high risk

projects (with chances of very high returns).

4.1.4. In general, the top managers at our firm believe that, owing to the nature of the environment, bold, wide-ranging acts are necessary to achieve the firm's objectives.

4.1.5. When confronted with decision-making situations involving uncertainty, our organization typically adopts a bold, aggressive posture in order to maximize the probability of exploiting potential opportunities.

4.2. New business venturing.

4.2.1. The organization has stimulated new demands on the existing products/services in the currents markets through aggressive advertising and marketing.

4.2.2. The organization has broadened the business lines in the current industries.

4.2.3. The organization has pursued new businesses in new industries that are related to the current business.

4.2.4. The organization has found new niches for the products/services in the current markets.

4.2.5. The organization has entered new businesses by offering new lines and products/services.

4.3. Self-renewal.

4.3.1. The organization has revised the business concept.

4.3.2. The organization has redefined the industries in which the company will compete.

4.3.3. The organization has reorganized units and divisions to increase organizational innovation.

4.3.4. The organization has coordinated activities among units to enhance organizational innovation.

4.3.5. The organization has increased the autonomy (independence) of different units to enhance their innovation.

4.3.6. The organization has adopted flexible organizational structures to increase innovation.

4.3.7. The organization has rewarded employees for creativity and innovation.

4.3.8. The organization has trained and encouraged to the employees to be creative and innovative.

4.9. Organizational innovation.

4.9.1. The organization has significantly increased:

4.9.2. The emphasis on developing new products/services.

4.9.3. The rate of new products/services introduction into the market.

4.9.4. The spending on new products/services development activities.

4.9.5. The number of products/services added by the organization and already existing in the market.

4.9.6. The number of new products/services introduced for first time in the market by the organization.

4.9.7. Percentage of revenue generated from new businesses/services that did not exist three years ago.

- **Organizational Performance.**

5. Relative to your main competitors, what is your firm's performance in the last three years in the following areas?

5.1. Organizational performance measured by return on assets (economic profitability or ROA).

5.2. Organizational performance measured by return on equity (financial profitability or ROE).

5.3. Organizational performance measured by return on sales (percentage of profits over billing volume).

5.4. Organization's market share in its main products and markets.

5.5. Growth of sales in its main products and markets.

THE ADOPTION OF AMERICAN HURMAN RESOURCE MANAGEMENT AMONG JAPANESE SUBSIDAIRES IN MALAYSIA: MYTH OR REALITY?

ABSTRACT

The success of Japanese firms in the 1980s has often been associated with their unique HRM model. However with the recent global recession, many firms in Japan are abandoning their traditional HRM model. Japanese firms are now seeking the Western HRM, and in particularly the American model as their source of inspiration. Although they have been a lot of related articles on the success of Japanese style HRM, only a handful articles are available on the end of the Japanese style HRM. Moreover, the articles are often limited from the context of Japanese firms operating in Japan. In relation to the end of the Japanese HRM abroad and the emergence of 'dominance effect' theory, research findings are even limited. Hence, we hope to close the cross-national gap by adopting a multiple-case study approach that addresses on the HRM practices of 5 Japanese subsidiaries in Malaysia in view of the recent economy crisis. Among the major HRM practices examined are remuneration systems, training and development and employment policies and practices. In particularly, the study examined whether there is a possibility of convergence towards the American model among the subsidiaries. General findings appear that some HRM practices does resemble the American model. The study is perhaps one of the first to address the HRM practices from the viewpoint of key people such as CEO, Managing Director and Human Resource Director.

Keywords: Japan, Human Resource Malaysia, Malaysia, Dominance

INTRODUCTION

The ongoing global recession in 2009 has a major impact on emerging markets like Malaysia. The sales value of the manufacturing sector in 2009 decreased 25.5% or RM13.5 billion as compared to RM52.7 billion in June 2008 (Department of Statistic Malaysia, 2009). At the same time, employment rate in the country was also reported to be at 3.6 percent which is 0.1 percent higher when compared to 2008. The Malaysia's GDP growth rate remains sluggish and even at a point turns negative at 3.9% per cent in 2009 (Department of Statistic Malaysia, 2009). The decrease was a result of a falling global demand from the United States which is one of the major consumer markets in the world. With unemployment rate in the United States forecasted to be above 10 per cent in 2009 (STAR, 2009), many firms are reorienting their

corporate strategy in respond to the recession. Griffin and Smith (2010) explained that some organizations reacts to the recession by cutting training budgets, freezing recruitment and omitting redundancies. Regardless of the strategy, the ongoing downturn has indeed resulted in global pressure on foreign firms in overseas such as the Japanese firms in Malaysia. Due to the pressure from the drop in global demand, companies have to re-balance their resources well and one key area of resources is the human capital in the firm. Thus it is likely that their Human Resource Management (HRM) policies may need to be modified and tailored to the current challenging economic scenario.

In this time of uncertainly, many Japanese firms are also abandoning or modifying their traditional HRM practices. Large Japanese firms and public administration in Japan are moving away from their traditional HRM practices (McCune, 1990; Morishima, 1995; Hircomichi, 2000; Masabumi, 2005). Japanese HRM model are no longer view by the Japanese employers as the critical success factor as they are not flexible. The once 'key success factors' has now becomes a burden and to some extend was regarded as a 'key failure factors' (Maanen, 2006). Unlike in the 1980s, the once celebrated Japanese HRM is now even viewed negatively by both the American and German HR experts (Pudelko, 2004). Instead, the Japanese firms are now seeking the Western HRM model as their source of inspiration (Pudelko & Mendenhall, 2007; Miles 2007). Interestingly, the American model is viewed as the best model to adopt in this challenging environment (Muller, 1999; Edward et al., 2005). This is because the model represents modernity and the future (Smith & Miksins, 1995). Similar sentiment was echoed by Pudelko (2004) in which the American model was viewed previously with skepticism are now viewed positively than ever by the Japanese HR experts. The finding was also supported by Masabumi (2005) and Chaudhuri (2010) in which the Japanese HRM styles in Japan are indeed leaning towards the American HRM. Pudelko and Harzings (2007) further explained that the emergence of the American model is the result of 'dominance effect' which is based on highly competitive national model of best practices. They further explained that the model neither follows the localization nor the country-of-origin effect, but instead the pole is headed towards the nation that sets the standards as the global best practices and in this case, the United States of America.

RESEARCH OBJECTIVE

The literature reviews of Japanese HRM is in crisis and the emergence of 'dominance effect' in the convergence theory seems to suggest that the Japanese HRM model has lost its appeal and is widely believed to be heading into a declining stage. This has lead us to trying to understand if this pattern also occurs for most of the Japanese subsidiaries abroad and in this case in Malaysia. We also seek to understand how Japanese firms abroad are responding to the recent crisis especially from the HRM perspective and whether this impact will lead to a transformation to a more American Model. In this context of the study, Malaysia which plays host to Japanese firms since the 1980s is a good base to examine on the above mentioned theory. Firstly, there are more than 3000 multinational enterprise in Malaysia and out of the 3000 organizations, Japanese firms has the highest number at 18.5 percent (Sambasivan and Jacob, 2008). Moreover Japan has been Malaysia top three investors since year 2000 and their

Foreign Direct Investments (FDI) has surpassed the United States and other Western nations in 2006 and 2007 with RM1,195 millions and RM6,129 millions respectively (Embassy of Japan, Malaysia, 2008). While empirical evidence exists on the uniqueness of the Japanese HRM as the secret of success (Ouchi, 1981; Fukuda, 1988; Jenkins and Florida, 1999; Masabumi, 2005) only a handful articles are available on the end of the Japanese HRM (McCune, 1990; Harada, 1999; Pudelko & Mendenhall, 2007). The articles however are also limited to the context of Japanese firms operating in Japan. While, in relation to the end of the Japanese HRM and the emergence of 'dominance effect' on and towards the Japanese subsidiaries abroad, research findings are even more limited, let alone any. The little empirical work is surprising as Japan is regarded as one of the biggest investors in the world and thus without the view of cross-national adaption, there seems to be a missing gap in the understanding of Japanese management. Our papers plan to address the missing gaps by attempting to answer to the following questions. In view of the perception that Japanese HRM is in crisis and the emergence of 'dominance effect, are the Malaysia Japanese subsidiaries orientating themselves towards the American HRM model as the best practices as the result of this recession? If so what are the changes in the HRM functions as a result of this recession? Secondly, what are some of the perceptions and views of HR Managers on the Japanese HRM practices in Malaysia in the coming years? Is Japanese HRM outdated? What are some of the Japanese HRM elements they wish to retain and change?

The research paper is important at least for three reasons. Firstly, the research is important as it helps to understand the survivability of Japanese HRM in Malaysia in the coming years. Secondly, the result can also help to explain and predict the HRM patterns of other Japanese subsidiaries abroad such as in Indonesia, Thailand, Singapore, etc. The findings also serve as valuable information to foreign companies which are competing against the Japanese firms. Lastly, the research will also help to shed lights on the HRM strategies and behavior for most of the overseas Japanese firms as the result of the crisis in which we believed there will be a lesson learnt. The article is structured as follows. First we provide an overview of the current literature of Japanese HRM and the debates between home country and host country practices. This is followed by the research methodology and the findings and discussion. Finally we present the conclusion and as well as the implications and limitation for future studies.

LITERATURE REVIEW

The End of Japanese HRM Practices

One of the key factors in the rise of most Japanese firms from the early 1970s to the early 1980s is attributed to their unique Japanese HRM (Ouchi 1981; Amante, 1993; Jenkis and Florida 1999). Masabumi, (2005) accredited the success to the 'three scared treasures' of HRM, which is the lifetime employment, seniority systems and company-based union. The combination of the 'three sacred treasures' improved productivity and led to stronger employee identification within the organization (Moore, 1987). However since early 1986, the Japanese economy has been facing with constant challenges. The rise in the exchange value of Japanese Yen in 1987, has lead Japan to lose their comparative advantages. Exports became too expensive in anticipating of the rise of labour cost. Jain (1987) explained that the

unemployment rate for the first time even jumped to about three percent and there was a fall of 1.9 percent in the manufacturing sector in 1994 (Ministry of Labour, 1996). The Japanese economy continues to remain sluggish and at a point even turn negative during the Asian fiscal crisis (Porter & Takeuchi, 2000). Orders fell and many Japanese organizations were badly affected (Benson and Debroux, 2004). In order to survive, many Japanese organizations decided to transfer their manufacturing firms abroad and many employers were compelled to retire early (Miles, 2007). Similarly, Japan also underwent a painful restructuring and business difficulties in 2008 as a result of the global recession. In view of the disappointing economy, Japan continues to face with strings of challenges from both the domestic and overseas markets (Takeuchi, 2009). In the wake of this long recession and disappointing economic performance, scholars have begun to call for reforms (Dore 1999; McCormick, 2004). The traditional Japanese HRM practices are now viewed as outdated and no longer important in today's reality (Smith, 1997; Crawford, 1998; Pudelko 2005). Ornatowski (1998) called for the end of the Japanese HRM. Stiles (2009) on the other hand, linked the Japanese HRM to as 'Japanese disease'. Dalton and Benson (2002) concluded that the 'traditional' Japanese HRM model is in crisis and is subject to major change. Similarly, Lonien (2003) concluded that the three pillars of the Japanese model are in the midst of collapse and were forecasted to be replaced with the Western management model soon. Thus in order to survive many Japanese firms are abandoning or modifying their traditional management practices (Benson and Debroux, 2004; Miles 2007; Takeucho, 2009).

Large Japanese companies and public administration are indeed moving away from their traditional HRM practices (McCune, 1990; Morishima, 1995; Hiromichi, 2000). The changes has taken place not only in large international firms such Sony, Matsushita Electrics, Toyota, Canon, Yamaha, Hitachi and Mitsubishi but also within small Japanese organizations (Sanchanta 2002; Economist, 2007). In order to minimize cost, many Japanese organizations have begun to abandon the lifetime employment system (Masabumi, 2005; Stiles, 2009). Lonien (2003) shed lights by providing evidence that only 10 percent of Japanese domestic firms are still practicing the system in 1999 unlike at 27% in 1990. Furthermore, Sony Corporation has also recently announced its desired to reduce 10,000 positions worldwide in March 2008 with 40 percent alone in Japan (Worthleya et al., 2009). Thus this seems to suggest that the lifetime employment (Abegglen, 1958) may not be as important as previously. The lifetime employment is gradually being replaced with the individuated 'lifetime employability' perspective (Brislin, MacNab and Worthley 2005) and contract employment (Benson and Debroux, 2003). The traditional recruitment style are also seems to be moving away due to the changes in the lifetime employment. The practices now appear to be more flexible (Benson and Debroux, 2004). More Japanese companies are allowing for the entry of new and experience employees throughout the year rather than in spring (Bamber, and Shadur, 1992). The hiring of inexperienced graduates from elite universities was also being called into questions as more companies are now hiring white-collar technical workers without a college degree (Salmer, 2001). Seiko-Epson Corp recently had broken away traditional hiring process by recruiting 100 'mid-term' employees from other companies (McCune, 1990). Large companies are also trimming down on the recruitment of new graduates while giving emphasis to candidates who are immediately operational such as the unemployed workers (Ogashi, 2006). Similarly, finding

from scholars also indicated that more companies are now recruiting specialist while less emphasis has been given on generalist workers (Pudelko and Mendenhall, 2007). The new characteristic of the Japanese recruitment style resemble to three new patterns namely the 'multi-stream employment patterns', 'multi-stream recruitment' and an 'intermediate labour market' (Masabumi, 2005). The remuneration and promotion which was based on seniority are also currently losing its significance. They are currently being replaced with merit performance (Ornatowski, 1998; Hiromichi 2000; Salmer, 2001; McCormick, 2004; Morris, Hassard & McCann,2006; Pudelko and Mendenhall, 2007; Takeuchi, 2009). The increased movement towards promotion-for-performance schemes was largely due to the introduction of management-by-objective (MBO) (Morishima, 1995; Chaudhuri, 2010). As such younger employees are now being promoted over their elder employees (Benson and Debroux, 2003). Evidences from RIALS (2002) indicate that there are differences in the manager's salary of large Japanese organizations. Consistent with the changes towards the merit performance, corporate welfare programs, corporate pensions, and retirement pay-outs of the particular employees is also dependable on the employee's performance (Ogashi, 2006). The across-the-board pay increases has also been offset by the variances of bonuses among employees (Ministry of Health, Labour, and Welfare, 2002). Unlike before, Japanese organizations are also creating dual career paths for specialist and generalist (Sethi et al., 1984; Kubo & Saka, 2002; Beson and Debroux 2004). Similar statements were made by Bamber and Shadur, (1992) in which there are evidences pointing to the mixture of managerial and specialist stream with the combination of managerial and professional/specialist/functional strata in some Japanese organizations.

Home Country versus Host Country Debate

Many scholars have attempted to shed lights whether the HRM practices of multinational firms overseas will resemble the home country or the host country practices. Many Japanese parent organizations believe that their operating systems are the source of their competitive advantages and therefore they transfer the practice to their foreign affiliates (Roger and Wong, 1998). As HRM plays a vital role in the implementation of strategy for most multinationals (Lorange and Murphy 1984) failure to transfer HRM effectively between business elements and across national settings will significantly jeopardize the longer term strategic success of the Japanese overseas affiliates (Edstrom and Lorange, 1984). Thus in order to stay efficient, most multinational parent company may push for the adoption of HRM policies which resemble the headquarters' value and culture (DiMaggio and Powell, 1983), resulting the overseas subsidiaries practices to resemble more of the home country practices than the host country practices (Pudelko and Harzing, 2007). On the other hand, in order to encourage mobility of managerial staff between overseas subsidiaries and multinational enterprise, a standardized corporate HRM practices are important as it promotes 'internal consistency'(Evans and Lorange, 1989). Hence, local affiliate HRM practices are molded by the pressure for internal consistency (Rosenzweig and Nohria, 1994) and the overseas subsidiaries practices will likely again to resemble to the home country practices. However, a host country pattern may also appear when the national cultural and institutional characteristic restricts the transfer of HRM practices abroad (Shuler and Rogovsky, 1998; Myloni et al., 2004). Similar sentiments was

endorsed by Hofstede and Bond (1988), Awasthi, Chow & Wu (2001), Zhu, Warner and Rowley (2007) in which HRM in the Asia pacific is influenced by the national institutions, state policy on industrial relations and culture. As such the multinational organizations will adopt to the practices of host country. Hofstede (1983) demonstrated that differences in national cultures vary substantially. A classification of culture index was developed to represent the culture dimensions of each national culture distance. They are the power distance index, individualism and collectivism in the society, masculinity, uncertainty avoidance and Confucianism/Dynamism. As the consequences of the differences in the dimensions across different countries, there is a barrier in transferring HRM practices (Dore, 1973). This is because organization practices are the result of the national culture (Abegglen 1958; Vogel, 1979). For example, Japanese is said to have high collectivism index, which rewards group achievements (Hosftede, 1997) while Malaysian is regarded to have a high individualism index (Lim, 2001), thus individual rewards is more important. In view of the differences between the homogeneous, collectively eastern countries and heterogeneous and individually oriented society (Hofstede, 1983) it is therefore impossible to transfer practices between the two countries (Beechler and Yang, 1994). Similar sentiments were echoed by Kenny and Florida (1993) where the transfer of Japanese managerial practices to the United States was hampered due to the differences of national culture (Abo, 1994). Finally, institutional characteristics such as labour market conditions, social-political environment and unionization (Brewster, 1995; Jackson and Schuler, 1995) can also influence the transfer of HRM practices to the overseas firms thus resulting to the subsidiaries resembling to the host country practices.

The Dominance Effect

The current debate between home country versus host country mainly focuses on the country-of-origin and localization's effect. However there is a new study that focuses on a different pole of dimension. Pudelko and Harzings (2007) concluded this new dimension as the 'dominance effect' model which is based on a highly competitive national model of best practices. Thus, the model acts as a role model for other nations to follow. Takeuchi (2009) explained that the model is applicable to any type of organizations and will result to economics benefits for organizations that adopt to such best practices. In the dominance model the management practices of an organization will neither resemble the country-of-origin nor the localization effect but according to the best practices model (Smith and Meiksins, 1995; Pudelko and Harzings, 2007; Takeuchi, 2009). However, the exact to which country the model follows differs according to time and economic performance. The model resemble closely to the American model from the 1950s to 1960s (Keer et al., 1962). However from the late 1970s to the early 1990s the model appears to resemble to the Japanese model (Oliver and Wilkinson, 1992).

The recession in the Japanese economy in the last decade has encouraged Japanese organizations to shift their attention to Western management practices (El Kahal, 2001; Matanle, 2003). In fact, many Japanese organizations are already converging their HRM practices towards a 'universalist' approach and this approach will continue to follow the best practices from worldwide (Mroczkowski and Hanaoka 1998). Summarizing the findings from the Japan Federation Employer's Association, Takeuchi (2009) concluded that many Japanese

organizations are attempting to inject Western ideas into the old fashion Japanese management system. Masabumi (2005) explained that that the move to 'autonomous worker' management was unavoidable in view of the threats from emerging markets such as China. American HRM practices are now suggested as the 'role model' (Edwards et al., 2005) for most of the Japanese companies in Japan to follow in order to regain its competitiveness (Pudelko and Mendenhall, 2007; Pudelko, 2009). Pudelko and Harzing (2010) shed lights by concluding that that the Japanese subsidiaries in the United States increasingly resemble the local practices. In one of the survey conducted, most Japanese interviewees unanimously concluded that their organizations should be orienting towards the Anglo-Saxon model (Pudelko, 2009). One important aspect of the American HRM is the concept of 'individual work' in which 'ability is equal to work and is also equal to wages' (Tokoro, 1992). The American HRM was seen naturally as a potential solution for Japanese companies to compete globally due to its ability to create competitive advantages among the Japanese firms (Takeuchi, 2009). The findings form Pudelko and Mandenhall (2007) was not surprising as organizations outside the US are already adopting to the 'best HRM practices' from the United States (Zhu, Warner and Rowley, 2007). Take for example, the flexibility to hire and fire, the freedom to downsize and retrench employees, individualized career development system, merit performance evaluation for promotion and welfare (Zhu, Warner and Rowley, 2007). The best practices will resemble closely to the American multinationals due to three important reasons (Smith and Meiksins, 1995). Firstly, this is due to the dominance of American business schools which has been aggressively spreading new frontier of knowledge. Secondly the American consultancies play an important role in disseminating management knowledge worldwide. Lastly this is due to the strengths of the American economy and their multinationals company.

RESEARCH METHODOLOGY

Although the study on the end of Japanese HRM has received a widespread of attention recently, much of the research predominant focuses at the macro view. Thus previous studies may not have gained a true picture necessary to explain on the HRM changes. In this case, we hope to readdress this research gap by adopting a detailed case analysis. In addition, we have decided to adopt the qualitative method because the qualitative method provides an epistemological position (Bryman and Bell, 2003) especially when addressing to questions such as 'how' and 'why (Yin, 1984). Thus this helps to provide a better explanation and addresses to the research objectives in a clearer manner. The sampling for our research paper is adopted from the Federation of Malaysian Manufacturer (FMM) directory. The FMM which was established in 1968 includes more than 2200 manufacturing and industrial service firms in Malaysia (FMM, 2010). We decided to focus our study in the state of Perak, Malaysia which has received a fair attention of Japanese investment in the recent years. Within the different Japanese subsidiaries in the state of Perak, first the Japanese subsidiaries are divided according to the industries. In view of our project timeline, we decided only to focus on a few industry and they are the firebrick, electric and electronic and woodwork industry. According to Kuruvilla, Frenkel and Peetz (2003), the diffusion of HRM practices varies by industries rather than countries. Thus the different industry will provide varieties to this case study. Three requirements were subsequently added. They are as follow (1). Wholly owned Japanese-owned

organizations. According to Purcell et al., (1999), Japanese subsidiaries with majority Japanese shareholders are likely to adopt to Japanese style management when compared to a minority Japanese shareholders. The criterion is important as we do not want the HRM practices to overly resemble to the local practices which would seriously jeopardize our study. (2). Have more than 100 employees in their operation. According to Beamish and Inkpen (1998), subsidiaries with less than 50 employees are usually agency or sales subsidiaries. (3). More than 15 years in operation. The study deliberately chooses to only consider subsidiaries operating more than 15 years so that any HRM practices can be clearly reflected by the timeline. Stratified sampling was then applied to obtain random samples, thus leading us to the five subsidiaries of study. The data used in this case study were obtained through intensive interviews all conducted between May 2010 to January 2011. We decided to adopt a semi-structured style, as it allows us the flexibility to vary the sequence of the questions and moreover the interview style reduced the amount of missing data (McKnight et al., 2007) in the quantitative study. The HRM practices examined are such as remuneration systems, training and development and employment policies and practices. The practices above are considered to be the most extensively used practices in most HR literatures (Lewis, 2003). The interview questions were addressed to key personal of the organizations such as Chief Executive Officer, Managing Director, Human Resource Director, Human Resource Manager, Factory Manager, First-line supervisor, Japanese expatriate and employees. The Chief Executive Officer, Managing Director and Human Resource Director were chosen because they are assume to know the hidden information regarding the HRM directions of the subsidiary and the ability to understand the Japanese and American HRM practices more than the other employees within the firm, whereas the local Human Resource Manager and Factory Manager are assume to know more about the implementation and operation of the HRM policies within each departments. Furthermore the changes of the policy at the top levels does not give change to the day-to-day strategies of the bottom level, thus the view of the first-line supervisors are equally important. The information provided by the employees on the other hand serves as a triangulation method to verify and ensure reliability of information collected. The numbers interviews conducted in total within the 5 subsidiaries are 1 Chief Executive Officer, 4 Managing Directors, 2 Human Resource Directors, 3 Human Resource Managers, 3 Factory Managers, 4 First-line Supervisors, 2 Japanese expatriates and 16 employees. Interviews generally took about one-to-two hours per session to complete. The data was recorded and transcribed subsequently. In line with most of the case study approaches, the study shall give priority to 'voices' of the respondents. This is important as their voices provide a genuine mood of the dilemmas, process and strategies faced especially during the economy crisis. For this research, we have also adopted the following research methods such as gathering other unpublished data such as the HRM policies, brochures, site-visit and website information. In view that most of the respondents were able to speak in fluent English, the interviews were conducted in English apart from the two Japanese expatriates where the study engaged the help of a translator. In terms of drawing the conclusion, the study adopts the bipolar dimensions. By drawing contrast between two different practices e.g. American practices versus the Japanese practices (e.g., performance based as opposed to seniority based; specialist training as opposed to widespread training; individual achievements as opposed to collective achievements) we

were able to characterize whether the subsidiaries HRM practices fall between localization, country-of-origin or hybridization.

Overview of the Japanese Subsidiaries

In order to maintain the anonymity of the subsidiaries of study, the subsidiaries are not written as firm-specific but in general names such as Company A, B, C, D and E.

Case 1: Insulating Firebrick Firm

The first business setting studied for the first case (referred to as 'A') is a 100% Japanese-owned subsidiary with a presence in Japan, Korea, Singapore, Taiwan, China and Germany. The parent company which is a public listed company in Japan was established in 1927. In Malaysia, the company was established in Chemor, Perak in 1990 with RM24 million paid up capital. Apart from the factory in Chemor, the company also has another sister division in Johor, Malaysia. The company is one of the leader in producing insulating firebricks and serves major industries such as petrochemical, ceramics, iron and steel within Japan and abroad such as in Australia, China, Japan, Singapore, South Africa, South Korea, Taiwan, United Kingdom, Thailand and Indonesia. The company currently has staff strength of 250 employees.

Case 2: Electric and Electronic Firm

In the second case, the business setting studied concerns a Japanese-owned subsidiary with presence in Singapore, Thailand, Hong Kong, China, Taiwan, Japan and the United States. The company shall be referred to as 'B'. The company has been incorporated since 1993 with over 90 percent investments from Japan. Likewise, the company is also located in Perak has over 700 employees under its wing. Among the products manufactured are such as Fixed Fusible Resistors, Hybrid LC, Fixed Carbon Composition Resistors and etc. The products are mainly exported to Japan with key buyers such as Sony Group, Toshiba, NEC, Fujitsu, Canon, Aiwa, Alcatel, Thomson, Siemens, Motorola, Compaq, Mitsubishi Groups, Sharp Groups, Apple, Philips and Ford.

Case 3: Electric and Electronic Firm

The company in the third case studied is referred hereto as 'C'. It was incorporated in 1993 with a paid up capital of RM6 millions. The business unit belongs to a Japanese organization of a multinational enterprise and is located in the Perak region. Among products produced are such as ceramic electronics components and advanced electronic materials such as thermostat and onboard sensor and mostly are for both local and export markets. The company at the moment has a total workforce of 440 employees.

Case 4: Woodwork Firm

The company in the fourth case studied, was established in 1993 as a manufacturer of coffee table parts. The company shall be referred to as 'D'. Since then they have been diversifying their business and currently also produce furniture for bedrooms and living gardens. Among the products manufactured are premium quality tables, beds and chairs. Most of the products are however not for local sales and only exclusively for the Japanese market. The company likewise is also located in the heart of Perak. The company has a total of 250 employees as at 2011. There are 5 Japanese managers, two managers in the production area, one in the human resource area and 2 managing directors that serve as a liaison role between the company's parent company and subsidiary.

Case 5: Woodwork Firm

The company in the last case studied, was established in 1994 with over 90 percent of investment from Japan. The company shall be referred as 'E'. The company produces wooden component parts and builders joineries. The company has regional offices and presence in all South East Asia countries. Unlike company D the products manufactured by the company are distributed to local furniture suppliers in Malaysia and also exported abroad. In view of the rapid progress and growth, the company has been able to transform into a holding company with three more additional subsidiaries under its belt. At this very moment, the company has approximately 600 employees.

FINDINGS

Employment Policies and Practices: Staffing Practices

The Japanese subsidiaries HRM policy resembles the hybridization model previously. In view of the recession, the policy has changed and stricter rules were introduced. The practices now resemble the American HRM. Unsatisfactory work performance and misconduct would lead to termination and even job downgrading. Similarly, upon retirement, previously employees were allowed to continue their employment on a yearly contract basis. However, this has been abolished during recession to save cost. Below are statements made by the Chief Executive Officer and the Managing Director;

Company A: 'Previously, if the employee fails to perform, we will issue him/her with 1st, 2nd and 3rd warnings. Again, if the employee is still not able to perform, we will repeat the warnings to 1st, 2nd and 3rd. We have no intention to sack the employee. However, in view of the global meltdown, we are stricter. Upon the 1st third warning, we will immediately issue the employee with a termination letter. In response to the retirement policy, previously employees were allowed to work beyond 56 years old with a yearly contract and 30 percent reduction in salary. However, this practice was abolished during the recession.' (Managing Director)

Company B: 'Yes, we are certainly more aggressive and demanding during the recession. If the employee is not able to perform, we will not hesitate to take disciplinary action or to transfer the employee to another department. As for the policy after retirement, previously the employees were allowed to continue working on a yearly contract with 30 percent reduction in salary subject to the management approval, but this has also been abolished.' (Managing Director)

Company D: 'Previously we will do counseling and only issue the employee with verbal warnings. However now we issue the employee with warning letters. We have also recently downgraded an employee in which we have never done it before. As regards to work policy after retirement, previously most of the white-collar employees were allowed to work after the retirement age. Our practices were slightly similar to the practices in Japan but not common among the local firms in Malaysia. However, we have abolished the practice during the recession to save cost.' (Chief Executive Officer)

Employment Policies and Practices: Recruitment

There practices are converging towards the American HRM model for most of the Japanese subsidiaries. Selections of new recruits now are based on performance rather than interpersonal skills. Moreover most subsidiaries would not mind to hire the best candidate from outside the organization for a pre-defined position if no suitable employees were found within the organization. Short-term employment relations are also on the rise with some organizations preferring to engage employees on fixed term basis. Below are the comments given by the Local Human Resource Director and Local Human Resource Manager;

Company A: 'Our recruitment style is very much based on ad-hoc. We have no preference to recruit new graduates from the top universities in Malaysia. But if you are a graduate from Japan, we would hire you. The top positions within the company are normally occupied by our internal staff and we will never hire someone outside from the organization. However beyond the management level, we are trying to recruit the best employees for a pre-defined position from outside the organization. We certainly would prefer experienced employees than the inexperienced one. This is because many good employees left due to recession and now we need experienced employees to train those without any experience. EQ is certainly important for us, but we would prefer IQ for the white-collar employees.' (Local Human Resource Director)

Company B: 'We are certainly more stringent in our recruitment during this recession. Previously we do not open up vacancy for outsiders unless it's a new position, but as a result of the recession, many good employees have left us. We have no choice but to recruit experienced employees for the particular job. We make sure that our blue-collar employees passed the product knowledge test, have some basic knowledge on reading electric circuits, schematic diagram and basic mechanical circuits prior to hiring. In terms of promotion, if our internal staff is not experience enough, we will not hesitate to recruit employees from outside the organization. In terms of our selection preferences, although good behavior such as cooperativeness, attitude and willingness to try are important to us, we would prefer to recruit

employees with high IQ. Why? At this point of recession, we need to hire employees who are aggressive, energetic and intelligent so that they are able to guide the organization out of this recession and by helping to push the older employees to be more competitive.' (Local Human Resource Director)

Company D: 'We are recently recruiting employees based on contract rather than on a permanent basis. Although interpersonal and EQ are important in our recruitment, IQ nevertheless is given more emphasis. We certainly would like the best people to occupy the job. We have implemented several new tests for our blue-collar employees prior to hiring. For example, we now have 'drawing test'. (Local Human Resource Manager)

Remuneration systems: Welfare system

In terms of the welfare system, there is no indication that the welfare is orienting towards the American HRM model. Although the recession has implication on the welfare systems to some extent, the features however still resemble closely to the traditional Japanese HRM style. Below are statements made by the Factory Manager, Local Human Resource Director and Local Human Resource Manager;

Company A: 'In term of bonus payouts, it is contractual of 1 month regardless of the employee's position in the Company. Moreover our organizations do not discriminate in terms of welfare benefits. All employees regardless of the category (except the top management level) receive the same benefits and there had been no change even during the recession. For example, full attendance (RM70), meal allowances (RM15), transport (RM70), and housing allowances (RM60). Benefits for the top management level however have been decreased to save cost.' (Factory Manager)

Company B: 'The bonus payment is 1 month like previously. Allowances and benefits are equal for both the blue and white collar employees. However if you are at the managerial level, there are added allowances such as car, cell phone and entertainment allowances. However due to recession, we have limited the allowances. However, there are no changes to the benefits for the non-managerial employees.' (Local Human Resource Director)

Company E: 'Bonus payment used to be twice a year, but due to recession, we pay 30-40 percent lower for each of the bonus payout. There are no changes to the benefits among the blue and white collar employees. However we have eliminated some activities which do not add value such as annual dinner and local trip. Entertainment, medical and car allowances have also been reduced at the managerial and expatriate level. Unlike before, they also need to pre-apply for the allowances.' (Local Human Resource Manager)

Remuneration systems: Promotion System

However on the promotion system, there seems to be a declination in the seniority principle. There are evidences that employees are being promoted regardless of the length of service.

This however is exceptional and not widespread. In general, most of the Japanese subsidiaries still value the seniority principles. Likewise behavior and internal promotion are still heavily stressed while on the whole, MBO still serve no purpose apart from formality. Below are the comments given by the Local Human Resource Manager/Factory Manager/First-line Supervisor;

Company A: 'Promotion for the blue and white collar employees is still based on the seniority principle even after the recession. Behavior is still important as part of the appraisal system and we have no plan to abolish them. Although promotions are based on seniority, we do promote exceptional employees. However, that will not lead to higher pay. We only give out additional administrative allowances.' The director further gave an example of an employee has been promoted rapidly and is currently heading one of their sister subsidiary in Johor, Malaysia. Whether there are changes in terms of promotion preference, he concluded that the internal promotion is still very much preferred although he thinks this will be unlikely in the near future. On the appraisal system, the manager stressed that the MBO is just for formality as it is part of the organization's requirement. 'Grades will be revealed for the white-collar employees but not the blue-collar employees, but at the end of the day they serve no purpose.' (Local Human Resource Director)

Company B: 'There is no indication that promotion is moving towards the merit system. As for now it is still very much based on seniority. Again behavior is also important for both the blue and white collars. The policy remains that the vacancy for any higher posts are meant only for their internal staff. However, external employees will be taken into consideration if there is a vacancy for a new post. MBO is also conducted but not revealed.' (First-line supervisor)

Company C: 'The promotion system for our employees is moving towards the merit system. However, the weightage for behavioral function is given more emphasis than performance function. Promotion is still very much internal based while external recruitment is only for new post. MBO is a close concept. We conduct the MBO as it is part of the organization procedures but we do not reveal the results.' (Local Human Resource Manager)

Company D: 'Our promotion system for the blue-collar employees is based on seniority and also 'attendance'. Seniority assessment however is only limited to 60 percent for the white-collar employees. Merit performance however is important for the top management level. We have tried to push for the implementation of MBO style across the board but was not approved by our headquarter in Japan'. (Local Human Resource Manager)

Career development practices: training and development

The training and development style of the Japanese subsidiaries are still very much geared towards generalist approach. Much effort has also been given to mould the culture of the particular employee with the organization's culture by training and focusing on work group more than the particular individual. Hence we doubt that there is any convergence towards the American HRM model. Below are the statements given by the Factory Manager, First-line Supervisor and Factory Manager;

Company A: 'Shaping the employees' character towards our organization's culture is very important regardless of the employee's ranking. As such, we normally have a long employee orientation to introduce our employees to our work and organization's culture such as the practices of 5S and so on. Moreover we have Japanese classes organized by FMM. Our training is overall oriented towards maintenance and not related to job improvement in view of the high accident rate. Training for the white-collar is however selective and is in accordance with their job scope and not based on their preference or interest.' (Factory Manager)

Company B: 'Our training is more focus towards work group than on individual. Our training needs are planned by the production side rather than the HR department. Our training days for the blue-collar employees are between 5 and 6 days while the white-collar employees are between 3 and 4 days. The additional days are for safety and health classes. We like to give a wide range of training to our employees rather than a specialized one.' (First-line supervisor)

Company D: 'Our training funds come from the HRD funds. On most of the occasion, the HR department will propose the training as the HRD funds are parked under their belt but at the end of the day, the production side will decide whether to give the green light or not. Teambuilding training is very much stressed as our culture emphasized a lot on good teamwork.' (Factory Manager)

The Future of Japanese HRM

On the perception and view of the future of Japanese HRM practices in Malaysia, will it be replaced by a full American HRM model one day? Is the Japanese HRM outdated? What are some of the Japanese HRM elements they wish to retain and change? Here are some of the opinions of the Chief Executive Officer, Managing Director, Local Human Resource Director and Local Human Resource Manager;

Company A: 'The Japanese HRM practices are not outdated but there are certainly things that can be further improved. Take for example the inclusion of MBO and merit payment in the appraisal system. We would certainly like this to be adopted. The American HRM has never been any source of inspiration in our company. Perhaps the Japanese way should be the best approach in view of the failure of the American model during this recession in the United States.' (Managing Director)

'The senior management team in our Japan headquarter are mainly between 60-70 years old. Although most Japanese expatriates and CEOs at Malaysia are oversea trained and have a flair ideas of American HRM, they are unlikely to adopt them. This is in view of their character which is to respect the elderly and in most of the situation; the elderly would certainly not want to change to this new approach.' (Local Human Resource Director)

Company B: 'The Japanese are taking back control of their subsidiaries' as a result of the recession, by replacing the local Managing Director with their expatriates. As such the

management-style within our local subsidiaries resembles much closer to the traditional Japanese HRM. Moreover many Japanese companies are now becoming more conservative as the result of the recession and many key decision needs permission from our headquarter in Japan.' (Managing Director)

'One reasons why Japanese establishes their firm in Malaysia is due to cost saving. By practicing the American HRM, the product cost will increase due to job specialization, merit payments and so on. Moreover the American model emphasis too much of human rights and this may hamper the way we run our business in Asia. Take for example the working hours. We are not saying that we have bad ethics but too much of rights and protections will slow our production and this is impossible for Asian companies like us to survive!.' (Local Human Resource Director)

Company C: 'There will not be changes in terms of whether we will like to adopt to the American HRM as at the end, the decision is very much dependable on the management teams who are Japanese expatriates. They are unlikely to change as most of them are from the technical background, e.g., engineering. So long as the company is making profit, why need to change? Moreover most expatriates' contract is between 3-5 years, thus they have no motivation to change anything drastic in view of their short term duration here. They would of course prefer status quo.' (Managing Director)

'The American HRM practices although are very flexible in a way but at the same times it is very insecure. Like for example the hire and fire style. This is not motivating for our employees. Thus we have no plan to introduce the full practices here at Malaysia. Many staff in our organization are not also ready for the American way as we have many staff who has been attached here for a long time and have been very customized to how the Japanese HRM practices are being practiced.' (Local Human Resource Manager)

Company D: 'The Japanese HRM is certainly outdated and not good for the growth of the organization. Promotion and remuneration for example must be based on merit. However the Japanese HRM are here to stay and it would be impossible for us to move on to a total American HRM model. Our Japanese expatriates are very conservative and only want to implement whatever they know best. Moreover implementing the American HRM can be very costly. So long as the American model can be cost effective we would certainly be happy to adopt them, but their HRM system does not work in this way.' (Local Human Resource Manager)

Company E: 'The Japanese HRM is outdated and no longer relevant. Our Japanese headquarters are already moving away from the traditional Japanese HRM. However the American HRM are still not being adopted here in Malaysia.' One possible explanation he stressed was due to the resistance by some of the employees. 'Many employees have already been with the company for a long time, thus they are very comfortable with the Japanese HRM as they felt that it is more stable and secure.' (Managing Director)

CONCLUSION

The paper has attempted to evaluate whether there is a convergence towards the American HRM practices. Research findings from the above interviews in Malaysia present a very mixed picture. The staffing practices previously resembled a hybridization model. In view of the recession, the practice now resembles closely to the American HRM model. In terms of the welfare system, there is no indication that the practices are orienting towards the American HRM model. However on the promotion system, there seems to be a declination in the seniority principles. There are evidences that employees are being promoted regardless of the length of service. The case however is exceptional and not widespread. In general, most of the Japanese subsidiaries still value the seniority principles. Likewise behavior and internal promotion are still heavily stressed on, while MBO still serve no purpose apart from formality. Thus, we opine that there are indications of movements towards the American HRM model although they are not particularly strong. By and large, training and development practices are also not orienting towards the American HRM model. The training and development style of the Japanese subsidiaries is still very much geared towards generalist style except for a few fields. Lastly, evidences suggest that the recruitment practices are already orienting towards the American HRM model. Selections of new recruits now are based on performance rather than interpersonal skills. Moreover most subsidiaries would not mind to hire the best candidate from outside the organization for a predefine position if no suitable employees were found within the organization.

Thus in relation to the emergence of 'dominance effect' on the Japanese subsidiaries, findings conclude that the effect will not take place on practices which would lead to higher production cost. This will probably be true for all emerging markets context. American HRM interestingly was never viewed by any of the subsidiaries as their source of inspiration. In fact the local management does not have much confidence in the particular model as it's regarded as costly, burdensome and does not provide much flexibility. Ironically, local managers are against the idea of adopting to a total American HRM model. Whether the Japanese HRM model will be outdated? It is too early to predict as the conclusion is mixed. Japanese HRM is still regarded as practical and cost effective by the Japanese subsidiaries. However, majority of the respondents agreed that they should do away with seniority principles, more merit payments, benefits and promotions and realistic MBO. Thus, will there be an end to the Japanese HRM model in the coming years? Insights and perspectives from the top managements suggested otherwise. Strong conclusive points were given. Japanese HRM practices will go through major reforms especially in staffing and recruitment practices while the other practices are likely to remain as hybrid or resemble the Japanese HRM practices due to economic considerations and organization strategies.

STOCHASTIC FUNCTION APPROXIMATION BASED NEURAL NETWORK

Sirimas Pongjanla, Kasetsart University, Thailand

Suparerk Sooksmarn, Kasetsart University, Thailand

Pornthep Anussornnitisarn, Kasetsart University, Thailand

ABSTRACT

Using discrete event simulation is a popular choice in complex system evaluation. However, to identify the right set of system parameters, which give the best system performance, is a time consuming process due to stochastic uncertainty behavior of system simulation. This research demonstrates an alternative method to the discrete event simulation as a system model where system performance can be evaluated within a short period of time in comparison to discrete event simulation. However, typical approximation function based neural network need to be re-trained when setting environment has changed. This research intends to address both weakness in the time of simulations and a rigid structure of system learning of neural network.

The objectives of this research is to develop and study the scalable artificial neural network system for approximating performance function in case study of the buffer optimizing of pull-control system of multiple workstations, the network system separated 3 types of single workstation by training data from simulation are initial workstation, intermediate workstation and final workstation, approximation by interconnecting 3 types of network systems and to study factors that affect the performance function approximation efficiency, performance measure are the average number to meet demand (sale), the average number to not meet demand (lost sale), the average of work-in-process and the average cycle time.

From the study, the neural network system can use to approximate performance measures of this case study system. The approximation function based neural network does not only determine the mean of the stochastic system performance but also its variation (the length of the mean confidence interval). Therefore, we can use this approximation function based neural network to find the size of appropriate buffer much more quick than does the method by simulation optimization.

Keywords: Artificial Neural Network, Function Approximation, Stochastic Search, Variation analysis.

INTRODUCTION

A simulation model is regarded as popular and established method to solve a problem. Moreover, it is also used to study a complicated stochastic system because it is adjustable into many types for policy test before real practice. However, it has to take a long time to apply the simulation model to find an optimal solution. If the most proper solution is needed, the more time is required to repeat process to retain the best parameter value of the system because of abundant possible incidents which are nearly impossible in practical way as shown in table 1. Several applied methods for optimization algorithm such as Branch and Bound Algorithm may cause difficulties and limitations. Another interesting technique is artificial neural network. It is able to be used for data analysis gained from the simulation model not depending on distribution types. Besides, it can be utilized to analyze incomplete data but average value is not enough to be representative of the stochastic system. Therefore, variation value is another necessary parameter for consideration as well.

Table 1: Time to find the number of buffer

Number of workstation	Number of feasibility	simulation: days (20 sec/event)*	Neural Network: Days (2 sec/event)*
3	24,000	6	1
4	640,000	148	15
5	16,000,000	3,704	370

THEORY AND RELATED WORKS

The artificial neural network system is a processing technique that developed by basic principles of creature' neural network. The artificial neural network work likewise a brain to collect knowledge through learning process and keep it as weight which is adjustable when accepting new things. General aspects of the developed network are different weight of connection link between each node and signal. The weight value is regarded as the knowledge gathered for specific problem resolution. There is a function within the node to determine output signal or called transfer function. The characteristics of node in the artificial neural network are presented in Figure 1.

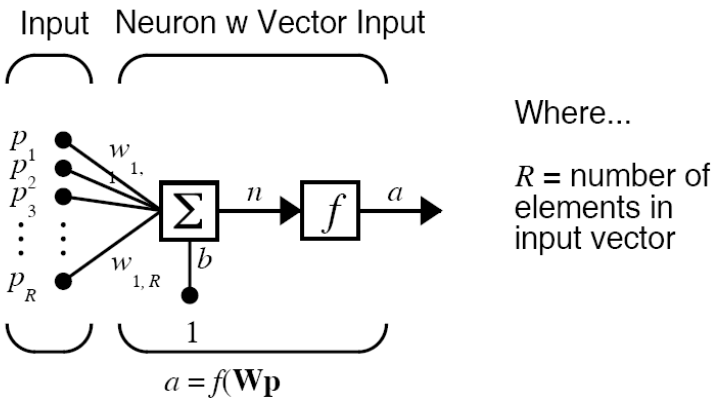

Figure 1: Neural Network Model

The production pull control system has special characteristic such as the data production will flow reversely to the flow of material. The latter production process will take necessary material when needed by using Kanban card to bring the material of the earlier production process. After that, such process has duty to only produce sufficient amount to reach equal number of taken materials or following the Kanban card. (Monden, 1994)[5]. It can be said that the latter process will control the production rate of the earlier process as show in Figure 2.

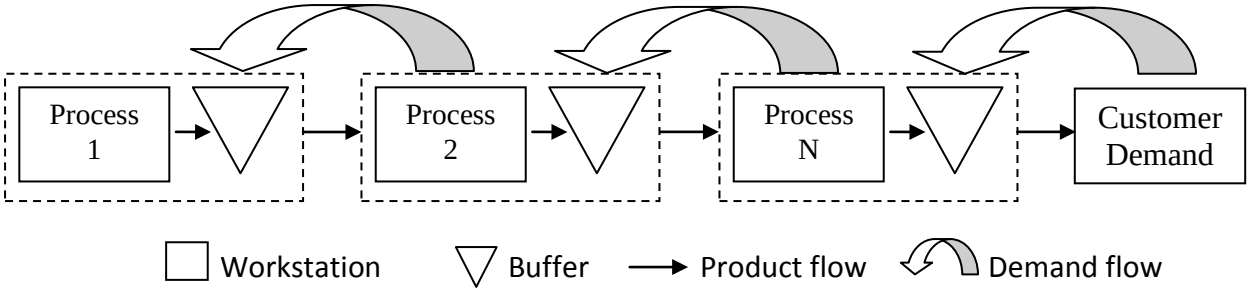

Figure 2: Pattern of pull control system

Albino (1995)[1] studied to increase efficiency of throughput time evaluation and work-in-process for Kanban system analysis and design to suit real production line. He applied the creation of the queuing system's model by using Markov process to evaluate behavior of the pull production process. A significant characteristic of this evaluation is simple allocation of production line used for the queuing system like M/M/1/L. The result found that the behavior of the pull production process and other greater production lines could be well evaluated by this method.

Neural Network is extensively used to forecasting. Chambers (2000)[2] investigated the buffer size of the queuing system by studying possibility of single workstation building to forecast the result of the queuing system. The single workstation is connected following the queuing system of two products and used the back-propagation artificial neural network to teach the network. According to the situation simulation, the connected workstations in the queuing system can

predict the performance value of the system which is an approximate with the result of the situation simulation.

In 2006 Fulya (2006)[3] applied the back-propagation artificial neural network to identify the buffer quantity in asynchronous assembly systems by using the data from situation simulation to compare with a prediction method, regression metamodels. The analysis showed that the back-propagation artificial neural network can be use as the suitable model to identify the buffer quantity with low sensitiveness. Furthermore Piromya (2006)[6] used the back-propagation artificial neural network to assess the performance of the pull production process consisting of 3 and 4 workstations. The data apply for teaching neural network is collect from the situation simulation to examine the result of different data of entire possible situation of the system. It found that the evaluation of the artificial neural network is a very good level. Besides, when there are more data in the network, the efficiency of system's performance evaluation also increased too.

Manusak (2007)[4] developed and studied the scaleable artificial neural network system for performance function approximation in case study of the buffer optimizing of pull control system of multiple workstation ,the network system separate 3 types of single workstation by training Data from simulation are initial workstation network , intermediate workstation network and final workstation network , approximation by interconnecting 3 types of network systems. From the study, the scaleable artificial neural network system can use to approximate performance measure of this case study and from this studying factors that affect the performance efficiency, increasing the factor of number of workstation in the system make the efficient of approximation decrease. For sample size used training network increased make the efficient of approximation increase.

METHODS

Because of stochastic system is determine mean and variation, therefore approximation function not should consider only mean but it should approximate variation too. This research use concept of Scaleable Aritifitial Neural Network System: SANN for create pull system model, in order to be training data for neural network. The situation simulation of the pull production control system is divided into three types of single workstation including initial workstation, intermediate workstation and final workstation. The initial workstation is the first workstation and the intermediate workstation is the second workstation to the workstation n-1, n is number of total workstations in the system and the end single workstation is the last workstation or 'n' workstation.

After that, three models of the situation simulation are created. The data collect from the situation simulation of each workstation is brought for the network teaching to produce the three types of the networks. The pull production control system with several workstations can be built by SANNS to link each workstation and evaluate 8 performance values including average response time of sale, variation response time of sale, average response time of lost sale, variation response time of sale, average of cycle time (CT), variation of cycle time, average

of work-in-process (WIP) and variation of work-in-process.

The artificial neural network is a hidden layer with 20 nodes using two levels of data that teach in the network at 30% and 50% of all data. Probability of processing time is normal distribution with standard deviation at 5% of the processing time (P) of each workstation only. The processing time value is between 0.6-1.0 separated by 0.1 time unit in each interval. The highest buffer size (B) is 5 while the lowest buffer size is 2. The demand rate (D) are dispersed as exponential distribution with average of one processing time at 0.8, 0.9, 1, 1.1, 1.2 of time unit and normal distribution with average of one processing time at 0.8, 0.9, 1, 1.1, 1.2 of time unit, standard deviation at 5% of processing time.

Mean case, the method of network connection start from checking the pull production control system if there is any workstation with highest processing time or not. If such workstation is found, it will be defined as a bottleneck workstation. Then the average of demand rate of any earlier workstation of the bottleneck workstation will be equal to reverse value of time to submit into each type of networks. The outcome is the average of production interval regarded as the input rate for the next workstation. This process will thoroughly run in whole workstations as demonstrated in Figure 3 - 4.

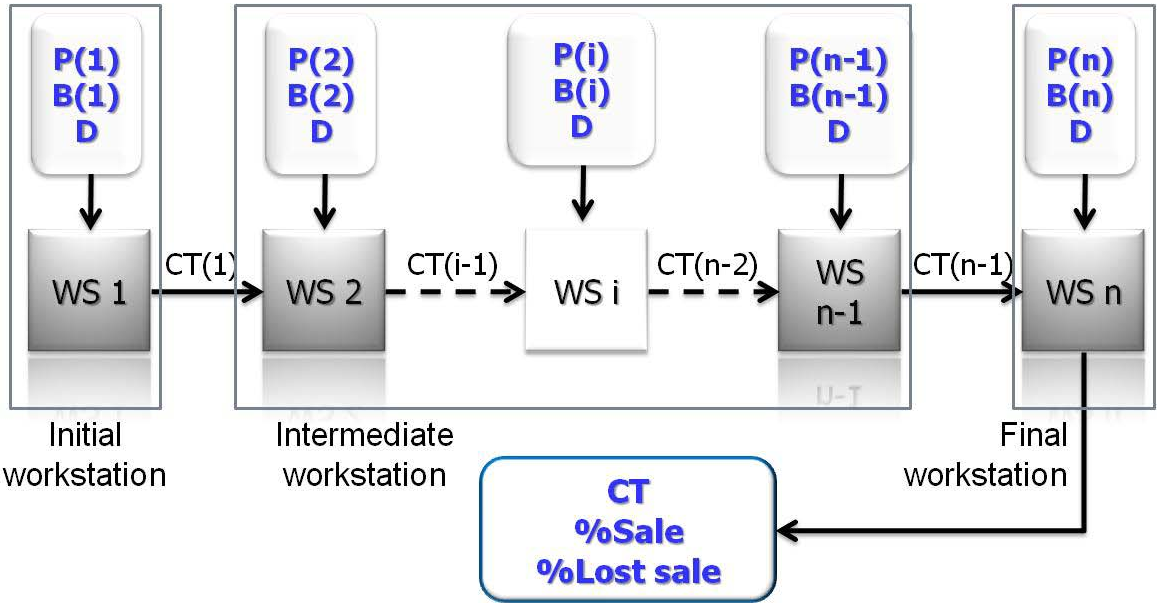

Figure 3: Connector of workstation for find mean of cycle time, %sale and % lost sale

Because of work in process of previous workstation have effect to work in process of next workstation therefore work in process is necessary become to input for find suitable weight.

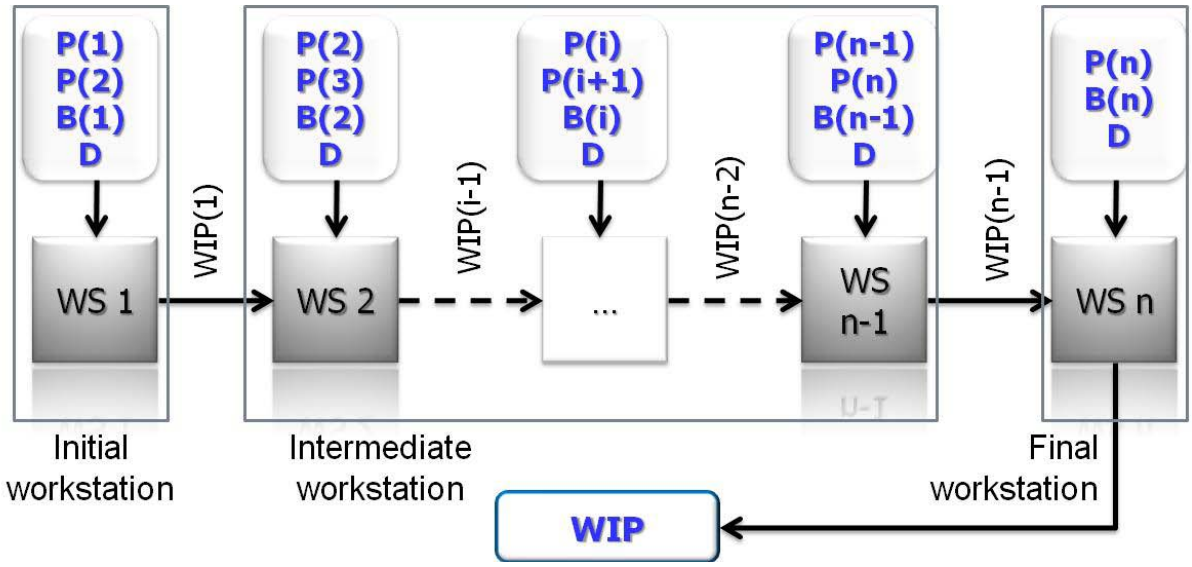

Figure 4: Connector of workstation for find mean of work in process

Variation case, add standard deviation of processing time as input of interconnect of network as demonstrated in Figure 5 – 6. In case of demand is normal distribution, add standard deviation of demand as input of interconnect of network as demonstrated in Figure 7 - 8.

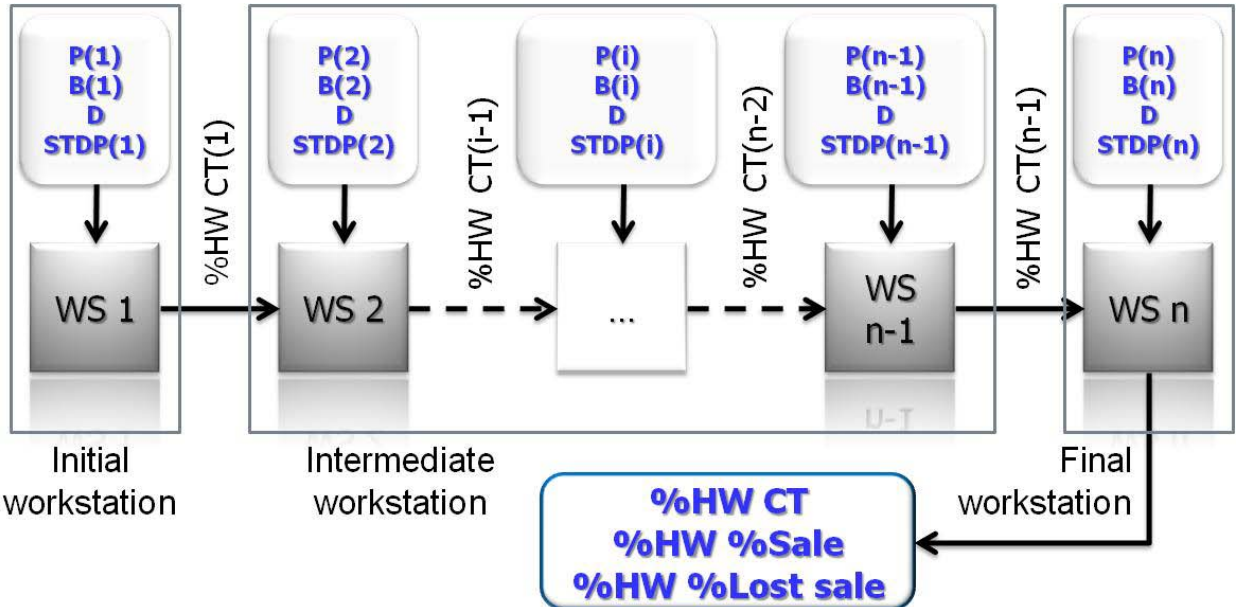

Figure 5: Connector of workstation for find variation of cycle time, %sale and % lost sale (Demand: Exponential distribution)

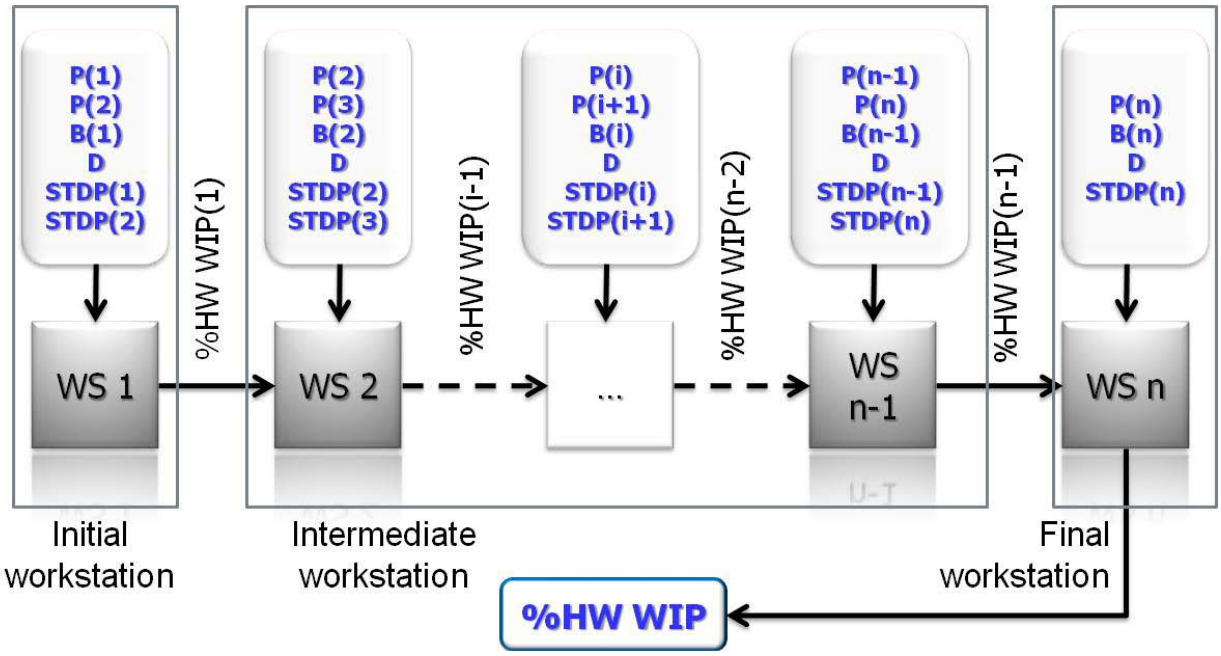

Figure 6: Connector of workstation for find variation of work in process
(Demand: Exponential distribution)

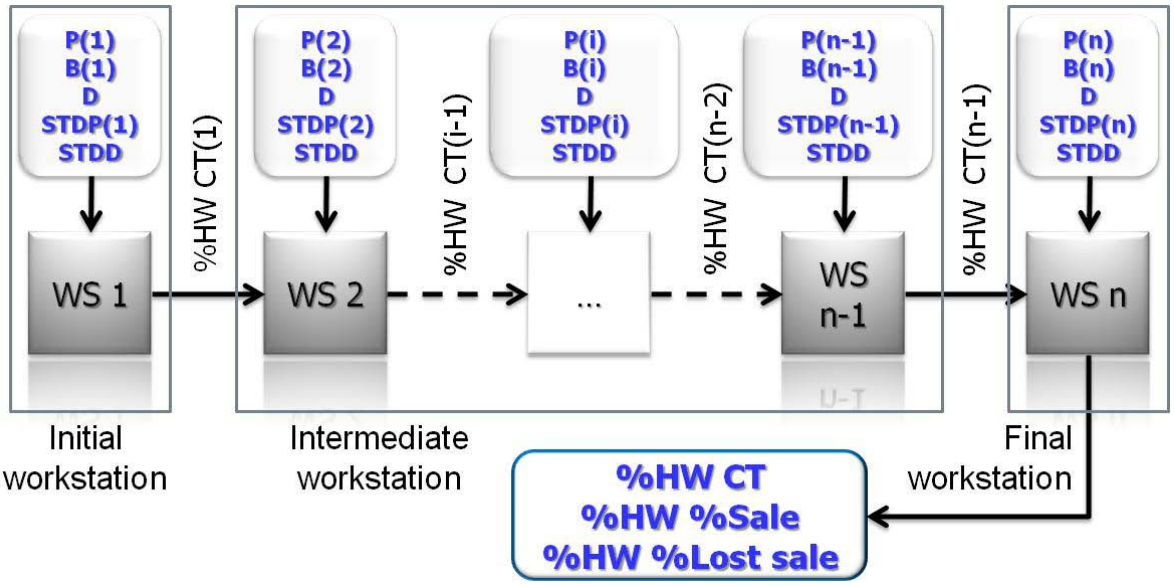

Figure 7: Connector of workstation for find variation of cycle time, %sale and % lost sale
(Demand: Normal distribution)

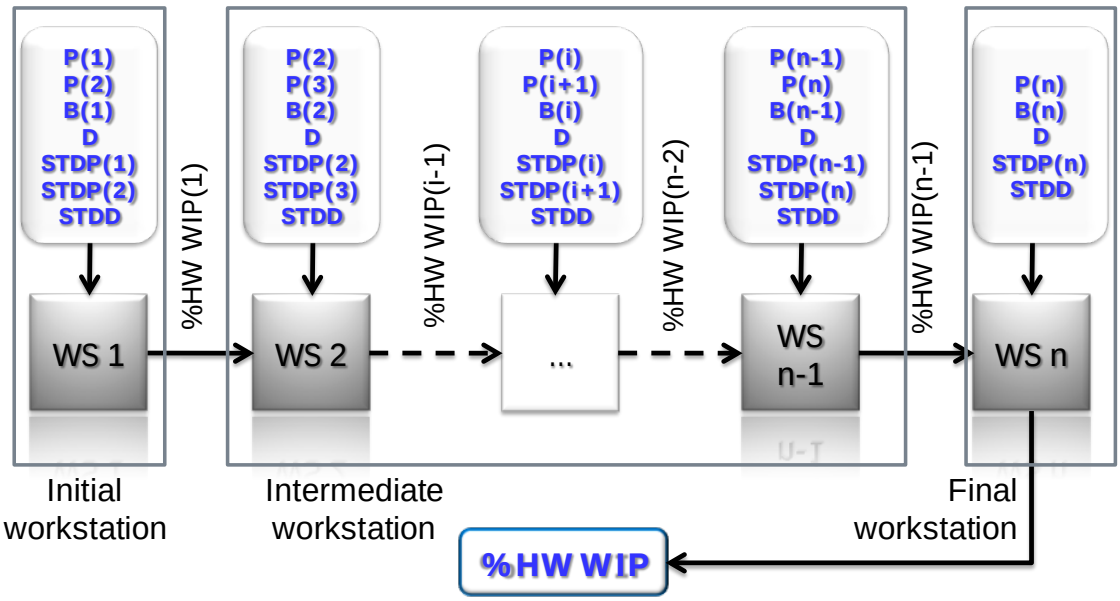

Figure 8: Connector of workstation for find variation of work in process (Demand: Normal distribution)

Training network use data from pull system simulation at 3 workstation. Then use weight acquired from network to estimate value of pull system at 4, 5, 10, 15 and 20 workstation. Collect 5,000 simulation examples per 1 system for compare with value that estimate from SANN. Indicator of mean is R-Square and indicator of variation is ratio of number error data per all data (%Miss).

After that, test capability by change standard deviation of processing time from 0.05 to 0.01. Collect 1,000 data for estimate value. Use weight from network that used training data 50% of all. Consider efficiency of mean with R-Square and variation with ratio of number error data per all data (%Miss).

RESULTS AND DISCUSSION

R-square is used to measure the efficiency of the result as illustrated in Table 2 - 3.

Table 2: R-square value of mean (Demand: Exponential distribution)

R-Square	%Train	Number of workstation					
		3	4	5	10	15	20
Cycle Time	30%	0.99	0.99	0.99	0.90	0.76	0.70
	50%	0.99	0.99	0.99	0.98	0.98	0.98
Work in process	30%	0.97	0.93	0.91	0.66	0.54	0.58
	50%	0.97	0.91	0.90	0.78	0.69	0.70
R-Square	%Train	Number of workstation					
		3	4	5	10	15	20
%Sale	30%	0.99	0.88	0.71	0.40	0.38	0.37
	50%	0.99	0.99	0.97	0.96	0.95	0.93
%Lost sale	30%	0.99	0.99	0.98	0.84	0.77	0.72
	50%	0.99	0.99	0.98	0.97	0.96	0.94

Table 3: R-square value of mean (Demand: Normal distribution)

R-Square	%Train	Number of workstation					
		3	4	5	10	15	20
Cycle Time	30%	1.00	0.82	0.71	0.52	0.55	0.49
	50%	0.99	0.99	0.97	0.84	0.91	0.91
Work in process	30%	0.98	0.96	0.94	0.68	0.64	0.65
	50%	0.97	0.96	0.95	0.83	0.50	0.78
%Sale	30%	1.00	0.99	0.97	0.90	0.78	0.79
	50%	0.99	0.99	0.97	0.87	0.69	0.72
%Lost sale	30%	1.00	0.99	0.97	0.91	0.77	0.79

50%	0.99	0.99	0.97	0.94	0.74	0.76

Table 2 shows result that SANN estimate mean of system. Data are trained with 50% of all data have efficient more than data are trained with 30% of all data. Besides increase of work station will reduce efficient of estimate mean.

However estimate variation cannot perform with R-Square. From analyst variation data are found that rang of half-width are small gap. So separate rang of half-width to 0%, 1%, 3%, 5%, 7%, 9%, 10%, 15%, 20%, 30%, 40%, 50% and 60% and then get this value to train network for find suitable weight at 3 workstation. Next use this weight to approximate variation at 4, 5, 10, 15 and 20 workstation. Consider efficiency of variation with ratio of number error data per all data (%Miss) as shown at table 4 - 5

Table 4: %Miss value of variation (Demand: Exponential distribution)

%Miss	Number of workstation					
	3	4	5	10	15	20
Cycle time	0.00	0.00	0.00	0.00	0.00	0.00
Work in process	3.63	4.56	4.36	11.28	16.46	18.28
%Sale	0.00	0.00	0.00	0.00	0.00	0.00
%Lost sale	2.17	2.14	1.1	2.34	2.76	2.82

As shown in Table 4 above, estimate %Miss of Cycle time and %Sale do not have error while %Lost sale and Work in process have tend to increase when number of workstation increase. However %Miss are not over 2% and 20% respectively.

Table 5: %Miss value of variation (Demand: Normal distribution)

%Miss	Number of workstation					
	3	4	5	10	15	20
Cycle time	0.00	0.00	0.06	0.00	0.00	0.00
Work in process	1.00	4.44	4.36	0.00	0.18	0.16
%Sale	0.04	0.10	0.20	0.00	0.00	0.00
%Lost sale	1.67	1.30	2.26	3.54	4.88	9.64

As shown in Table 5 above, although number of workstation increase to 20 workstation but %Miss of Cycle time and %Sale are not over 0.5% while %Miss of Work in process are not unstable. However %Miss of Work in process are less than 5%. For %Lost sale, %Miss will increase when number of workstation will increase, but not over 10%.

For test capability, the result of estimate performance of pull system is shown that SANN can estimate mean and variation at standard deviation of demand is 0.01. But efficiency of estimate will reduce when number of workstation increase which shows in table 6 – 9.

Table 6: R-square value of mean (Demand: Exponential distribution)

R-Square	Number of workstation				
	4	5	10	15	20
Cycle Time	0.98	0.97	0.94	0.94	0.94
Work in process	0.93	0.90	0.78	0.69	0.69
%Sale	0.99	0.98	0.97	0.93	0.95
%Lost sale	0.99	0.98	0.94	0.88	0.90

Table 7: R-square value of mean (Demand: Normal distribution)

R-Square	Number of workstation				
	4	5	10	15	20

%Lost sale	99.3	98.5	94.5	85.8	73.3

CONCLUSION

The results of this research show that SANN effectively predicts (approximates) the mean and variation of the four performance measures of the pull-control production system. The recommended train data size is fifty percent of the set of solutions for individual workstation in developing SANN for the Initial workstation, the intermediate and the final workstation. From the results, direct approximation of the confident interval of performance measures is not possible. However, when using SANN to predict the range of variation in all performance measures, the results indicate the effective prediction. The predictability of variation in cycle time and the number of sales are about 99%. The predictability of variation in work-in-process is about 80% due to the impact from the increase of the number of workstations. The predictability of variation in the number of lost sales is about 90% due to the impact from the small and non continuous value of measures. In conclusion, SANN has shown a great promised in accessing the stochastic measures in large production system.

BANK VALUE AT RISK DISCLOSURES AND RISK PREDICTABILITY: THE EFFECT OF DERIVATIVE USE

ABSTRACT

Banks disclose value at risk (VaR) data that is, in principle, instrumental in predicting the subsequent variability of trading income. Using a sample of 18 United States commercial bank holding companies from 1997 to 2006, we find that VaR is a predictive risk measure. Nevertheless, we find that derivative use reduces the predictability of VaR-based measures of volatility. Thus, investors and analysts are cautioned when using VaR disclosures of banks with large derivative positions.

Keywords: value at risk disclosures, predictability, derivatives, banks

INTRODUCTION

The increase in the number, range, and scope of mandatory disclosures by bank holding companies has been notable; in particular, the publication of value at risk (VaR) estimates by banks has received considerable attention. This was mandated by Financial Reporting Release No. 48 published in 1997 that requires public traded firms to disclose their market risk exposure using a tabular presentation, a sensitivity analysis, or value-at-risk (VaR) (Linsmeier and Pearson 1997). Since then, VaR disclosures have been used by analysts to gauge the market risk of banks. However, several papers have questioned the suitability of VaR as a risk measure. Berkowitz and O'Brien (2002) indicate that banks' VaR models are not superior to a simple volatility measure. Dowd and Blake (2006) further argue that VaR is seriously flawed as a measure of risk. On the other hand, Jorion (2002) and Liu, Ryan, and Tan (2004) find evidence that banks' trading value-at-risk disclosures are informative in predicting the variability of future trading revenues. They also find that derivative use by banks increases the variability of unexpected trading revenues.

Banks, acting both as derivative dealer and end-user, participate in the derivative markets. Over the past decade, banks have been increasing their use of derivatives. Banks' trading revenues have also gradually become more and more important for their profitability.[1]

[1] The 1996 Amendment divides a bank's assets into two categories: the trading book and the banking book. The trading book consists of financial instruments that are traded by the bank and is typically marked-to-market daily, while the banking took mainly consists of loans and is not marked-to-market (Hull 2007, p. 176). Trading-related revenues include direct trading revenues, fees, and interest revenues on trading assets net of the costs to fund trading positions. Trading revenues consist of realized and unrealized gains and losses from trading activities, changes in fair value associated with financial instruments held by the bank for which the SFAS 159 fair value option was elected, and loans held-for-sale within the wholesale lines of business.

Banks' use of derivatives leads to greater variability of future trading revenues. The use of derivatives by banks is sophisticated. As a derivative dealer, banks provide quotes to other market participants, while, as end-user, they use derivative contracts to manage portfolios, or to hedge risk. Empirical evidence on the relation between banks' derivative use and risk is inconclusive. Venkatachalam (1996) and Yang, Song, Yi, and Yoon (2006) find that bank holding companies use derivative contracts to reduce risk. Sinkey and Carter (2000) also note that banks with a higher likelihood of financial distress are more likely to use derivatives to hedge. Thus, the relation between derivative use and risk is an empirical question.

VaR disclosures seem not to properly account for derivative use. In part, this is due to the fact that VaR models have their strengths and weaknesses and work best with particular types of portfolios (Jorion 2000; Linsmeier and Pearson 2000). When optionality in portfolios is significant, the predictability of VaR measures will be adversely affected if the appropriate VaR models are not used. Beder (1995) points out that the increasing complexity and optionality of derivatives makes the scenario selection for VaR calculations even harder. VaR is difficult to apply when portfolios include significant non-linear derivatives such as options and option-like instruments (El-Jahel, Perraudin, and Sellin 1999). For instance, the delta-normal approach entails mapping instruments to delta-equivalent positions and mapping derivatives, especially options, can be more complicated than other assets (Linsmeier and Pearson 2000). The delta-equivalent method inadequately measures the risk of non-linear instruments with asymmetric payoffs because it does not take account of their gamma (convexity) (Jorion 2000; Hull 2007). However, it works well for portfolios with little option content, especially when the holding period is short (Linsmeier and Pearson 2000).

The historical simulation method is onerous for complex portfolio structures (Jorion 2000). The Monte Carlo simulation involves model risk because it requires the stochasticity of underlying market risk factors and pricing models for options. Given these modeling issues, the predictability of VaR is reduced when banks use more derivatives.

Banks' disclosures are intended to reveal their market risk profile. Jorion (2002) was the first to examine the predictability of banks' VaR disclosures. Using a sample of eight banks for the period 1994 to 2000, he finds that VaR disclosures are informative in forecasting the subsequent variability of their trading revues. Using a larger sample of 17 banks from 1997 through 2002, Liu, Ryan, and Tan (2004) also find that VaR disclosures have predictive power for trading revenues variability.

In this paper, we reexamine the question using a larger and extended sample of 18 commercial banking holding companies from 1997 to 2006. As with earlier studies, we find that banks' trading VaRs have predictive power in accounting for the variability of trading revenues, but find that derivative use significantly reduces predictability. To investigate the moderating role of derivative use, we include a variable that interacts the volatility measure inferred from VaR disclosures with the derivative use variable. To our knowledge, the current study is the first to examine the moderating effects of derivative use on the relation between forecasted trading revenues volatility—inferred from VaR disclosures—and unexpected trading revenues.

The remainder of the paper proceeds as follows. Section 2 introduces the sample, data, and research design. In Section 3, we present the empirical results from which we offer some conclusions and their implications in Section 4.

DATA AND METHODOLOGY

To examine the moderating effects of derivative use on the predictability of the VaR numbers, we collect data on U.S. commercial bank holding companies from their 10-Q and 10-K filings from the EDGAR database.[2] Larger banks generally have more technical sophistication with which to develop VaR systems and thus better capability of using VaRs to predict unexpected trading revenues (Liu, Ryan, and Tan 2004).[3] Moreover, these banks generally engage in derivative markets. We therefore collect the data for the largest 100 banks in terms of total assets. Banks without trading revenues, VaR and derivative use disclosures in their 10-Q and 10-K reports are excluded. The final sample includes 18 commercial bank holding companies and 396 firm-quarter observations. Table 1 provides the sample banks' names, total assets, SIC and CIK codes, and the time they first disclosed VaRs in their quarterly and annual filings. Table 2 shows the descriptive statistics for the sample banks.

[2] The keywords used in finding value-at-risk are "VAR", "Value at Risk", "Value-at-Risk", and "trading VaR". We also collect banks' approach to calculating their VaR, confidence level, and holding period.

[3] The initial sample has 987 commercial bank holding companies in this database as of the end of 2006.

Table 2. Descriptive Statistics of Sample Banks (unit: in millions of $)

	Mean	Median	Maximum	Medium	SD
Trading revenue	470	80	8,986	-49	114
Unexpected trading revenue	102	14	3,105	0.04	262
Standardized VaR for 1-day holding period and under the 99% confidence level	65.51	19.08	419	0.05	94.50
Notional amount of derivative contracts	4,011,613	140,778	49,041,398	570	8,426,061
Total assets	309,297	91,501	1,746,248	6,842	394,244

We first scale up daily VaRs collected from banks' 10-Q and 10-K filings to quarterly VaRs using the square root of time rule (Smithson 1999; Jorion 2002; Liu, Ryan, and Tan 2004). According to this rule, we multiply daily VaRs by the square root of 63 to obtain quarterly VaRs based on the assumption that a quarter has 63 working days. We then infer the volatility in quarterly trading revenues from the quarterly VaR divided by α, the standard normal variable. For one-tailed 99%, 97.5%, and 95% confidence levels, the values of α are 2.33, 1.96, and 1.645, respectively. In our sample, most banks present their VaR under the confidence level of 99%. If banks report the VaR under different confidence levels, however, we follow Linsmeier and Pearson (2000) to normalize the VaR.[4]

We measure the unexpected quarterly trading revenues as the difference between the actual quarterly trading revenues and the expected quarterly trading revenues. Like Jorion (2002) and Liu, Ryan, and Tan (2004), the expected quarterly trading revenues are proxied by their moving average over the previous four quarters.

Following Jorion (2002) and Liu, Ryan, and Tan (2004), we examine the predictability of VaR disclosures by estimating the following equation:

$$\text{Unexpected trading revenues}_t = f(\text{VaR-based volatility, Derivative use, VaR-based volatility}\times\text{Derivative use}) + \varepsilon_t \quad (1)$$

where the unexpected trading revenues are proxied by the difference between the actual quarterly trading revenues and the expected quarterly trading revenues; VaR-based volatility is the standard deviation inferred from the VaR disclosures; derivative use is the notional amount of derivatives used by banks, deflated by firm size; VaR-based volatility×Derivative use is the interaction between VaR-based volatility and derivative use.

EMPRICAL RESULTS

Table 3 shows the pooled ordinary least squares regression results for the unexpected trading revenues. The adjusted R-squared across models ranges from 0.31 to 0.37, and their *F*-tests are all significant at the 0.01 level. As expected, VaR-based volatility has statistically significantly positive effects on unexpected trading revenues, suggesting that banks' VaR disclosures have predictive power in forecasting the next quarter's variability of unexpected trading revenues with/without controlling for derivative use. This finding is consistent with Jorion (2002) and Liu, Ryan, and Tan (2004). We also find that the coefficients of derivative use are positive and highly significant. This suggests that banks' derivative use increases the risk of next quarter's trading revenues.

[4] For instance, a bank discloses its daily VaR under the 95% confidence level. The equivalent quarterly VaR under the 99% confidence level is its daily VaR under the 95% confidence level times the product of the square root of 63 and 2.33/1.645.

Notes: ***, **, and * indicate statistical significance at the 1 %, 5%, and 10% levels, respectively.

Finally, we find that the coefficients for the interaction term, VaR-based volatility×Derivative use, is significantly negatively related to unexpected trading revenues, indicating that derivative use adversely affects the predictive power of VaR disclosures.[5] This is possibly because banks' portfolios may include large quantities of options or option-like instruments with asymmetric payoffs. The asymmetric payoff of these instruments reduces the ability of VaR to correctly capture the risk.

CONCLUSION

Prior research has suggested that VaR disclosures reveal the market risk profile of firms. Jorion (2002) and Liu, Ryan, and Tan (2004) finds that banks' VaR numbers significantly predict the next quarter's risk. Due to the complexity of derivative instruments, it is to be expected that the predictability of VaR disclosures should be reduced for banks with large derivative positions in their portfolios.

In this paper, we provide evidence that this has been the case. Using a sample of 18 U.S. commercial bank holding companies reporting trading VaR during the period 1997 to 2006, we find that VaR predicts the subsequent variability of trading revenues. Furthermore, we find that the predictability will be reduced for banks with significant derivative positions.

Our study has a significance for those interested in using risk disclosures made by financial institutions, such as regulatory authorities, analysts, and stakeholders. They are cautioned about the predictability of VaR numbers disclosed by banks heavily engaged in the derivative markets.

[5] As a robustness check, we use an alternative proxy for derivative use, namely the notional amount of derivatives used by banks, and examine the sensitivity of our results. We find that using the alternative proxy does not qualitatively affect the results on other variables.

THE RETURN ON EQUITY (ROE) FOR FOOD SECTOR COMPANIES LISTED ON THE WARSAW STOCK EXCHANGE

slawomir_juszczyk@sggw.pl

mgr Artur Jan Nagórka, Warsaw University of Life Sciences (SGGW), Poland
artur_nagorka@sggw.pl

ABSTRACT

The key systematic issue tested throughout this paper is finding the reason for the relative low representation of the food sector on the stock exchange. Research on the performance of food sector companies within 1998–2008 led authors to the conclusion that one of the potential reasons of such under representation might be low level of ROE relative to the return from available investment opportunities made at the market free risk rate during the matching period.

Polish investors enjoy a large scope of investment options, some relatively safe and capital market risk free, including a number of Treasury Bills and Treasury Bonds.

Key thesis in this paper show substantial discrepancy between the level of return (ROE) on Polish listed food sector companies and the level of return acceptable for investors. For the purpose of the research the authors used several available ways to calculate ROE and compared in this paper to the market risk free rates for the period.

Results clearly confirm that ROE of food sector companies remains on lower levels than the market risk free rates, sometimes even remaining on negative territories.

Keywords: Return on Equity ROE, stock exchange, food sector, market risk free,

INTRODUCTION

The problem of the financial result worked out basing on assets used by the company is present in the practice of corporate finances since the 30's of the XX century, when the pioneer works were conducted in the financial division of the chemical giant Du Pont. The general practice of comparing appropriate elements from companies' financial statements and on these basis calculating appropriate measurements of the companies' performance thus has taken the name of Du Pont system. While describing the issue, authors use sometimes different taxonomy: „Du Pont system" (Ross, Westerfield, Jaffe, 1990, p.42 – 44), (Bodie, Kane, Marcus, 2009, p. 636 – 641), (Brealey, Myers, Marcus, 2001, p. 142 – 146), „Du Pont model" (Brigham, Daves, 2007, p. 259 – 270), „Du Pont equation" (Brigham, Ehrhardt, 2008, p. 132 – 141), while "Du Pont pyramid" is generally used term in Polish language literature.

Within the Du Pont system there are three ratios related to defining return: ROS - Return On Sales, ROA - Return On Assets, and ROE - Return On Equity. The most important for the company's owners is the third ratio which shows how efficiently equity (what in reality is the owners own capital invested in the company) has been used by the company. There are several approaches to which level of the result of the company's business shall be used for the most relevant calculation of the return shall be measured (i.e. what to use as a numerator). It is sure that it should be one of the forms of earnings or profit but the concepts vary starting from the level of net profit to the level of EBIT. In the case of ROE the majority agrees that the numerator should consist of the net profit what in general practice is equal with net profit payable to the owners. However there is a view (Garrison, Noreen, Brewer, 2008, p. 724 – 727) that the numerator should be clearly calculated as net profit corrected by the payment of preferred dividends. This is largely unimportant for the concept of ROE and secondly the voice is an isolated one.

As far as denominator is concerned it is crucial to use a correct figure for equity. The first concept is that it should be the level of equity as stated for the last day of the accounting period. This view was largely present at the initial stages of the development of the concept of ROE (Bień, 2008, p. 99 - 103), (Micherda, red., 2005, p. 63 - 66), (Pastusiak, 2009, p. 99 - 101), (Sierpińska, Jachna, 1996, p. 103 - 107), (Siudek, 2004, p. 185 - 187), (Wędzki, 2003, p. 20 - 23), (Bodie, Merton, 2003, p. 121 - 130), (Brigham, Houston, 2005, p. 119 - 122), (Adair, 2006, p. 46 - 47), (Bodie, Kane, Marcus, 2009, p. 636 - 641), (Brigham, Daves, 2007, p. 259 - 270), (Brigham, Ehrhardt, 2008, p. 132 - 141), (Damodaran, 1996, p. 79 - 86).

Alternatively, it is acceptable to argue that the applicable correct figure for the equity shall be calculated as the simple average of the two consecutive accounting periods, the current and the previous one. This point of view becomes more and more generally recognised since it is acknowledged that the average for the year (the beginning and the end of the accounting period figures) describes the condition of the company more precisely that the fixed figure of the year end (Brealey, Myers, 1999, p. 1083 - 1087), (Bodie, Merton, Cleeton, 2009, p. 83 - 88), (Brealey, Myers, 1991, p. 680 - 682), (Brealey, Myers, 2003, p. 828 - 831), (Brealey, Myers, Marcus, 2001, p. 142 - 146), (Garrison, Noreen, Brewer, 2008, p. 724 - 727), (Harrington, Wilson, 1989, p. 8 - 16), (Ross, Westerfield, Jaffe, 1990, p. 42 - 44).

USAGE OF ROE

In short and simplified summary, the ROE ratio shows the company's ability to generate profits through the period using available means, i.e. the equity. In practice there may be some difficulties in using ROE as a comparison tool to judge the performance of the company – mainly because of the weakness of the net profit parameter which is the accountancy figure versus the real money worked out by the company as shown in the cash flow. Thus net profit is rather more a paper figure than real money in the company's disposal. Because of different law systems and various numerous tax exemptions plus different manners to count depreciation and amortization it is difficult to use ROE ratio as a simple comparison between the companies. It is similarly difficult to use ROE to compare companies from different sectors which have different capital needs.

ROE in % in various sectors in 2007:

Cigarette Industry	35,0	
Iron/Steel making	26.7	
Soft Drinks	19,2	
Banks	17,1	
Data storage	16,5	
Farm products		16,5
Software for business	12,8	
Telecommunication	12,3	
Food	11,8	
Airlines	8,5	

Source: Bodie, Kane, Marcus, 2009, p. 568, from Yahoo! Finance of 5.11.2007

There are other issues that influence usage of ROE (Brigham, Houston, 2005, p. 135) related to business risk, scale of activity and project implementing. Because of its construction, ROE ignores the risk factor. It is possible that a very risky project, that in one accounting period was very successful, in the next period is much worse. In this respect, judging through the past, it would have been better to choose the project with inferior ROE but with a significantly higher risk that would enable generating profit in the long run.

The ROE ratio does not take into account the scale of the project. There are various cases where the high level of ROE is possible to achieve only when investing in projects of lower scale (i.e. not using whole available capital). Managers in such circumstances should rather decide to take on the project of lower ROE but allowing the usage of larger amount of capital.

ROE is as well difficult to use when it deals with sections of an enterprise. It may happen that the managers evaluated solely on the basis of the level of ROE ratio, i.e. have a clear goal of a certain ROE level acceptable, after having reached such sufficient level for the positive evaluation of the management, are then reluctant to take risk of new projects for the fear that this would lower the achieved level of return.

Important feature of ROE is that using the financial statements it is possible to calculate its level from the past (Bodie, Kane, Marcus, 2009, p. 637), but for the recommendations and assessment of the future financial events, it is advised to employ forecasts, not the historical data.

Another significant remark towards ROE is the fact that it is calculated for the nominal values. The calculation for the real figures requires refining the ratio from the effect of inflation. It is particularly important from the point of view of an investor who anticipates the growth of the wealth.

ROE IN FOOD COMPANIES LISTED ON THE WARSAW STOCK EXCHANGE

The aim of this research is to calculate the ROE ratio in the food sector companies listed on the Warsaw Stock Exchange during the period of 1998 – 2008 and formulating using different methods of calculation and indications of its changes. In this respect authors take into consideration two basic methods of calculating ROE

1. ROE end =
Net profit / Equity at the end of the accounting period
2. ROE avg =
Net profit / The average of the equity from the beginning and end of the accounting period

It happens that changes of the equity do not occur during the accounting period or sometimes are relatively small, however, from the point of view of dynamic character of equity and the fact that actual figures are counted in small percentage points it is better to calculate on the basis on the average equity.

The food sector companies listed on the Warsaw Stock Exchange may be characterized by three subperiods within the years 1998 – 2008.

1. 1998 – 1999, when ROE was relatively at low level and in several cases it reached negative territories.
2. 2000 – 2003, when ROE was at relatively low level but the negative figures were sporadic.
3. 2004 – 2008, when ROE was at relatively higher level and the average for the sector reached double figures values.

Analysis of all above companies prove that only in the period 2006-2007 all of them displayed ROE at the positive levels. In all remaining years at least one food company demonstrated the negative ROE.
It is symptomatic that among 8 companies listed constantly on the Warsaw Stock Exchange within the research period, as many as 7 recorded at least once the negative ROE. There is only one company “Jutrzenka S.A.”, which ROE has been always at the positive territories, however, twice only at decimal fractions of a percent. It seems that the fact of listing on the stock exchange, the experience of the management of the publicly listed company, advise from the professional consultants and observing investors’ expectations, and in some cases extorting necessary changes in operations result in gradual growth of the ROE ratio. The periods of the negative ROE are never longer than two years and the return on the positive levels is in majority durable and the gradual consolidation is noted.

For all food companies listed on the Warsaw Stock Exchange in years 1998 -2008 the ROE ratio was calculated with the implementation of both possible denominators: the amount of equity at the end of the year and the average equity for the given year. Calculating the average equity is justifiable, because the profit is made throughout the year, so one has to implement the level, that is the most close to the year average equity.

Table 1: Return on Equity (ROE) calculated on the basis of end of the period figure and on the basis of the average for the accounting period.
Source: own calculations

The results showing the difference between two formulas are presented in the table in the position:
difference between ROEend and ROEavg = (ROEend – ROEavg)/ROEavg x 100%.

The average of these values in the consecutive 11 years is shown in the last column. For 7 among 8 researched companies this deviation is in negative territories between -5,0 and -0,9 % what indicates the systematic growth of the equity in these companies.

The significant remark is that the figures obtained with the calculations using the average amount of equity are usually higher than these obtained with the calculations using the period end figures. Such a phenomenon is to be explained by the fact that the equity in companies has a general growth tendency what is in line with the real sense of the company's existence whose aim is the maximisation of the profit from the owners capital. The part of this profit after taking off the dividend is retained in the company and in the consequence makes the equity grow.

From the point of view of the investor a question arises, how to evaluate the economic gist of the investment in the food sector companies listed on the exchange. For the financial investor the return of such an investment is measured as the total of the paid dividend and the capital gains measured as the difference between the selling price and the purchase price reduced by the transaction costs. Such a view includes in itself two main factors influencing the market price of shares: the company's financial results raising or lowering its value and the influence of general market forces not linked with the financial situation of the particular company – and these two independent factors are always interacting in the same time. If so to exclude the influence of the market forces as general, the basic factor to measure the economic meaning of the investment should remain the net profit. In the context of the capital investment it is shown in the ROE ratio.

In this case the question arises to what level compare the ROE ratio in order to receive the answer for the real meaning of the investment in the given company. It is possible to compare this ratio to the level of inflation to receive the return in the real values rather than in the nominal values. This approach has a substantial limitation because the way of construction of the ratio by taking numerator and denominator from the same moment of time reduces the influence of the inflation.

MARKET RISK FREE INVESTMENTS

An alternative way to calculate the efficiency of the investment is to compare it with the market free risk investments. The scientists from the corporate finance domain do not agree as to the exact definition of the "market free risk investment". In a logic sense, it means the investment at the highest return without any risk. The question of risk is crucial. It possible to assume that the instruments issued by the State Treasury or by a bank of the highest rating are the market risk free instruments. However even at the best banks and even in the case of countries there is a certain risk of insolvency. To create the market risk free investment level it is possible to calculate the average of the deposit interest for all the banks in the given economy. The solution is however not acceptable from the point of view of a real investor because as the place for creating a deposit only one or just a few banks could be used, and they may carry much higher risk than an average for all the banks.

There is a possibility to use the deposit level on the interbank market as this one which is minimal to reach in the given market conditions, so in the case of Poland it may be WIBOR (Warsaw InterBank Offered Rate). The argument to reject this rate is that in the given moment it is a result of the current market forces and its employment at the date of the end of the year bares the risk of tampering with the results.

Another benchmark for the market risk free investment could be one of the National Bank of Poland interest rates. Among these rates the most suitable seems to be the reference interest rate as this one which is the basis to calculate other interest rates and instruments in the national economy. The weakness of this approach lies in the fact that there are no instruments accessible for the financial investors that would use as the basis the reference interest rate.

As the proper benchmark to use as the market risk free investment one can employ only the instruments issued by the State Treasury. From all of them as the market risk free one can point at the Treasury Bills and Treasury Bonds. In respect to the multitude of these papers, the fundamental question arises which of them are the best to implement. In the practice of investment banking as the most suitable one considers 52 weeks Treasury Bills or current Treasury Bonds. Treasury bills are the instruments that bare slightly lower risk but at the same time are less commonly accessible.

From the above reasoning the conclusion comes that the best solution would be to use the return obtained either from 52 week Treasury Bills or from 2 years Treasury Bonds. During the research the list of returns of these bills and bonds was created and the levels were compared. The figures concern the levels from the last trades in the given calendar year.

Table 2. The market risk free investment in Poland

last trades in year	**2002**	**2003**	**2004**	**2005**	**2006**	**2007**	**2008**	**total**
52 weeks Treasure bills	5,69	5,97	6,37	4,32	4,21	5,74	5,92	
2 years Treasury bonds	5,51	6,14	6,12	4,54	4,62	6,19	5,47	
difference	0,18	-0,17	0,25	-0,22	-0,41	-0,45	0,45	
mean of differences								-0,05

Table 2: The market risk free investment shown as the 52 weeks T-bills and the 2 years T-bonds and the difference between them.
Source: own calculations

In the header of the table the years are put in the meaning of the date of the last trading session for the given year. In the lines of the table there are: return on 52 weeks T-bills, return on 2 years T-bonds, the difference of these instruments in the percentage points, the mean of the differences in the percentage points.

The above conducted calculations show that the long term difference between the return of 52 weeks T-bills and the 2 years T-bonds is negligible, sometimes the first is higher,

sometimes the second, and the mean of the differences for the whole period is very small and amount to only 0,05 of a percentage point.

Table 3: The return on equity (ROE) versus the market risk free investment.
Source: own calculations.

In line with the above conducted calculations to the further calculations as the market risk free investment it was taken the 52 weeks T-bills as presented by the National Bank of Poland. In practical frame the market risk free maximal investment brings the highest possible rate of return. One can say that it is the highest return for the investor without risk and effort from the side of the investor. As the benchmark it is going to be compared with the ROE ratio of the food sector companies listed on the Warsaw Stock Exchange. For the comparisons two parallel calculations are implemented

1. ROE with denominator as at the end of the year and the return of 52 weeks T-bills as at the end of the year.;
2. ROE with denominator as the yearly average of equity and the return of 52 weeks T-bills shown as the yearly average.

The aim of this research is to show an economic meaning of an investment in the company as such. The crucial counting lies in the proper return on equity and in this context several questions are ignored: a) possibility to achieve capital gain on the stock exchange, b) the dividend, which in practice during this period was very rarely paid on the Warsaw Stock Exchange.

From the point of view of the investor two alternative investments are concerned:

1. In the food sector company listed on the stock exchange with return shown in ROE
2. Market risk free investment assumed in the 52 weeks T-bills.

Some purists say that there should be no use of negative ROE because while there is a net loss at the end of the accounting period one cannot count return because there is no return. In mathematical meaning however the negative ROE shows the loss on the capital invested in the company. ROE is a measure of effectiveness of the equity, but not the real return for the investor – as it is in the case of the 52 weeks T-bills – so it measures how effectively the capital given by the shareholders is employed, but not how much earning it gives. Hence it is treated here as the theoretical measure of the return on investment.

CONCLUSIONS

Characteristic feature is that in the years 1998 – 2001 all food sector companies listed on the WSE has shown the ROE below the market risk free levels. It proves that during these years the investors would have been better of just to buy the alternative market risk free instruments rather than invest in the companies.

There are as well companies that almost in all the years show the ROE below the market risk free investment (Pepees, Wilbo, Mieszko). It leads to the conclusion that the shareholders of these companies would have done better if they have had invested in the 52 weeks T-bills instead.

The positive feature is that during the period 2003 – 2008 majority of researched companies from food sector listed on the WSE have shown that the managers of these companies were able to use properly the equity available.

The food sector is represented on the Warsaw Stock Exchange weaker than it is in the whole Polish economy. This sector is not searched by the financial investors. As the result many companies were withdrawn from the exchange during the listings. The presented research is an attempt to find the answer to the question why the food sector is so little represented on the stock exchange. The indicated low levels of ROE may be one of the crucial reasons. The positive feature is that in recent years the level of ROE is gradually rising.

The practice of the Warsaw Stock Exchange was that the dividend was rarely paid off to the investors and the market was a subject to substantial fluctuations so the capital gain was very unstable.

The same research tool served as well to indicate that at the end of the researched period the food sector companies that survived on the stock exchange began to show the ROE results much higher than alternative ways of the safe market risk free instruments.

DETERMINANTS OF THE FINANCIAL RESULTS IN THE TERMS OF THE WORLD CRISIS IN SMALL AND MEDIUM-SIZED ENTERPRISES IN POLAND - ANALYTICAL APPROACH, PART 1

Dr hab. Justyna Franc-Dąbrowska, Warsaw University of Life Science

Dr Małgorzata Porada-Rochoń, University of Szczecin

ABSTRACT

As a result of the global crisis, the sector of small and medium-sized enterprises identify and partially will continue to identify a number of dysfunctions in the financial condition leading to growth of financial insolvency and bankruptcy. The changes in the macroeconomic condition have had and still will have a negative impact on the operating results and financial conditions of companies.

In the situation in which the great financial crisis took down almost all of the world markets, either directly or indirectly having an impact on the financial situations of enterprises. An important research problem seems, to develop in such circumstances as the level of profit/ loss in SME in Poland. The study will cover service companies located in the Westpomeranian Region. An sample of 288 companies were selected at random, making it possible to generalize the results of research.

The data was analyzed using: the volatility of the financial results for the entire group of companies as well as ‚for analytical purposes will be transferred between companies into quartiles. Additional calculations were carried out for the 10th and 90th percentile. This analysis will permitted the separation of these groups to determine which parties and under which circumstances caused their rankings. The analysis was carried out in 6 groups (quartiles, and percentiles), which may help identify distinct behavioral strategies in the future depending on the obtained level of net profit or loss.

Studies carried out in the article will serve as the foundation for creating model solutions, and collectively can bring important information about theoretical or/ and practical implications.

Key words: financial results, small and medium-sized enterprises

THE FUNCTIONING OF SMALL AND MEDIUM-SIZED ENTERPRISES IN CRISIS – FROM THE PERSPECTIVE OF THE IMPACT OF GLOBAL CRISIS

Changeability of environment causes that contemporary companies are more often vulnerable to functioning in a crisis. There are many definitions of a crisis in reference books and so far no uniform definition has been worked out. Although, the diversity in the extant crises literature has caused the refinement of a clear definition of crisis to be problematic at best, but it has allowed researchers to identify some common characteristics of all crises.

The term ‘‘crisis’’ is typically used as a catchall concept encompassing a variety of ‘‘un-ness’’ events (Hewitt 1983). Events that are considered to be crises in nature are usually

characterised by high consequence, low probability, ambiguity, and decision making time pressure (Hills, 1998; Pearson and Clair, 1998) It applies to situations that are unwanted, unexpected, unprecedented, and almost unmanageable and that cause widespread disbelief and uncertainty (Hermann, 1963, Carley & Harrald, 1997, Rosenthal, Boin, and Comfort 2001; Stern and Sundelius 2002).

It can be accepted that: A crisis in a company is a process determined by a range of events and situations synchronized in a specific period of time, and as a result leading to the dysfunctions of basic company actions (Porada – Rochoń 2006).

According to the research done by M. Porada – Rochoń[1] at the turn of 2007 and 2008 it is clear that 69% of Polish and as many as 81% American companies have already experienced a crisis at some point. It must be emphasized that the crisis in the enterprise can occur in any phase of the cycle of his existence. The crisis is an integral process in the functioning of a modern company. The crisis is a normal, transitional period to the next stage of development.

We live in an era in which business-related crisis is relatively commonplace. For business managers who are responsible for seeing their business through crises, the questions are no longer whether they will experience crises, but rather when and in what form. Successfully navigating a crisis will depend on the actions a business takes in the time between accepting that crisis can happen and the actual crisis itself.

Typically, the crisis causes the deterioration of the financial health of businesses, starting with reduction in sales and ending with the fall in earnings, which, consequently, often leads to bankruptcy. The financial crisis, that begun in the summer of 2007 was an extraordinarily complex event with multiple causes. Although it concentrated in the United States but quickly metamorphosized into a global financial crisis where financial institutions teeter on the edge of bankruptcy in many countries in addition to the United States. A global economic crisis ensues in which nonfinancial firms around the world appear to spiral downward as well. Companies around the world have had to cope with its effects. The crisis and the rapid change implies the need for an active, forward-looking thinking and effective action. Every company, even in the face of adverse consequences compilation, may retain its competitiveness, undoubtedly.

Especially small and medium enterprises[2] and entrepreneurs play a significant role in all economies and are the key generators of employment and income, and drivers of innovation

[1] The author did carried out research in 2007 and 2008 on financial restructuring processes of 167 Polish and 115 American companies Presented results are some part of the result of research grant of Polish government. no 113.

[2] Definition of micro, small and medium enterprises according EU legislation Micro, small and medium-sized enterprises are defined according to their staff headcount and turnover or annual balance-sheet total (European Commission, 2005): A medium-sized enterprises are defined as enterprises which employ fewer than 250 persons, and whose annual turnover does not exceed 50 million euro or whose annual balance-sheet total does not exceed 43 million euro. Small enterprises are defined as enterprises which employ fewer than 50 persons and whose annual turnover and/or annual balance sheet total does not exceed 10 million euro. Micro enterprises are defined as enterprises which employ fewer than 10 persons and whose annual turnover and/or annual balance sheet total does not exceed 2 million euro.

and growth. During the period since the global financial crisis began, SMEs in many economies have seen demand for their products fall, have experienced difficulty in obtaining working capital, and in many cases have been forced out of business. With customers canceling orders and delaying payment, many SMEs have had problems with liquidity, and have found themselves urgently seeking bank loans. However, banks tend to lack confidence in SMEs' financial health and their ability to achieve sales growth in the future. Banks' cautious lending policy has in many cases amounted to a freeze on the granting of loans to SMEs, and SMEs' funding costs have increased dramatically.[3]

According to OECD Report: The Impact of the Global Crisis on SME and Entrepreneurship Financing and Policy Responses, there is evidence that SMEs in most countries are confronted with a clear downturn in demand for goods and services if not a demand slump in the fourth quarter of 2008. Many expect a further worsening to come. For SMEs there are two related stress factors: a) increased payment delays on receivables which added - together with an increase in inventories- result in an endemic shortage of working capital and a decrease in liquidity and b) an increase in reported defaults, insolvencies and bankruptcies.

Extended payment delays on receivables, especially in times of reduced sales, are leading rapidly to a depletion of working capital in many countries. For example, in Belgium 43 % of surveyed SMEs recently experienced extended delays in their receivables and in the Netherlands 50 % of SMEs have to deal with longer payment terms from their customers. In New Zealand, the share of enterprises waiting over 60 days for payment has risen dramatically from 4.8 % to 29.5 % between February 2007 and 2008. In Denmark, Italy, Ireland, Norway and Spain the surge in corporate insolvencies was higher than 25 %. In Finland, while short-term solvency problems among SMEs normally involve 6-8 % of these firms, in January 2009 more than 17 % of small firms with less than 50 employees declared insolvency problems. In Sweden, according to ALMI (the Swedish state owned Development Bank), bankruptcies increased over 50% in the first two months of 2009 compared to the same period in 2008. Table 1 presents select countries in terms of indications on the magnitude of demand shock.

[3] Principles and Checklist of Financial Crisis Management for APEC SMEs . This document is the output of APEC Symposium on SME Strategies to Manage the Impacts of the Global Financial Crisis held in 2009 in Taipei, and was endorsed by 2009 APEC SME Ministerial Meeting.

Table1: Indications on the magnitude of demand shock.

Country	Assessment of intensity of experienced or expected demand shock
Australia	According to a survey conducted among small enterprises only (firms employing up to 19 employees), more than 1/2 reported either an increase or no change in sales;. In terms of anticipations, almost 2/3 were expecting a recession to occur within the next year. According to another survey covering enterprises with up to 199 employees, business confidence fell during the Q1-2009 to its lowest level, also showing a record low in the sales performance indicator. Only around 31 per cent of enterprises reported facing no problems in their business. Lack of work or sales is the primary concern of SMEs Q1-2009, remaining close to its highest level since May 1998. Medium-sized businesses were more confident than small businesses.
Belgium	According to an "Access to Finance" survey, 60% of respondents report falling sales as the main manifestation of the crisis, followed by a worsening of their financial condition (52%) and extension of their clients' payment delays.
Canada	According to Business Barometer (Dec 2008) : 29% of SME owners say their performance in 2008 was much stronger than in 2007, while 40% say performance is much worse or somewhat worse. Only 17% expect improvement and 44% anticipates worsening performance.
Finland	For a majority of SMEs, orders or pre-orders have been postponed (47%) or cancelled (24%) during the last few months. Demand conditions were worsening further from Q3-2008, when postponed orders affected 34% and cancellations 14% of SMEs.
Germany	According to the National Federation of Independent Businesses, in Q4-2008 poor sales were seen as the single most important problem for 25% of businesses, while financial issues were a top concern for about the same proportion of enterprises.
Greece	The current economic crisis has affected businesses in different ways: for 58% it has been through insufficient working capital, for 55% by way of insufficient sales.
Italy	According to Eurostat, retail trade volume fell by 4.9% in December 2008 compared to December 2007 (new car registrations fell by 17.2%). According to Istat (National Institute of Statistics), exports in 2008 rose by 2% compared to 2007, but fell during the last quarter (5.5% in December 2008 as compared to December 2007. Industrial orders in manufacturing fell by 13.1% in December 2008 compared to the same period of 2007. Business confidence recorded in the ISAE (Institute of Studies and Economic Analysis) surveys has fallen in recent months to all-time lows in all the sectors.

Source: Source: Country Responses to the OECD WPSMEE Questionnaire on the Impact of the Global Crisis on SMEs and Entrepreneurship Financing and the Policy Responses, launched on 14 January 2009 and publicly available information. (in:) The Impact of the Global Crisis on SME and Entrepreneurship Financing and Policy Responses Organisation For Economic Co-Operation And Development OECD 2009.

The financial condition of Polish companies due to the crisis have been quite badly damaged but only in 2008. The strongest impact of the crisis was evident in the financial decline in net financial result. Compare 3Q of 2009 to 3Q of 2007 reported 57% decrease, but compare 3Q of 2009 to 3Q 2008 was evident 40%. According to Polish economists forecast in 2010 net financial result is expected to increase.

The year 2009 showed that Polish companies are able to adjust their activities to current business conditions. The year 2009 was said to bring a crisis which would lead to the loss of mld PLN and thousands of Poles were said to lose their jobs. Yet, the companies in Poland coped with this situation perfectly and financial results support it. However, according to A.T. Kearney, Poland can benefit from a global crisis – in their opinion Polish companies coped well with the first wave of a crisis but they should be prepared for a decrease of orders.

Experience from previous crises suggests that even short-lived shocks can have adverse permanent consequences. Being laid off during a recession can have a scarring effect; evidence from Finland suggest that those laid off during a recession suffer an earnings penalty that only gradually declines over time (Verho 2008). Shocks can also have a lasting adverse effect on firms, as crises may drive otherwise viable firms out of business (Dollar and Hallward-Driemeier 2000; Casacuberta and Gandelman 2009).[4]

However, at the present time, SMEs have been especially hard hit by the global crisis. These firms are more vulnerable now for many reasons: not only has the traditional challenge of accessing finance continued to apply, but new, particularly supply-side, difficulties are currently apparent. It is important to stress that SMEs are generally more vulnerable in times of crisis for many reasons among which are:

- it is more difficult for them to downsize as they are already small;
- they are individually less diversified in their economic activities;
- they have a weaker financial structure (i.e. lower capitalisation);
- they have a lower or no credit rating;
- they are heavily dependent on credit and
- they have fewer financing options.

SMEs in global value chains are even more vulnerable as they often bear the brunt of the difficulties of the large firms. There is evidence that SMEs in most countries are confronted with a clear downturn in demand for goods and services if not a demand slump in the fourth quarter of 2008. Many expect a further worsening to come. For SMEs there are two related stress factors: a) increased payment delays on receivables which added - together with an increase in inventories- result in an endemic shortage of working capital and a decrease in liquidity and b) an increase in reported defaults, insolvencies and bankruptcies. [5]

INTRODUCTION TO EARNINGS MANAGEMENT

Earnings represent the single most important item in the financial reports. Earnings are closely monitored by several parties including financial analysts, executives, and boards of directors etc. The significance of earnings is further emphasized by the fact that the medium and long-term stock returns are overwhelmingly explained by the firm's cumulative earnings. Earnings also have implications for senior executives' employment and compensation benefits.[6] Schipper (1989) defines earnings management as purposeful intervention in the external financial reporting process, with a view to obtaining private gain for stockholders or managers.

Recent studies show, that generally during recession or crisis, companies generate lower financial result compare to economic expansion. Earnings is sensitive to the business cycle.

Individual firms may have different incentives for earnings management. However, the tools that firms use in managing earnings can be systematically associated with the decomposition of total accruals.[7]

In II part of the paper : DETERMIANTS OF THE FINANCIAL RESULTS IN TERMS OF THE WORLD CRISIS IN SMALL AND MEDIUM -SIZED ENTERPRISES IN POLAND – ANALYTICAL APPROACH, PART II there will be extend the theoretical approach to earnings management. The paper will analyze the determinants affecting level of financial results, for small and medium-sized enterprises used in our sample over the years 2006-2009. Particularly interesting seems to establish the factors that shape these financial results (profit or loss) enterprises under the conditions of the recent financial crisis. The study will cover Poland, chosen at random (the sample consists of 288 commercial companies)

PURPOSE AND METHODOLOGY OF RESEARCH

The data was analyzed using: the volatility of the financial results for the entire group of companies as well as ,for analytical purposes will be transferred between companies into quartiles. Additional calculations were carried out for the 10th and 90th percentile. This analysis will permitted the separation of these groups to determine which parties and under which circumstances caused their rankings. The analysis was carried out in 4 groups (percentiles), which may help identify distinct behavioral strategies in the future depending on the obtained level of net profit or loss.

DESCRIPTION OF THE EXAMINED COMMUNITY

Table 1 presents selected variables characterising small and middle enterprises covered by the study. They were divided into equal groups according to their net financial result and were analyzed within these groups. Due to the distribution of variables, the figures presented are median, and not average, values. It was established that companies with higher net financial result are characterised by a larger scale activity expressed as net sales income. Enterprises from 3G and 4G exhibited considerably even several times higher sales levels. Thus, it may be assumed that enterprises from 1G and 2G (as regards sales volumes) were entities smaller than enterprises classified to 3G and 4G. From the point of view of the great financial crisis that took place in the years 2007-2008 it is clearly visible that in 2008 in enterprises from 1G sales diminished and that in enterprises from 3G it was considerably reduced in 2008 r. as compared with 2007 (by nearly 50%). Enterprises from 2G, in which in 2007 sales income was by far higher than in years 2006 and 2008, exhibited significant fluctuations as regards sales volume. The only entities which in 2008 increased their sales (as compared with the preceding year) ware enterprises from 4G.

The observed fluctuations in the sales volume did not directly translate into changes in the total assets value. Enterprises from 1G systematically increased book value of their assets, whereas assets of enterprises from 2G diminished. The situation was similar in the case of enterprises from 3G. In confrontation with the value of fixed assets it must be noticed that this was mainly due to changes in the level of working assets. Conducted analyses

[7] Yoon, S. and G. Miller, Earnings Management of Seasoned Equity Offering Firms in Korea, International Journal of Accounting 37 (2002a), pp. 57–68.

demonstrate that enterprises from 1G systematically increased the value of their fixed assets by way of executing investment projects in spite of a difficult macroeconomic situation. Enterprises from group 2G and 3G increased the value of their fixed assets in 2007 as compared with 2006, but in the following year their value diminished. In 4G the level of fixed assets systematically decreased and entities from this group curbed their investment projects. Slightly different relationships may be observed as regards the level of equity. Taking into consideration that in particular during the financial crisis equity is an indicator (or at least some security) of the enterprise's financial standing, changes in the level of equity observed in 1G, 2G and 4G must be assessed as positive. A significant decrease in the level of equity was observed in entities from 3G, in particular in 2008, which is a disturbing phenomenon (cf. Fig. 1.).

Table 2 presents selected financial variables characterising the enterprises covered by the study. Among the most important parameters illustrating the financial situation of enterprises in the times of financial crisis there are: stock levels, receivables and short-term investments. These variables determine an enterprise's ability to cover its current liabilities. The ability to settle the enterprise's liabilities in a timely manner is the precondition for remaining on the market, in particular in times of unfavourable macroeconomic conditions. Especially interesting are large stock fluctuations in the studied groups of entities. Stock levels were particularly high in 1G in the years 2006-2007, which could be due to accumulation of products that were difficult to liquidate (1G comprises enterprises which on average sustained losses). What is also alarming is the fact that in 2008 the value of stock in enterprises from 2G increased several times and a significant rise in stock levels in enterprises from 4G. In general, it must be noticed that in all groups of enterprises (with the exception of 3G) there could be observed considerable fluctuations in stock levels, which was most probably caused by the financial crisis and which thus must be assessed as a negative development (from the point of view of the entities' financial situation).

It is worth noting that these considerable fluctuations in stock levels were not reflected in varying levels of receivables. They increased significantly in enterprises from 1G and 4G, which can be explained with payment difficulties of their contracting parties. It was established that enterprises classified to 2G and 3G were in a good shape. The level of their receivables went down, which in connection with increased sales must be assessed positively, as it (indirectly) points to an improvement in the financial liquidity of these entities.

A very interesting phenomenon was observed as regards short-term investments (cf. Fig. 2) in 1G and 3G. In these groups short-term investments systematically increased, indicating that the enterprises maintained higher levels of cash and cash equivalents, which was probably due to the operation of the prudence motive (in the Keynesian approach[8]).

[8] Cf. Keynes J.M., 2003. *The General Theory of Employment, Interest and Money*, PWN.

It is also worth noting that enterprises were classified into individual groups according to their net financial result. In the analysed years enterprises from 1G on average sustained losses (which increased in the subsequent years of the crisis). Enterprises from 2G neither sustained losses, nor generated profit. Managers of enterprises from 3G achieved variable financial results exhibiting neither an upward, nor a downward tendency. As regards enterprises from 4G, they systematically increased their financial results. On this basis it was established that the level and direction of changes in the financial result in the studied groups of enterprises was diversified (cf. Fig. 3).

Table 3 presents selected financial indicators describing individual groups of enterprises covered by the study. As no enterprise can effectively operate on the market if it does not settle its liabilities upon maturity, the context of the study was taken into due consideration. It was observed that enterprises from 1G exhibited the lowest liquidity indicators, which were below recommended levels. Other groups of enterprises were characterised by current liquidity levels which may be assessed as optimal (enterprises from 2G and 4G) or excessively high (enterprises from 3G, in particular in 2008). Taking into consideration the difficult macroeconomic situation, slightly higher current liquidity indicators may not be assessed as inappropriate, as many enterprises consistently maintained liquidity indicators on a higher level. This observation finds its confirmation in the quick liquidity ratios, which in enterprises from 2G, 3G and 4G were also much above the recommended level. Only immediate liquidity ratios may be considered target values. What is interesting here,

however, is group 3G in 2008, when this ratio amounted to 0.92, i.e. was much above the recommended level. Taking into consideration the macroeconomic situation, it must be stated that enterprises acted rationally in that they preferred to maintain liquidity on levels higher than the ones characteristic for enterprises outside the times of crisis.

From the point of view of efficient management we should also note the return on equity, which in 1G enterprises due to sustained losses was negative, and in 2G enterprises amounted to 0. Enterprises classified to 3G considerably improved their profitability ratios in 2007, but they worsened in 2008 (this was caused by significant fluctuations in the value of equity). However, enterprises from 4G managed to maintain return on equity on a relatively stable level. Similar relationships were observed in the case of return on assets (ROA).

Another parameter that is worth analysing in the times of the great financial crisis is the share of equity in total liabilities. It is not without cause that special attention is paid to the level of self-financing and the capacity to increase the share of equity in liabilities. Share of equity in liabilities in enterprises from 1G was varying and on the downward trend, which was due to the losses incurred. Poor financial results (expressed as net financial result) also precluded enterprises from 2G to significantly increase their level of self-financing. Enterprises from 3G maintained share of equity in total liabilities on a relatively stable level. Enterprises from 4G, which systematically increased the level of self-financing and consequently their financial security, were in best shape.

SUMMARY AND CONCLUSIONS

1. It was established that financial indicators fluctuated within the groups of enterprises covered by the study in response to the microeconomic situation, i.e. the great financial crisis.
2. Division of sample enterprises into four groups according to their net financial result allowed to select entities which sustained losses, neither sustained losses nor generated profit, and two groups of entities with higher and highest net financial results. This rendered it possible to establish some regularities typical for periods of crisis.
3. The enterprises covered by the study were characterised by instability as regards sales income, fixed assets and total assets levels. Therefore, it may be concluded that they had problems with a systematic sell of the manufactured goods and execution of investment projects. This phenomena had their roots in the macroeconomic situation.
4. It was established that enterprises strived to maintain financial liquidity, which found its reflection in higher levels of cash and cash equivalents that were maintained. There was visible the prudence motive as regards levels of cash and cash equivalents, which translated into a satisfactory level of all liquidity ratios.
5. Enterprises which achieved best financial results in the times of the great financial crisis systematically increased the level of self-financing and their financial security. They also exhibited an upward tendency as regards profitability, i.e. return on assets and return on equity, which must be assessed as a positive tendency. The conducted analyses demonstrate also that enterprises from 4G were to the least extent affected by the great financial result.

DETERMIANTS OF THE FINANCIAL RESULTS IN TERMS OF THE WORLD CRISIS IN SMALL AND MEDIUM -SIZED ENTERPRISES IN POLAND – ANALYTICAL APPROACH, PART II

Dr hab. Justyna Franc-Dąbrowska, Warsaw University of Life Science

Dr Małgorzata Porada-Rochoń, University of Szczecin

ABSTRACT

This paper analyzes the determinants affecting level of financial results, for small and medium-sized enterprises used in our sample over the years 2006-2009. Particularly interesting seems to establish the factors that shape these financial results (profit or loss) enterprises under the conditions of the recent financial crisis. The study will cover Poland, chosen at random (the sample consists of 288 commercial companies). The collected data are a balanced panel, so it is possible to eliminate random fluctuations.Results obtained will attempt to verify hypothesis: in terms of financial crisis on the final level of financial results of small and medium-sized enterprises are the variables different from the classic, familiar with the science.

To test the hypothesis, research was be carried using out extensive literature and analysis will be applied to a model: a classical method of the smallest squares and fixed effects model.

Qualities of application of research results – in a situation in which clearly would be able to get the determinants influencing the financial results and economic value added of small and medium-sized enterprises in Poland – during the recent financial crisis, it would give an opportunity for entrepreneurs to pay special attention to these factors and to influence the final shape built up the financial result. In the longer term, it is the financial result is the goal, or provide opportunities to achieve their development goals.

Key words: financial results, small and medium-sized enterprises

INTRODUCTION

The traditional concept of the business, which is striving to establish profit maximization is often criticized as unrealistic, and bypass the many important aspects of economic activity of the company. This theory claims that the unrealistic assumptions not only about the same for the business, but also about her relationship with the environment, lack of regard for the interests of other stakeholders, motifs of human behavior in the company making key decisions about the procedures and rules of making those decisions, etc.

In addition:

- profit may not be the sole and a key measure of assessing the condition of the company,
- Profit is an internal goal,
- Gain a synthetic indicator does not show the impact of various factors on the level,

the impact of such negative phenomena as the loss of loyal customers, the best suppliers, reducing the value of the brand, or reacts to them too late
• Profit is susceptible to manipulation accounting.

Although the traditional approach to profit maximization as the overriding purpose of the company, which is based on the interests of owners and is consistent with the principles of market economy, is facing criticism, but many places in literature (in terms of theoretical and practical) is devoted to issues of managing earnings.

EARNINGS MANAGEMENT – LITERATURE REVIEW

Potential earnings management has become a concern throughout the world.
Most of the prior studies on earnings management have focused on why firms manage earnings. Earnings management incentives originate from diverse reasons including:

- income smoothing (Moses, 1987; Yoon and Miller, 2002b),
  More specifically, earnings smoothing includes two metrics: the variability of the change in net income, and the variability of change in net income over the variability of change in cash flow from operations. A high variability is consistent with less earnings smoothing (Lang et al. 2003, 2006; Leuz et al. 2003; Ball & Shivakumar 2005, 2006; Barth et al. 2008; Christensen et al. 2008)[1],
- management compensation (Healy, 1985; Gaver et al., 1995; Holthausen et al., 1995),
- ownership control (DeAngelo,1986, 1988; Perry and Williams, 1994),
  Prior research has found that managerial ownership is associated with lower levels of earnings management (Dhaliwal et al., 1982),
- equity offerings (Loughran and Ritter, 1995; Loughran and Ritter, 1997; Rangan, 1998; Teoh et al.,1998; Yoon and Miller, 2002a),
- maximization of earnings-based compensation (e.g., Healy 1985),
- avoidance of debt-covenants violation (e.g., DeFond and Jiambalvo 1994),
- to manipulate earnings to avoid losses (Burgstahler and Dichev 1997)[2]

---

[1] H. Chen, Q. Tang, Y. Jiang, Z. Ling,The Role of International Financial Reporting Standards in Accounting Quality: Evidence from the EuropeanUnion. Journal of International Financial Management & Accounting, Volume 21 Issue 3 (Autumn 2010), pp. 1-58.

[2] Burgstahler and Dichev (1997) present two theories that can explain loss avoidance (and earnings decrease avoidance). First, their transactions costs theory predicts that stakeholders, such as customers, suppliers, short-term creditors, and employees, use heuristic cut-offs at zero earnings or zero earnings changes to value their implicit claim on the firm and to determine the terms of transactions with the firm. As a consequence, the firm manipulates reported earnings beyond such cut-offs to improve its terms of transactions (see also Bowen, DuCharme, and Shores 1995). Second, prospect theory indicates that when individuals' wealth is at risk, they tend to evaluate potential wealth changes in reference to their current wealth, and attach a higher disutility to an actual decrease in wealth than to a foregone increase in wealth (Kahneman and Tversky 1979). In the research setting of Burgstahler and Dichev (1997), it is the value of shareholders' and creditors' explicit claim on the outcomes of the firm that is at risk. Shareholders and creditors who use accounting earnings to estimate the change in the value of their claim on the firm (economic performance), may experience higher disutility from an accounting loss of one dollar than they experience utility from an accounting profit of the same amount. As a consequence, shareholders and creditors may be averse to (small) accounting losses, if they perceive these losses to be persistent.
L.Coppens E. Peek , An analysis of earnings management by European private firms Journal of International Accounting, Auditing and Taxation Volume 14, Issue 1, 2005, pp. 1-17.

They find that firms appear to manipulate earnings to avoid losses and earnings decreases as there is a higher than expected frequency of firms reporting slightly positive earnings changes and a lower than expected frequency of firms reporting small decreases in earnings.

- political costs (Liberty and Zimmerman,1986; Jones, 1991; Cahan, 1992; Maydew, 1997; Han and Wang, 1998).

A number of academic studies have argued that earnings management may be beneficial because it potentially enhances the information value of earnings. Managers may exercise discretion over earnings to communicate private information to stockholders and the public (Subramanyam, 1996; Watts and Zimmerman, 1986; Healy and Palepu, 1993; Guay, Kothari, and Watts, 1996; Demski, 1998; Arya, Glover, and Sunder, 2003). If this is the case, then, earnings management may not be harmful to the stockholders and the public. In fact, the empirical evidence in Subramanyam (1996) supports the contention that managers exercise their discretion to improve the ability of earnings to reflect fundamental value. Other studies, nevertheless, argue in favor of the opportunistic use of earnings management (Healy and Palepu, 1993, for instance). Misalignment of managers' and shareholders' incentives could induce managers to use the flexibility provided by the Generally Accepted Accounting Principals (GAAP) to manage income opportunistically, thereby creating distortions in the reported earnings. Thus, earnings management can be viewed as either opportunistic or beneficial[3].

Some studies take a more general approach by investigating whether under all circumstances managers have an incentive to exceed certain thresholds, such as prior year earnings (Burgstahler and Dichev 1997; Degeorge, Patel, and Zeckhauser 1999). These studies find that managers are inclined to manage earnings upward when this would lead to earnings that are just above the thresholds, while previously being below these thresholds.

Burgstahler and Eames (1998) suggest that managers tend to report earnings that meet or beat analyst estimates. It is found that there is a psychological distinction between positive and negative numbers (or zero). Individuals usually form a negative perception when they see negative reported earnings; hence it is important to report positive profits to avoid unfavorable perceptions. A drop in reported earnings that are benchmarked against past year's performance will give a negative signal to the investors, thus it is equally important for the firm to sustain its recent performance. By meeting analysts' consensus forecast, firms are considered to be meeting the industry norm, as well as having comparable performance against other firms in the same industry.[4]

Earnings management may take the form of either income-increasing or income-decreasing accounting choices.

---

[3] Jiraporn, Pornsit & Miller, Gary A. & Yoon, Soon Suk & Kim, Young S., 2008. Is earnings management opportunistic or beneficial? An agency theory perspective, International Review of Financial Analysis, Elsevier, vol. 17(3), pp. 622-634.

[4] Ch. Charoenwong, J. Pornsit, Earnings Management to Exceed Thresholds: Evidence from Singapore and Thailand, 2008 Electronic copy available at: http://ssrn.com/abstract=1104523.

Under certain conditions, managers may prefer to engage in income *decreasing* earnings management. Healy (1985), Gaver et al. (1995) and Holthausen et al. (1995) report evidence of income-decreasing accounting choices when managers' accounting-based bonuses are at their maximum. Several explanations for these income-decreasing accounting choices have been suggested. One possibility is that managers prefer to shift abnormal positive earnings forward in order to make future thresholds easier to attain. Another possibility is that managers are reluctant to report large gains because of fears that their performance target will be ratcheted up in the future. If downward manipulation imposes significant costs on external parties, boards should be as concerned with income-decreasing manipulations as they are with income-increasing earnings management[5].

Without any doubt, it looks different approach to earnings management in healthy than distressed companies. Due to the timeliness of the issue of global crisis further part of the considerations will be concentrated among the issues the earnings management of distressed companies.

Recent studies show, that generally during recession or crisis, companies generatelower financial result compare to economic expansion. Earnings is sensitive to the business cycle.

In particular, the Earnings Response Coefficient (ERC) has been shown to be higher during economic expansions than during contractions (Johnson, 1999). This result can be largely explained by the defining characteristic of macroeconomic expansion – broad-based economic growth. Furthermore, expansions are typically longer and thus more persistent than contractions. The higher growth and persistence associated with macroeconomic expansions alter the contextual expectations related to reported corporate earnings, resulting in a higher ERC[6]

There are a number of reasons to believe that conditional earnings conservatism is higher during periods of economic recession:

- securities litigation typically occurs following economic declines, when events such as sharp declines in stock prices are more likely. To address the heightened litigation risk during economic contractions, firms generally report more conservatively.
- the threat of increased regulatory scrutiny, resultant from more public uncertainty about the existence and impact of hidden bad news, arguably motivates the reporting of conservative accounting numbers. During such periods of uncertainty and heightened interest in information about bad news, regulators tend to respond with increased scrutiny.
- firms normally prefer internal sources of funding to external sources, and of the external sources, debt over equity financing. This is the result of adverse selection and increased information costs associated with obtaining external financing, especially as it relates to equity financing

Prior studies suggest that the management of firms in distress may have various incentives or feel pressure to manage financial information in different ways. The literature provides mixed results with regard to the earnings behaviour of distressed firms. Some studies find that the management of financially distressed firms adjusts earnings upwards (DeFond and Jiambalvo, 1994; Rosner, 2003; Beneish *et al.* 2004) while other studies show that the earnings of such firms are shifted downwards (DeAngelo *et al.*, 1994)[7].

Management of distressed firms has motivation (acting on behalf of shareholders or institutional investors) to report higher earnings in order to avoid debt covenant violations and probable bankruptcy. In such cases managers are primarily concerned with the short-term survival of their firm (which does not necessarily imply self-interested manipulation). For instance, DeFond and Jiambalvo (1994) show positive unexpected accruals in the year prior to default, consistent with managers manipulating earnings to prevent default. Dichev and Skinner (2002) also provide evidence that managers take actions to avoid debt covenant violations. An alternative explanation is that management of financially distressed firms may manipulate earnings upwards out of self-interest for various reasons, such as to avoid management turnover during the distressed period, or temporarily inflate the market price to increase their compensation or gain from cashing stock-based compensation holdings[8].

Prior literature shows that earnings management of financially-distressed firms is mixed (Bradbury, 2007)– distressed firms may engage in income-increasing accruals manipulation to reduce the impact of negative signals from financial distress (Burgstahler & Dichev, 1997; DeFond & Jiambalvo, 1994; Sweeney, 1994), or engage in incomedecreasing accruals manipulation for renegotiating debt contracts with lenders (DeAngelo, DeAngelo, & Skinner, 1994; Saleh & Ahmed, 2005). Jaggi and Lee (2002) further argue that the choice of income-increasing (or -decreasing) is influenced by the severity of financial distress[9].

Financial disterss is often contected with debt. It is interesting how debt influence on earnings management. When debt is relatively high, managers have strong incentives to make accounting choices and reporting decisions that reduce the likelihood of possible debt covenant violations (Watts and Zimmerman, 1986).1 Opportunistic managers are more likely to use their financial reporting discretion because:

1. financial leverage frequently serves as a proxy for closeness to accounting-based covenant violations (Billett et al., 2007; Dichev and Skinner, 2002; Press and Weintrop, 1990; and Smith, 1993),
2. the cost of violating debt covenants is large (Beneish and Press, 1993).

Therefore, when debt is high, accounting numbers may not represent faithfully the underlying future economic performance because of the aggressive use of accruals to

[7] A. Charitou, N. Lambertides and L.Trigeorgis Earnings Behaviour of Financially Distressed Firms: The Role of Institutional Ownership ABACUS, Vol. 43, No. 3, 2007, pp. 271-296.

manage earnings in an effort to avoid covenant violations (Sweeney, 1994; and DeFond and Jiambalvo, 1994)[10], [11].

Prior accounting literature (e.g., Leuz, Nanda, &Wysocki, 2003) shows that earnings management is a pervasive corporate phenomenon under particular market regulations. In order to meet a pre-determined earnings target, earnings management is often the first choice:

1. a firm's earnings manageability may be constrained on some occasions. For example, severe loss firms may not be able to manage accruals (such as credit sales) at full discretion if operations are partially discontinued or substantially reduced.
2. loss firms threatened by delisting risk are subject to stronger scrutiny from auditors and stock exchanges. For example, financial statements in the loss reversal year should receive an unqualified audit opinion.
3. Earnings management does not improve economic viability, and firms turning into profits through earnings management could easily move back to losses again in the near future. In this vein, distressed firms may opt to use alternatives to enhance operating performance: such as employee layoffs and asset restructuring activities[12],

Individual firms may have different incentives for earnings management. However, the tools that firms use in managing earnings can be systematically associated with the decomposition of total accruals.

PURPOSE AND METHODOLOGY OF RESEARCH

The article is a continuation of the analysis described in the study: Determinants of financial result in terms of a global crisis in small and medium-sized enterprises in Poland - an analytical approach, part I

This paper analyzes the determinants affecting level of financial results, for small and medium-sized enterprises used in our sample over the years 2006 to 2009. Particularly interesting seems to establish the factors that shape these financial results (profit or loss) enterprises under the conditions of the recent financial crisis. The study will cover Poland, chosen at random (the sample consists of 288 commercial companies). The collected data are a balanced panel, so it is possible to eliminate random fluctuations. These analysis are possible for a constant group of companies.Results obtained will attempt to verify hypothesis: in terms of financial crisis on the final level of financial results of small and medium-sized enterprises are the variables different from the classic, familiar with the science.

[10] The two conflicting perspectives of debt suggest that the relationship between debt financing and earnings quality is ultimately determined by the interactions of the positive and negative influence of debt.

[11] Aloke (Al) Ghosh and Doocheol Moon Corporate Debt Financing and Earnings Quality Journal of Business Finance & Accounting, 37(5) & (6), pp. 538–559, June/July 2010.

[12] P. Cheng, W. Aerts, A. Jorissen, Earnings Management, Asset Restructuring, and the Threat of Exchange Delisting in an Earnings-based Regulatory Regime Corporate Governance: An International Review, 2010, 18(5), pp. 438–456.

To test the hypothesis, research was be carried using out extensive literature and analysis will be applied to a model - panel models: a classical method of the smallest squares and fixed effects model.

The classic estimation by the smallest square method of the panel model is realized with the use of the following formula:

$$y_{it} = x_{it}\beta + v_{it}$$

where: y_{it} – endogenous variable,

x_{it} - exogenous variable (generally a vector of exogenous variables),

β - N -dimensional vector of structural parameters of the model,

v_{it} - total random error consisting of a totally random part ε_{it} and an individual effect u_i related to a specific "it" panel unit ($v_{it} = \varepsilon_{it} + u_i$) [Kufel, 2007].

In the smallest square estimation it is assumed that the index $i = 1,..., N$ signifies consecutive objects, whereas the index $t = 1,..., T$ stands for units of time. The estimation is permissible when there is no individual effect and the panel is treated as the cross-sectional data collection [Kufel, 2007].

Next the fixed-effects panel analysis in the following form was used:

$$y_{it} = x_{it}\beta + u_i + \varepsilon_{it}$$

where u_i - individual effect,

ε_{it} - pure random error.

In the fixed-effects panel model fixed individual effects are eliminated by averaging the model against time (t index).

Explanatory variable is the variable financial result (profit or loss) among the variables under consideration will be 30 variables (metrics and financial ratios), which will undergo an initial substantive and statistical verification

Qualities of application of research results - in a situation in which clearly would be able to get the determinants influencing the financial results and economic value added of small and medium-sized enterprises in Poland – during the recent financial crisis, it would give an opportunity for entrepreneurs to pay special attention to these factors and to influence the final shape built up the financial result. In the longer term, it is the financial result is the goal, or provide opportunities to achieve their development goals.

DESCRIPTION OF THE EXAMINED COMMUNITY

The first stage of the project involved panel data analyses using the least squares estimation method. Table 1 contains the results of the calculations, and graph 1 shows a normal Q-Q plot for the model. It has been found that during the great financial crisis, the majority of the determinants had a negative effect on profit at the small enterprises included in the research project, reducing the amount of profit. The strongest variables reducing the level of profit were as follows: (a) interest paid on loans and credit facilities and (b) loss on

business operations. The determinants that improved the level of net profit included operating profit and financial revenue. The model as developed must be considered only as an initial model to be used for further analyses, as it is not fully correctly conditioned. Although the basic parameters of the model are satisfactory, the normal Q-Q plot distribution is not appropriate. Although it is not a critical condition for the correctness of the model, model 1 cannot be considered as a fully satisfactory model.

Source: own.

In order to achieve fully reliable results, panel data estimation was carried out, i.e. fixed effects estimation, and the results are shown in Table 2. In addition, figure 2 shows a normal Q-Q plot for model 2. The model covers a large number of the variables defined as net profit determinants in model 1. Note should be taken, as is the case of model 1, of the following variables: financial expenses, interest paid and loss on business operations. These variables significantly reduced the level of net profit. Variables that improved net profit include, in particular, the following: operating profit and financial revenue. The results achieved did not

allow for specifying “new” variables, but they did allow for confirming the common truths that the source of value growth for shareholders should be operation revenue and that additional benefits can be achieved by investing available cash in alternative portfolios (and not only in core business operations and fixed assets). The parameters of the model should be considered as satisfactory, and the normal Q-Q plot as close to normal, thus also acceptable. In order to verify the observations and whether or not the fact that the variables relate to a given period affects the final shape of the model, panel estimations (panel model with fixed effects) were carried out, taking into account a time variable. The results achieved are shown in Table 3 (the normal Q-Q plot is shown in figure 3).

The results achieved allowed for confirming the earlier observations, and the final modelling effects were relatively slightly affected by the fact that the data related to the year 2008. It can therefore be expected that the middle year of the great financial crisis (2007-2009) was specific enough to affect the model, taking into account the financial results achieved by the group of enterprises included in the project. The parameters of the model should be considered as satisfactory, and the model as correctly conditioned, with a high degree of explanation of the process studied as part of the project.

Small enterprises are a specific group of business entities. Therefore, an attempt was made to define the determinants affecting net profit using panel data estimation (random effects estimation). The results achieved are shown in Table 4. The analyses carried out confirm the significance of the determinants defined in models 2 and 3. However, model 4 is not correctly conditioned. As it can be seen from graph 4, the normal Q-Q plot is significantly different from the level that could be considered as close to normal. In order to verify whether or not the inclusion of a time variable improves the parameters of the model, panel data estimations (random effects) were carried out, taking into account a time variable. The results achieved are shown in Table 5.

It is evident that the inclusion of a time variable did not significantly affect the determinants and their effect on the variable in question, i.e. net profit. Moreover, the d2_2 and dt_3 time variables were not statistically significant in the model. Additionally, this did not improve the parameters of model 5 (cf: the normal Q-Q plot – figure 5). It can therefore be stated that models 2 and 3 (fixed effects and fixed effects with a time variable) best describe the level of net profit achieved by small enterprises.

Findings of research

The results of the research allowed for defining net profit determinants at small enterprises during the great financial crisis. Determination of the factors that affect the level of net profit achieved by enterprises, particularly during a financial crisis, is of great practical significance. Knowing such factors, managers can include, in their decision-making processes, those variable which most significantly affect net profit levels achieved by enterprises.

SUMMARY AND CONCLUSIONS

1. It can be concluded based on the research that no such non-standard variables were observed during the great financial crisis which might significantly affect net profit levels achieved by small enterprises. Therefore, despite the difficult macroeconomic circumstances, managers continued to be interested in those areas which require special attention also under non-extreme conditions.
2. Those variables which had a particularly strong adverse effect on the level of net profit included interest paid on loans and credit facilities. Therefore, it is not advisable for small enterprises to take out debt during a financial crisis, as it may, in extreme cases, lead to the enterprise losing its financial liquidity and going bankrupt. The negative effect of incurring considerable financial expenses reflected in some of the enterprises included in the project recording losses on business operations. Because, in the opinion of the authors, profit/loss on business operations is that type of results which should be subject to in-dept analysis (as the level of net profit/loss on business operations depends, above all, on the managers/owners' decisions), this type of results should be given special attention during crisis years.
3. The determinants that positively affected the final results of the enterprises' operations were operating profit and financial revenue. This, therefore, confirms the common rule accepted in economics that special attention should be given to core business operations and that any other revenue should be considered as supplementary, particularly during crisis years. The positive effect of financial revenue shows that the managers were enterprising in their decisions and worked to generate additional benefits from alternative sources, in particular from bank term deposits.
4. It can be concluded based on the research that in the case of the enterprises included in the research project, the most appropriate method was panel data estimation (fixed effects panel models) and that the models developed best describe the process in question and are best conditioned.
5. Based on the model analyses conducted as part of the project, it can concluded that the "outstanding" year during the great financial crisis was the year 2008, and the fact that the variables related to the year 2008 was of significance in the final shape of the model. Therefore, in the group of enterprises included in the research project, special attention should be given to the variability of data between the years 2007-2008 and 2008-2009.

SPATIAL ANALYSIS OF RISK VS. EFFICIENCY OF LIFE INSURANCE CONTRACTS[1]

Dr Adam Sliwinski, Warsaw School of Economics, Poland
asliwin@sgh.waw.pl

ABSTRACT

The main aim of the paper is to show the changes of the efficiency of life insurance by implementing the spatial analysis of death risk calculation. The death risk is differentiated by the regions of Poland. Such an aim involves answering the question of whether the application of regional death risk differentiation in the process of financial management can improve effectiveness of life insurance companies or rate of return of life insurance contract?

The above issue is explored on the basis of empirical research undertaken by the author. The research followed the pattern of premium differentiation for the whole life insurance by special so called profitability regions. The study is based on the demographic data which refers to the territory of Poland. The final stage is an approach to proof that the regional differentiation of an insurance rate (by spatial death risk analysis) has an improving effect on overall efficiency of an life insurance contract. That is checked by implementation of an approached provided by D. Moffet [2]who calculated effective rate of return on life insurance. Then the financial balance after insurance ends is calculated based on the regional risk analysis and the data concerning the risk in whole territory of Poland.

Keywords: life insurance, rates optimization, financial management,

INTRODUCTION

The economic processes taking place in Poland in recent years has affected also the broad insurance sector. The social and economic transformations, the break-up of monopolies and intensifying competition contributed to the development of business insurance. This is demonstrated by both the growing numbers of entities offering insurance products in the Polish market and the increase of the written premium. During the transformation the total life insurance market gross written premium has been rising by 36% annually.

Despite such strong growth, the Polish insurance sector is still lagging considerably behind the Western economies. While the Polish insurance market is generally believed to be in the growth stage, it is of particular significance given the integration of Poland with the economic system of the European Union. EU integration and the progressing globalization of financial services create a need for on-going monitoring and a revision of the current operating strategies, notably in their financial aspect. The continued development of the insurance sector is in the interest of the insurance companies operating in Poland. Insurance companies should seek to optimize their financial performance and to improve

[1] The research are financed by Polish National Science Center.

[2] D. Moffet, *An analysis of the Demand for Life Insurance: Mathematical Foundation*, The Journal of Risk and Insurance, Vol.46, No 2 (Jun 1979) pp.87-98

the flexibility of their insurance services to contribute to improving the financial standing of the insured businesses and households as well. This is possible by an on-going search for factors improving the competitiveness of businesses and increasing insurance awareness among the general public. This is a difficult challenge. One of the success factors is the ability to combine the efforts of the management teams of insurance companies with research findings.

The increasing attractiveness of the insurance market in Poland results in a rapid growth of competition. The tough competition forces insurance companies to take specific actions which should, above all, seek to improve flexibility via product and organizational innovation. The strong competition creates the need to look for ways to optimize the performance of insurers, and to develop on a continuous basis new insurance products that meet the needs of customers. The products should fully meet the needs of customers at the lowest possible insurance premiums. On the other hand the product should assure financial stability of insurance companies and ultimately ability to pay insurance claims. This is particularly important in the case of life assurance. The long-term nature of life assurance and the special nature of the attendant insurance risk (being the risk of death) render the financial management at insurance companies offering life assurance products highly difficult and complex. Each decision has specific ramifications for a period of several, or even a dozen or so, following years.

There are few publications, either in Poland or in the world, examining in detail the risk of death and the application of the findings in assurance processes. It is even more difficult to find sources explaining and demonstrating the effect of regional differentiation of insurance (rates) premiums on the financial management of insurance companies. Analyzing the literature of the subject it is possible to find some example of the similar studies. However it is not so popular. For example the approach to spatial analysis of death risk is described in the paper written by B. Babel, S. Eckel, R Schmidt and V.Schmidt, Mortality maps based on spatial extrapolation, working paper of University of ULM[3].

There are a number of researches that examine effect on different factors on the purchases of insurance product from costumer's side (life insurance demand determinants). However it is very difficult to find a study that examines the effect of regional differentiation on life insurance companies' profitability and effectiveness of life insurance by affecting insurance rates.

The main aim of the paper is to show the changes of the efficiency of life insurance by implementing the spatial analysis of death risk calculation. The death risk is differentiated by the regions of Poland. Such an aim involves answering the question of whether the application of regional death risk differentiation in the process of financial management can improve effectiveness of life insurance companies or rate of return of life insurance contract?

The above issue is explored on the basis of empirical research undertaken by the author. The research followed the pattern of premium differentiation for the whole life insurance by special so called profitability regions. The study is based on the demographic data which refers to the territory of Poland. The final stage is an approach to proof that the regional differentiation of an insurance rate (by spatial death risk analysis) has an improving effect on overall efficiency of a life insurance contract. That is checked by implementation of an approached provided by D. Moffetapproached provided by D. Moffetapproached provided by D. Moffet[4].

METHODOLOGY AND DATA

The paper consist two main parts. In the first part the regions are merged into so- called profitability regions. That part consist the demographic analysis. To provide the study the demographic data are used. The database covers 16 Polish provinces (regions) and includes information about the population of regions in the years 1999 to 2003. For regions obtained the following data:

1. size of the population by individual age (from 0 to 100 years), separately for men and women;
2. number of deaths from regions (deaths in older and younger deaths by individual age from 0 to 100 years),
3. number of births in different regions.

Table 1 presents the summary of established regions taken together with their coding used by Polish Central Statistical Office.

Table 1: The codes and researched regions.

Code	Regions
D02	Dolnoslaskie
C04	Kujawsko-Pomorskie
L06	Lubelskie
F08	Lubuskie
E10	Ludzkie
K12	Malopolskie
W14	Mazowieckie
016	Opolskie
R18	Podkarpackie
B20	Podlaskie
G22	Pomorskie
S24	Slaskie
T26	Swietokrzyskie
N28	Warminsko-Mazurskie
P30	Wielkopolskie
Z32	Zachodniopomorskie

Source: Polish Central Statistical Office.

In the first stage there is an estimation of the frequency of deaths for the people aged from 5 to 84 years. The calculations were made separately for all studied regions. Age restriction stems from the fact that in the age ranges from 0 to 4 years we have a heterogeneous distribution of empirical probabilities of death. Thus in this age range processes, extinctions processes are difficult to theoretical modeling. The probabilities of death over the age of 84 years are extrapolated on the assumption of exponential function. In the presented studies frequency of death is used to characterize different regions. Narrowing the age range will not affect the importance of the achieved results and their interpretation from the perspective of optimizing the level of premiums for life insurance. The largest groups of life insurance customers are people in so-called production aged. The general conditions of insurance companies offer life insurance limit access to the upper age 65-70 years depending on the type of product and system of premium payment. Age of admission to life insurance contracts more than 65 years usually refers to the situation of one - installment of total premium, and it is associated

with the unit – linked life insurance products. Analysis of risk of death in the accepted age range, and the separation regions on the basis of a similar level of probability will correspond to the needs of life insurance companies.

Then after the calculation of frequency of death by individual ages and separately for the regions other variables were chosen to compare the regions by probability of death distribution. The comparison let to merge the regions in so-called profitability regions.
In order to identify the profitability regions cluster analysis were used. Cluster analysis was made separately for two moments in time. The first group was made for the implementation of features evaluated on the basis of data from the years 1998/1999. Then the analysis was repeated using the characteristics of the estimated value based on data from the years 2002/2003. This approach allowed the analysis of the changes that have occurred in the 5 years period. Segmentation was based on the Ward algorithm for 16 regions with 5 variables.

Used variables are:

1. the average age of people living in the region (Var1),
2. frequency of deaths in middle-aged people living in the region (Var 2),
3. parameter B of Gompertz function (Var 3)
4. parameter h of Gompertz function (Var 4),
5. participation of men in the average age in the total number of people in average age residing in the region (Var 5).

The results of the first part of the research are clusters which includes the regions that could be characterized by similar probability of death distribution. The results could be used by life insurance company to implement risk based pricing of life insurance contracts. The company could value the premiums separately for achieved profitability regions.
In the second part of the paper Moffet's approach is implemented to check if the risk based strategy influences the effective rate of return of life insurance contract.

CHOSEN VARIABLES – SHORT CHARACTERISTIC

Average age of the region's population

Average age is a variable chosen for the test. This variable was chosen because the distribution of the probability of death determines the level of that probability for a person at a given age. Average age was counted as a weighted average, where weights are the number of people living in the age of the region. Table 2 presents the results of calculations of average age in the different regions in the analyzed periods.

Table 2: The average age of population living in the region between 1999 and 2003.

No	Regions	Code	Average age		Difference	Change [%]
			1999	2003		
1.	Dolnoslaskie	D02	36	38	2	5,6%
2.	Kujawsko-Pomorskie	C04	35	36	1	2,9%
3.	Lubelskie	L06	36	37	1	2,8%
4.	Lubuskie	F08	35	36	1	2,9%
5.	Ludzkie	E10	38	39	1	2,6%
6.	Malopolskie	K12	35	39	4	11,4%
7.	Mazowieckie	W14	37	38	1	2,7%
8.	Opolskie	O16	36	37	1	2,8%
9.	Podkarpackie	R18	34	36	2	5,9%
10.	Podlaskie	B20	36	37	1	2,8%
11.	Pomorskie	G22	35	36	1	2,9%
12.	Slaskie	S24	36	38	2	5,6%
13.	Swietokrzyskie	T26	36	38	2	5,6%
14.	Warminsko-Mazurskie	N28	34	36	2	5,9%
15.	Wielkopolskie	P30	35	36	1	2,9%
16.	Zachodniopomorskie	Z32	35	37	2	5,7%

Source: Calculation done by the author based on data published by Polish Central Statistical Office.

In the period considered the average age increased in all regions analyzed. The largest increase, equal to 11.4% took place in the region of K12 (Malopolskie). In nine regions, the average age has increased more than 2%, but not more than 3%. The other six regions, the average age increased by more than 5%. The lowest average age change occurred in the region of W14 - Mazowieckie region. This may be due to the arrival of younger people in connection with the dynamically developing economy of the region, labor market and in total better prospects for the future.

Frequency of death

Second variable includes information about the number of people living and the dead at a given age. It is an estimator of the probability of death. The adopted frequency of death takes into consideration the information on the number of people who died in average age. This information is important for life insurance. The risk of death is the primary factor determining the level of insurance premiums. For the study the frequency of death counted on the basis of empirical data is used. Frequency comparisons were made for people in average age in the regions separately for two moments in time. Taking into account the characteristics of the distribution of probability of death is known that the level of the probability increases with age. For life insurance companies is important to have information about the direction and strength of changes in the frequency of deaths of people at any given age. Table 3 presents estimates of the frequency of deaths of people in average age, and changes in a given period of time for different regions.

Table 3: The frequency of death in average aged of population living in the regions between 1999 and 2003.

No	Region	Code	Frequency of death		Difference	Change [%]
			1999	2003		
1.	Dolnoslaskie	D02	0,00127	0,00115	-0,00012	-9,5%
2.	Kujawsko-Pomorskie	C04	0,00173	0,00154	-0,00019	-11,1%

13.	Swietokrzyskie	T26	0,00159	0,00094	-0,00065	-40,8%
14.	Warminsko-Mazurskie	N28	0,00114	0,00164	0,00050	44,4%
15.	Wielkopolskie	P30	0,00174	0,00155	-0,00019	-10,8%
16.	Zachodniopomorskie	Z32	0,00273	0,00187	-0,00086	-31,4%

Source: Calculation done by the author based on data published by Polish Central Statistical Office.

Analyzing the results shown in the table 3 it is visible that the level of death rates behaved differently depending on the region. In eight regions, there is a fall in the frequency of deaths in average age. The highest decrease was observed in the region W14 - Mazowieckie. In other regions, the frequency of death of people in average age increases. The highest increase was recorded in the region of B20 - Podlaskie.

Parameters of Gompertz law of mortality

Gompertz law of mortality [5]is based on the assumption of exponential distribution of probabilities of death. The law is based on the hypothesis of the so-called the human life force. Gompertz understood human life force as an inverse of the force of mortality (1 / μx (t)). He accepted that the loss of life force is proportional to the size of this force at any given time and the period in which the loss occurred. At the end he received the following formula:

$$\mu_x = Be^{hx} = Bc^x, \qquad (1)$$

where *B* and *h* are constant over the range of age considered. The parameter *B* determines the level of force of mortality of infants. However, the higher the value of the parameter *h* the force of mortality for the population is changing slower. Calculation of parameters may give rise to calculate force of mortality for separate Polish regions. Table 4 contains the estimates of Gompertz parameters of the exponential function (B, h) for all investigated regions separately. The analysis was based on

[5] The full description of Gompertz law of mortality could be found for example at: A. Neil, *Life contingencies*, Heinemann, London 1983, pp.27

demographic data from 1999 and 2003. This approach allows the assessment of changes in the force of mortality in regions within the period of 5 years. Estimates were based on the smoothed distributions of the probabilities of death in different regions. In order to smooth the empirical probabilities of death by individual ages moving average was used according to the Polish Central Statistical Office's methodology approach allows the assessment of changes in the force of mortality in regions within the period of 5 years. Estimates were based on the smoothed distributions of the probabilities of death in different regions. In order to smooth the empirical probabilities of death by individual ages moving average was used according to the Polish Central Statistical Office's methodology approach allows the assessment of changes in the force of mortality in regions within the period of 5 years. Estimates were based on the smoothed distributions of the probabilities of death in different regions. In order to smooth the empirical probabilities of death by individual ages moving average was used according to the Polish Central Statistical Office's methodology[6]

Table 4: Parameters of Gompertz law of mortality.

No	Region	Code	1999		2003		Change [%]	
			B	h	B	h	B	h

Source: Author.

Analyzing the above parameters of Gompertz function is visible that they differ in the regional section. For example, the parameter *B* for the region marked with the symbol Z32 is *0.0003* for the parameter *h* equal to *0.0793*. For the region D02 *B = 0.0002*, *h = 0.0817*. In 1993, the coefficient *B* takes three values equal to: *0.0001*, *0.0002* and *0.0003*. According to this parameter, all analyzed regions can be divided into three groups corresponding to three different values of the parameter. In 2003, you cannot see the value of *0.0003*.

Population structure

The share of middle-aged men in the total number of persons of the same age living in different regions were used due to the fact that the probability of death for men in that age is higher than the probability of death of women in the same age. This trend is visible by analyze the life expectancy tables on Polish territory. Table 5 compares the probability of death of selected age

[6] The methodology could be found at: *Life Table of Poland 2007*, GUS, Warsaw 2008, pp.34

group of men and women. The probabilities are estimated based on data from the year 2006 for whole territory of Poland.

Table 5: Comparison of probabilities of death for men and women in Poland.

Age	Probability of death		Difference
	Men (1)	Women (2)	(1-2)

Increased participation of men in total region population, due to higher probability of death would have negative impact from the perspective of life insurance company. Table 6 contains the estimated share of men in the population of polish regions.

Table 6: The share of middle-aged men in the total number of people living in the region at this age in the years 1999 and 2003.

No	Region	Code	Share [%]		Difference

The share of middle-aged men in the total number of persons in this age of regions varies around 50%. Comparing the shares in two periods, could be seen that the share has changed slightly. In the nine regions male participation has decreased, but increased in seven. The highest growth was recorded in the region G22 - Pomorskie. The decrease occurred in the region A16 - Opolskie.

SPATIAL ANALYSIS OF RISK OF DEATH AND THE SO-CALLED PROFITABILITY REGIONS

Cluster analysis was made separately for the two moments in time. The first grouping was made for the implementation of variables evaluated on the basis of data from the years 1998/1999. Then the analysis was repeated using the estimated value characteristics based on data from the years 2002/2003. This approach allowed the analysis of the changes that have occurred in the period of 5 years. Segmentation was based on the Ward's algorithm for 16 regions with 5 above described variables. Before cluster analysis all variables were standardized. Standardized values of variables for the years 1999 and 2003 are summarized in Tables 7 and 8.

Table 7: Values of the variables after standardization – 1999.

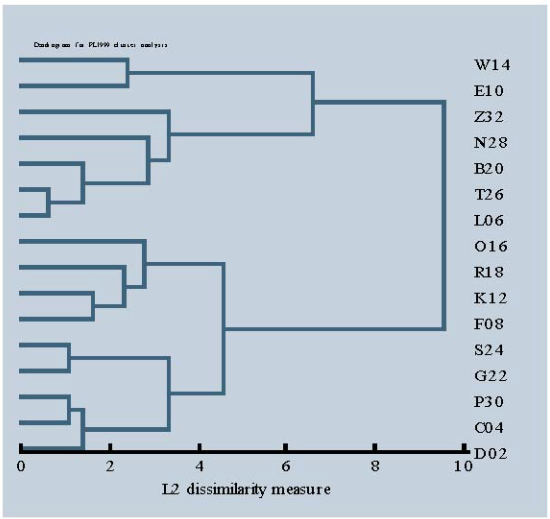

Figure 1. Clusters for the regions – 1999
Source: Author.

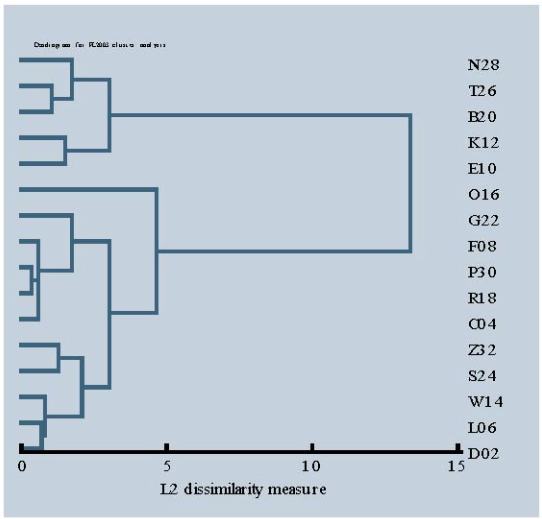

Figure 2. Clusters for the regions – 2003
Source: Author.

There has been a change in the similarity of the regions due to the value of the analyzed variables within the period of 5 years. Presented clusters differ. The allocation of regional groups (clusters) has changed in the period under review. For example, at the level of similarity measure equal to 6 in 1999 is subdivided into three clusters. With the same similarity measure in 2003, the regions can be grouped into two clusters. Extracted at a fixed level of similarity measurement areas (clusters) and regions belonging to them are summarized in Table 9. The extracted regions could be characterized by different risk of death. Therefore life insurance companies might implement the proposed approached to risk based pricing strategy. However before the implementation the influence has to be proved. If there is an influence on overall profitability of life insurance contract the regions could be so-called profitability regions. To show the possible effect of regional risk differentiation on the life insurance contract effectiveness Moffet approach is used. The results are shown and described in the next section of the paper.

EFFECTIVE RATE OF RETURN OF LIFE INSURANCE CONTRACT

The characteristic of distribution of probability of death was used as a general factor of merging regions. However, Moffet proved that the effective rate of return on life insurance seen to be related to the consumer's subjective probability of survival. There is an obvious relation between probability of death (q) and the probability of survival (p) where q=1-p. Moffed in his research introduced new approach to the topic of life insurance based on matrix analysis. The life insurance contract [7]in the year t_{th} could be written as the following vector:

$$[P+V_{t-1},Q,V_t], \qquad (2)$$

where:
P- premium,
Q – face amount,
V_t – cash value available at the end of the t_{th} year.
Application of the *principal of equivalence*[8] yields the following expressions for the effective rate of return r_t:

[7] D.Moffet, *An analysis of the Demand for Life Insurance: Mathematical Foundations*, The Journal of Risk and Insurance, Vol. 46, No.2 pp.96

[8] The paradigm of traditional life insurance is the so-called principle of equivalence, which is based on the notion of risk diversification in a large portfolio under the assumption that the future development of interest rates and other relevant economic and demographic conditions are known.

$$r_t = \left[\frac{(1-p_t)Q + p_t V_t}{P + V_t} - 1 \right] (100) \quad , \qquad (3)$$

where:

p_t – policyholder survival probability in the year *t*. Using the above formula probability in the year *t*. Moffet calculated the rate of return on an example of the $10.000 whole life insurance policy issued for a male age 22, at an annual premium of $101. The rate of return is sensitive to the probability of survival. The same example is used to show the influence of the probability of survival calculated separately for polish received clusters. The results are shown in table 10.

Table 10: Rate of return for received clusters – 2003.

t	V_t	p_t	r_t (%)	Cluster I		Cluster II		Difference
				p_t	r_t(%)	p_t	r_t (%)

Source: D. Moffet. op.cit. pp.97 and own calculation for cluster I and cluster II.

In general the differences are not so significant however the rate of return varies by received clusters. The smaller probability of survival the higher rate of return. It could be seen that the rates are higher in terms of cluster I.

FINANCIAL BALANCE AFTER IMPLEMENTATION SPATIAL RISK ANALYSIS APPROACH

It should also be examined whether the level of rates resulted by the application of the proposed manner (spatial analysis of risk) may cause an increase in the efficiency of life insurance before the final verification of the main idea of the research. To do that the sample portfolio of mixed life insurance[8] is used. Insurance portfolio consists of a group of 10,000 men at the age of 55 years, the face value is $ 1,000. Contribution (premium) in the amount of $ 90 is payable at the end of each year. Death benefits shall be paid on December 31 each year. In the last year of insurance the value of the survival benefits resulting from multiplying the number of persons alive by the sum insured. The interest rate used for the calculation is 5%. To simplify the calculation there is no profit participation. The comparison was made by the prism of estimated fund in hand at the end of the duration of the insurance. This fund has a direct impact on the technical provision of the insurance

[8] Benefit is payable if the insured person reached the age of 65 years or died before that age. undertaking. Increase of the technical provision has direct impact on overall financial results (net profit) of insurer. The increase of both technical provision and net profit has an impact of profitability ratio. As a result the changes of profits influence overall effectiveness of insurance activity. On the other hand, the insurer may reduce its premiums without any interference of solvency. In that case the operation part of activity of insurer is not so effective however the insurer may gather more capital (by intensifying sales level) to invest and at the end generate more capital income. Estimated fund's values in terms of separated clusters and whole territory of Poland are shown in table 11.

Table 11: The value of the fund remaining after life insurance (mixed) for a sample portfolio (10,000 men at the age of 55 years old).

No	Profitability region	Value of the fund [PLN]
1.	Cluster I	628.543
2.	Cluster II	637.433
3.	Comparison fund*	379.777

Source: calculation done by the author,
*fund remaining after endowment insurance ends provided in a sample described by E.Stroiński, *op.cit…*, LAM&E.Stroiński, Warszawa 1996, s.110, the fund is calculated based on demographic data concerning all territory of Poland

Spatial analysis of the risk of death and its application into the process of premium calculation could be the way of optimizing profits by life insurers. As could be seen from the summary presented in table 11, there has been a significant increase in the value of the fund remaining after endowment insurance ends. On the other hand there is a possibility of decreasing life insurance rates with no risk of losing financial stability and solvency. In the presented example (table 11) the reduction in rates by about 6% will result that the fund remained after the insurance is equal to 0 PLN. Such a range of possible reducing seems no very high however on the competitive market it could be a significant source of market competition.

CONCLUSIONS

The Polish life insurance industry has grown rapidly during the transition period. The changes concern almost all life insurance aspects, especially the level of competition. The number of companies rose more than eight times in comparison to 1991 when new reforms were implemented. Life insurance companies should constantly improve their competitiveness to attract more customers. The negative influence of financial crisis and the final loss of trust to life insurance companies also caused the need for new strategies of life insurers. One of the new approach to the costumers could be risk based pricing of life insurance contract. Currently life insurers differentiate premiums by sex. The results described in the paper proved that the premiums could also be differentiated by regions. However, first the demographic study is needed. There is no need to calculate premiums separately for each regions of particular country owe to the level of risk of death which is similar for some regions. Therefore, before the premium calculation the regions could be merged in to so-called profitability regions. Seem like cluster analysis is really useful to do that merging. However the variables chosen for the study are always disputable and the final result of merging depends on the kind of variables used to compare the regions. The main intention of the author of the paper was to show the possible direction for life insurers in terms of risk based pricing. Implementation of that approach also has an influence on the rate of return on life insurance and overall effectiveness of life insurance business activity. Hence the results of the study should be in a scope of interest of life insurers. There are also no legal limitations. According to polish insurance law insurance companies are obliged to collect statistical and actuarial data which might be used to calculate insurance premiums and eventually to the process of premium differentiation. Only the differentiation of the premium by pregnancy and maternity is

formally prohibited.

ABSTRACT

Efficiency of water and sewage services has been studied worldwide for decades and it has also raised interest in Finland. Public authorities have deployed several different ways to organize these services, even in the national level. Governance of these models has also been distributed. Objective of this research is to find out if a governance model has an effect on the efficiency of waterworks in Finland. Data Envelopment Analysis (DEA) was used as a tool to measure the efficiency of 19 waterworks. The efficiency results were analyzed in a way to see possible differences between different governance models. Research results indicate some differences in efficiency levels between different governance models. These results are, however, only suggestive because of the small sample and different constraints encountered in the research process. This research was the first attempt to compare efficiency of waterworks' governance models in Finland and it should be used as a foundation for improved and perfected models in the future.

Keywords: efficiency, data envelopment analysis (DEA), waterworks

INTRODUCTION

Efficiency of waterworks has been studied worldwide for decades (Coelli & Walding, 2006; García-Sánchez, 2006; Thanassoulis, 2002). Efficiency has been very important issue when evaluating all kinds of productive activities, and research around the subject has produced a variety of evaluation techniques (Abbott & Cohen, 2009; Coelli, Rao, O'Donnell, & Battese, 2005; Corton & Berg, 2009). According to Abbot & Cohen (2009), the estimation of cost functions by various techniques has been the most commonly used method of determining the levels of efficiency in the water industry.

Efficiency of waterworks is a complex thing to be defined and consists of various "dimensions". There have been difficulties in getting comprehensive, comparable, and plausible results. The objective of waterworks is not to deliver as much water as possible, but rather to connect as many households as possible at efficient cost and quality. The general problems in measuring efficiency of water and sewage services concerns data quality issues such as differences in the valuation methods of capital, price deflators, influence of public funding and outsourcing of different activities (Coelli & Walding, 2006). The water sector is also characterized by a high degree of complexity

which requires a large number of observations while data availability is most often very restricted.

Currently there has been a growing interest towards the subject also in Finland. New governance models have been presented and implemented in many municipalities as an attempt to solve different problems, but has this helped to improve the overall efficiency of water and sewage services? The information about the ideal properties of waterworks would be very welcome to the decision-makers of water sector, because at the moment there are some presuppositions about the goodness or badness of the different governance models, but it is not possible to reliably state the differences between these models.

The objective of this study is to find out if the waterworks efficiency is related with waterworks' governance models. The goal is to see if there are differences in efficiency levels between the different governance models. The problem is defined and approached with help of the following research question: *Are there any differences in efficiency levels between waterworks different governance models?*

RESEARCH ENVIRONMENT

From 5.3 million inhabitants of Finland, more than 90% belongs to the water system and around 80% to the sewage system of Finnish waterworks (Silfverberg 2007). Arranging water and sewage services for municipal residents is the fundamental obligation of municipalities (Act on Water Services 119/2001). Municipalities (336 in 2011) are self-administrative units of the Finnish government. Waterworks are governed by the law in Finland if it delivers drinking water or receives sewage more than 10m³ per day, or serves more than 50 inhabitants and at the same time serves more than one property (Act on Water Services 119/2001). According to the statistical system for Finnish waterworks (VELVET), there are currently approximately 1500 water and sewage service providers in Finland. Most of the waterworks are extremely small, providing water only to few dozens or hundreds of customers. 25 largest municipal waterworks provide about 60% of the total amount of water sold in Finland (Kuntaliitto 2007).

According VELVET, the most common ownership and governance models in the Finnish water sector measured in number are respectively: private cooperative, municipal department (MD), municipal-owned enterprise (MOE), municipal-owned company (MOC) and federation of municipalities (FoM). In addition, there are hundreds of small water service associations and partnerships, which provide services to less than 50 people. According to the VELVET statistics, 222 of Finnish waterworks are organized as MDs, 54 as MOEs, 155 as MOCs and 886 as cooperatives. The rest of the roughly 1500 waterworks are organized as partnerships, limited partnerships and federations of municipalities.

Waterworks as a municipal department (MD) is an integral part of municipal organization. They are part of the municipal budget and investment program. MDs have a defined income source (user fees), but it can receive additional income transfers from the state or the municipality. (Heikkinen, Tapio, Haikko, & Paloposki, 1996; Kähkönen, 1996) Reasons to include business activities, like waterworks, into municipality's budget can be e.g. temporary

financing of investments with taxes, avoiding extra costs that arise from creation of new administrative body, or keeping the pricing policy under political control (Myllyntaus, 2001).

Municipal owned enterprise (MOE) is a business unit, for which municipal council has defined the state of (financial) independence. Although MOEs are fully owned by the municipality, their budget is separated from municipality's budget and they have their own financial statement including profit and loss statement, balance sheet, and funds statement. Public ownership ensures that the municipality can reap the benefits of operations and at the same time have democratic control over the operations. (Heikkinen et al., 1996; Jalkanen et al., 1996; Kähkönen, 1996; Myllyntaus, 2001) Because MOE is part of the municipality it cannot go bankrupt and it is not tax liable when operating within the municipality's territory (Heikkinen et al., 1996).

Municipal owned company (MOC) is owned and controlled by one or several municipalities. It is a legal entity whose operations and management are regulated by Limited-liability Companies Act (624/2006). They operate as commercial businesses and do not have societal obligations like the MDs and MOEs. (Kähkönen, 1996) They can also be expected to make profit and to provide reasonable return on capital to the municipality (Jalkanen et al., 1996). MOC has its own budget, investment program and financial statement. MOC is subject to taxation at the tax rate on profit of 26 %. It is also liable to a property tax. MOCs can decide on investments independently and freely acquire financing from the financial markets. (Heikkinen et al., 1996)

A cooperative is owned by its members, who usually are the customers of the service. Cooperatives are thus communities by nature, and although they are running business operations, their main purpose is to support their members' welfare instead of sharing profit why cooperatives often operate on non-profit basis. Cooperative needs to comply with the Co-operatives Act (1488/2001) and they have the same tax on profit as the limited-liability companies, 26 %. In addition to loans provided by banks, financial institutions and insurance companies, the cooperatives can get financing from government and municipal subsidies. (Mynttinen & Taipale, 2007)

METHODOLOGY

Efficiency is often defined simply as *"the ratio of the output to the input of any system"* (Cooper et al., 2000). It means the amount of desired outcome that is produced with a certain amount of resources. When looking at the whole picture, typical approaches to efficiency tend to focus on subjects like cost reduction (reducing inputs), quality control (reducing waste), technology investment and time management (increasing productivity). The ultimate goal thereby is to reduce inputs, increase outputs, or both at the same time in order to improve profitability. (Witzel, 2002)

Some of the most commonly used dimensions of efficiency and their definitions are:

- *allocative efficiency:* refers to the responsiveness of service to public preferences (Leibenstein, 1966)

- *technical efficiency:* measures a firm's success in producing maximum output from a given set of inputs (Farrell, 1957; Leibenstein, 1966)
- *price efficiency:* measures a firm's success in choosing an optimal set of inputs (Farrell, 1957)
- *cost efficiency:* refers to the least amount of inputs used to produce a fixed level of output(s) at minimum possible cost (Coelli et al., 2002)
- *scale efficiency:* tells about the optimal size and scale of operations of an entity under efficiency analysis (Cubbin & Tzanidakis, 1998; Coelli et al., 2005).

In this research, Data Envelopment Analysis (DEA) was selected as a tool to measure the efficiency of waterworks. It has been used in various studies to measure waterworks' efficiency in different countries (Abbot & Cohen, 2009). As a non-parametric method, DEA concentrates on variations in performance among entities under comparison. It describes the subjects of efficiency evaluation as decision making units (DMU). These DMUs are thought to be any kind of entities, e.g. waterworks, that convert multiple inputs into multiple outputs, and the estimate of relative efficiency is derived from comparison of the ratios of total inputs used to total outputs produced by each DMU (Cooper et al., 2004). DEA uses linear programming techniques, which create an efficiency frontier that is used as a benchmark when comparing the DMUs with each other (Coelli et al., 2005). This frontier in a way "envelopes" the data leaving the measured efficiency values below the plotted curve in the graph (e.g. Cubbin and Tzanidakis, 1998).

In the case of single input and output, the *constant returns to scale (CRS)* assumption is based on thought that all observed production combinations can be scaled up or down proportionally. This kind of DEA model is named as CCR-model (due to Charnes, Cooper, and Rhodes, 1978) and it is one of the two most widely used DEA models together with BCC-model (due to Banker, Charnes, and Cooper, 1984). BCC-model uses *variable returns to scale (VRS)* assumption, which allows the returns to scale vary when observed production combinations are scaled up and down (i.e. it does not have to result in equivalent changes in efficiency level). (Cullinane et al., 2006)

As an example of these two assumptions, there are 6 points (A, B, C, D, E, and F) in Figure 1 representing 6 companies, which each has different combinations of one input and one output. The straight line from origin represents the efficiency frontier under *CRS* assumption and the piecewise line going via points A, B, C, D, and E forms the efficiency frontier under *VRS* assumption. Only the company C is *CRS*-efficient, but all the companies A, B, C, D, and E are *VRS*-efficient. When comparing the efficiency scores derived from both methods, it is possible to separate the effects of technical efficiency and scale efficiency and get information about their proportions. Let us take a look at company F, which is inefficient under both *CRS* and *VRS* assumptions. The input orientated technical inefficiency of the company F under the *CRS* is the distance FH, but under the *VRS* the same technical efficiency is only the distance FG, while the difference between these two, the distance GH, is considered as *scale inefficiency*. So at its current size, company F should improve its position at least to the point G, if it would like to become technically efficient under the *VRS* and further improvement would require changes in the company's size. (Cubbin & Tzanidakis, 1998; Coelli et al., 2005).

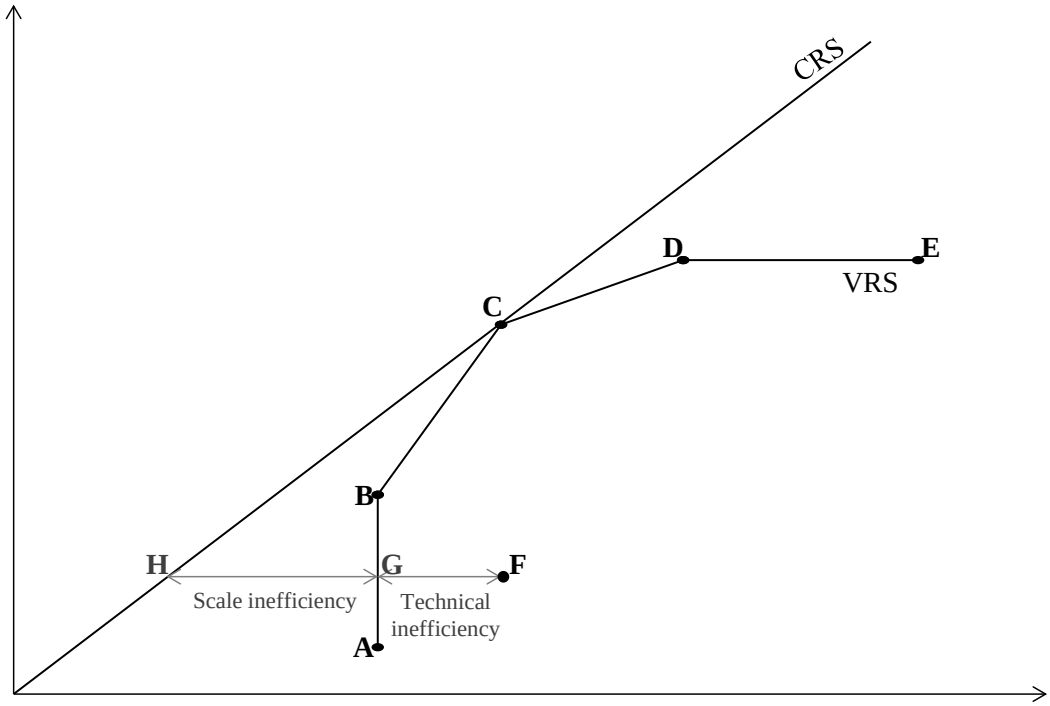

Figure 1: CRS vs. VRS, single input and single output example.

Input oriented CRS model

Assume there are data on *N* inputs and *M* outputs for each *I* firms. For the *i*-th firm these are represented by the column vectors $\mathbf{x}_i$ and $\mathbf{q}_i$, respectively. The *N*×*I* input matrix, **X**, and the *M*×*I* output matrix, **Q**, represent the data for all *I* firms. For each firm, a measure of the ratio of all outputs over all inputs is needed, let that be $\mathbf{u'}\,\mathbf{q}_i\,/\mathbf{v'}\,\mathbf{x}_i$, where **u** is an *M*×1 vector of output weights and **v** is a *N*×1 vector of input weights. (Coelli et al., 2005). The optimal weights are obtained by solving a mathematical programming problem:

$$\max_{u,v} (\mathbf{u'}\,\mathbf{q}i\,/\mathbf{v'}\,\mathbf{x}i),$$

subject to $\mathbf{u'}\,\mathbf{q}j\,/\mathbf{v'}\,\mathbf{x}j \le 1, \quad j = 1,2,\ldots,I,$

$\mathbf{u}, \mathbf{v} \ge 0.$ (1)

This involves finding values for u and v, such that the efficiency measure for the *i*-th firm is maximized, subject to the constraints that all efficiency measures must be less than or equal to one. The linear programming problem is solved for each of the *I* firms in the sample, so each of these firms is assigned a set of weights that are most favorable to them. One problem in this formulation is that it has infinite number of solutions. (Coelli et al., 2005). To avoid this, one can impose a constraint v' xi = 1, which provides:

$$\max_{\mu,v} (\boldsymbol{\mu'}\,\mathbf{q}i),$$

subject to $\mathbf{v'}\,\mathbf{x}i = 1,$

$\boldsymbol{\mu'}\,\mathbf{q}j - \mathbf{v'}\,\mathbf{x}j \le 0, \quad j = 1,2,\ldots, I,$

$\boldsymbol{\mu}, \mathbf{v} \ge 0,$ (2)

The change of notation from u and v to μ and v is used to stress that this is a different linear programming problem. The form of the DEA model in linear programming problem 2 is known as the multiplier form. (Coelli et al., 2005). Anyhow, the generally preferred form to solve this problem is called the envelopment form:

$$\min_{\theta,\lambda} \vartheta,$$

$$\begin{aligned} \text{subject to} \quad & -\mathbf{q}i + \mathbf{Q}\boldsymbol{\lambda} \geq 0, \\ & \vartheta \mathbf{x}i - \mathbf{X}\boldsymbol{\lambda} \geq 0, \\ & \boldsymbol{\lambda} \geq 0, \end{aligned} \qquad (3)$$

Here θ is a scalar and λ is a *I*×1 vector of constants. The value of θ obtained is the efficiency score of the *i*-th firm. The linear programming problem must be solved *I* times, once for each firm in the sample. A value of θ is then obtained for each firm. (Coelli et al., 2005).

Input oriented VRS model

In a case when the firms face imperfect competition, government regulations, constraints on finance etc. the *VRS* assumption is more appropriate, because the *CRS* assumption is mainly for situations where all firms are operating at optimal scale. To separate the effects of scale efficiency and technical efficiency, the *CRS* linear programming problem can be modified to account for *VRS* by adding the convexity constraint: $\mathbf{I}1'\boldsymbol{\lambda} = 1$ to equation 3 to provide:

$$\min_{\theta,\lambda} \vartheta,$$

$$\begin{aligned} \text{subject to} \quad & -\mathbf{q}i + \mathbf{Q}\boldsymbol{\lambda} \geq 0, \\ & \vartheta \mathbf{x}i - \mathbf{X}\boldsymbol{\lambda} \geq 0, \\ & \mathbf{I}1'\boldsymbol{\lambda} = 1, \\ & \boldsymbol{\lambda} \geq 0, \end{aligned} \qquad (4)$$

where **I**1 is an *I*×1 vector of ones. Technical efficiency scores provided by VRS are greater or equal to those provided by CRS, thereby the number of efficient firms is often higher in VRS. (Coelli et al., 2005).

Calculation of scale efficiency can be done by conducting both a *CRS* and a *VRS* DEA for all firms in the sample, and then decomposing the technical efficiency scores obtained from the *CRS* DEA into two components, one due to scale inefficiency and due to "pure" technical inefficiency. Figure 1 helped to explain the inefficiencies as distances, now let us take a look at how to express the technical and scale efficiencies as ratio measures. TE^{CRS} is technical efficiency given by *CRS*, TE^{VRS} is technical efficiency given by *VRS*, and SE is scale efficiency. (Coelli et al., 2005) These expressed as ratios from Figure 1 are the following:

$$TE_{CRS} = YH / YF$$
$$TE_{VRS} = YG / YF$$
$$SE = YH / YG$$

So the scale efficiency can be expressed as:

$SE = TE_{CRS} / TE_{VRS}$. (Coelli et al., 2005).

Finally, in order to know if the firm is operating in an area of increasing or decreasing returns to scale, one has to run an additional DEA problem with *non-increasing returns to scale (NIRS)* imposed. This is done by substituting the $\mathbf{I1'\lambda} = 1$ restriction in eq. 4 with $\mathbf{I1'\lambda} \leq 1$, to provide:

$$\begin{aligned} &\min_{\theta,\lambda} \vartheta, \\ &\text{subject to} \quad -\mathbf{q}i + \mathbf{Q\lambda} \geq 0, \\ &\qquad \vartheta\mathbf{x}i - \mathbf{X\lambda} \geq 0, \\ &\qquad \mathbf{I1'\lambda} \leq 1, \\ &\qquad \mathbf{\lambda} \geq 0, \end{aligned} \tag{5}$$

By comparing the inefficient firms' *VRS* technical efficiency scores with technical efficiency scores obtained with *NIRS*, one can determine the nature of returns to scale. If a firm has an equal technical efficiency (TE) score from both the *VRS* and *NIRS*, *decreasing returns to scale* exist for that firm, i.e. the firm could become more efficient by decreasing its size when the productivity of its inputs would increase. If TE scores from *VRS* and *NIRS* are unequal, *increasing returns to scale* apply and the company could improve efficiency by increasing its size again. (Coelli et al., 2005). In a case where scale inefficiency exists and the company is otherwise technically efficient, the efficiency improvement is achievable only through a change in the size of a company, or otherwise it cannot achieve the maximum productivity for its inputs (Jaforullah & Whiteman, 1999).

RESEARCH RESULTS

DEA model and explanation of its variables

The selection of the input and output variables that are to be included in a DEA model is a complicated exercise. Variables for this study were selected according to the previous waterworks efficiency evaluation studies which have used the DEA method. Different variables used in the past 20 years are listed by Abbot & Cohen (2009) and summarized in Table 1.

Table 1: Variables used in water sector DEA studies (summarized from Abbot & Cohen 2009).

INPUT variables	**OUTPUT variables**
personnel (numbers) / labour (p/t and f/t)	volume of water delivered
operating expenditure	number of properties connected/supplied
energy	population served
length of mains	length of mains
capital expenditure	annual water consumption
chemicals	sewage treated
other costs	potable water
materials	volume of delivered potable and non-potable water
specific wastewater treatment costs	physical amount of wastewater
proportion of water delivered to non-households	primary treatment
management cost	secondary treatment

maintenance and operation costs	analyses performed
capital replacement cost	number of assessments (services to properties)
outside services	average pumping head
groundwater, surface water, purchased water	average peak
treatment plants	size of area served
storage capacity	capacity of pumping
	water quality index
	water service index

In this research, DEA model by Coelli and Walding (2006) has been applied. They used operating and capital expenditures as inputs and number of properties connected and volume of water delivered as outputs. Figure 2 shows the variables used in this research.

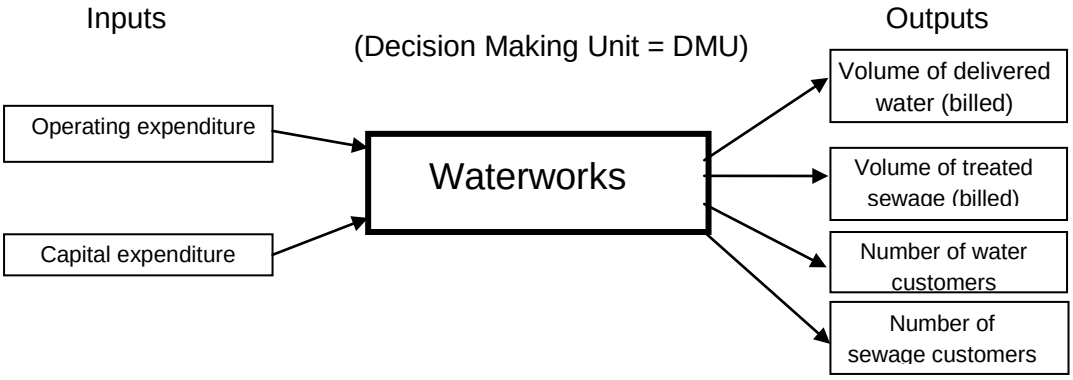

Figure 2: DEA model used in this study.

Operating expenditure variable as an input includes all operating costs of waterworks. It is formed by summing up the following income statement items: materials and supplies, change in stock value, outsourced services, wages and salaries, pension expenses, other indirect employee costs, and other operating expenses. *Capital expenditure* variable is formed by summing up the following income statement items: depreciations to plan and write-downs, interest expenses (all of them including interest expenditure to municipality, interest expenditure to others, income transfers to municipality), compensation for capital invested, and other financial expenses. Output variables include *volume of billed water, volume of billed sewage, number of water customers* and *number of sewage customers*.

The idea was to create a DEA model that takes into account both of the two dominating factors in the water industry, economies of scale and density (Walter et al., 2009). When the capital expenditure as input is related mostly to the network density (sparsely populated areas usually have higher amounts of pipeline capital relative to the operating costs), it should ensure that the waterworks with highly dense networks are benchmarked with other similar high density waterworks, low density firms with other low density companies etc. (Coelli & Walding, 2006). In addition, the capital costs of waterworks and the length of water and sewage mains are tied strongly together (Coelli & Walding, 2006), so instead of placing the "length of mains" as a variable, it was included in the model without excluding the capital costs caused by other sources in a similar way. The number of water and sewage service customers as an output together with the measures for two basic services water delivery and sewage treatment (which can be seen as the main tasks for any waterworks) is

also related to the scale of operations. The bigger the ratio of the capital costs to the number of customers is, the more sparse tend the network structure be as well.

Since one of the main goals of the study is the ranking of waterworks according to their efficiency, the total number of variables has to be kept low enough in order to avoid the loss of discrimination power the DEA method offers (Ajodhia et al., 2003; Tone & Tsutsui, 2009), because the comparison group is known to be relatively small.

Data collection and DEA solver program

The required data for the study is collected from the financial statements of the waterworks from the year 2008 (or the financial statement of a municipality in a case when the waterworks is operating as a municipal department). Choosing the financial statements as the primary source of data partly relates to the data quality requirement set by the DEA method. Common and tightly controlled rules for accounting are seen as the best insurance available against the errors in data. If all the necessary information was not found this way, the missing info was obtained from the waterworks' Internet pages or by asking directly from the waterworks themselves.

An efficiency analysis was carried out for a selected group of 19 waterworks (see Table 2). Waterworks from the most common ownership and governance models (municipal department, municipal owned enterprise, municipal owned company, and cooperative) were included in the study and for comparability all waterworks provide all core functions of water and sewage services (water acquisition and treatment, water delivery, sewage collection and sewage treatment). The results are analyzed so that the possible differences between different governance models efficiency can be identified.

Table 2: Size and governance models of waterworks included in the DEA analysis.

		Number of water customers		
		< 10000	10 000 - 60 000	> 60000
Municipal owned company (MOC)	MOC 1		X	
	MOC 2			X
	MOC 3			X
	MOC 4	X		
	MOC 5		X	
Municipal owned enterprise (MOE)	MOE 1		X	
	MOE 2			X
	MOE 3			X
	MOE 4			X
	MOE 5		X	
	MOE 6		X	
	MOE 7			X
Municipal department (MD)	MD 1	X		
	MD 2		X	
	MD 3	X		
	MD 4	X		
	MD 5		X	
Cooperative (COOP)	COOP 1	X		
	COOP 2	X		

The actual analysis has been carried out with the help of DEA solver program called Win4DEAP (version 1.1.2) which is developed by Michel Deslierres. The original DEAP program is written by Tim Coelli at the Centre for Efficiency and Productivity Analysis in University of New England. In final comparison, the input oriented model is selected along with the variable returns to scale assumption and DEA (multi-stage) calculation method. With these selections the program calculates the constant returns to scale (CRS) results also. This is important considering that under the variable returns to scale (VRS) assumption the inefficient waterworks are often benchmarked only against waterworks of similar size, but in a CRS DEA the waterworks can be benchmarked against substantially larger or smaller waterworks as well (Coelli et al., 2005).

Results

The final efficiency scores are shown in Table 3. The abbreviation crste means CRS technical efficiency under CRS assumption, vrste means technical efficiency under VRS assumption, scale means scale efficiency, and final column tells if the waterworks was considered to have increasing (irs) or decreasing returns to scale (drs) in its current situation. The crste scores compare all the waterworks with each other assuming that every one of them is able to reach the same efficiency level no matter their size. Vrste, instead, allow different levels of returns to scale occur, thereby resulting in better efficiency scores.

Table 3: DEA efficiency scores for reviewed waterworks.

Waterworks	crste	vrste	scale	irs/drs/-
MOC 1	0,954	0,968	0,986	drs
MOC 2	0,539	0,782	0,690	drs
MOC 3	0,834	1,000	0,834	drs
MOC 4	0,719	0,761	0,946	irs
MOC 5	0,810	0,810	1,000	-
MOE 1	1,000	1,000	1,000	-
MOE 2	1,000	1,000	1,000	-
MOE 3	1,000	1,000	1,000	-
MOE 4	0,950	1,000	0,950	drs
MOE 5	0,870	0,895	0,972	drs
MOE 6	0,934	1,000	0,934	drs
MOE 7	1,000	1,000	1,000	-
MD 1	0,893	1,000	0,893	irs
MD 2	0,811	0,826	0,982	irs
MD 3	0,830	1,000	0,830	irs
MD 4	0,861	0,998	0,863	irs
MD 5	0,571	0,619	0,922	drs
COOP 1	1,000	1,000	1,000	-
COOP 2	0,712	0,793	0,897	irs

The scale efficiency score is derived from the crste and vrste scores. So when e.g. MOE 4 has a crste value of 0,950, it means that it is reaching 95% of the efficiency that it should achieve, i.e. it should be able to reduce its use of inputs by 5% and still be able to produce the same amount of inputs. MOE 4 seems to get a vrste score of 1, so its inefficiency can be seen to result solely because of its wrong size (drs = too big). However, waterworks are not

necessarily the best targets for specific size determination, because they have their area of operation and they usually cannot change it radically in the short run. Consequently, this research concentrates mainly on crste and vrste efficiency values which are shown for reviewed waterworks in Figures 3 and 4.

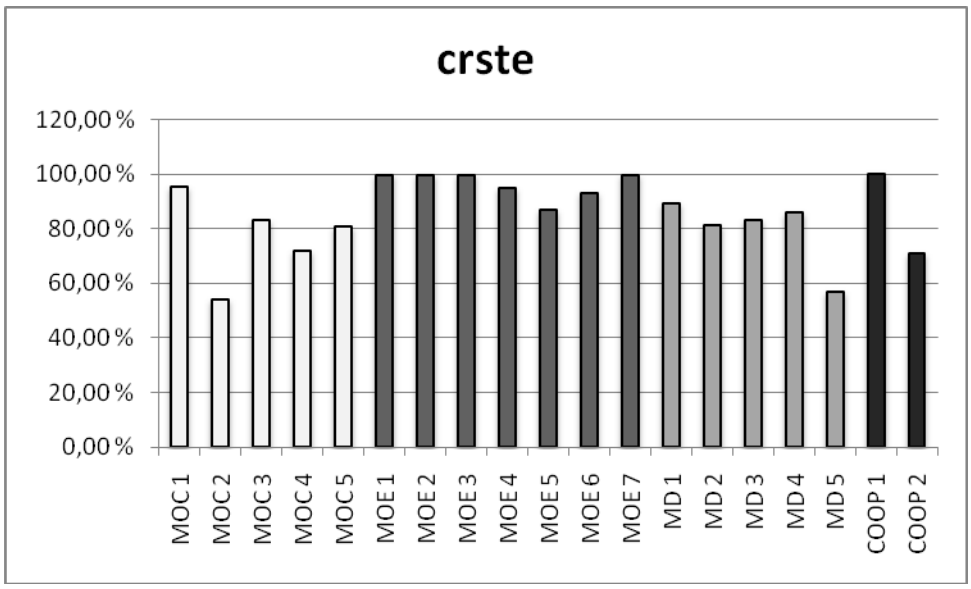

Figure 3: crst scores of reviewed waterworks.

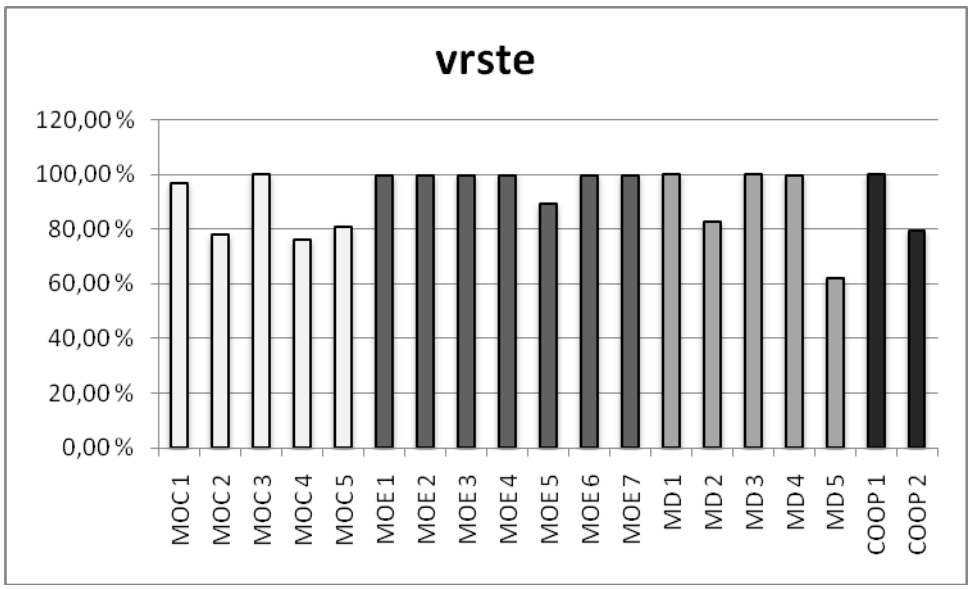

Figure 4: vrst scores of reviewed waterworks.

Research results seem to indicate, that municipal owned enterprises (MOE) are clearly best performers among the reviewed waterworks. The efficiency scores of MOEs are generally very good and it seems that MOE is the only governance model getting consistently good scores. Presupposition was that the municipal owned companies (MOC) would be generally efficient because of their greater freedom and independence compared to MOE and municipal department (MD), but the results showed poorer overall performance compared to MOEs. MD's showed systematically inferior scores compared to MOEs and MOCs although the municipalities may have their ways to make MD's look like more efficient than they really are by means of creative accounting.

Research results were tested for statistical significance with the Kruskal-Wallis and Mann-Whitney tests. The Kruskal-Wallis test showed that there exist statistically significant differences between some of the groups. Mann-Whitney tests revealed that the relation between MOEs and MDs is statistically significant, which means that MOEs are more efficient than MDs when measuring them with the DEA model. Despite these results, the MOCs seem to be doing worse than MOEs as well, which could have been verifiable with a larger sample size.

DISCUSSION

It was noticed during the research process, that there are numerous factors affecting the efficiency of waterworks which were not completely included in examination. Most of these exclusions were unwanted though, and caused by the lack of recorded information or homogeneity constraints of the group.

The literature and managerial interviews clearly pointed out that the comparisons of waterworks should take into account also quality and operation reliability factors. In order to achieve a balanced and applicable DEA model, these factors were however excluded since the number of variables was already at its maximum limit. This is a consequence of the small size of the comparison group of waterworks, which in turn is caused by homogeneity, representativeness, and applicability constraints. By excluding quality and reliability issues from the comparison, the reasons behind the different costs at different waterworks are not completely clear. Anyhow, inclusion of the quality and reliability issues in the same DEA model could have resulted in failure, because their cost correlation is not clear. Before there is evidence how to balance different quality factors in a way that their effect on total costs would be equal, it is hard to use them on similar grounds for cost related evaluation purposes.

The quantity, quality and availability of information are also somewhat hindering the implementation of accurate and plausible benchmarking studies. Despite the changes in law to improve transparency of waterworks there are still problems with its application. According to the research, it seems that in some cases all the costs are not recorded in waterworks departments' balance sheets, but instead in the balance sheets of municipality thereby blurring the real financial situation of the waterworks. In addition, there may be difficulties in defining the accurate cost allocation of billed and delivered water and billed and treated sewage since many waterworks sell water and/or sewage treatment services to other waterworks. Also in reality, for example rain waters increase (often more than double) the amount of sewage treated thereby causing costs that are not directly covered by sewage fees. A similar effect can be seen in the amount of billed water, which does not include the unaccounted-for-water which is lost and never gets to the customer.

CONCLUSIONS

The objective of this study was to find out if there are any differences in efficiency levels between waterworks' governance models. Data envelopment analysis (DEA) was selected as a research method since it has been widely used in previous waterworks benchmarking

studies and seemed to offer the best tool for assessing efficiency of different governance models. Previous literature has introduced dozens of different variables for DEA studies from which the most suitable ones were selected by taking into account the constraints of information availability and homogeneity of comparison group. Input variables used in this study were operating expenditure and capital expenditure and output variables volume of billed water, volume of billed sewage, number of water customers and number of sewage customers.

The results of this study indicate that there are differences in waterworks' governance models efficiencies. Statistically significant difference between the reviewed waterworks was found to exist among municipality owned enterprises and municipal departments, where municipality owned enterprises were generally more efficient ones. Municipality owned companies had very unequal efficiency results and the sample group of cooperatives was very small, why statistical difference could not be found regarding these groups. Furthermore, because the sample group included only 19 waterworks, these results cannot be generalized to the national level or too general level.

During the research it became clear that waterworks efficiency research has a lot of constraints to overcome of which availability of transparent and accurate information is the most prevailing one. Perhaps this has been contaminated by the heterogeneous public management policy. The efficiency scores from this DEA study are thus suggestive and they cannot be taken as an absolute truth because of many influencing factors in the background. This research was the first attempt to compare efficiency of waterworks' governance models in Finland. It gave interesting and somewhat promising results which should encourage researchers to investigate the matter further. This research should be used as a foundation for improved and perfected models in the future, since the findings seem to be logical. Future research could for example investigate how strongly each quality and reliability factor correlates with the total costs in order to ease the future efficiency evaluations and add also quality aspect into it. In addition, larger sample groups and more data should be collected in order to get more reliable and generalizable results.

ABSTRACT

The development and application of information technology makes it possible to automate the tasks of approving, recording, processing and reporting of transactions. To ensure operational performance, financial reporting reliability and legal compliance, internal control mechanisms should be gradually constructed into the information systems, according to the computerization of the enterprise, in order to continue to exercise the internal controls. Therefore, the main purpose of this study was to develop a model, in which internal controls adaptability affects internal controls efficacy and operating performance, and internal controls efficacy influences operating performance. Research hypotheses derived from the model were tested using regression analysis on the questionnaire data and financial data from Taiwanese listed companies. The results showed that not only internal controls adaptability had an impact on internal controls efficacy and operating performance, but also internal controls efficacy had a partial influence on operating performance. The research findings could be a theoretical foundation for further study.

Key words: information systems, computerized internal controls, internal controls adaptability, internal controls efficacy, operating performance

INTRODUCTION

The development and application of information technology (IT) makes it possible for companies to support operations with IT systems in order to improve operating performance. The approval, recording and processing of transactions, as well as the generation of reports can be automated, to ensure operational effectiveness and efficiency, financial information reliability, and legal compliance [4, 5, 13, 17, 25]. Companies have to adjust the techniques and methods of internal controls in accordance with computerization, in order to exercise effective controls. The internal control techniques used in an IT environment are quite different from those used in a manual environment. Transactions are automatically triggered or executed in an IT environment, and the internal controls are supported with information technology. Therefore, the internal control techniques in a manual environment cannot be migrated to an IT environment [19].

The formation of paperless trading environment means changes of the internal control techniques are required, so as to ensure consistency with the IT environment and the efficacy of internal controls. Therefore, the adaptations of internal control techniques are a

critical management issue in order to ensure the efficacy of internal controls and the achievement of operational objectives.

In the IT environment, the quality of internal controls adaptation affects operations and management, and in turn, influences the efficacy of internal controls [29]. Internal controls aim to ensure the reliability of financial information, the effectiveness and efficiency of operations and the compliance of laws and regulations [41]. Therefore, the efficacy of internal controls can be divided into the reliability of financial information, the effectiveness and efficiency of operations and the compliance with laws and regulations. The efficacy of the control over financial information reliability allows managers to gain a timely and in-depth understanding of business operations. This empowers them to make the right decisions and improve operational performance [7, 21, 40, 41]. The effectiveness and efficiency of operations ensures the outcomes of resources utilization reduce unnecessary waste in operational activities and eventually boost operating performance [18,29]. The control efficacy of the compliance with laws and regulations can prevent illegal or fraudulent behavior and ensure operating performance [1, 21, 39].

The robustness of an internal control system affects the efficacy of internal controls. Meanwhile, the efficacy of internal controls influences operational performance via information reliability, operational effectiveness and efficiency, and legal compliance [7, 21, 41]. In the IT environment, adaptations on computerized internal controls have effects on the efficacy of internal controls and the performance of operations. In fact, the efficacy of internal controls also affects operating performance.

Literature suggests that the importance of computerized controls on operations [18, 19, 21, 41]. However, there are no discussions regarding how the adaptability of computerized controls affects operational performance through the efficacy of internal controls. Therefore, this paper reviewed literature and examined how the adaptability of computerized controls affects operational performance through the efficacy of internal controls. Meanwhile, this paper referred to operational metrics such as ROA (return on assets), ROE (return on equity) and EPS (earnings per share) as dependent variables to perform an empirical study on how the adaptability of computerized controls affects operating performance and the efficacy of internal controls, and how the efficacy of internal controls affects operating performance.

RESEARCH MODEL AND HYPOTHESES DEVELOPMENT

Internal controls

Internal controls, implemented by the board of directors, management and others, aim to provide a reasonable assurance of the reliability of financial reporting, the compliance with laws and regulations and the effectiveness and efficiency of operating [4, 5, 13, 17, 25]. The quality of the design of internal controls, more often than not, is critical to the success of an organization. Therefore, to ensure the efficacy of internal controls, managers have to pay attention to the design of internal controls.

The internal control- integrated framework proposed by COSO (Committee of Sponsoring Organizations of the Treadway Commission) consists of five control components, i.e. the

control environment, risk assessments, control activities, information and communication, and monitoring. The control environment is the foundation of the other four components [17]. Risk assessments refer to the process of identifying and evaluating risks. Control activities are a set of policies and procedures to assist and ensure the implementation of the instructions from management. The setup and execution of these policies and procedures should target identified risks. Information is defined as the objects the IT system identifies, measures, processes and reports. Information can be generated internally or acquired externally. Information aims to assist decision-makers in reaching decisions. Communication is the process of delivering information to others. Monitoring is the process of evaluating internal control implementations, in order to decide whether control activities are still relevant, whether risks can still be identified and whether the design and implementation of control activities remain effective.

Companies have to implement various control measures to achieve targets. On the basis of the timing of control events, internal controls can be divided into preventive controls, detective controls and corrective controls [17]. Preventive controls are ex-ante in nature, such as the control over accounts and passwords for the prevention of illegal uses from logging into the system. Detective controls are the control over the happening of events, e.g. the inspection of product codes to confirm the existence of products. Corrective controls are ex-post nature. For example, an automated procurement system can calculate the procured quantity once the inventory falls below a control point, and then generate a purchase order to make up for the inventory shortfall.

The execution of internal controls can be divided into manual controls and computerized controls [12]. Manual controls refer to the control mechanisms implemented by users, e.g. manual reviews of the results processed by the computer. Computerized controls refer to the automated control run by computer programs, such as a check on whether debts and credits are balanced in the accounting entries made by users.

According to No. 3 of the Statements of Auditing Standards (SAS) set forth by the American Institute of Certified Public Accountants (AICPA), the structure of internal controls in the EDP environment can be divided into general controls and application controls [24] General controls can be further divided into organization and operation controls, systems development and documentation controls, built-in equipment controls, access controls and other data and procedural controls. Application controls can also be further divided into input controls, processing controls and output controls. In other words, general controls are about the control of the whole IT environment, with the goal of ensuing the security and reliability of the IT system. Application controls are about the control over application software, aiming to maintain the accuracy and integrity of data from inputs when processed to outputs. Regardless of how perfect the design of an internal controls system, it is difficult to completely work out the functions of internal controls, due to practical limitations and the cost/benefit tradeoff, as well as the continued likelihood of illegal activities [27,31].

The assessment of enterprise computerization

The digitalization, mobilization and ubiquity of information technology extend the virtual boundaries of organizations. As a result of the integration of workflows both inside and

outside the organization, electronic transaction data has replaced paper-based data [22, 32]. The extension of virtual boundaries of organizations and the digitalization of internal and external transaction data lead to organizational transformations and changes in corporate structures, flows and behavior [10, 11, 12, 17, 30, 34, 38]. The adoption of new information technology extends the reach of IT systems and changes the integrated processing capacity of transaction data. As a result, corporate structures, work flows and behavior also shift. The computerization process to extend the reach of the IT system and the capability to integrate and process transaction data is, in essence, the transformation process of corporate structures, work flows and behavior. Therefore, the enterprise computerization can be explained using the extensibility of information systems and integrated processing capability of transaction data as two indicators [22, 26, 32].

IT systems may consist of platforms such as a single computer, LANs(local area networks) and the Internet. LAN-based IT systems have a stronger extension capability than single-computer-based systems, and Internet-based systems are even stronger than LAN-based systems in terms of extension capacity. As far as the transaction integration is concerned, Manufacturing Resources Planning Systems are better than Material Requirement Planning Systems, and Enterprise Resources Planning Systems are superior to Manufacturing Resources Planning Systems.

The adaptation of computerized internal controls

The adoption of new information technology means computerized controls should be built into the IT system. The higher the degree of computerization, the more likely transactions will be generated or implemented automatically. Hence, computerized controls will gradually replace manual controls, in order to establish an automated and timely control mechanism. Jackson (2000) indicated that despite constant advances of information technology, many internal auditors stick to the traditional approach of control applications and IT system controls. This is how many internal control defects emerge. Tuttle (2007) suggested that the responsibility of computer auditors is to ensure that the control and security of the IT system is taken into consideration during its planning and development. Given the development and application of information technology, it is necessary to switch internal controls from the traditional manual approach to an automated and programmed approach in order to ensure security and reliability of the IT system [29].

Bierstaker et al. (2001) indicated that changes of the IT environment affect internal control techniques and audit methods. Therefore, adaptation is required between computerization and internal control techniques. Weber (1982), and Davis and Weber (1986) proposed an adaptation model for internal control and audits based on the theory of a computerized data processing system. This system consists of nine levels, i.e. environment, organization, user divisions/departments, the data processing facility, data processing systems, computer data processing subsystems, components, controls and audit procedures. Adjustments are made to the environment or technology of the lower level in response to dynamic pressure from the upper level, in order to identify the control and audit techniques required. Therefore, the IT environment affects IT system changes, the IT system influences changes of the internal control techniques, and the internal control techniques drive changes of the audit procedures and methods.

The development and application of information technology changes the extensibility of information systems that support an organization and the integrated processing capability of transaction data. The extensibility of information systems that support an organization refers to the level of openness of the extensibility of information systems networks. In other words, it is an indicator of whether transaction data can be entered in a timely manner. An open information system allows operators to immediately input transaction data no matter where the transactions take place. To ensure the security and reliability of operations, it is necessary for the internal control mechanism to acquire transaction data on a timely basis. A timely internal control mechanism should be deployed to ensure the efficacy of internal controls. The integrated processing capability of transaction data refers to the capability to integrate and process the data of related transactions via networks and databases. In such a paperless IT environment, managers should establish a programmed and automated internal control mechanism to implement automated control and ensure internal controls efficacy.

The maturity of IT applications and the development of network technologies mean there are no restrictions of time or space on the extensibility of the information systems. No matter where the transactions occur, operators can immediately enter transaction data into an information system over open network. The maturity of network and database technologies makes it possible to integrate and process transaction data across divisions over networks and databases. In a paperless and digital trading environment, internal control techniques must be timely and automated to ensure control efficacy and achieve operational goals [8, 14]. Therefore, this paper referred to internal controls automation and internal controls timeliness as the two indicators to explain internal controls computerization.

According to Figure 1, enterprise computerization consists of the integrated processing capability of transaction data and the extensibility of information systems. The internal controls computerization consists of the internal controls automation and the internal controls timeliness. Any increase of computerization means the adaptations of automation and timeliness of internal controls become necessary on the basis of the integrated processing capability of transaction data and the extensibility of information systems. The establishment of computerized internal controls is essential to ensure the efficacy of internal controls. Throughout the computerization process, certain corporate characteristics make it impossible to adapt internal control techniques accordingly, and hence, internal control deficiencies occur. The quality of the adaptation towards computerized internal controls influences the efficacy of internal controls and the performance of corporate operations.

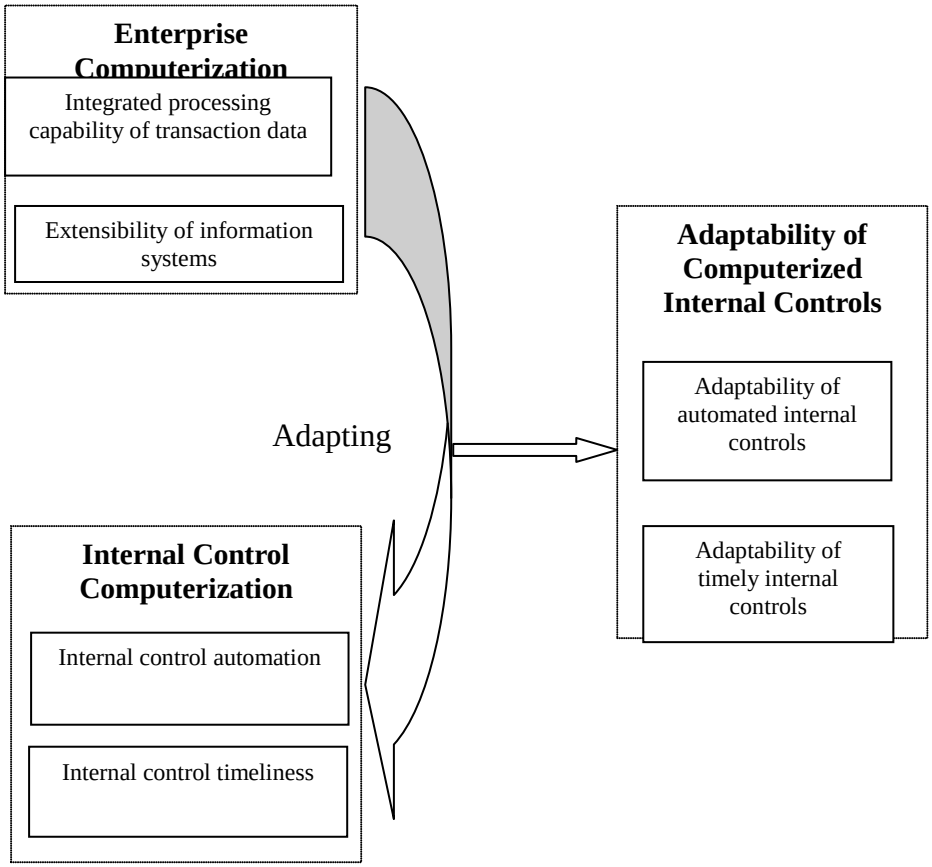

Figure 1: Computerized internal control adaptation.

Hypotheses development

Companies are utilizing IT and network technologies to integrate functions across the value chain so as to best allocate limited resources, to exercise effective control, and to achieve operational goals. Hardy and Reeve (2000) indicated that a reliable internal control structure aims to ensure information accuracy in the integration process of the EDI (electronic data interchange) system. Davis and Weber (1986) argued that the application of control procedures and methods at the right time and in the right environment can achieve good cost efficiency. Doty et al. (1989) suggested that internal control methods should be in line with the structure of the databases from the perspective of database designs, in order to adjust internal control formats, ensure internal control efficacy and boost operational performance. Harper (1986) examined the level of computerization in the context of network developments. Networks and optical infrastructure speed up transmissions and data exchanges between computers. As a result, management is more able to exercise timely controls and achieve business objectives. Therefore, internal control techniques should change in accordance with the IT environment. The adaptability of computerized internal controls affect internal controls efficacy, and hence, operating performance.

Performance evaluations and control management are highly related. Operating performance plays a pivotal role in control management and affects the operations of the whole organization. Incentives and rewards to employees, as well as operational targets and

overall goals, are all based on the evaluation of operating performance [33]. There is extensive literature addressing operating performance, and most of it centers on the three financial metrics of ROE, ROA and ROS, as proposed by Venkatraman and Ramanujam (1986). This paper also referred to ROE and ROA but added EPS as another indicator to evaluate performance. These three dependent variables, ROE, ROA and EPS, were used to examine the influence of internal control efficacy on operating performance.

As Figure 2 illustrates, the adaptability of computerized internal controls affects internal control efficacy and operating performance. Internal control efficacy can be divided into the control efficacy of financial information reliability, the control efficacy of operating effectiveness and efficiency and the control efficacy of laws and regulations compliance. The efficacy of internal controls, in turn, affects operating performance.

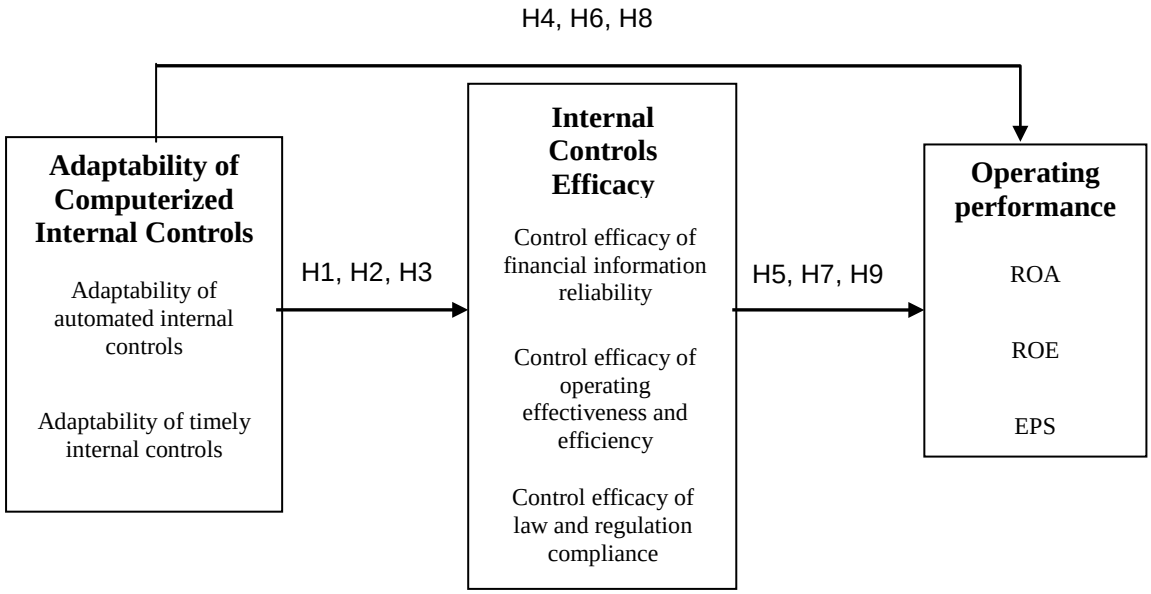

Figure 2: the proposed research model.

The completion of the IT systems required for transactions allows users to experience the efficiency and convenience brought about by the IT system. Users will request to integrate more functions into the IT systems in order to integrate and process transaction activities. After the replacement of the manual environment with the IT systems, it is necessary to deploy more computerized controls in order to avoid any control loopholes [19]. If companies are able to adjust their computerized control mechanism according to the degree of IT applications, they will be able to ensure the reliability of financial information processing and boost the control efficacy of the financial information reliability [21]. Hence, this study developed the following hypothesis:

H1: The higher the adaptability of computerized internal controls, the better the control efficacy of financial information reliability.

With the deployment of the required internal control mechanisms into the IT system, the IT system can effectively and efficiently support transaction activities as well as ensure operational effectiveness and efficiency, information quality and legal compliance. This leads to the improvement of the control efficacy of operational effectiveness [6, 21]. Hence, this

study developed the following hypothesis:

H2: The higher the adaptability of computerized internal controls, the better the control efficacy of operating effectiveness and efficiency.

Good adaptability of computerized internal controls and the deployment of the automated and timely internal control mechanisms in the IT system can prevent and detect in a timely-manner any erroneous or illegal transactions. This improves the control efficacy of legal compliance [21]. Thus, this study developed the following hypothesis:

H3: The higher the adaptability of computerized internal controls, the better the control efficacy of laws and regulations compliance.

Internal controls are run to ensure the achievement of operational goals and performance [9]. The more enterprise computerization and internal controls are aligned, the more reliable the financial information, the smoother the operations and the better the legal compliance. This leads to internal control efficacy and operational performance improvements [41].

Return on assets (ROA) is an indicator of operating performance because it represents the efficacy and efficiency of asset utilization. There is a certain correlation between the adaptability of computerized internal controls, the efficacy of internal control and operating performance. Internal control efficacy also has a positive influence on operating performance [7,41]. Therefore, this study developed the following hypotheses:

H4: The higher the adaptability of computerized internal controls, the higher the ROA.

H5: The better the internal control efficacy, the higher the ROA.

Return on equity (ROE) is the speed of growth of shareholders' equity. It measures whether management's goals and the shareholders' goals are aligned. ROE is a valuation metric of operating performance. The adaptability of computerized internal controls and the efficacy of internal control affect operating performance [21]. Thus, this study developed the following hypotheses:

H6: The higher the adaptability of computerized internal controls, the higher the ROE.

H7: The better the internal control efficacy, the higher the ROE.

Earnings per share (EPS) are the profitability of a company. The higher the EPS, the better the profitability per unit of capital is. A high EPS is the result of good marketing, technologies and management, which makes it possible to create better bottom lines with fewer resources. EPS is an important performance indicator.

The adaptability of computerized internal controls saves transaction costs and improves operational efficiency via operations and efficiency control efficacy. It also reduces cases of fraud and mistakes via the efficacy of control over legal compliance, and in turn, influences operating performance [1, 6]. Hence, this study developed the following hypotheses:

H8: The higher the adaptability of computerized internal controls, the higher the EPS.

H9: The better the internal control efficacy, the higher the EPS.

RESEARCH METHODS

Variables definitions

In order to operate and measure the variables, table 1 defines the related variables of this study.

Table 1: definitions of variables.

Constructs	Variables	Definitions	References
Enterprise Computerization	Integrated processing capability of transaction data	Capability of integrating and processing transaction data in the IT systems.	Hong and Kar (2006), Krishnan et al. (2005), Serenko et al. (2008)
	Extensibility of information systems	Capability of the IT system in extending the reach of virtual boundaries of transaction activities for an organization	
Internal Control Computerization	Internal control automation	Capability of deploying automated internal controls in the IT system	Ashbaugh-skaife et al. (2007, 2009), Bailey (1985), Grant et al. (2008), Hardy and Reeve (2000)
	Internal control timeliness	Capability of deploying timely internal controls in the IT system	
Adaptability of Computerized Internal Controls	Adaptability of automated internal controls	Adaptability between integrated processing capability of transaction data and internal controls automation.	Weber (1982), Davis and Weber (1986)
	Adaptability of timely internal controls	Adaptability between extensibility of information systems and Internal controls timeliness.	
Internal Control Efficacy	Control efficacy of financial information reliability	Internal control efficacy to ensure financial information reliability.	Barra (2010), Boone et al. (2000)
	Control efficacy of operating efficacy and efficiency	Internal control efficacy to ensure compliance with laws and regulations.	
	Control efficacy of law and regulation compliance	Internal control efficacy to ensure operational effectiveness and efficiency	
Operating performance	Return on assets (ROA)	Net income divided by average total assets	Venkatraman and Ramanujam (1986), Snell (1992)
	Return on equity (ROE)	After-tax profits divided by weighted average shareholders' equity	
	Earnings per share (EPS)	Net income divided by the number of weighted average common shares outstanding	

The adaptability of computerized internal controls refers to the capability of deploying computerized internal controls according to the levels of computerization. Enterprise computerization is defined as the integrated processing capability of transaction data plus the extensibility of information systems. The internal control computerization is defined as the internal controls automation plus the internal controls timeliness. Therefore, the adaptability of internal controls automation is defined as the internal controls automation divided by the integrated processing capability of transaction data. The adaptability of internal controls timeliness is defined as the internal controls timeliness divided by the extensibility of information systems. The adaptability of computerized internal controls is defined as the internal controls computerization divided by the enterprise computerization. The value of the adaptability of computerized internal control is between 0 and 1. A value of 0 means a complete lack of adaptability. A value of 1 indicates the best adaptability. To ensure the validity of the questionnaire data, the samples with adaptability values of greater than 1 were deleted.

Measurement

The questionnaire survey consisted of four parts. Part 1 detailed the basic data of the sampled companies, and there were five items. Part 2 contained items about enterprise computerization. Part 3 contained a set of items on the computerization of internal controls. Part 4 contained items on internal control efficacy. There were ten items in Part 2 and these items were designed for IT personnel. The purpose was to acquire the assessment values of enterprise computerization. There were ten items in Part 3 and nine items in Part 4. These items were designed for auditing staff, in order to acquire the assessment values of the capability of computerizing internal controls and the efficacy of internal controls. The items in Parts 2, 3 and 4 were all based on the Likert Scale. All items were positive statements. There are five answers to each question, stated as: “strongly agree” (5 points), “agree” (4 points), “uncertain” (3 points), “disagree” (2 points) and “strongly disagree” (1 point). Among the ten items in Part 2, items 1 to 5 aimed to evaluate the integrated processing capability of transaction data. Items 6 to 10 intended to assess the capability of extending the IT system. Among the ten items in Part 3, items 1 to 5 sought to measure the capability of automating internal controls, whereas question 6 to 10 intended to gauge the timeliness of internal controls. Among the nine items in Part 4, items 1 to 3 aimed to assess the efficacy of control over financial information reliability, items 4 to 6 intended to measure the efficacy of control over the compliance of laws and regulations, and items 7 to 9 sought to evaluate the control efficacy of operational effectiveness and efficiency.

To ensure the content validity of the questionnaires, this paper developed the items by referring to relevant literature and the research model. The questionnaire was finalized with minor changes after a pre-test on the IT and auditing personnel of a large global corporation and other three companies.

Data collection

Listed companies tend to be large in scale, and are usually generous in IT investments. As heavy users of information technology, they have higher levels of computerization. This paper hence decided to randomly sample listed companies in Taiwan across different

industries. A total of 601 companies were selected. The questionnaires were released to the CEOs of sampled companies by post or email in mid December 2010. The CEOs were requested to forward the questionnaires to relevant IT and audit personnel. The purpose of this survey was to gather construct data concerning the capability of computerization, the capability of computerizing internal controls and the efficacy of internal controls. Quantitative metrics, such as ROA, ROE and EPS, were sourced from the Taiwan Economic Journal. This paper referred to the mean values of the three most recent years (2007~2009).

ANALYSIS AND RESULT

There were 67 valid questionnaires returned, showing a response rate of 11%, which could still be accepted. Table 2 shows the descriptive statistics such as means and standard deviations of variables.

Table 2: Descriptive statistics of variables.

Variables	Mean	Standard deviation	Theoretical score range	Real score range
Integrated processing capability of transaction data(IPCOTD)	20.27	2.434	5-25	15-25
Extensibility of information systems(EOIS)	20.27	2.700	5-25	15-25
Internal controls automation(ICA)	18.01	2.555	5-25	13-23
Internal controls timeliness(ICT)	18.01	2.371	5-25	13-23
Controls efficacy of financial information reliability(CEOFIR)	11.45	1.247	3-15	9-14
Controls efficacy of operating effectiveness and efficiency(CEOEAE)	11.58	1.170	3-15	9-14
Controls efficacy of law and regulation compliance(CEOLAR)	11.51	1.284	3-15	8-14
Adaptability of internal controls automation(AOICA)	0.892	N/A	N/A	N/A
Adaptability of internal controls timeliness(AOICT)	0.890	N/A	N/A	N/A

According to Table 2, the mean values of IPCOTD and EOIS as two variables were both 20.27, and were close to the highest value of 25. In general, listed companies in Taiwan have high levels of computerization. The adaptability values, AOICA and AOICT, were 0.892 and 0.890, respectively. These numbers suggested a strong adaptability of computerized internal controls. In other words, most listed companies in Taiwan can adjust their internal controls in accordance with their levels of computerization.

Table 3 summarizes the descriptive statistics of ROA, ROE and EPS of the sampled companies for 2007, 2008 and 2009.

Table 3: descriptive statistics of performance indicators.

Performance indicators	Mean	Standard deviation	Maximum	Minimum
ROA	1.58%	0.97%	3.50%	-1.10%
ROE	2.17%	1.22%	4.70%	-1.70%
EPS	1.75	1.09	4.37	-1.73

Reliability and validity

In order to evaluate the consistency of the construct factors, such as computerization capability, the capability of computerizing internal controls and the efficacy of internal controls, this paper referred to Cronbach α values to validate reliability. The Cronbach α values for integrated processing capability of transaction data, extensibility of information systems, internal controls automation, internal controls timeliness, control efficacy of financial information reliability, control efficacy of operating effectiveness and efficiency, and control efficacy of laws and regulations compliance were 0.869, 0.821, 841, 0.826, 0.709, 0.603 and 0.614, respectively. Five of them met the threshold of 0.7, as suggested by Munnally (1990). The other two 0.603 and 0.614 could also be accepted. These values demonstrated the reliability of the constructs was high.

Regarding the measurement of construct validity, this paper referred to seven indicators, i.e. the integrated processing capability of transaction data (IPCOTD), the Extensibility of information systems (EOIS), the Internal controls automation (ICA), the internal controls timeliness (ICT), the control efficacy of financial information reliability (CEOFIR), control efficacy of operational effectiveness and efficiency (CEOOEAE) and the control efficacy of laws and regulations compliance (CEOLARC) for the confirmatory factor analysis. The results are shown in Table 4. The coefficient of each construct was larger than the coefficients with other constructs. In every domain, the factor loadings of items for each construct were greater than 0.5, and the factor loadings for other constructs were less than 0.5. This suggested that convergent validity and discriminant validity were good and that further analysis was possible [28].

Table 4: confirmatory factor analysis.

Domain	Constructs	Items	Factor loadings	Eigenvalue	Cronbach's Alpha
Enterprise computerization	Integrated processing capability of transactions data(IPCOTD)	IPCOTD1	0.817	3.372	0.869
		IPCOTD2	0.747		
		IPCOTD3	0.742		
		IPCOTD4	0.673		
		IPCOTD5	0.711		
	Extensibility of information systems(EOIS)	EOIS1	0.653	3.097	0.821
		EOIS2	0.792		
		EOIS3	0.556		
		EOIS4	0.635		
		EOIS5	0.561		
Internal controls computerization	Internal controls automation(ICA)	ICA1	0.773	2.935	0.841
		ICA2	0.639		
		ICA3	0.527		
		ICA4	0.621		
		ICA5	0.729		
	Internal controls timeliness(ICT)	ICT1	0.673	3.023	0.826
		ICT2	0.594		
		ICT	0.729		
		ICT4	0.626		
		ICT5	0.677		
Internal controls efficacy	Control efficacy of financial information reliability(CEOFIR)	CEOFIR1	0.525	1.870	0.709
		CEOFIR2	0.578		
		CEOFIR3	0.622		
	Control efficacy of operating effectiveness and efficiency(CEOOEAE)	CEOOEAE1	0.667	1.961	0.603
		CEOOEAE2	0.633		
		CEOOEAE3	0.576		
	Control efficacy of laws and regulation compliance(CEOLARC)	CEOLARC1	0.674	2.174	0.614
		CEOLARC2	0.751		
		CEOLARC3	0.770		

Regression models

The proposed hypotheses were tested using regression analyses. The results are summarized in Table 5. The F values of the nine regression models all reached the significance level of 0.001, and the coefficients of the independent variables were all greater than 0. This suggested that there was a significant correlation between the independent variables and dependent variables. The modified coefficients were Adj R^2=0.685, Adj R^2=0.695, Adj R^2=0.700, Adj R^2=0.762, Adj R^2=0.735, Adj R^2=0.757, Adj R^2=0.695, Adj R^2=0.722, and Adj R^2=0.685. Therefore, the independent variables could explain 68.5%, 69.5%, 70.0%, 76.2%, 73.5%, 75.7%, 69.5%, 72.2% and 68.5% of the variances of dependent variables, respectively.

Table 5: Results of regression analyses.

Hypotheses	Adjusted R^2	F values	Regression equations	Hypotheses testing
H1	0.685	72.693***	CEOFIR = -1.517 + 7.120(AOICA***) + 7.435(AOICT**)	Supported
H2	0.695	76.060***	CEOOEAE = -0.574 + 7.228(AOICA***) + 6.418(AOICT**)	Supported
H3	0.700	78.095***	CEOLARC = -2.090 + 6.782(AOICA***) + 8.484(AOICT***)	Supported
H4	0.762	106.465***	ROA = -0.092 + 0.049(AOICA***) + 0.072(AOICT***)	Supported
H5	0.735	62.115***	ROA = -0.067 + 0.001(CEOFIR) + 0.003(CEOOEAE*) + 0.003(CEOLARC***)	Partially Supported
H6	0.757	103.813***	ROE = -0.114 + 0.050((AOICA**) + 0.103(AOICT, t=5.197***)	Supported
H7	0.695	51.136***	ROE = -0.067 + 0.001(CEOFIR) + 0.003(CEOOEAE*) + 0.003(CEOLARC***)	Partially Supported
H8	0.722	86.722***	EPS = -10.235 + 3.910((AOICA*) + 9.544(AOICT***)	Supported
H9	0.685	48.891***	EPS = -0.067 + 0.001(CEOFIR) + 0.003(CEOOEAE) + 0.003(CEOLARC***)	Partially Supported

Other than H5, H7 and H9, the remaining six regression models had positive coefficients and significant t values. The t values for CEOFIR, an independent variable, of H5 and H7 did not reach significance levels, meaning the control efficacy of financial information reliability did not have a significant influence on ROA and ROE as dependent variables. In the H9 regression model, the t values for CEOFIR and CEOOEAE as independent variables did not reach statistical significance, meaning the control efficacy of financial information reliability and the control efficacy of operational effectiveness and efficiency did not have a significant influence on EPS as a dependent variable. As Table 5 shows, H1, H2, H3, H4, H6 and H8 were supported and H5, H7 and H9 were partially supported.

FINDINGS AND DISCUSSION

The adaptability of computerized internal controls affects the efficacy of internal controls, and the efficacy in turn affects operating performance. The internal control mechanism, however, will lead to operating performance only through the process of internal control efficacy. The comparison of the H1, H2 and H3 results and the H5, H7 and H9 results showed that the explanatory power of the capability of computerized internal controls on variances of operating performance indicators (i.e. ROA, ROE and EPS) was stronger than that of internal control efficacy. In other words, the capability of computerized internal controls could better predict operating performance than internal control efficacy. The capability of computerized internal controls was therefore shown to be an effective predictor of operating performance.

The H5, H7 and H9 results also showed the different levels of influence of the three independent variables, i.e. the control efficacy of financial information reliability, the control efficacy of operational effectiveness and efficiency and the control efficacy of laws and regulations compliance on the dependent variables, i.e. operating performance indicators of ROA, ROE and EPS. The control efficacy of financial information reliability had no significant

influence on these three performance indicators, i.e. ROA, ROE and EPS. Operational effectiveness and efficiency control efficacy had a significant influence on ROA and ROE, but not on EPS. Control efficacy on legal compliance had a significant influence on ROA, ROE and EPS. Control efficacy of financial information reliability may be relevant to external users of financial information but not directly related to internal operations. Hence, it did not have a direct impact on operating performance. Legal compliance may boost operating performance by reducing errors and fraudulent behavior, so it had direct effects on operating performance.

The major contribution of this paper was to examine the importance of the adaptation of computerized internal controls in a digital environment, and to perform an empirical analysis on the influence of such adaptation on internal control efficacy and operating performance. The deployment of automatic and timely computerized internal controls in an IT system, in accordance with the levels of computerization, means good adaptation capability in computerized internal controls. This will influence internal control efficacy and operational results. The results can serve as a foundation for further studies, as well as a reference in the deployment of internal controls for the adoption of a new IT system.

This paper endeavored to be robust in its approaches, but it had two research limitations due to environmental factors such as time, manpower and resources.

- The empirical research was based on a questionnaire survey. It gauged the perceptions of respondents but could not ensure whether the respondents truly understood the items and provided factual answers.
- The research scope was limited to listed companies in Taiwan pursuant to the Taiwan Securities and Exchange Commission.

CONCLUSION

Based on literature reviews and empirical studies, this paper proposed an adaption model for the computerization of internal controls, as a reference for the establishment of internal controls in an IT system along with the evolution of the IT environment. The adaptation capability of computerized internal controls and the efficacy of internal controls were defined as the dependent variables of internal control efficacy and operating performance in the regression analysis. The results showed that the adaptation capability of computerized internal controls had a significant influence on internal control efficacy and operating performance. However, the influence of internal control efficacy on operating performance indicators such as ROA, ROE and EPS was significant only in the case of certain independent variables.

The formation of paperless transactions means computerized controls should make adjustments accordingly, in order to ensure the consistency between internal control techniques and the IT environment. This will ensure the efficacy of internal controls and the achievement of organizational objectives.

ABSTRACT

This research investigates how the most effective key performance indicators (KPIs) can be selected for a customer-oriented company in the heavy-duty vehicle (HDV) industry. It is emphasized that there is a need for identification and utilization of KPIs based on the most important critical success factors (CSFs) of a customer-driven enterprise in order to create value, responsiveness, innovativeness, and differentiation. The stepwise procedure is applied to identify the most important KPIs. Firstly, sample mission statements and vision statements were analyzed. In the second step, CSFs of a consumer-oriented enterprise in the HDV industry were specified. In the third step, a characteristics table with regard to CSF was designed in the context of requirements, benefits, risk and limitation. In the fourth step, the KPI pool with 42 KPIs was generated. In the last step of stepwise procedure, KPI value table was established with the help of analyzed CSFs and the selected departments, which are thought as a link between company and its customers. Moreover, as a result, there are selected 17 KPIs. They are analyzed in the context of competitiveness, consumer-driven point of view, and accuracy in operations. This research shows that there is a strong correlation between mission statements and vision statements, strategic goals, CSFs and KPIs. Also, all of these components should focus on the same idea to be able to develop a consumer-driven structure.

Keywords: Consumer Driven, Key Performance Indicators, Critical Success Factors, Heavy Duty Vehicle industry, Competitiveness

INTRODUCTION

The globalization in the heavy-duty vehicle (HDV) industry is evident. Vehicle producers have spread their supply operations around the world and are selling products worldwide. In recent years, the vehicle market has increased drastically in e.g. India, Brazil and China, which are dominant part of the newly industrialized countries (NIC) with a rapid growth and fairly low labor costs. Less constraints and agility in just-in-time supply services make this industry larger in the globalization and more favorable (Frost and Sullivan, 2006). In the global HDV market, customer and market data and information are important for every company in order to understand the market and its potential. The holistic understanding and benchmarking succeed the firm to achieve appropriate levels in different aspects such as customer satisfaction (Hanman, 1997; Ittner et. al., 2003).

The HDV industry focuses on operational efficiency thus a firm focusing on the consumers may become an innovator in this industry. This means that a consumer-oriented approach may offer opportunity for differentiation and creation of competitive advantage. Also, if the company focuses on demand chain management, it will turn into a pioneer in the industry (Walters et. al., 2004). Firms in this industry are facing many challenges with regard to environmental issues, market share, image, cost structure, and fuel efficiency. Competitiveness in volume, price, lead-time and quality can be achieved through increase in product customization requiring improve market mediation in the exciting structure (De Treville et.al. 2004). In addition, the trend of globalization causes hard competition, which leads to increased product variety and differentiation resulting in reduced product lifecycles. These difficulties explain the recent interest of changing the mindset from supply chain management (SCM) to demand chain management (DCM). The importance of being consumer oriented is the starting point for the shift from SCM to DCM and it implies that companies should aim to improve responsiveness in meeting specific consumer needs. This change is obviously bringing complexity and cost into the supply chain.

This research investigates how the most effective key performance indicators (KPIs) can be selected for a customer-oriented company in the HDV industry. Using the result of KPIs can promote a standard method of performance measurement and find potentials for improvements in DCM area (McKinnon, 2007). The study emphasizes that there is a need for identification and utilization of KPIs based on the most important critical success factors (CSFs) to create value, responsiveness, innovativeness, and differentiation in consumer-driven enterprises. There exists research about CSFs for various types of tasks and industries as well as on the issue of identifying and implementing KPIs. However, research has not targeted specific industries such as the HDV industry. Thus, there is a lack of knowledge about the development of effective KPIs from an industry-based point of view. There is also a lack of studies relating consumer-oriented CSFs with effective KPIs. The aim of this study is to provide a framework that helps to identify the most appropriate consumer oriented KPIs in HDV industry. The main research question is: “How can the most effective KPIs be selected for a customer-oriented company in the HDV industry”. In essence, this research addresses how measurable KPIs in the operational level can be selected to reinforce the enterprise to be more consumer-driven.

Before continuing the context of the study should be explained. In this research customer and consumer concepts is separated from each other. In general, the customer is a potential buyer but not necessarily the final user of the product and the consumer is a value receiver in form of the final user. This is also the case in the HDV industry where there are two types of commodity owners. The first category is private importers who buy the products to sell in the market (considered as a customer) and the second category is exact value receivers, who buy the product via dealerships (considered as a consumer). Being aware of the difference between consumer and customer concepts, a short chain is considered for heavy-duty truck automotive industry including supplier, manufacturer, and end-user.

LITERATURE REVIEW

According to Christopher et. al.(2003), increasing trend of globalization causes tough competition in the market. As parallel with competition, product variety and attention for customer-adapted products increase while product life cycle decreases. Companies come across new challenges and they need to be more flexible while reacting to changes in market. Customers have great impact on today's business market. The alteration in customer demand brings complexity and extra costs to the supply chain. This means that firms need to increase their investments for satisfying the needs of customers, create value for the customers and gain competitive advantage in the market (IBM Corporation, 2004).

The need for customer-oriented structures may be considered as a starting point for a big shift from SCM to DCM. During this change, companies should catch the continuous trend to improve responsiveness and meet specific needs of customers. At the same time, companies are able to achieve cost-efficiency (Christopher et. al., 2006). It is the right time to change strategy and create specialized demand-supply chain models, which are fast, reactive, and designed to meet all customer demands in order to stay competitive. Porter (1996) argued that companies have some problems during alteration process of their strategies. The failures occur in distinguishing between operational effectiveness and strategy. Hilletofth et al. (2009) argues that by developing a supply chain strategy, which is based upon differentiation, is the way to meet varying needs of customers and maintain economies of scale at the same time. Some deductions can be mentioned such as, in order to gain competitive advantage, companies should get a deep understanding of which components should be rearranged in current business environments. It is obvious that changed market environment asks companies for an appropriate strategy in order to find its' own market niche and stay competitive.

When we come to CSFs, it is a crucial activity to define CSFs because they help companies achieving their missions and strategic goals of the organization. Some success factors can be obvious while others invisible. There exists many different definitions for CSFs. Bullen et. al. (1981) mentioned CSFs as not overwhelming in numbers but players of a significant role in the success of an individual, group or organization in a competitive environment. CSF detects performance areas, where managers must continually manage, and the issues, which provide a healthy and vital environment for the organization. CSFs are described as the most important components of strategy implementation. Brotherton et. al. (1996), see CSFs as the vital points that the company must reach or focus on which areas will bring the maximum "competitive leverage". It is very common that CSF are confused with strategic goals, and to avoid this confusion. Brotherton et. al. (1996) emphasize that CSFs are not equal to goals, but they are more related to activities and performing processes that can be administered/affected by managers to achieve goals of the company. Based on the best practices in the market, it is suggested that there should be limited number of CSF, perhaps between five and eight (Parmenter, 2007). Definitions provided by earlier researches have one common feature – they emphasize obtaining a competitive edge.

As Parmenter (2007) pointed out, the need of an organization is to define KPIs in order to focus on aspects, which are the most crucial for the current and further success of the company. Any business, regardless of industry and size, can better manage market

performance with the help of performance measurement metrics (Parmenter, 2007). Bauer (2004) stated KPIs are quantifiable metrics, which reflect the performance of the organization while reaching its goals and objectives. Companies should identify KPIs in the light of CSFs and strategic objectives in order to link actual performance and expected results to CSFs. As Parmenter (2007) argued that KPI should be related to the organization's CSF and objectives to be called as a performance measurement tool. After identification of the right CSFs, it is easy to define KPIs, just because of the reason that they will exist within chosen CSFs. Furthermore; Bauer (2004) adds that all individuals involved in the business processes of organization are moving in the same direction of achieving the same goals and strategies.

Today, due to strong competition, globalization and technology development, firms have no choice but to operate in a changing environment, which leads to dealing with plenty of different performance indicators. This resulted in development of different methods of setting up and prioritizing KPIs. The questions about KPI prioritization and the number of KPIs are the most popular ones in the literature. There should be a limitation on the number of KPIs. No more than 20 KPIs are recommended. Organizations, which have more than 20 KPIs, lack focus and do less than expected (Kaplan & Norton, 1996; Parmenter, 2007). While prioritizing KPIs, it is important to remember that KPIs for a company may differ depending on the nature of the business and its strategy. Nevertheless, literature review suggests that the standardized method is missing for KPI prioritization.

Consumer-driven enterprises must continuously enhance value for a customer by developing value-adding products and services to gain competitive advantage (Hilletofth et al., 2009). Furthermore, selected KPIs may give an idea to customers about companies' way of doing their jobs in order to improve customer service level by increasing value added activities.

METHODOLOGY

A framework for KPI selection in HDV industry was developed to provide in-depth understanding of how the most effective KPIs can be selected from a consumer-driven point of view. The objective is to show the relations between CSFs and KPIs to establish a framework rather than doing any numerical analysis of these concepts.

A stepwise procedure was used from mission statements to KPI selection. In the first step, a sample of mission and vision statements from some companies operating in the HDV industry (Table 1), have been evaluated to provide a foundation for the specification of CSFs in this industry. Some common points between these evaluated statements were found, including value creation according to customers' needs, long-lasting occurrence in the market, innovativeness, and product and service excellence. It is important to note that, mission and vision statements are not enough by themselves for developing CSFs. There are other variables that also affect the characteristics of CSFs.

In the second step, CSFs of a consumer-oriented enterprise in the HDV industry were specified based on the evaluation of mission and vision statements as well as a wide range of literature (Table 2). It can be mentioned that some of the CSFs focus on the customer side (target to achieve missions on customer side), such as responsiveness in new product

development (NPD), speeding up to deliver innovation to the market, developing marketing channels, improving product delivery processes, value creation activities, and increasing level of information sharing with customers. On the other hand, some of the CSFs focus on the company side (target to achieve missions inside company) and are not directly related to customer operations, such as continuous coordination between departments.

In the third step, a CSF characteristics table has been designed (Table 3), including aspects such as requirements, benefits, risk, and limitation of a consumer-oriented enterprise. In essence, this table provides in-depth analysis of the selected CSFs. This analysis has crucial importance, since companies should be aware of that they have proper environment for making strategic decisions.

Table 1: Sample Vision and Mission Statements.

Company	**Vision**	**Mission**
Volvo	To be valued as the world's leading supplier of commercial transport solutions. (Official Website, Accessed: November 2010)	By creating value for our customers, we create value for our shareholders. We use our expertise to create transport-related products and services of superior quality, safety and environmental care for demanding customers in selected segments. We work with energy, passion and respect for the individual. (Official Website, Accessed: November 2010)
Scania	To deliver optimized heavy trucks and buses, engines and services, provide the best total operating economy for our customers, and thereby be the leading company in our industry. (Annual Report, 2009; Accessed: November 2010)	Scania's identity is shaped by its customers and products – vehicles, services and financing – and by the people in the company, their values and working methods. Three core values − "customer first", "respect for the individual" and "quality" − tie the company together and form the basis of Scania's culture, leadership and business success. . (Annual Report, 2009; Accessed: November 2010
Man	To be number one in commercial vehicles and power engineering (Official website, Accessed: November 2010)	The MAN Group places its customers' requirements and expectations at the center of its corporate strategy. Our products and the services that accompany them throughout their entire life cycle are nothing less than high quality. From the very first moment of contact, we respond to our customers' specific requirements and work together with them to create customized solutions. (Official Website, Accessed: November 2010)

Table 2: Modification of critical success factors.

Critical Success Factors	**References**
Responsiveness in new product development in order to achieve competitive advantage - Getting the right product in the right place at the right time - Speeding up to deliver innovation to the market	Childerhouse et.al. (2002), Heikkilä (2002), Jüttner et.al. (2007)
Developing marketing channels that identify specific needs of different customers - Market segmentation - Product and service differentiation	Griffin et al. (1993) , Walters et al. (2004), Al-Mudimigh et.al. (2004), Jüttner et.al. (2006),
Improve product delivery process in full on time to the customers - Increase customer service level	Woodruff (1997), Wang et.al. (2001), Heikkilä (2002), Walters (2008),
Value creation activities at the side of customers that builds loyalty - Customized and innovative products - Brand loyalty - Successful brand image - Value delivery	Treacy et. al. (1993), Mazumdar (1993), Delgado-Ballester et. al. (2000), Walker et. al. (2000), Kumar et. al. (2000),
Increasing level of information sharing with customers - Open communication	Burns (1995), Fundin (2003), Oleksak (2005)
Continuous coordination between departments - Internally - Externally	Dyer et al. (1998), Lambert et. al. (2000), Simatupang et al. (2002), Keller (2001)

Table 3: CSF characteristics table.

CSF	Requirement	Benefit	Risk & Limitations	HDV View
1. Responsiveness in new product development in order to achieve competitive advantage	- Flexibility - Being adjustable	- Catching new potential markets	- Market response to the new product - Lack of experience in both new product and new market	- Improving the product families
2.Developing marketing channels that identify specific needs of different customers	- Local resources (i.e. Local employees & consultancy) with the knowledge of the market	- Successful identification different customers' needs	- Adaptation of the partners/ suppliers to the new strategy of marketing channels	- Segmentation of the market, designing different packages
3.Improve product delivery process in full on time to the customers	1. EDI infrastructure to arrange forward an backward relation - Tracking and tracing progress of the process	- Cost reduction: decreasing the rate of inventory and back-ordered sales, to increase customer satisfaction	- Bullwhip effect - Over promising	- Organizing the delivery related interruptions such as campaigns in a structural way in the case of having problems with suppliers
4.Value creation activities in the side of customers that builds loyalty	Proactive markets research and sensibility to the value creation in the whole supply chain	- Customer base less sensitive to the marketing efforts of competitors reinforcing - The brand image and price policy of the product	- Customers uncertainty or ambiguity in the satisfaction of his/her consumption expectations	- Designing packages in for of offering complete solutions including soft offers for services and extra options for each specific fleet costumer
5.Increasing level of information sharing with customers	- Transparency and systematic information flow	- Faster decision making based on updated facts	- Leakage of information to the competitors/internal and external - Attitude towards sharing information	- Same systems authorization for both costumers and the company
6.Continuous coordination between departments	- Cross-functional integration of departments - A qualified information-sharing system to share required information	- Maximize the potential for converting competitive advantage into profitability - Better technical quality, faster schedule	- Confusion in different role descriptions - Pro-long the project time	- Face to face meetings and updates - Sharing positive results visually in the meeting points of the departments - Planning common activities

In the fourth step, a KPI pool was established. 42 different KPIs were selected based on a wide range of literature (McKinnon et al. 2006; McKinnon 2007; Report: ISA 95, 2006) and own experience. We desired to establish a comprehensive KPI pool, because an industrial firm has a complicated structure and there are many processes. Companies should be able to see different perspectives of these processes and they should be able to make detailed performance analysis. The selected KPIs can be seen in Table 4.

In the last step of the procedure, a KPI value table has been developed (Table 4). In this table each KPI is analyzed according to its correspondence with the selected CSFs in order to identify relevant KPI-CSF pair. In addition, the set of departments that play an important role in integration between the company and its customers is specified. It is important to mention that each department in a company has unique responsibilities and they are indispensable parts of the company. However, some of them have great importance to establish a relationship between company's side and consumer's side. Specification of the departments is a requirement to provide a better understanding while implementing KPIs on the operational level in a consumer-oriented enterprise. This because departments are responsible to implement CSFs and KPIs into the company's processes and the same departments are also responsible to measure the efficiency of KPIs during processes. During selection process of the most important KPIs an empty cell implies that no connection or relation between the KPI and the CSF was found. If they are related, the cell is said to be *tagged* and it contains the list of involved departments. For each KPI-CSF pair, one or more departments have been assigned. The departments considered are as follows: After sales (AS), Business solutions (BS), Logistics (L), Marketing (M), Product development (PD), Sales (S), and Quality (Q)

Table 4: Key performance indicator value table.

KPI	CSF 1	CSF 2	CSF 3	CSF 4	CSF 5	CSF 6
1.Vehicle Fill	PD			PD		
2.Empty running						
3.Fuel consumption				PD		
4. Vehicle time utilization						
5. Reject or return rate on finished products (quality)				AS/Q	AS	AS/Q
6. Actual versus planned volume (order fulfillment)		M/S	S/L	BS/M/L	L	
7. Percentage reduction in the manufacturing cycle time (planning and productivity)	PD		PD/L	PD		PD
8. Production and manufacturing schedule adherence			PD/L	PD		PD/M/S/L
9. Rework and repair hours cost comparing to direct manufacturing (quality)					AS	PD/AS/Q
10. Percentage of the automated assembly steps (engineering and Productivity)	PD		PD/L			PD
11. Hours lost due to technical equipment problem or downtime (assets utilization)			Q			Q/L
12. Hours lost ratio due to material or missing parts (assets utilization)	PD/Q					PD/Q/S
13. Production equipment set-up or availability time and uptime (manufacturing)						
14. Average machine availability rate or machine up-time (asset utilization and manufacturing)						
15. Reject-rate reduction (quality)			L	Q/AS	AS	AS/Q/L
16. Number of process changes per operation due to errors (quality)	PD/Q					PD/Q
17. Percentage increase in output per employee (personnel and staff)			PD			PD/S
18. Percentage unplanned overtime (personnel and staff)			PD			PD/S
19. Safety and security incidents (personnel and						
20. Productivity based on the number of units per labor hour (productivity)			L	PD		PD/L
21. Cost of supplier shortages per period (material and supplier)	Q/PD		PD/Q/L			PD/Q/L/S

22. Variances of the material from standard units for Non-standard vehicles (material and supplier)	PD/BS	M/BS		M/BS	S	S/M/BS
23. Standard order-to-shipment lead time for major products (planning)		M	L	PD/M/L	S/L	PD/M/L
24. Time required to incorporate engineering changes (planning)	PD					S/M/PD
25. Turn around time						
26. Average carbon dioxide emissions of vehicles by its type (environment)	PD	M		PD/BS/S/M		
27. Number of visits of the costumer per month to service centers for repairs: (after market)		M	M	AS/BS	AS	AS/M
28. Parts availability at the service centers (after market)			L	AS/L	AS	L/AS
29. Average production costs of units produced within measurement period.				L/M/PD/S		
30. Average Unit Cost	PD	M/S		L/S/PD/S	L/M/D/PD	
31. Rate of damaged material by error of workers						PD/Q
32. Customer order cycle time based on time from the request to fulfilling the order	PD	M	L/M	S/L	S/L	S/L/M/PD
33. Order to delivery fulfillment measurement	PD	M	L/M	S/L	S/L/M	S/L/M/PD
34. Accuracy in request delivery date, confirmed delivery date, actual delivery date to be the same	PD	M	L	L/S	S/AS	PD/L/S
35. Supply chain cycle time	PD	M/S	L	M/L/S	M/S	PD/M/S/L
36. Ex-work performance						
37. Accurate information on inventory levels			L	S/M	S	S/M/L
38. Availability of all order classes and augmentations	PD	M		S	S/M	S/M/PD
39. Improved customer satisfaction	BS/PD/Q	M/S	M/L	BS/M/L/AS	S/AS/M	AS/L/M/S
40. Lower distribution costs as a percentage of order management costs		M/L	L	S/L		
41. Decreased transportation cycle time		M/L	L		L	M/L
42. Increasing collaboration between dealers and top management	PD/M	M		M/PD/BS	S	PD/BS/S/M

RESULTS & ANALYSIS

As a result of the KPI value table, 17 *tagged* KPIs out of 42 KPIs were identified as the most valuable and measurable guidelines, that can respond to the customers' demands and interests within the HDV Industry on the operational and strategic level. Selection was made between KPIs, which have 6, 5, and 4-tagged cells (Table 5) and they were divided into 3 groups according to number of tagged cells.

Selected KPIs can specifically be used for this industry to meet consumer demands and satisfy their needs. The core expectations of the selected KPIs should stay aligned to help the managers of the companies in the strategic, operational and tactical decision making processes to gain benefits and reach the position of a high performance organization. They can establish a guideline for the enterprises, which desire to become more consumer-driven.

The benefits of selected KPIs can be evaluated from different aspects. These KPIs provide holistic view on the whole demand chain, adaption to consumer-driven philosophy, and

monitoring suppliers in terms of its quality, capability, credibility. The question of what they have in common can be a guideline for the enterprises to become more consumer-driven based on the shifts in the market. There will be made an analysis in the following parts for selected KPIs and excluded KPIs with various reasons.

Table 5: Selected and excluded KPIs.

KPI	6 tags	5 tags	4 tags	Excluded
1.Vehicle Fill				
2.Empty running				X
3.Fuel consumption				
4. Vehicle time utilization				X
5. Reject or return rate on finished products				
6. Actual versus planned volume			X	
7. Percentage reduction in the manufacturing cycle time			X	
8. Production and Manufacturing schedule adherence				
9. Rework and repair hours cost comparing to direct manufacturing				
10. Percentage of the automated assembly steps				
11. Hours lost due to technical equipment problem or downtime				
12. Hours lost ratio due to material or missing parts				
13. Production equipment set-up or availability time and uptime				X
14. Average machine availability rate or machine up-time				X
15. Reject-rate reduction			X	
16. Number of process changes per operation due to errors				
17. Percentage increase in output per employee				
18. Percentage unplanned overtime				
19. Safety and Security incidents				X
20. Productivity based on the number of units per labor hour				
21. Cost of supplier shortages per period				
22. Variances of the material from standard units		X		
23. Standard order-to-shipment lead time for major products		X		
24. Time required to incorporate engineering changes				
25. Turn around time				X
26. Average carbon dioxide emissions of vehicles by its type				
27. Number of visits per month to service centers for repairs		X		
28. Parts availability at the service centers			X	
29. Average production costs of units produced				
30. Average Unit Cost			X	X
31. Rate of damaged material by error of workers				
32. Customer order cycle time	X			
33. Order to delivery fulfillment measurement	X			
34. Accuracy in delivery date	X			
35. Supply chain cycle time	X			
36. Ex-work performance				
37. Accurate information on inventory levels			X	
38. Availability of all order classes and augmentations		X		
39. Improved customer satisfaction	X			
40. Lower distribution costs as a percentage of order costs				
41. Decreased transportation cycle time			X	
42. Increasing collaboration between dealers and top management		X		

The benefits of using the most prioritized KPIs, which have 6 tagged cells, can be put in an order like that gaining a point of view for holistic planning across the chain, adapting consumer-driven philosophy and following its progress internally and externally, monitoring INCOTERMS, suppliers performance, capability, credibility and providing commitment to them in order to be in the same level with the company. Companies should fulfill the requirements of this tough competition to be alive in the market. Level of competition, potential entrants of the market, and changes occurred in customers' needs due to dynamic market conditions are some points that companies take into the consideration.

The second groups of KPI, which have 5-tagged cells, highlight the importance of variation of offers and availability of the services and/or products for customers at right place on the right time. In addition the technological knowledge and innovation will be adding extra value to the variety and quality of the products/services. However, service-minded and reflecting stuff for planning in all levels (from top manager to the technicians) is also evaluated to affect the business.

The third group of KPIs helps empowering the time and price management in sub-categories. Also, they help having accurate and better mechanisms of controlling in planning, cost and time reductions and finding new saving ways (methods), which will lead into improvement of internal manufacturing processes. In addition, the future performance can be improved by using standardized and compiled past data

The last group of KPIs are excluded KPIs. Some KPIs, which are related to the employment conditions and regulations such as safety and security incidents and ex-work performance, might be important in majority of countries, but it is not in focused in the rest of the countries at the same level, therefore the related KPI has not been valued as a relevant option. Consumers' ways of dealing with the products after buying them and the usage purpose of those products have been considered as an external affect in this article. The manufacturing set-up times, machine availability rates, equipment usages and asset utilization may affect the cost indirectly in the matter of process development, but is not having high priority from costumer point of view and for customer satisfaction. For sure, all the aspects have important role in the business' processes but they are not directly related to processes, which are achieved especially for turning the company to more consumer-driven structure. To be mentioned that external activities done by customer and transport companies are out of the short chain that we had defined in the framework of this study.

CONCLUDING DISCUSSION

The critical point is to be able to move on the right path, which helps finding the most efficient KPIs. This study shows that there is a strong correlation and harmony between mission, strategic goals, CSFs and KPIs. In order to develop a consumer-driven structure, all components of the company such as mission and vision statements, strategic goals and objectives, CSFs and KPIs should focus on the same idea. Especially the departments should implement the selected KPIs strictly and also they should measure the current performance periodically. In the light of selected KPIs, companies should be able to satisfy customers' needs with the right product and services at the right time, and adapt themselves to rapid

changes in customer demands. Also they should perform value-added activities on the products with the help of technological knowledge and innovative ideas. In addition, the selected KPIs enable having more accurate control mechanisms in terms of cost and time reductions. Competitiveness is another critical aspect for the companies. The selected KPIs help specifying market opportunities and changes in customer preferences due to market trends in the middle of tough competition. Companies also should keep volatile and fluctuated customer demand in mind. In addition, the updated technological knowledge and innovation will be adding an extra value to the variety of the product range. Additional benefits of the selected KPIs such as providing effective control on accuracy in planning, reductions in cost and time and finding potentials saving areas which will lead to improvement of internal manufacturing processes. It is important to note that the KPIs should be repeatedly measured and their periodical analysis should be done to evaluate the progress of activities, which are executed for customer orientation and satisfaction.

Implication of the research can be grouped under three points such as theoretical implications, practical implications and suggestions for further researches. From theoretical point-of-view, this research targets to fill the gap of knowledge about the development of effective KPIs. Also, this research proposed a guideline with exciting findings relating consumer-oriented CSFs with effective KPIs. From practical dimension, the findings can be applied in the strategic, tactical, and operational planning level of a company to gain the competitive advantage in the market. The proposed framework can provide useful and innovative ideas for the strategic decisions inside the company, e.g., in the new product development and soft offers designing. Also, for decreasing the risk rate involved in the goal setting process, KPI prioritization should be seen from a multi-criteria decision making perspective.

For further research, more detailed investigations can be prepared for the different KPIs with different units and scales. Developing various questionnaires and distributing them among consumers may accomplish this aspect. Some tools for examining and testing the efficiency of KPIs have been proposed in the literature and these could be suggested as further research topics. Analytical Hierarchy Process (AHP) is a powerful tool for decision-making (Saaty, 1980) and, thus may be used in the process of prioritizing KPIs. Furthermore, SMART criteria (Significant, Meaningful, Appropriate, Relevant and Time-bound) are widely used for evaluating objectives and goals of the firm.

ABSTRACT

According to ISO ISO9001 version 2000 requirement 8 were released methods of analysis to general production and design manufacturing. This work has design to carry out the performance and benefit of R&D in point of financial index on new product to end customer.

It is 4 parameters under Balance Scorecard Concepts in this study; financial perspective, customer perspective, internal process perspective, and innovation and learning perspective. Those parameters have look in single point of view with no inter linkage. Normally, most the top managements have relied on financial data or cost and benefit issues to monitor and control the business with less consideration of other factors such customer analysis, internal process, and innovation and learning. It was found crucial factors that able to improve the financial statement of RPP. The results in terms of mathematics index were confirm the believing of management such over time benefit to RPP, labor cost control, and other un-seen factors. It was found the innovation and learning has reflect to company social quality and derived the by positive product of earning before interest and tax (EBIT).

Keywords: balanced scorecard, key performance measurement / time lag analysis / management process / performance improvement, operation management, modeling.

1. INTRODUCTION

Since the earlier of the year 2008, the oil price was increasing sharply (international energy agency - oil market report; 10 July 2008) and direct effect on plastics business. Absolutely, Any Plastic film production affected directly by this phenomenon. Where, the selling price can not much adjust to the end user such packaging provider, card supplier, advertisement business, and others who use a Rigid film as an intermediate. So the role of Key Performance Measurement becomes an important role to monitor and control each of involved facility to; meet the plant optimality; and meet the global customer requirement.

Most organizations now faced on opportunities, threats, and change on an unprecedented scale. Decision making is seen as synonymous with management (Simon, 1977). It affects the actions through the whole operational process and determines the level of management success in any organization (Kurstedt, 1992).

The quality of a decision is based on the experience of the decision maker and supporting information. According to Kaye (1995), a decision is made on the basis of hunch and intuition, but is legitimated by dressing it up with supporting facts and data. Longbottom (1672) and Mintzberg (1976) advocated that effective decision making occurs where managers actively select situations which require decisions and seek information regarding those decisions. Forrester (1961) also suggests that the level of success in decision making primarily depends on information since decision making is the process of converting information into action. Therefore, good information is necessary for decision making. If an organization is to survive and prosper, it must understand both its own internal workings and the nature of the environment to which it has to adapt and respond (Kaye, 1995). Thus, good information should reflect both internal processes and external agencies such as governments, competitors, and social groups.

Refer to Phusavat K. *et al*., (2007), the organization data was study in terms of internal relationship of productivity, quality of work life on each accounting parameter finally the data were kept as a data base to monitoring and control the business. Where, statistics and mathematics were applied. The study is conducted to help address the concern of the company's top management and the FG management team on how to demonstrate their ISO 9001:2000 compliance and TQA commitment. The lessons from the impacts from the existing customers, as well as the potential benefits from new customers, are summarized. The changes in the company paradigm on the roles of the existing customers and its sales workforce have emerged.

Appropriate PM need to be aligned with the organization's strategy. It should lead to attainment of strategic goals and impact on the goals and strategies needed to achieve them (Dixon *et al*., 1990). Among the most popular PM systems is the balanced scorecard (Yeniyurt, 2003). The Balanced Scorecard Concept (BSC), developed by Kaplan and Norton (1996), is a widely used management framework for the measurement of organizational performance which evaluates both financial and non-financial perspectives. It suggests that the state of process of an organization can be best assessed by taking a "balanced" view across a range of performance measures. This paper studies the relationship between financial and customer perspectives as suggested in the BSC in an attempt to provide analyzable information for management to improve the quality of decisions. In this study, the case study business unit is the plastic resin conversion factory which locates in Thailand. This plant may called Rigid Plastic Production Plant or RPP. It's organization is consisted of production, ware house, and logistics department; technical department (R&D); and maintenance department. All departments are under plant manager, general manager, and top management of petrochemical business group.

2. PROBLEM BACKGROUND

There are two critical problems facing the management team at the RPP. The first one is the management want to know how is the time lag effect of new products which derived by R&D department to out put such new revenue from a new customer. Second, the data which related to ISO 9000 version 2000 item 18 does not much fit to a current system. The key performance measurement has done by each department. For example financial

department look at the financial status, human resources management look at working overtime, leave, cost of development. Where those key performance measurement does not represent total company performance. So the RPP managements want to know in depth of the detail to improve the quality objectives. Over the past few years, the term performance-based management has gained more attention among SMEs, manufacturing, trading, and government sectors in Thailand due to the need to comply with Requirement 8 of ISO 9001:2000. This requirement stresses the explicit linkages among performance measurement, analysis and improvement. Complying with this Requirement 8, especially between measurement and analysis, cannot simply be achieved through technical investment alone. It is important to note that the certification of ISO 9001: 2000 is recognized as a necessity for enterprise development, customer acceptance and market access in the globalisation period.

During the time of study, the RPP management givens financial information and R&D information collected by the accounting department and R&D/Production department but they never did analysis for interrelation ship on it. Refer to financial information and R&D data; there are no other intangible factors such as product satisfaction or service quality, customer satisfaction, or employee morale, collected. The lack of information assessment and the failure to collect the information aligned to the organization's goals result in many unsolved strategic problems as mentioned above.

3. OBJECTIVES

The purposes of this study are assess the suitability of information currently collected and used in an organization and assess and evaluate the usefulness of the results of performance analysis in improving the quality of management's decision making. Where the decision make factors have derived from mathematical analysis. This recommendation target to ensure that key performance measurement under internal relationship from balance scorecard method able to illustrated the company figure. The expected impacts from this research are the improvement of the RPP management process and to prepare the the ISO 9001: version 2000 application.

4. METHODOLOGY

It was several steps to execute during this study. The first important step is to determine the possibility of completing the management process as stated and required by ISO 9001:2000. It can be described as follows.

4.1 Grouping and rearranging the existing Key Performance Indicators (KPIs) into Balanced Scorecard (BSC) framework.
4.2 Identify the information to be tested.
4.3 Collect information from the RPP.
4.4 Examine and establish the possible relationships between the financial, R&D, and the customer perspectives information.
4.5 Analyze the appropriateness of the information based on the examining results together with R&D section manager.

4.6 If the information is inappropriate; establish a new set of performance metrics to be measured based on the BSC.

4.7 Interview the management team at RPP to assess the usefulness of the analysis results and the new set of performance metrics in terms of the attempt to improve the management's decision making process.

4.8 Report the results in written literature.

4.9 Release methods of analysis to RPP to use in further as a requirement of ISO9001:2000 requirement 8.

RESULTS AND DISCUSSION

Refer to methodologies of regression, Table 1 represent for given financial data, customer issues, internal process, innovation and learning. It was selected to plot in single and multiple model. Where, Table 2 is a result for simple regression model, Table 3 for polynomial regression model, and Table 4 for multiple regression model. To study time lag effect the statistics and mathematics is required. Thus, the agreed conditions for an model's development are identified and finalised together with the RPP management team. A selected model is based on p-value < 0.3, Adj-R2 > 70% and VIF < 5.0 (for a multiple regression model). The variance inflation factor (VIF) is used to detect whether one predictor has a strong linear association with the remaining predictors (the presence of multicollinearity among the predictors). VIF measures how much the variance of an estimated regression coefficient increases if predictors are correlated (multicollinear).

Table 1: The common KPIs data collection based on Balanced Scorecard.

Financial	*Customer*	*Internal Processes*	*Innovation and Learning*
F1 = Interest per man-day cost (Baht/Baht)	C1=New customer per total customers (%) (Based on 100 number of December 2007)	IP1 = On time sample delivery (%)	IL1 = R&D cost per new products order intake (Baht/Baht)
F2 = Revenue per trial order (Baht/Baht)	C2 = Claim per total claim of each year (%)	IP2 = Output per head (Tons/head)	IL2 = Bonus per salary (%)
F3 = EBIT per number of R&D staffs (Baht/head)	C3 = Number of customer complaint per month (Time/Month)	IP3 Product quantity (tons)	IL3 = Over time per salary (%)
F4 = Revenues from new product per total revenue (%)	C4. Successful order (Approved Art Work) per total order (%)	IP4 = Labor cost (Baht/Kilogram)	IL4 = Welfare per salary (%)
F5 = Revenue per raw material cost (Baht/Baht)		IP5. Labor Cost per production output (Baht/Kilogram)	IL5. Marketing expense per customer (Baht/customer)
		IP6 = Yield (%)	IL6. Investment in new product per R&D staff (Baht/head)
			IL7 = Employee training cost per number of employee (Baht/head)

Note : 35 Baht is approximately equivalent to 1USD.

Table 5: The results from the simple regression model.

	Relationship	p-value	Adj-R2 (%)
F1	487 - 20.1 IP4	0.000	79.7%
F2	2119 - 20.02 IP1	0.000	70.0%
F3	252.5 - 39.70 IP5	0.000	70.5%
F5	2016 - 47.38 IP5	0.000	71.4%

As a results from Table 5, the RPP R&D management need to see in case of this study is the finance perspective F4 (Revenues from new product per total revenue (%)) and IL1 (R&D cost per new products order intake (Baht/Baht)). This preferred relationship will answer the top management of RPP for the return of investment on R&D cost for new products. However, it did not found any relationship between these expected two parameters.

Table 6: The results from polynomial regression model.

	Relationship	p-value	Adj-R^2 (%)
F1	677.5 - 47.32 IP4 + 0.954 $IP4^2$	0.000	79.5%
F1*	397.5 - 29.15 IP5* + 0.8765 $IP5*^2$	0.001	74.4%
F2*	8823 - 194.7 IP1* + 1.090 $IP1*^2$	0.000	81.8%
F3*	- 224.4 + 44.06 IP5* - 3.275 $IP5*^2$	0.000	71.4%
IP1*	91.36 + 378.8 IL3* - 4586 $IL3*^2$	0.000	94.6%

Note : * Meant the data is account only in fiscal year 2008 for none * mean the data from fiscal year 2007 and 2008 was accounted in regression.

Refer to Table 6 the results from polynomial regression; it was found that IP4 has effect on F1 at significance level. IP4 has the average points during 11-14 Baht/Kg. As per discussion with the management of RPP, the F1 that the RPP need is the lower the better to operate this kind of business where the IP4 has to concerns at the optimum point. For this case it hard to point out which is the optimal point for F1 and IP4 on operation. The higher IP4 the lower F1, where IP4 can not go at thigh value due to it will effect on products base price.

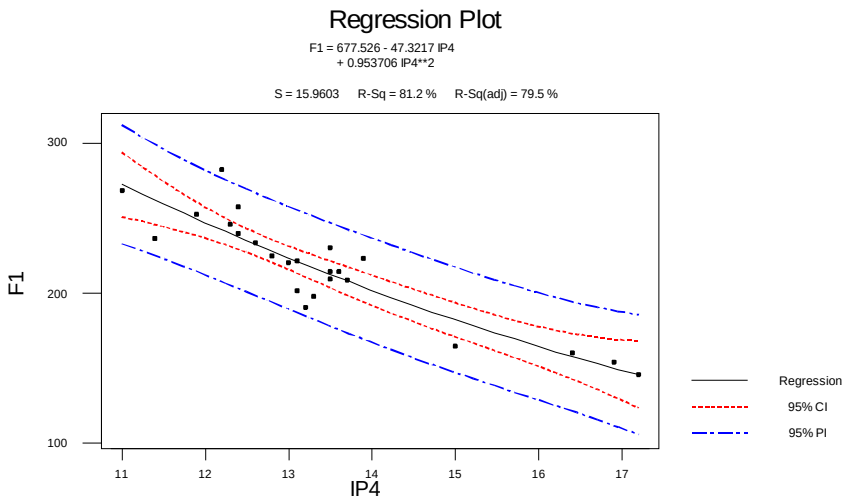

Figure 8 Regression plot IP1 and F1 for polynomial model

So for this case, the management did agreement to do so the operation point must control during 11-14 for IP4, while accepted F1 is ranging from 200-300 Baht/Baht. According to polynomial regression model between IP5 and F1, it was found the bottom of polynomial plot for IP5 value at 17 Baht/Kg and F1 at 155.26 Baht/Baht. This bottom point is mean if the IP5 value going high than 17 Baht/Kg, the production yield is going worse due to production output less production manager expectation, design value is ranging from 11-17 Baht. For financial perspective F1, the interest rate for capital investment, the management needs to minimize this value as much as possible. However, it related direct to labor cost and production cost for RAW material, the accounting system of RPP is account all cost for production to be terms of loan. So the interest rate has involved in every unit that able to count for money. Refer to Figure 9, the F1 touch down at the bottom line at 155.26 which can not reduce any more in term of cost-saving for interest rate.

Refer to Table 6, it was found the relationship between IP1 (On time sample delivery (%)) has influent on F2 (Revenue per trial order (Baht/Baht)). The polynomial model for IP1 and F2 is representing for the bottom line of operation figure. The relationship between IP1 and F2 is also representing for the success of R&D to effort the company income. The RPP top management is prefer to see the value of F2 as much as possible. F2 will reflect to revenue of the factory each of period during new released products from R&D sector. Refer to Figure 10, it was found that fast response does not mean higher in revenue but it is mean fast in customer response for secured order.

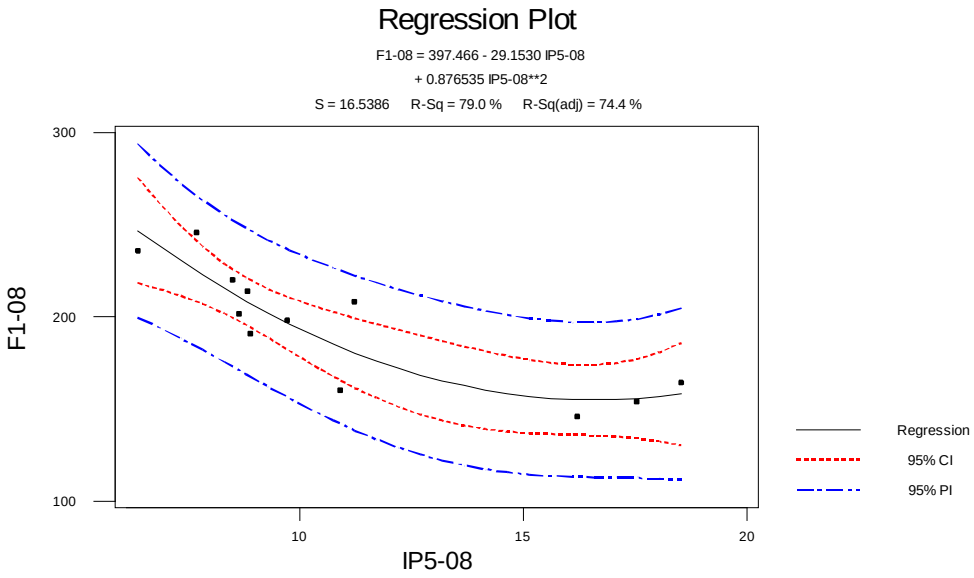

Figure 9: Regression plot IP5-08 and F1-08 for polynomial model.

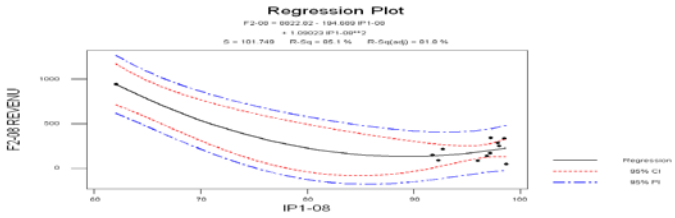

Figure 10: Regression plot IP1-08 and F2-08 for polynomial model.

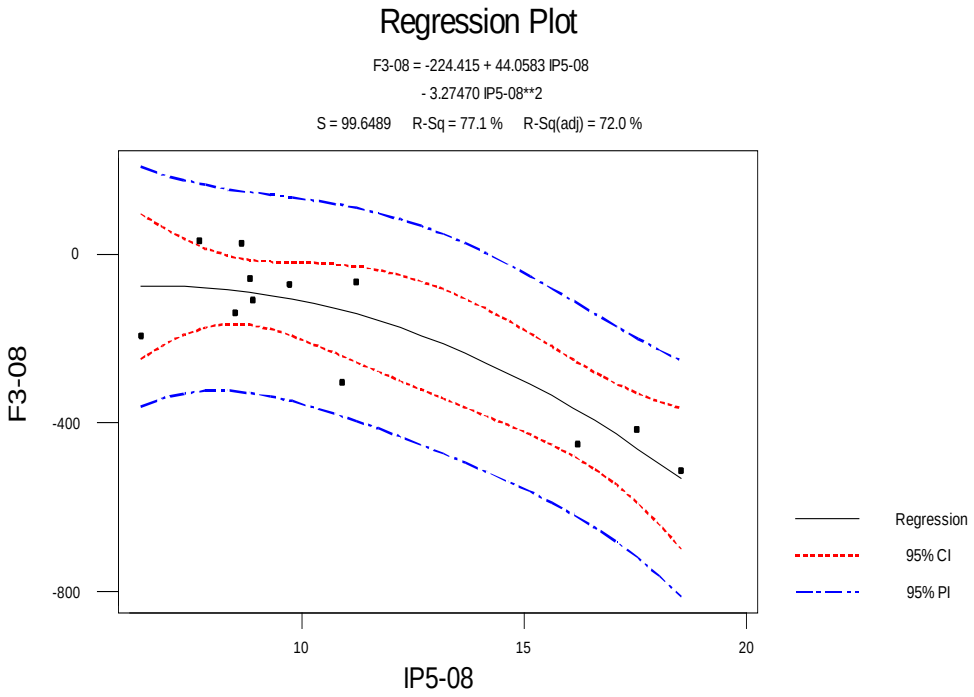
On the other hand the higher revenue F2 in Figure 10 was derived from a complicated formulation product which has large quantity of order from end customers. The response time for the complicated product leads R&D sample preparation officer did slow in sample preparation. A new sample request from end customer need to re-formulation and test for physical properties based on end customer requirement. Several trial orders have to given up due to the complicate of the formula and the specifications are not meet the requirement.

Refer to financial perspective; the EBIT is the most important for business operation. According to polynomial plot model between F3 (EBIT per number of R&D staffs (Baht/head)) and IP5 (Labor Cost per production output (Baht/Kilogram)) for the plot, it was fitted based on division criteria only for the data which done during fiscal year 2008. During fiscal year 2008, world economic was under crisis which derived from the United State of America sub-prime problem. The sub-prime problem was effected directly to Thai economic with out any abstain.

For the period fiscal year 2008, RPP EBIT is a bit higher or less than zero which mean the company getting worse from the economic situation. IP5-08 in any value cannot fulfill the company profit F3-08. However, refer to Figure 11 the best way to maintain the business profit to minimize lost in EBIT; the production section has to produce more goods at

maximum capacity, where the IP5-08 region is around 7-10 Baht/Kg. It is possible to monitor and control IP5 to let F3 on positive value. Figure 12 is representative for successful IP5 control to let F3 getting positive value. Figure 12 is point for the region that monitored IP5 to support F3 to get positive

Figure 11: Regression plot IP5-08 and F3-08 for polynomial model during year 2008.



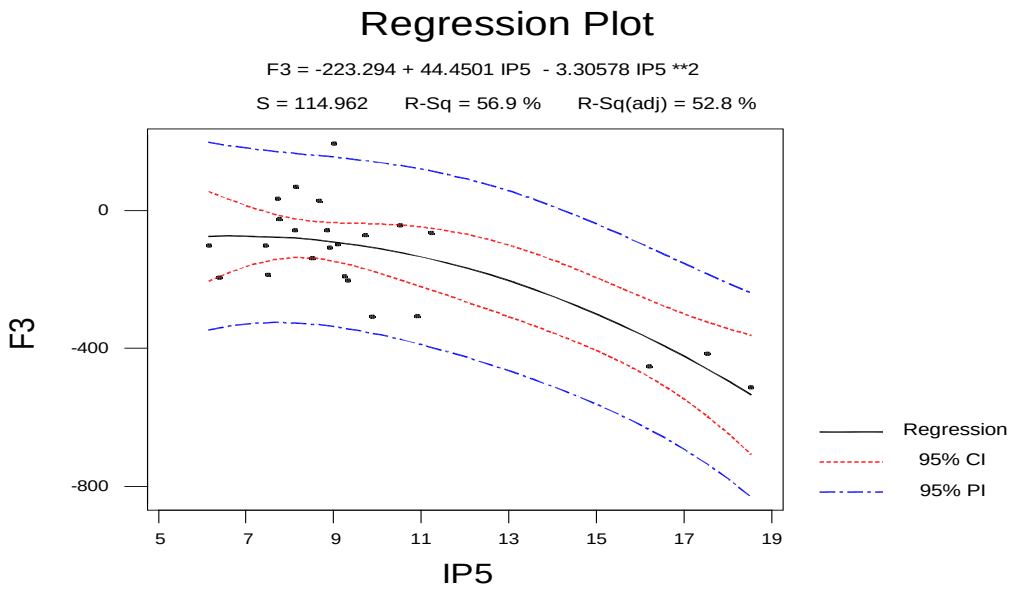


Figure 12: Regression plot between IP5 and F3 for polynomial model during year 2007-2008.

The optimal values are ranging from 7-9 for IP5 to let F3 to be in positive value. However, Figure 12 is un-qualified model based on model selective criterion. So the Figure 12 is use only for monitoring only. Refer to Table 6 it was also found the relationship between IL3 (Over time per salary (%)) and IP1 (On time sample delivery (%)). Working overtime is not preferred too much from the top management of RPP except the order that has large quantity and quality guarantee of products are committed to customers. According to polynomial model plot between IL3 and IP1 for fiscal year 2008, it was carried out for maximum IP1-08 at 99.20% where IL3-08 is at 0.04. As a result, the over time is no need to apply for the response of customer on time delivery. Even though the operator work only standard working hour (12 hours/shift), IP1 at 91.35% is still accepted by the management of RPP. This result is support to a real working life. At RPP, the employee for production line is work for 8 hours standard with special additional 4 hours for extra wages. So that max capability of workers was completely included for productivity. The data from IL3-08 is included for office employee overtime wage. The normal office hour for office worker (white collar) is standard 8 hours which starting from 8:00 to 17:00 in the evening. Refer to Figure 3, the optimal over time for white collar worker is no more than 4% of 8 hours or half an hour/day on average for all employee (265 Man). On the other point of view with multiple regression model results in Table 7. It was found that many parameters which represented in balanced scorecard with combination are reflected to finance perspective. As a result, the combination of IP4 (Labor cost (Baht/Kilogram)) and C2 (Claim per total claim of each year (%)) is play the important role for F1 (Interest per man-day cost (Baht/Baht)). The model F1 = 486 + 0.016C2 - 20.1IP4, means the increasing of IP4 where C2 is constant. It makes F1 decreasing significantly. While IP4 is constant, the increasing of C2 is not much effect on F1. In actual the increasing of C2 will effect to customer trust or the quality of goods. This result agrees with simple regression between IP4 and F1, where the increasing of IP4 is converse to F1 value.

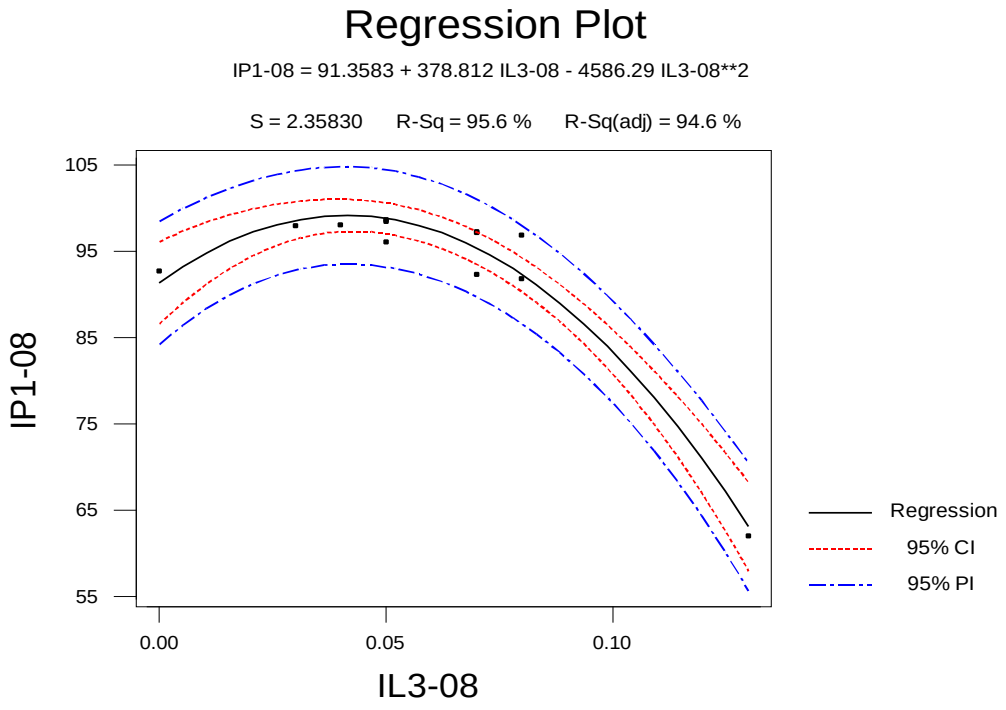

Figure 13: Regression plot between IL3-08 and IP1-08 for polynomial model during year 2008.

The combination between IP1 and IP4 is also effect on F1 value, model F1=507 - 0.270IP1 – 19.8IP4. Where the increasing of IP4 and IP1 lead to decreasing in F1, while IP4 has more important effect than increasing of IP1 in value. To consider the combination between IP3 (Product quantity (tons)) and IP4, the increasing of IP3 leads to increasing of F1 in contrast with the increasing of IP4. In fact the more products output mean the more capital cost that RPP has invest in raw material, so the production output is accounted in terms of interest rate expense together. See IP4 (Labor cost (Baht/Kilogram)) and IP5 (Labor Cost per production output (Baht/Kilogram)) combination, the increasing of IP4 and IP5 lead F1 to deduct in value. IP4 is normally fixes for all operation year but the IP5 is varied by the production output tons/month. It is representing to the management of RPP for 'to control the interest rate effect the output has to maintain at a high level as much as possible'. High production output is induce IP5 lowering in value and leads the F1 lower based on the relation accordingly. Similar IP4 (Labor cost (Baht/Kilogram)) and IP6 (Yield (%)) combination is effect on F1 at the same trend.

Table 7: The results from the multiple regression model for F1 group.

	Relationship	p-value	Adj-R2 (%)

F1*	457 - 17.9 IP4* - 0.000436IL6*	0.000	91.2%
F1*	428 - 16.6IP4*+ 0.046IL7*	0.000	84.7%

Note : * Meant the data is account only in fiscal year 2008 for none * mean the data from fiscal year 2007 and 2008 was accounted in regression.

The increasing of IP4 and IP6 leads F1 to reducing in its value. Where increasing of IP4 has higher effect than increasing of IP6 about 4 times/unit. Refer to simple regression model and polynomial regression model, IP6 is not present for any internal relation to the financial perspective, but for the multiple regression model products yield has relative important to financial interest. Higher yield mean higher in good product output from processing unit, it is make production line do optimum cost based on financial designed (labor cost/kg), the

loss in energy, labor, time, and material are minimized. Thus the interest cost (F1) by accounting calculation for loss in capital cost has minimized at the same time.

Innovation and learning perspective has effect to F1 as it represent in Table 7. where the combination of IP4 is involved. As a results, IL1 (R&D cost per new products order intake (Baht/Baht)), IL4 (Welfare per salary (%)), IL5 (Marketing expense per customer (Baht/customer)) and IL6 (Marketing expense per customer (Baht/customer)) lead the result in reducing of F1 in value, when it is increasing in value. However, the number of IL5 and IL6 can be negligible due to the multiplier is small in number. In contrast with the combination between IP4 and IL2 (Bonus per salary (%)), IL3 (Over time per salary (%)), and IL7 (Employee training cost per number of employee (Baht/head)) effect on F1, it given the positive results to F1. The most effect that given the F1 in positive value are IL2 and IL3. As usual on accounting system IL2 and IL3 have accounted for expense. So some interest rate has applied to IL2 and IL3. In this moment, the new data that keep during fiscal year 2008 has play some effect to financial perspective. Therefore, to monitor and control for F1 innovation and learning perspective able to adjust F1 in some degree. Where the RPP management has to use those new parameters from innovation and learning to adjust the financial perspective (F1) in proper conditions and proper time. The above results for F1, is only guide line for monitoring and control of business direction. In actual it must use together with the management experience to do double check with achieved data and results.

Table 8: The results from the multiple regression model for F2 group.

	Relationship	p-value	Adj-R2 (%)
F2*	1727 - 22.3IP1* + 43.2IP4*	0.000	79.5%
F2*	7921- 22.9IP1* - 59.2IP6*	0.000	72.6%
F2*	2030 - 18.4IP1*- 283 IL1*	0.000	77.9%
F2*	1983 - 17.4IP1* - 0.00470IL6*	0.000	77.9%

Note : * Meant the data is account only in fiscal year 2008 for none * mean the data from fiscal year 2007 and 2008 was accounted in regression.

According to Table 9 it was found the relationship between internal process perspective combination and innovation and learning perspective. The combination which effect to F2 (Revenue per trial order (Baht/Baht)). F2 is the most RPP management need to see for the advantage of new material design from R&D department under cooperative with production department. The models in Table 8 are based founded with IP1 which it has similar trend. The increasing of IP1 (On time sample delivery (%)) make F2 a little deduction in value. IP1 value in decimal increment for all F2 model has play a little role for F2 value. However, in fact if the value of IP1 is less than 50% or 0.5 in model, it is possible to make RPP faced on problem for customer trust. The other internal process effect on F2, it is IP6 (Yield (%)), the increasing of yield deduct the value of F2 maximum at 59.2.

This relationship is not mean the lower yield the better in F2. Production manager are normally concern of percentage of yield (Output good products/Input Raw Material). Higher yield means higher in production out put for good products. Refer to Table 8 it was only found two parameters from innovation and learning, which effect on F2. It is IL1 (R&D cost per new products order intake (Baht/Baht)) and IL2 (Bonus per salary (%)). IL1 is the most effective factor to rise up or rise down the F2 value. In real life if R&D cost going high, it is

absolutely effect on revenues. Where, the trial order cost which is dividend of revenue from total products will going high. Thus the F2 is going small in this case. Effect of IL6 on F2 is completely infinitesimal amount to overall F2 with IP4 combination. IL6 is a representative for new products investment, which means the company concern in innovation point of view.

In the innovation company such software computer, computer hardware, and short life cycle products company; the value of IL6 is crucial important on company revenue. Event the IL6 is trivial factor on F1; the RPP managements are still concern for long term of employee development. Refer to the act of Ministry of Labor and Social Welfare, the training course able to deduct for TAX at 200%. If the accounting system by RPP has changed for employee training expense to employee training income, the IL6 will change F1 on positive site.

Table 9: The results from the multiple regression model for F3 group.

	Relationship	p-value	Adj-R2 (%)
F3*	126 + 16.5C1*- 39.4 IP5*	0.001	71.7%
F3*	123 + 6.94C2* - 33.4IP5*	0.001	75.4%
F3*	811 - 70.8IP4* + 273IL2*	0.001	71.9%
F3*	850 - 66.8IP4* - 12.4IL4*	0.001	74.3%
F3*	3530 - 42.8IP5* - 34.7IP6*	0.002	70.9%
F3*	359 - 43.7IP5* - 1030IL3*	0.002	70.0%

Note : * Meant the data is account only in fiscal year 2008 for none * mean the data from fiscal year 2007 and 2008 was accounted in regression.

According to Table 9, it is representative for interrelationship between BSC parameters on F3 (EBIT per number of R&D staffs (Baht/head)). the combination between C1 New (customer per total customers (%)) and IP5 (Labor Cost per production output (Baht/Kilogram)), C1 is given the positive site on F3, while IP3 is given negative site on F3. C1 is clearly shown that new customer able to enhance RPP revenue significantly. In general, to increase the numbers of new customer products and marketing cost (IL5) have to strongly invest. However, the increasing value of marketing cost will lead interest cost increasing unavoidably. When the RPP managements were consider between C1 and IL5, the decision to make profit to RPP is increasing number of C1 instead of IL5 concerning.

Refer to Table 9 the combination of C2 (Claim per total claim of each year (%)) and IP5 (Labor Cost per production output (Baht/Kilogram)), it is also effect to F3 value. C2 tend to increase the F3 value, in fact it is contra with management feeling, but the model state only in percentage level. C2 is claim in percentage of each month compare to total claim of each year. R&D and production department is not need to re-claim process occurred. Due to, most of customer of RPP locate outside Thailand, if the loss due to re-claim products means the lost of those goods which included labor cost, raw material cost, logistics. To take the goods back to recycle from over sea can not meet the economic cost.

Table 10: Claim summary from RPP, collection from fiscal year 2008.

Technical Claim		Commercial Claim	
Problem	Time	Problem	Time
Thickness	4	Key with wrong price	20
Stick Mark	-	Special Price	-
Black Spot	1	Customer Cancel Tax Invoice	-
Oil Mark	2	Issue Over P/O	-
Color	8	Weight	-
Scratch	-	Communication (Sales & Customer)	7
Snow	1	Delay of Shipment	1
Wrinkle	-	Damaged During Transportation	5
Wavy Edge	3	Loss (Transportation)	1
Fish Can	-	Accident (Transportation)	-
Size	-	Tax Invoice	5
Embossing Shrinkage	-	Other	2
Loss Roll	-		
Vacuum	1		
Heat Shrinkage	2		
Weight	-		
Squareness	-		
Take-Off Mark	3		
Wrong Packing	1		
Static	-		
Lamination	4		
Printing	1		
Other	-		
Total	31	Total	41

Top three of claims are key in wrong price (commercial), miss match color (technical), and communication break down (commercial). Those claim, if it is accounted for value. It is about 20,000,000 Thai Baht. From this study, claim value can reduce under increase training, working more concentrate on each order, and also the managements have to supervise for the important order. On the other hand, IP5 provide the negative site to F3, when its increasing in value. The more products out put in kilogram, the lower IP5 value, then F3 (EBIT) is increase later.

The result from the combination between IP4 (Labor cost (Baht/Kilogram)) and IL2 (Bonus per salary (%)) on F3 is shown that IP4 deduct the value of F3 while IL2 enhance the value of F3. If the labor cost in creasing, absolutely it defect on EBIT due to cost of production or cost of goods sold caused higher in price. Bonus over salary in percentage is able to enhance the value of F3 where that maximum value is 25% or 3 months bonus. It is true that, when the end of each year, the employee normally waiting for bonus which announced by the RPP management. In psychology point of view bonus is motivation tool to enhance the employee morality to make them eager to work, to eager to put the force in their own function, and to put a strong intention of own task. Finally, IL2 is a benefit to RPP in all rounds.

Result for the combination of IP4 and IL4 (Welfare per salary (%)) effect on F3, the result shown that IL4 given the negative value to F3 when its increasing. In RPP accounting system, welfare is the expense or cost of management. So it was effect in negative site for EBIT (F3).

For the IP4, it has a similar result to another combination of BSC parameters that discuss in above.

The result for IP5 (Labor Cost per production output (Baht/Kilogram)) and IP6 (Yield (%)) combination on F3, both IP5 and IP6 given a negative site for F4 when it increasing in number. IP6, increasing only in percentage level which ranging above 90%. Yield (IP6). So to maintain F3 on track, the only IP5 will take in charge for monitoring and control. To control value for IP5, the RPP managements have to minimize IP5 by increasing production output as much as possible.

To analyses the F3 under the effect of IP5 (Labor Cost per production output (Baht/Kilogram)) and IL3 (Over time per salary), it is given the negative trend for increasing both IL3 an IP5 in number. Labor cost which design by RPP management for entire of business year is direct effect to EBIT. Over time is a special labor cost is also effect to EBIT. In this case of combination, the management can do monitoring and control only for control the employee over time to maximize F3 value.

Table 11: The results from the multiple regression model for F5 group.

	Relationship	p-value	Adj-R2 (%)
F5*	2219 - 13.4C3* - 57.1IP5*	0.001	71.6%
F5*	1142 - 2.98C4* + 0.425IP3*	0.002	70.2%
F5*	2085 - 2.53C4* - 35.9IP5*	0.000	79.7%
F5*	2297 - 3.28IP1* - 45.2IP5*	0.002	70.8%
F5*	2267 - 25.5IP4* - 37.7IP5*	0.002	70.0%
F5*	2693 - 85.3IP4* + 326IL2*	0.001	74.2%
F5	2735 - 79.6IP4* - 15.8IL4*	0.000	80.4%
F5	1846 - 41.0IP5* + 1644IL3*	0.001	73.3%
F5	1991 - 41.0IP5* - 5.99IL4*	0.002	70.9%

Note : * Meant the data is account only in fiscal year 2008 for none * mean the data from fiscal year 2007 and 2008 was accounted in regression.

Refer to Table 11, the combination of C3 (Number of customer complaint per month (Time/Month)) and IP5 (Labor Cost per production output (Baht/Kilogram)) given the negative sign on F5 (Revenue per raw material cost (Baht/Baht)). High volume in customer complaint mean lower in income, while the RPP lost in opportunity to make profit from raw material via conversion. Because of during complaint the customer normally suspended the further order.

To consider C4 (Successful order (Approved Art Work) per total order (%)) and IP3 (Product quantity (tons)) combination effect on F5, C4 was given positive sign to F5 in contrast with the increasing of IP3. Similar result when combine C4 and IP5 (Marketing expense per customer (Baht/customer)) , C4 was given negative result. However, IP5 is given enormous negative sign for F5. This relationship let RPP acknowledgement that, the cost which invest on marketing issue will proportional deduct the revenue from raw material (F5).

The effect of combination between IP1(On time sample delivery (%)) and IP5 (Labor Cost per production output (Baht/Kilogram)) on F5 have provide negative side, when both IP1 and IP5 increasing its own value. The most effect on F5 is IP5. This case, it is normal analysis

cause and effect for finished goods production and selling. The combination model of regression between IP1 and IP5 has similar result as the combination of IP4 and IP5. It given the negative site to F5, IP4 is main cause for IP5. IP5 is the parameter which, divided by output of products (kg). So the result is similar to IP4, but depend on the products output of each month that RPP can produce.

Refer to the multiple regression model F5 = 2693 - 85.3 IP4* + 326IL2*, IP4 given the negative side to F5, in contrast with IL2 (Bonus per salary (%)) provide the positive side to F5 when both increasing in its own value. This is mean, the revenue from raw material able to to increase by gain up of IL2. However, the IL2 will effect to interest rate of RPP. So the IL2, control schematic has to consider with interest expense together.

When the combination between IP4 and IL4 (Welfare per salary (%)) took place IL2, IL4 was given the negative side to F5 at some degree. However, the increasing of IL4 has given maximum positive to F5 at 15.8 Unit. Welfare able to improve quality of employee working life, its made morality of employee come better. IP4 and IL4 regression model on F5, has similar trend as the combination of IP5 and IL4. IP5 is derivative of IL4, where production output was accounted for.

See the IP5 and IL3 (Over time per salary (%)) combination multiple regression model, when the value of IP5 and IL3 increasing, IP5 deduct on F5 value while IL3 enhancing F5 value. So that, the over time able to increasing, revenue from raw material as usual. However, overtime working has limitation at maximum IL3 value at 1 (100%). This result is going as the similar way as polynomial model plot between IP1 and IL3, where IL3 is complete at maximum consideration 100%. Overtime is a major policy that RPP management command to production employee to do. So this relationship, the only IP5, can do only parameter to control to get the maximum revenue from raw material.

CONCLUSION AND RECOMMENDATION

Refer to results and discussion, this thesis work able to support for the two major problems. First, the R&D and production department able to effort the RPP on new revenue from new customer; effect of C1 (New customer per total customers (%) on F3 (EBIT per number of R&D staffs (Baht/head)) which clearly founded under multiple regression method. Where (IP5 Labor Cost per production output (Baht/Kilogram)) is supportive parameter. model 6-1, is the relationship between C1 and F3, which C1 is mainly reflect to new customer, which intake from satisfaction of new product from R&D.

$$F3^* = 126 + 16.51C1^* - 39.4IP5^* \qquad (6\text{-}1)$$

New products from R&D derived to customer under C4 value (Successful order (Approved Art Work) per total order (%)). As results, C4 given revenue from raw material decrease at some degree. Due to a free sample to new customer or new order, it is absolutely deduct to F5 value (Revenue per raw material cost (Baht/Baht)).

$$F5^* = 1142 - 2.98C4^* + 0.425IP3^* \qquad (6\text{-}2)$$

$$F5^* = 2085 - 2.53C4^* - 35.9IP5^* \quad (6\text{-}3)$$

model 6-2 and 6-3, repents for relationship of new product to new customer by R&D (C4) on revenue per raw material cost (F5). Thus R&D can strongly effort RPP to get more new customer and enhance EBIT of RPP**.** Where F5 (revenue) is sub-unit of F3 (EBIT).

Second, the data which correct during fiscal year 2008 related to ISO 9000 version 2000 item 18, especially for innovation and learning focus let the RPP managements to concern on it. Innovation and learning perspective of RPP has shown that, it able to provide positive value to RPP firm. From polynomial regression model, it was found that innovation and learning parameter, which focus on over time working on work quality. During fiscal year 2008, 5% overtime can only provide on time delivery at maximum 99.2%. As a result, the over time is no need to apply for the employee.

This thesis work is carry out for the suitability monitoring and control parameter of information currently collected and capable to used in an organization based on balance scorecards frame work. Previously, the management focus only on one dimensional performance measurement, that is accounting system. Accounting system can only determine company profit or lost, but it does not inform the management level about internal process performance, customer relationship performance, and quality of work life performance. As a results from productivity and performance study, it was found that internal process perspective parameter (IP), customer perspective parameters (C), and innovation and learning (IL) perspective parameters able to enhance the RPP management on financial control (F). Furthermore the study of, it is also use as a general tool to motoring and control total plant operation, total quality policy, customer relationship management, and employee development. The out come of this work, states clearly for which parameters that managements of RPP are able to use to solve the company in further situation. Most of BSC parameters able to effort the performance of financial point of view especially for F1 (Interest per man-day cost (Baht/Baht)), F2 (Revenue per trial order (Baht/Baht)), F3 (EBIT per number of R&D staffs (Baht/head)) and F5 (Revenue per raw material cost (Baht/Baht)). Unfortunately, this thesis work is not find any relationship between IP, C, and IL on F4 (Revenues from new product per total revenue (%)).

Further information, the only study on simple regression from BSC parameter, the results from simple regression model does not provide sufficient data to the management of RPP. Additional study especially for polynomial regression given the RPP management able to view unseen result from polynomial model, as present in Figure 13, it is the relation ship between working overtime and results of on-time work. The result was answered the RPP management for the optimality of working. It was found that over time which no more than one hour is the maximum of RPP employee can release maximum productivity output. From multiple regressions, it was found the combination of each balance scorecards parameters effect on financial perspective. The combination of each parameters have dramatically shown side effect to financial perspective. The results from multiple regression model effort the RPP managements to firmly analyse the business situation based on mathematically analytic together with the management experience.

Finally, the firm foundation most wanted is income which is reflecting directly from EBIT. From this thesis work, it was found major relationship as summarized in Table 12. To increase EBIT or make more profit, the RPP management have to increase positive activity from Table 12. It is C1, C2, and IL2 to improve in EBIT. At the same time negative activity such IP4, IP5, IP6, IL3, and IL4 have to minimize. In some case the IP6 have to maintain based on production department to get maximum yield as much as possible. To keep the employee morality, event the RPP has negative activity such IL4, the management has to compensate at the optimum level to maintain and improve quality of working life of employee on track, and welfare is a face of company that represent to global.

Recommendation

This recommendation generates a strong evidence for compliance with Requirement 8 of ISO 9001:2000 (dealing with performance measurement, analysis and improvement) and Category 4 of the TQA (addressing the issues of performance measurement, analysis and knowledge management). The data especially for additional on fiscal year 2008, it is recommend to RPP to do continual collection to keep in data base for further knowledge management. The additional parameter for further study are ROI form R&D new products, Revenue per energy cost, satisfied customer index, customer repurchasing rate. Limitation of this thesis work, due to the time limitation some parameter such F4 (Revenues from new product per total revenue (%)) is not carried for interrelation between BSC parameter. If the data form RPP is more specific for only F4 and new products revenue it could found some relationship that how is a big effect from new product launching for new plastic application/products. The accounting system for RPP include R&D department in production department, so the core cost of R&D activities can not recognitions for this thesis work. To predict the results from regression model, maximum of 3 units forwarding is recommended.

APPLICATION OF THE TACIT SIGNAL METHOD FOR PERFORMANCE MANAGEMENT IN PROJECT-BASED ACTION LEARNING TEAMS

Kris M. Y. Law, The Hong Kong Polytechnic University, Hong Kong
kris.law@inet.polyu.edu.hk

Marko Kesti, University of Lapland, Finland
marko.kesti@mcompetence.com

ABSTRACT

This paper presents an integrative infrastructure for performance management in innovation-oriented learning organizations. The integrative design embraces both the concepts of project-based action learning (PAL) - driven organizational learning and tacit signal based performance management.

The concept of organizational learning (OL) has raised attentions of researchers and practitioners for a long time, from different perspectives. The studies of OL include the ideas of "continuous improvement, competence acquisition, experimentation, and boundary spanning" (Argyris, 1999). Learning Organizations (LO) are places where new and expansive patterns of thinking are nurtured, where collective aspiration is set free, and where people are continuously learning how to learn together (Senge, 1990). The effectiveness of OL process and better performance management is critical performance driver for many organizations.

This paper first discusses the background of the tacit signal method and how it is applied in performance management, and then describes the PAL framework with tacit signal e-HRM system embedded. In the integrative infrastructure presented in this paper, the tacit signal based e-HRM system is embedded as the built-in performance management tool under a Project-based Action Learning driven organizational learning setting.

The effectiveness of the proposed integrative infrastructure is verified by empirically grounded real company case studies. Case studies, in the form of tacit signal based action learning projects, were carried out in eight different SMEs at Finland. Results obtained from the case studies are very promising, and shows the proposed system supports innovation and learning.

Keywords: Organization learning, Learning organization, performance management, innovation management

INTRODUCTION

The concept of organizational learning (OL) has raised attentions of researchers and practitioners for a long time, from different perspectives (Argyris and Schon, 1978; Revans, 1982; Senge, 1990; Pedler 1991; Lyles, 1992; Garvin, 1993; Tsang, 1997; Garratt, 1999). The studies of OL include the ideas of "continuous improvement, competence acquisition, experimentation, and boundary spanning" (Argyris, 1999). Learning Organizations (LO) are places where new and expansive patterns of thinking are nurtured, where collective aspiration is set free, and where people are continuously learning how to learn together (Senge, 1990). The organization learning is the process by which the organization applies various modes of learning to achieve sustained competitive advantage (Wang and Ahmed, 2003).

Since the effectiveness of OL process can be hindered by some unprecedented events and organizational changes, the role of better performance management becomes even more critical and important. The OL vehicle, Project Action Learning (PAL) framework of Law and Chuah (2004) was developed for performance improvement and competitiveness sustainability.

The OL vehicle, Project Action Learning (PAL) framework of Law and Chuah (2004) was developed for performance improvement and competitiveness sustainability. Performance Management is one of the key features and supporting pillars of PAL implementation. Meanwhile, it has been found that management style leadership are influencing organizational performance (Schlevogt, 2002). Human factors such as stress and its impact on work performance have also been addressed (Putkonen, 2009). To understand these intangible factors, tacit signal method has been proposed to be used as an intelligent analytical tool to understand the competency levels of human resources (Kesti, 2007), and the tacit signal based e-HRM system is proposed as a human resources performance management infrastructure in the PAL-driven OL framework.

This paper first discusses the tacit signal method theoretical background and how it is applied in performance management, and then describes the PAL framework with e-HRM system embedded by the tacit signal method. A practical performance-managed-PAL framework is expressed and proposed.

BACKGROUND

The tacit signal method

The tacit-signal-based e-HRM system (Kesti et al., 2008) has been found effective in improving organization performance (Kesti and Syväjärvi, 2009) by offering intelligent analysis and monitoring. With the detailed analysis of competencies of human resources, this system can be used for competencies developments at collective levels. Therefore, it is definitely suitable for performance management in learning organizations.

Tacit signals refer to individuals beliefs concerning the improvement needs of human competencies. The tacit signals rise from personal tacit knowledge (Kesti, 2007). Tacit

knowledge is experience-based knowledge that is difficult to document or describe by words (Nonaka and Takeuchi, 1995). Tacit knowledge is highly personal and therefore it is difficult to express. The tacit-signal-based e-HRM system introduced as a human resource information system (HRIS) (Kesti et al., 2008) has been found effective in improving organization performance (Kesti and Syväjärvi, 2009). Nonaka and Takeuchi (1995) point out that each employee is a knowledge worker having important tacit knowledge about the organization's operations and work. This individual tacit knowledge can be used for competencies developments at collective levels. In many cases the most important competencies are leadership, team culture and work process (Kesti and Syväjärvi, 2009).

Leadership competencies at collective level

In working units the tacit signals can be used as guiding opinions to help solving problems by fundamental concepts such as participative and effective leadership. "The leader who wants to create an emotionally intelligent team can start by helping the team raise its collective self awareness," (Goleman et al., 2008), while collective emotional intelligence seems to be characteristic for top performing teams (Wheelan, 2005). In team performance improvement it is essential to recognize that they may be working on situations that are dissonant (Goleman et al., 2008). Festinger (1957) concludes that people are motivated to reduce dissonance by changing or modifying their attitudes and behaviors.

One negative way to resolve the dissonance is to create defensive reasoning for not to do anything about it (Argyris, 2004). Senge (2006) describes the same phenomenon so that organization learns harmful defensive routines which prevent problem solving and organization learning; "Defensive routines are so diverse and so commonplace, they usually go unnoticed" (Senge, 2006). A team's success depends on its ability to face the problem and to overcome defence mechanisms that surround the problems (Argyris, 2004; Senge, 2006).

Self recognition and performance

Another important issue to understand and surpass in management and organization development is the knowing-doing gap (Pfeffer and Sutton, 2000). The nature of the organization development is so that employee participation in planning and implementation will create sustainable productivity growth were quality of working life is improved along with performance (Ramstad, 2009). Organizations should not try to implement other organizations best practices but rather find out their own best value practices (Pfeffer and Sutton, 2000). Employees have ideas for optimal performance improvement. Succeeding in implementing these ideas to practice will create positive feelings. At Losada and Heaphy (2004) research the team performance seems to correlate with members positive feelings against negative. Positive/negative feelings ratio (P/N) exceeding 2.9 (Losada line) will speed up the team performance. In high performance teams the members experience positive feelings five times more than negative. In those teams the individual gets as much attention as team itself. (Losada and Heaphy, 2004).

Building a learning organization

Practical improvement actions at collective level are needed for development a learning organization. These actions need to come from the knowledge of the team members while optimal improvement actions arise from the team needs and situation (Hunt, 1992). Team members have both, the tacit and explicit knowledge. Tacit knowledge can be converted to explicit knowledge and can facilitate social interactions among the team members (Nonaka and Takeuchi, 1995; Nonaka and Konno, 1998). Social constructive communication produces dialogue, discussion and observation that speeds up the knowledge creation process and activates team learning.

Monitoring and control of team competencies

Kaplan and Norton have pointed out that there has been lacking good company specific measures for the learning and growth perspective. They note that absence of specific measures indicates that the company is not linking its strategic objectives to activities for re-skilling employees, supplying information, and aligning individuals, teams and organizational units to the company's strategy and objectives (Kaplan and Norton, 1996). Tacit Signals measurement and improvement actions follow-up makes it possible to measure organization learning and growth.

A holistic tool for organizational performance

To overcome above mentioned organization development obstacles the effective methods and proper tools are needed. It seems that organization can convert these problems in to great possibilities by developing every working unit's performance so that the whole organization productivity will improve (Welch and Welch, 2005; Kesti and Syvajärvi, 2009). Tacit signal development process with effective IC-tools have been proven to be effective in organizations continuous development (Kesti and Syväjärvi, 2009). With the help of systematic development process the leaders can learn to solve team problems and challenges in a constructive way and team members learn that problems can be turned to possibilities.

TACIT SIGNAL MEASURING AND ANALYZING PRINCIPLE

Research indicates that measured level of core competencies (leadership and culture) correlate with organization business performance (Kesti and Syväjärvi 2009). Improving competencies foresee better business performance. (Kesti and Syväjärvi 2009; 2010). Employee competencies, engagement and knowledge have great affect on internal process and business performance and they are critical in the organizational development process (Chareonsuk and Chansa-ngavej, 2009).

Tacit signal eHRM aims at providing clear overall view of the entire human resource competencies of the company. The competencies of a company in relation to its goals can be presented clearly and reliably for the resources allocation and relating decision making at management level.

The working principle of e-Tacit Signal System

Measuring the competencies can be done by survey studies relating to their improvement needs. Each group member has personal performance potential for doing the issues described by the competence attributes. Each person gives their personal feeling on the amount of efforts should be input or level of advancement should be made on a particular competence attribute. Personal competence is then calculated from potential (P) and the direction of the development need (Figure 1).

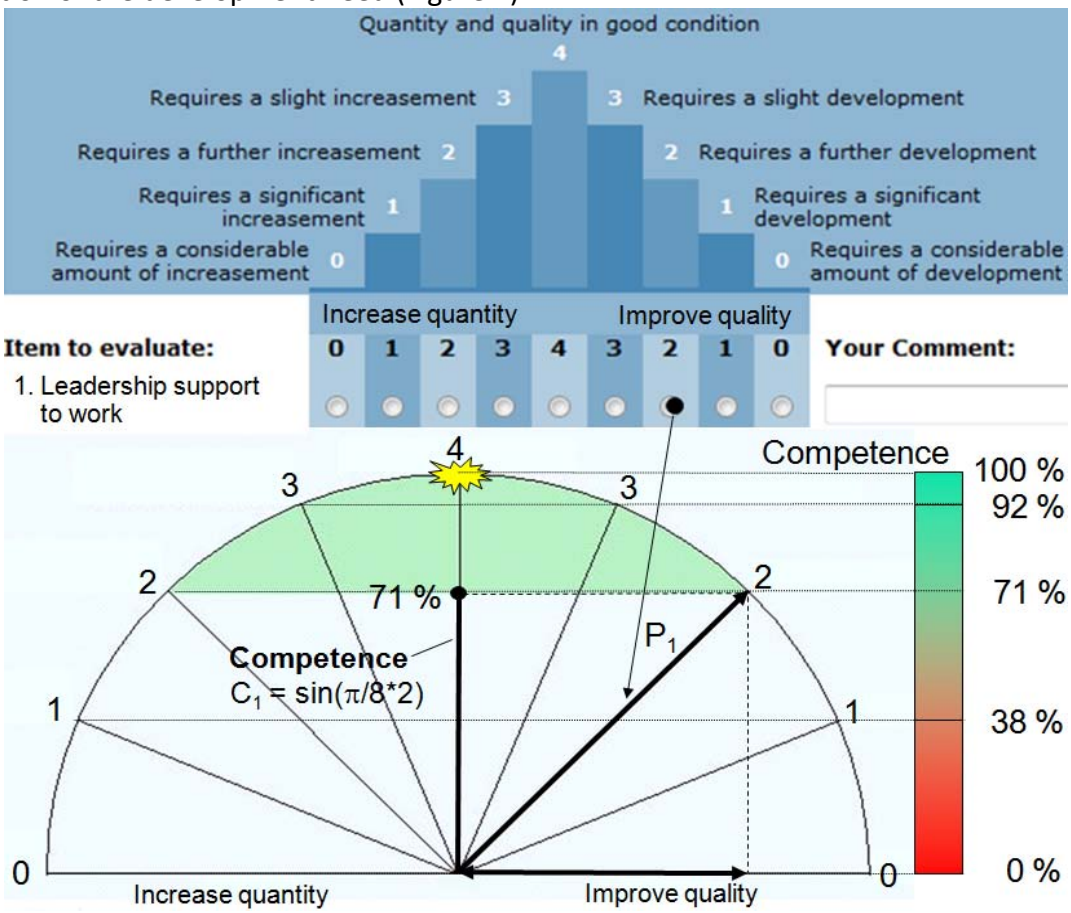

Figure 1: Personal competence measurement principle, where competence attribute is shown using vector that direction is according the person's opinion.

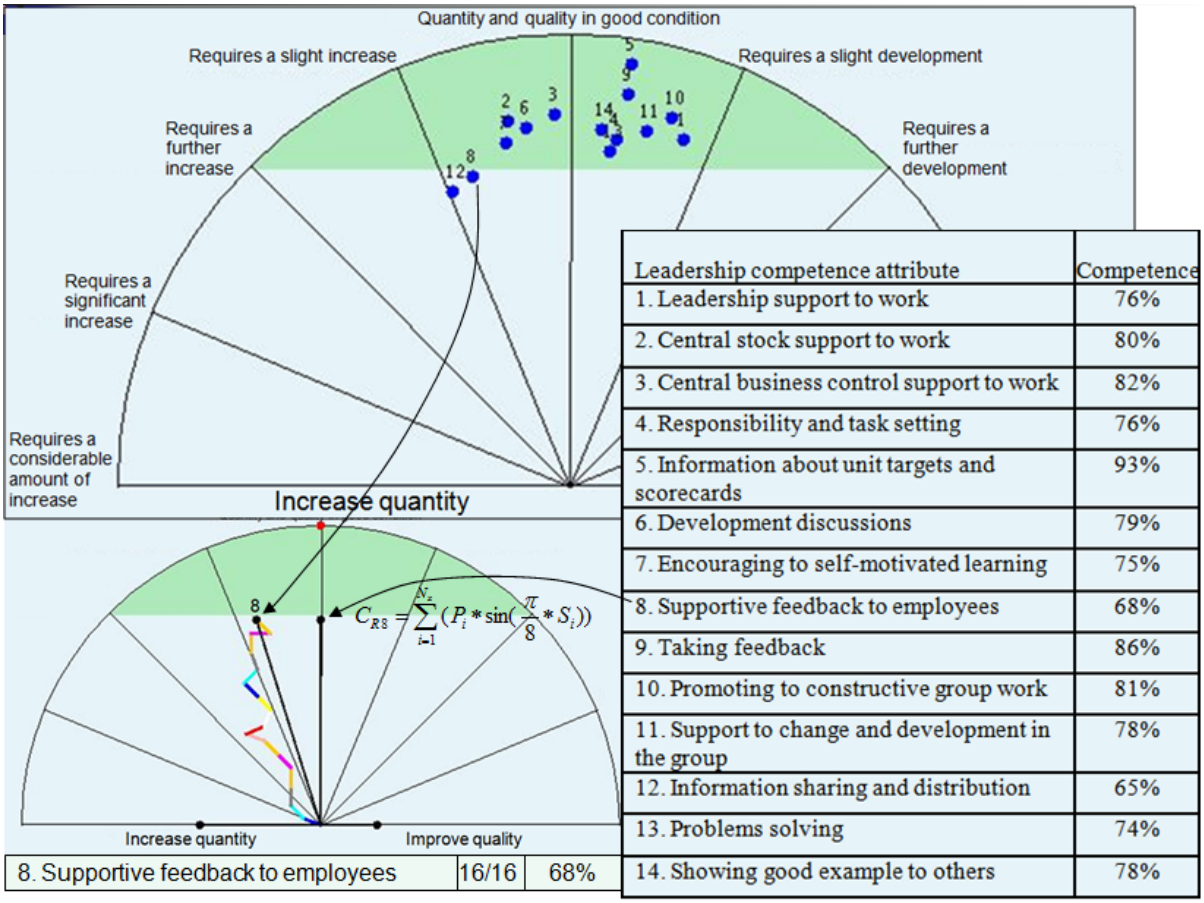
Each member's individual competence is measured based on the intensity of development needs (Value, S) on the particular competencies. The development value S of competency is represented by the angular vectors shown on the semicircular scale. Individual competency values would be then stored into the corresponding database.



Leadership competence attribute	Competence
1. Leadership support to work	76%
2. Central stock support to work	80%
3. Central business control support to work	82%
4. Responsibility and task setting	76%
5. Information about unit targets and scorecards	93%
6. Development discussions	79%
7. Encouraging to self-motivated learning	75%
8. Supportive feedback to employees	68%
9. Taking feedback	86%
10. Promoting to constructive group work	81%
11. Support to change and development in the group	78%
12. Information sharing and distribution	65%
13. Problems solving	74%
14. Showing good example to others	78%

Figure 2: Analyzing group collective competencies at semicircular scale (Kesti and Syväjärvi, 2010).

The tacit signal values are visualized by analyzer that supports both ASP- and Java-technology and the handling of html-files. Figure 2 shows the competence values presented with the aid of analyzer.

Development need values at collective level are then calculated by taking the average value of the summed up values of the entire group being measured. The mathematical formula for balanced total competence for the entire group is illustrated in Eq.1 as follows (Kesti, 2002).

$$C_{R1} = \sum_{i=1}^{N_x} (P_i * \sin(\frac{\pi}{8} * S_i)) = \sum_{i=1}^{N_x} (P_i * \sin(\alpha)) \qquad \text{(Eq. 1)}$$

where
C = Group competence
P = Group member competence potential
Si = tacit signal guiding opinion from the inquiry, Si ∈ (0 … 8)
π/8 = angle interval at the semicircle opinion scale
α = angle of the potential segment of a line ($0 \leq \alpha \leq \pi$)
Nx = number of group member answers

Tacit signal method is based on inquiry where individual gives development need for each competence attribute. Competence consist attributes of human performance drivers that are typical for high performance team emotional intelligence (see Goleman et al., 2008). Measurement can be seen as personal feeling of situation in pressure-performance curve.

This inverted U-curve is originally invented by Yerkes and Dodson (Yerkes and Dodson, 1908). Goleman (2007) points out that stressed people become defensive and too high stress hormone levels causes mistakes and disables learning new things.

PROJECT BASED LEARNING AS ORGANIZATIONAL LEARNING VEHICLE

Organization project action learning (PAL) framework is comprehensive for organizational learning and development (Law & Chuah, 2004). Organization systematic development can be seen as multiplied and repeated development projects for improving organization intangible assets. Built on the theoretical foundations of action learning (Revans, 1982), PAL is a practical OL solution that uses goals and project setting to drive both individual as well as team learning in a systematic way. Earlier research of Law & Chuah (2004) has identified that four supporting pillars, namely as Policy and Strategy, OL Facilitation, Technology and Resources, and Performance Management, are crucial to the PAL implementation success.

Integration of tacit signal HR system and PAL framework

Performance management concerns essential components of business excellence such as management, team factors and processes. There have been a number of frameworks developed striking for optimization of performance management, PAL is one of these, an effective measuring and monitoring tool for organizational performance is thus needed.

In this project, a comprehensive HR performance management system is development by integrating the tacit signal method into a development framework based on organizational learning concept (PAL).

The proposed tacit signal e-HRM system is anticipated to produce valid data for decision making, strategic planning, resource allocation and learning facilitation. Pfeffer and Sutton (2000) point out that it is essential to overcome the knowing doing gap that usually prevent learning. Performance improving learning comes from doing the right actions based on the existing knowledge of the organization (Pfeffer and Sutton, 2000). Therefore, knowing the current situation is the foremost task for further implementation of optimal improvement actions.

The **PAL-tacit signal performance** (PAL-TSP) **system** is applied throughout the entire PAL process, it facilitates, collects, measures, analyzes tacit competencies for the performance management (Figure 3).

The PAL framework embedded with e-tacit signal system facilitates the human resources performance goal setting, measuring and monitoring. The performance goals are well defined and agreed and thus can be further measured according to the human related performance quantifiable metrics like absence, turnover rate and competencies. Competencies are specific and are measured by tacit signals at different pre-set milestones throughout the PAL life cycle. Research studies indicate that tacit signal competencies can present organization performance in a systematic and quantifiable manner (Kesti and Syväjärvi, 2009; 2010). Some intangible indicators such as learning goals at collective levels can be measured with reference to the predefined performance indicators.

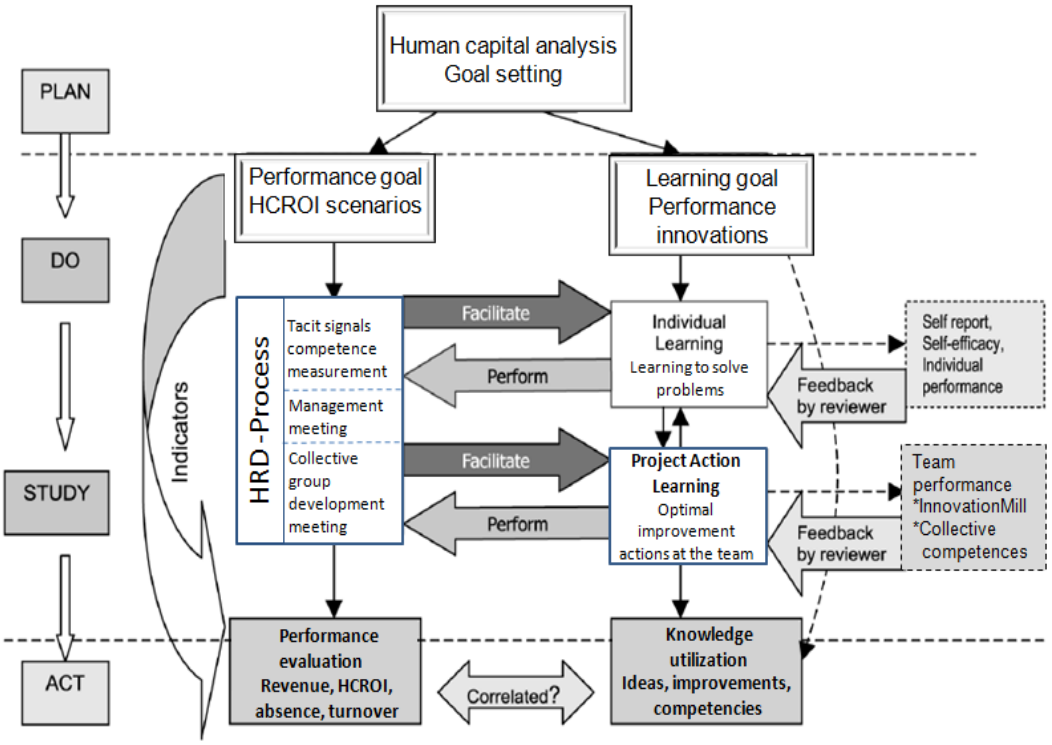


Figure3: The PAL-tacit signal performance (PAL-TSP) framework.

The PAL-tacit signal performance (PAL-TSP) framework is a comprehensive organization sustainable performance management framework with systematic and effective project action learning development process. Human capital can be seen as the capacity of an organization to use resources and human capabilities in order to achieve their organizational goals (Ulrich and Brockbank, 2005; Gratton, 2004). Human capital performance is analysed and the goals are set at strategic level. These goal settings form sustainable development goals that are based on human capital development strategies for three to five years time span. The strategic scenarios illustrate how the human capital development pay pack in better business performance (HCROI = Human capital return on investment).

Systematic and effective strategy is the key for human capital performance improvement. In the proposed framework, human resource development goals are developed based on the tacit signals analysis at team level, which provide the baseline for development process. This HRD development process aims at activating the individual learning as well as at team level learning.

ILLUSTRATIVE CASES OF TACIT SIGNAL E-HRM SYSTEM

To testify the effectiveness of the proposed system, case studies have been carried out at eight different SMEs at Finland. Study supports that tacit signal projects produce useful innovations at every company. Systematic development method with IC-tools speeds up learning process at teams. Teams have succeeded to carry out average three practical improvements in ten months follow-up time. These actions were collectively chosen and implemented in each group.

Table 1: Case study in 8 SME companies on tacit signal implementation.

Size	Teams	Business branch	No. of Ideas	Going on	Carried out	Ideas per team
50	6	Chemical industry	61	30	11	17,0
10	1	Trade and services	23	5	4	32,0
60	8	Tourist industry	63	29	28	15,0
54	5	Production industry (consumer)	53	10	19	16,4
46	3	IC industry	56	12	5	24,3
63	4	Production industry (B2B)	23	7	14	11,0
130	5	Rehabilitator	80	28	14	24,4
152	5	Hospital	56	29	13	19,6
565	**37**	**Total**	**415**	**150**	**108**	**18,2**

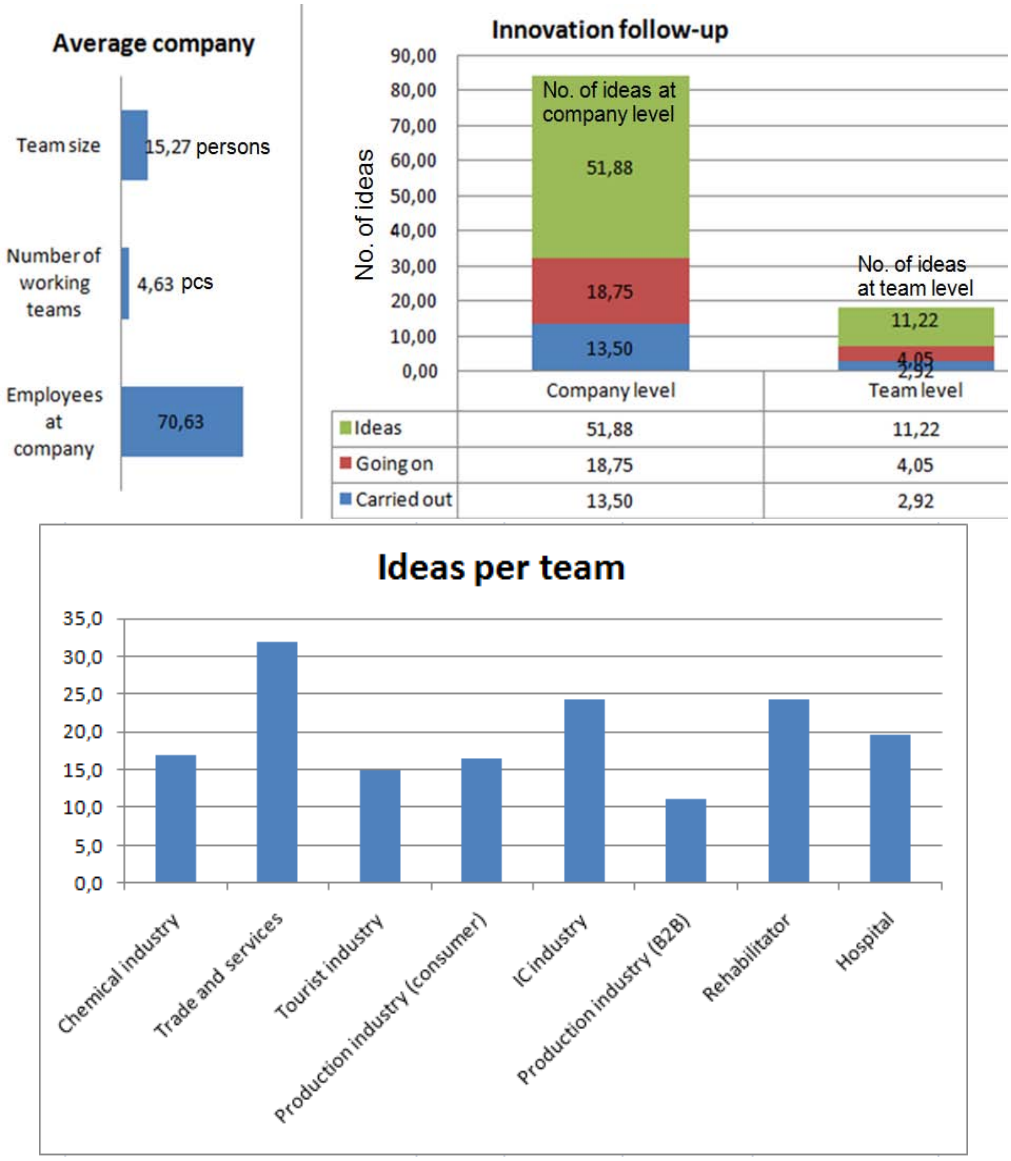

Figure 4: Summary of case studies illustrating how the proposed system supports learning and innovation.

In effective team the members must be able to adapt, learn and perform as a team (Law and Chuah, 2004). PAL development project reinforces the team level innovativeness to solve problems and improve operation proactively. Management needs balancing feedback to be able to implement strategy optimally (Senge, 2006). With the proposed e-HRM system better decisions can be made for optimal improvements. These actions, better understanding and decision making, are most optimal and contingent to the team performance excellence (Hunt, 1992).

CONCLUSION REMARKS

This paper presents an integrative infrastructure developed for effective performance management in innovation-oriented learning organizations. The integrative design embraces both the concepts of project-based action learning (PAL) - driven organizational learning and tacit signal based performance management. The effectiveness of the proposed integrative infrastructure is verified by empirically grounded real company case studies. Case studies, in the form of tacit signal based action learning projects, were carried out in eight different SMEs at Finland.

Results obtained from the case studies are very promising, and shows the proposed system supports innovation and learning. Teams are shown to have significant improvements in ten months. It seems evident that organizations can utilize their tacit knowledge better by implementing systematic and effective development process. It is essential that organization learning is properly managed so that the development is part of the organization sustainable performance improvement.

ABSTRACT

This paper presents a reference architecture for information integration in sustainable supply chain management. This architecture aims to provide an integrated information infrastructure across a supply chain. It is intended to provide support to the interchange of information related to the socially responsible management of corporations by coordinating and communicating the information stored in the different information systems of companies across a supply chain. The presented reference architecture has been designed as an improvement and application of data warehousing technologies to the field of sustainable management of supply chains. It contributes to the research on the development of information and communication technologies for the integration of Corporate Social Responsibility in organisations.

Keywords: Corporate Social Responsibility (CSR), Sustainable Supply Chain Management (SSCM), Data Warehouses (DW), Interoperability.

INTRODUCTION

The concept of corporate social responsibility (CSR) is increasingly present in the business and social environment. CSR entails the adoption by organisations of a very wide range of polices and compromises covering social, environmental and economic dimensions and their application over the whole organisation's influence area.

There are many expected benefits from a socially responsible management (Moneva et. al, 2007). Organisations adopting the CSR model are expected to improve their processes and their relationships with their stakeholders in a manner that they would increase their shareholder's value and at the same time they would fulfil all their responsibilities and commitments towards society and other stakeholders (Husted and Salazar, 2006). Therefore, the economic, social and environmental benefits achieved when adopting socially responsible behaviours go beyond the boundaries of organisations themselves and involve wider communities (Ciliberti et. al, 2008).

In the same manner than CSR benefits exceed the boundaries of organisations, the requirements for its effective adoption also entail organisations managing external aspects,

so that companies need all firms in their own supply chain to act in a socially responsible way.

Sustainable supply chain management (SSCM) can be defined as the management of supply chains where all the tree dimensions of sustainability, which are the economic, the environmental and the social ones, are taken in account in planning and management processes (Seuring and Müller, 2008). Special effort should be paid when supply chains include small upstream producers that work in developing countries, since the responsibility for their well-being and performance should also be assumed.

This paper aims to contribute in the research on sustainable supply chain management by providing a framework to integrate the information stored by the different companies across a company's supply chain. To this end, a reference architecture for information integration is proposed. This architecture is based on sustainable supply chain management requirements defined in different standards and norms, and has been designed upon data warehousing technologies. The rest of this paper is structured as follows. After this introduction, Theoretical Background section briefly reviews literature on sustainable supply chain management and data warehouses. Then it is presented reference architecture for CSR information interchange across supply chains and the methodology used for its development. Finally, future research and main conclusions are summarised.

THEORETICAL BACKGROUND

Sustainable Supply chain Management

According to CSR principles, companies adopting CSR should hold themselves accountable for the social and environmental impacts arising across their supply chain, and are compelled to integrate ecological and social aspects into their decisions and actions across their supply chains (Ciliberti et al., 2008). Organisations are not only responsible for the actions they do and the impacts those actions cause. They are also responsible for the actions of their suppliers and subcontractors (Neef, 2004).

Furthermore, as claimed by the Department of Trade and Industry "CSR is likely to become an increasingly important business issue for many SMEs in future. This is partly because of the increasing take-up of ethical codes of practice by their large customers, which is creating a pressure for demonstrably responsible behaviour back down the supply chain" (DTI, 2002). It is expected therefore large companies will stimulate the social responsible behaviour across their supply chain.

Sustainable supply chain management is defined by Seuring and Müller (2008) as "the management of material, information and capital flows as well as cooperation among companies along the supply chain while taking goals from all three dimensions of sustainable development, i.e., economic, environmental and social, into account which are derived from customer and stakeholder requirements". In this sense, the sustainable management of supply chain involves organisations efforts to further social and environmental goals in their supply chain.

Managing supply chains in according to sustainability principles brings many challenges to traditional supply chain management, which was mainly focused on efficiency, information sharing, and joint planning. (Foran et. al, 2005). In this regard, the sustainable management of supply chain involves transferring supply chain's partners socially responsible behaviours, and it helps corporate managers to "manage the environmental risks posed by their supply chain" (Gascoigne, 2002). To this end, companies can use the following management tools (Martela, 2005): a) establishing written requirements; b) monitoring supplier performance; and c) contributing to supplier's awareness building and training.

Establishing supplier requirements entails defining guidelines and requirements to establish social and environmental performance for the organisation's suppliers. It is usually the first step in managing the organisation's supply chain responsibility (Jamison and Murdoch, 2004), and suppliers are usually required to comply with law and some CSR standards.

Supplier performance monitoring consists of activities carried out to keep a close watch over suppliers to check that the their behavior is consistent with established requirements (Ascoly et al. 2001). One of the key characteristics and requirements of monitoring is that it is a frequent or continuous process. Otherwise, it would be very difficult to detect variations in partners' behavior or circumstances. An effective supplier performance monitoring requires companies to devote important resources in training their employees, instructing their buyers and establishing appropriate measures in cases of violation of the code including accompanying measures, among others. Furthermore, they also need to upgrade their information systems to comply with the new requirements.

Finally, contributing to suppliers' awareness building and training pursues to communicate and raise the awareness of the targeted audiences to the company's philosophy and policy about corporate responsibility issues. The potential audiences that should be addressed by this tool include, but is not limited to, the own organisation, the management level of supplier and the supplier's workers. This tool requires long term relations with a significant level of trust that enables effective communication, education and training of the different parts (Martela, 2005).

These three tools can be combined to define sustainable supply chain management strategies that range form compliance with requirements and capacity building (Jamison and Murdoch, 2004). The compliance with requirements approach focuses more on the establishment of written requirements and the monitoring of supplier performance. The capacity building approach is rather focused on awareness building and training.

The implementation of the above mentioned strategies in supply chains increases the interdependence between companies. Interdependence refers to the extent to which organisations need to exchange information or material to accomplish their tasks (Thompson, 1967). The increased interdependence that arises when sustainable supply chain management strategies are implemented is closely related to information interchange and analysis. Therefore, sustainable supply chain management requires organisations in the supply chain to share more information, and to provide them with the necessary tools to manage and analyse the shared information. Greater interdependence between

organisations requires greater coordination/communication mechanisms to promote information sharing.

A reference architecture for information integration has the objective of developing an integrated information infrastructure that communicates and coordinates the different technological devices that generate, process, distribute and supply information (Chalmeta et, at., 2001). Literature provides a wide range of technologies and tools for information integration, each one with specific characteristics and functionalities. Regarding CSR information integration across supply chains, a reference architecture should solve traditional problems related to technical and semantic integration, but it also should provide the necessary analytic functionalities to evaluate the performance of organisations and the whole supply chain according to different criteria. In this regard, over the past decade, many organisations have made multidimensional modelling and data warehouses (DW) the foundation of their decision support infrastructures (Ariyachandra and Watson, 2010), due to their capacity of integrating and storing data from different sources, and the analytic functionalities they enable.

DATA WAREHOUSES AND MULTIDIMENSIONAL MODELLING

The data warehouse technology was initially introduced by Devlin and Murphy (1998). According to their initial proposal, a data warehouse is a read-only database specially designed to store historical data for operating, which offers integration tools for users to query and search what they need for decision supporting and analysing.

By using data warehouse technologies, data is extracted from data sources, transformed, and loaded into data stores. The data is then made available for end user access and decision support applications. It can be considered as a decision support data infrastructure that is used for multiple and varied decision support purposes (Ariyachandra and Watson, 2010).

Data warehouses are designed to storage loans of data that may be used to “fuel” different applications, including traditional querying and reporting tools, but also more sophisticated systems that can be classified within what is generally known as busines intelligence tools. Those include decision support systems (DSS), executive information systems (EIS), online analytical processing (OLAP), or data mining, among others (Gray and Watson, 1998). Data warehouses are also enable and promote some of current strategic initiatives such as customer relationship management (CRM), business performance management (BPM), and supply chain management, among others (Ariyachandra and Watson, 2010).

What differences a data warehouse from traditional relational databases is that a data warehouse is a specially prepared data repository that is used to support decision making in an efficient way (Gray and Watson, 1998), in opposite to relational databases, which are designed to be efficient in registering transactions, saving storage space and granting consistency of data. To that end, data warehouses are designed using what is known as multidimensional modelling, rather than using traditional normalised relational modelling.

Multidimensional modelling structures information into facts and dimensions. Facts represent atomic information elements in a multidimensional database (Hüsemann, 2000), and they are used to memorise measures about situations or events (Schneider, 2008). Dimensions are used to analyse facts, particularly through aggregation operations. By means of dimensions, a fact consisting on simply measures can be qualified according to a specific context. (Hüsemann, 2000). In summary, facts contain interesting measures of a business process, whereas dimensions represent the context for analysing facts.

The implementation of a DW increases information processing capacity (Galbraith, 1974). That capacity is closely linked to the architecture used to implement the data warehouse. Literature upholds that the extent of information interdependence between organisations determines the need for different levels of information processing capacity, which in turn determines the most appropriate data warehouse architecture (Ariyachandra and Watson, 2010). At company level, two main architectures are generally used: the Enterprise data warehouse (EDW) architecture (Inmon et. al, 2001) and the Data warehouse bus matrix (Kimball, 2002).

EDW was the first method used in the development of enterprise wide data warehouses. With this method, data warehouses are implemented by a top down process, and they are architected, designed and constructed in an iterative manner. In an EDW, the entire enterprise data warehouse is modelled, and then small slices of subject areas are chosen for construction. This approach provides two major advantages from an implementation perspective: a coordinated environment and a single point of control & development.

With the Data warehouse bus matrix architecture, data warehouses are implemented by a bottom up approach. With this approach a smaller enterprise data mart architecture is developed to provide a context and foundation for further development, which is built from a series of incremental, architected data marts.

Both architectures have evolve during past decades, but they remain the base for other architectures such us central data warehouses, that usually employ a hybrid approach to overcome some of the limitations of previous architectures, or federated data warehouses, that attempt to consolidate distributed data warehouses.

This research uses the Data warehouses bus matrix due to their capacity for architecting incremental data warehouses. While this method was initially designed to be used in single organisations with multiple business units, its principles can be adapted to be used un supply chains.

SSCM ARCHITECTURE

Literature provides a wide range of methodologies, models and tools for the integration of different DW with the aim of generating a federated data warehouse that can be queried as a whole. Those contributions are, however, focused on solving the problem of integrating different DW in order to provide as integrated information as possible.

That objective is not the main one pursued by this research. This paper mainly aims to define a DW global schema for CSR integration across supply chains. Therefore, the objective is to help companies to interchange the required information to manage their corporate social responsibility across their supply chain, but not to reach the maximum level of integration among the already existing information systems of the companies in a supply chain. By defining a standard bus interface for CSR management across the supply chain, separate data marts from different organisations can easily be plugged together to provide a global view of the whole supply chain, and a more effective sustainable supply chain management is possible.

The proposed reference architecture is based on the data warehouse bus matrix architecture proposed by Kimbal (2002), which has been adapted to fulfil the CSR information integration requirements for sustainable supply chain management. This architecture has been designed with a methodology that can be used by companies with specific requirements, and is intended to design a reference model to the integration of information across supply chains.

The reference architecture defines a set of critical interoperability CSR facts. Furthermore, minimum facts' dimensions and dimensions granularities are defined, in a manner that a SSCM data warehouse bus matrix is defined. Finally, it also provides guidelines on defining information interchange procedures, based on the use of queries that are propagated along the supply chains and data-marts that are increasingly filled by organisations in the supply chain according to petitioner needs. The SSCM architecture is presented in the same order that the methodology which has been used in its development.

Phase 1. Identifying critical interoperability facts.

The development of a supply chains data warehouse bus architecture begins with the identification of the business requirements for the different business process that need to be supported. In the context of the problem being addressed in this research, it is necessary to analyse the different processes involved in sustainable supply chain management. Those processes may vary significantly among different organisations. However, many researches have attempted to generalise the main elements that characterise supply chain CSR in al industries. Literature pay special attention to elements such us logistics, purchasing, procurement, employee training, philanthropy, environment, urban renewal, workplace diversity, health and safety, human rights or labour practices, among others (Carter and Jennings 2002a; Carter and Jennings 2002b; Poist, 1998)

The first phase of the methodology aims to make a careful determination of which facts will be interchanged among companies. Critical interoperability facts can be defined as the set of facts of special of special value for the interoperability among organisations. In the scope of CSR, critical interoperability facts are those related to the sustainable managements of economic, social and environmental aspects across value chain.

The amount of facts that should therefore be addressed in sustainable supply chain management may be considerably huge. The facts included in the SSCM architecture (Table 1) have been defined as a result of a deep analysis of different international norms and

standards such as Global Reporting Initiative (GRI) guidelines, ISO 9000, 14000, 26000 families, OSHAS 18000 and SA 8000, as well as specific tools and protocols. However, organisations involved should negotiate a set of critical interoperability facts that they should share in order to enable an efficient supply chain management. This initial set can be enhanced later, thanks the incremental development capacity of the bus matrix architecture.

Fact	Description
Analysed business unit	Number of business units that have been analysed according stabilised CSR polices
Complaints	Number and monetary value of received complaints
Donations and other community investments	Number and Monetary value of donations
Economic value generated	Monetary value generated by the organisation
Employee training	Total hours and monetary value of employee training
Energy consumption	Amount of energy consumed
Environmental damages	Number of environmental damages caused by the organisation
Environmental protection investments	Number and expenditures invested for environmental protection.
Financial assistance	Monetary value of financial assistance received by goverment
Gas emissions	Amount of gases emitted by the organisation
Human Rights violation	Number of human rights violation arisen from organisation activities.
Incidents of discrimination	Number and monetary value of incidents of discrimination happened within the organisation
Labour accidents	Number and monetary value of labour accidents suffered by staff
Legal actions	Number and monetary value of legal actions initiated by the organisation
Materials comsumption	Amount of materials consumed by the organisation
Non-compliances	Number and monetary value of non-compliances with regulations and voluntary codes
Payments	Monetary value of payments to suppliers
Social investments	Number and total expenditures invested for social purposes.
Staff	Number of people and total workforce employed by the organisation
Staff turnover	Number of employee turnover
Staff wage	Wage received by employees
Suppliers	Number of suppliers monitored
Tax payments	Monetary value of taxes paid to governments by the organisation
Waste	Waste generated by the organisation
Water consumption	Amount of water consumed by the organisation.
water discharge	Amount of water discharged by the organisation

Table 1: Critical interoperability facts for sustainable supply chain management.

Phase 2. Identification of critical dimensions

During the second phase, the dimensions that will be used for facts analysis are defined. The different criteria which are needed to conduct analysis along a dimension are introduced through members. Members of a dimension are generally organised in a hierarchy which is a conceptual representation of the hierarchies of their occurrences (Schneider, 2008).

Although the identification of critical dimensions and their members is closely linked to the CSR aspects selected in previous phase, there are two dimensions that should necessarily be included in the model due to their importance in CSR management. Those essential dimensions are Date and Location:

Date

Date dimension refers to the moment of the time when the fact is produced, and it dimension allows to analyse how facts evolve over time.

The minimum grain detail for Date dimension in CRS management is one year, which is the minimum period in which CSR reporting is desirable. However, more detailed grains such as quarter, month or even day should be used if they provide material information for the analysis of facts.

Members of date dimension should represent the different period of time that may be used for facts analysis. At least a member for each year should be created, but years may be hierarchal decomposed if more detailed grains are defined.

Location

Location dimension refers to the place where the facts occurs. The minimum grain detail for Location dimension is a Country, although more detailed grains such as state, region, city or even building should be used if the provide material information for the analysis of facts.

In the same way than member for Date dimension, at least a member for each country should be created. Other members representing more specific locations for more detailed grains.

Apart from Date and Location dimensions, that should be inevitably included, other dimensions that should be considered when defining the reference architecture for information interchange for sustainable supply chain management are:

Employee

Employee dimension refers to the employee that has caused of suffered a specific fact. This dimension should be designed contained employee attributes relevant to CSR management. Outside the original company, facts will rarely analyse at single employee detail, but they will necessarily analysed according employees attributes.

This dimension should include some interesting attributes to enable value added analysis. Those attributes are Birth date; Contract date; Gender; Origin; and Contract type.

Each organisation may define its own members for this dimension. Employee dimension's members should be codified in a way that any code is repeated across supply chain, so using a company prefix or attribute is necessary.

Energy source

An energy source dimension is needed for analysing energy consumption facts. Members of Energy source dimension represent the different sources of energy that can be used by organisation. A hierarchy containing at least electricity, com,

Gas

Members of gas dimension represent the different gases that should be traced across the supply chain. A hierarchy containing greenhouse gasses, ozone-depleting substances and other relevant air emissions members should be defined in Gas dimension

Water

Members of water dimension represent different water qualities and locations where the water came from or where the water went to.

Those are only some of the dimensions that should be considered. Other dimensions should be defined to include the necessary criteria to fully analyse other facts such as Non-compliances, Complaints, Labour accidents, or Material consumption. While many of these dimensions may only be applicable for a single fact, others could be associated to some of them. The association of facts and dimensions is defined in next phase of the methodology.

Phase 3. Definition of the data warehouse bus matrix

In this phase, dimensions are associated to facts. Those associations will determine the multidimensional granularity with which facts will be analysed, and therefore it also determines the minimum granularity with which facts should be registered and stored by the organisations in the supply chain.

The data warehouse bus matrix architecture is defined with the help of a matrix where facts and dimensions are linked. While the Date and Locale dimensions should be associated to all the facts, the other dimension may be associated to a reduced or wide set of facts depending on the specific analytic need. Table 2 shows an example of how to use a matrix to define the data warehouse bus matrix.

	Date	**Location**	**Dim. 3**	**Dim. 4**	**…**	**Dim. N-1**	**Dim. N**
Fact 1	X	X	X		…	X	
Fact 2	X	X		X	…	X	X
…	X	X	…	…	…	…	…
Fact M-1	X	X	X	X	…		X
Fact M	X	X		X	…	X	X

Table 2: Bus matrix for sustainable supply chain management. Adapted from Kimball (2002).

The selected critical sustainability facts and dimensions, and the data warehouse bus matrix serves as a reference framework to interchange information about organisations in the supply chain, but it also may provide companies within the supply chain with a rational approach to decomposing their data warehousing planning task. Using the CSR data warehouse bus matrix, organisations across a supply chain can share a common interface that allow them to interchange and aggregate date, and therefore to improve interoperation skills.

Phase 4. Adaptation of local information systems

The CSR DW global schema should be used by organisations across the supply chain for integrating their local information systems with the supply chain reference architecture. During this phase, organisations should face the integration of local information systems with the global schema of facts and dimensions.

At this point, it may occur that some organisations's information systems do not provide support for the management of specific sustainability facts, or that granularities of facts are not fully compatible with dimensions defined in the reference data warehouse bus matrix.

Organisations across supply chain should negotiate whether it is necessary to adapt local information systems for managing unsupported interoperability facts and dimensions, or if undetermined values are allowed. Whatever option is chosen, organisation should implement the necessary translations between the structures in which they store their local data, and the data structure defined in the supply chain data warehouse. This translation will strongly depend on the information system of any organisation, and there exist many procedures and tools that may facilitate considerably the process.

Phase 5. Information communication and aggregation

Once a set of companies have defined their own SSCM DW schema, and have adapted their local systems to manage the information according this schema, the next phase is related to information interchange.

The bus matrix architecture here presented provides a common reference for information interchange between companies across a supply chain. Figure 1 illustrates that by using a common set of critical interoperability factors and dimensions, organisations can easily share local data marts to build a supply chain data warehouse. However, the adequate interchange of data across supply chain requires a set of well defined rules that guarantee the adequate communication and aggregation of data across the supply chain

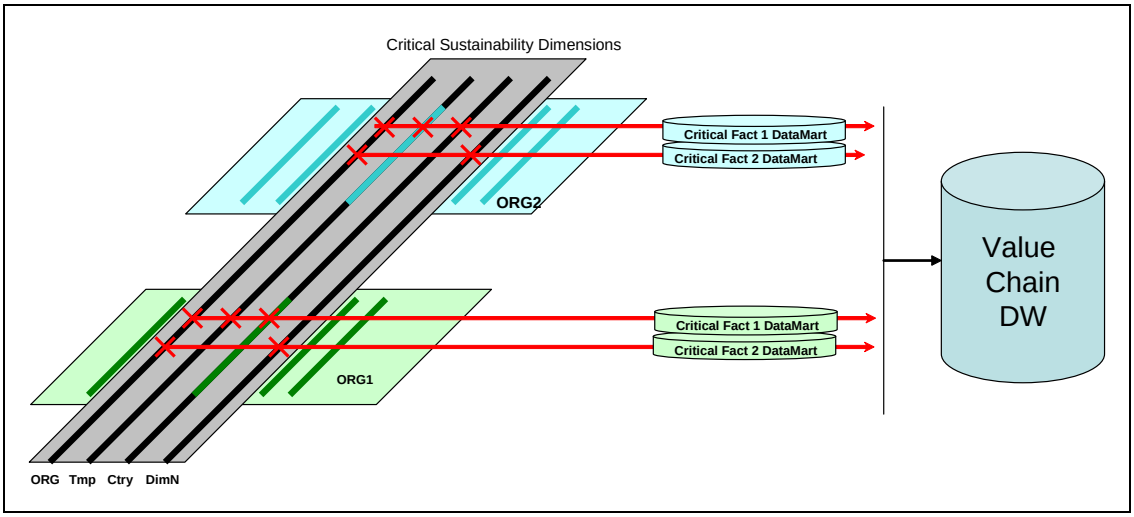

Figure 1: Data marts integration across supply chain by using a common data warehouse bus matrix.

Literature provides many alternatives to manage communication and aggregation of data between different organisations. This paper does not addresses low level implementation details, but presents some of the implementation guidelines that should be addressed.

As sustainable supply chain management does not need real time information integration, the architecture has been designed to integrate the information on demand. In this way, when an organisation needs to query supply chain information, it firstly compose the query in the same way than a local query. The query is formulated with a standard querying code, like SQL, but some meta-information is added. That meta-information includes the identification of the organisation starting the query, a query identification number, and a number indicating the levels the query must upstream in the supply chain. The query is therefore defined *Q={ OrganisationID, QueryID, NumLevels, SQLQuery}.*

The query *Q* is then submitted to direct suppliers of the organisation starting the query. The organisations receiving the query can act in two different forms depending on whether they are in the limit level stabilised in the initial query or not.

In the first case, the organisation answers the query with a response package *R* containing the requested data. Two additional dimensions are included in the returned data. One of them refers to the responding organisation identification. The other represents the level of the response, which is stabilised to value "1". The response package is defined as *R={QueryID, FactsSet, {DimensionsSet, OrganisationID, NumLevels}}*

In the second case, the organisation forwards the query to upper suppliers and waits for response. The forwarded query is modified as follows. The original value of CompanyID field is replaced with the identification of the organisation forwarding the query. The original value of CompanyID is added to the QueryID field. Finally, the number in NumLevels field is decreased by 1. Then, when the organisation receives the response packages, it aggregates all the responses, it subtracts the first company identification from the *QueryID* field in the responses, then it increases by 1 the values in the level dimension of responses, and finally it adds the data resulting from applying the query to its local data warehouse, with the value

of its identification in the dimension of responding organisation, and the value “1” in the level of response dimension. Once the response is completed, the responding organisations send the response to the querying organisation.

In this way, the query is propagated from the querying organisation to all organisations within the stabilised boundaries. All responses are increasingly integrated in a single data mart containing response data, which includes critical interoperability facts and the necessary dimensions for their analysis, but also the Organisation and Level dimensions to identify the facts across the supply chain.

It has to be noted that this process may introduce duplicated data when more than one path or circular relations, exist between querying organisation and any supplier within the boundaries of the query. Duplicated data can easily be identified in the response package because the same organisation identification code contains facts with more than one level or because exists duplicated facts. Those data should be carefully managed by querying organisation according its own needs.

CONCLUSIONS AND FURTHER WORK

This work contributes to research on extending corporate social responsibility management beyond organisation limits. To this end, this paper proposes a reference architecture designed to provide support to information integration and communication in supply chain management. The architecture explains the use of the data warehouse bus matrix as an interoperability standard for information interchange across the whole supply chain. It also includes some guidelines to define communication processes. Furthermore, the methodology is applied to build a standard information architecture for sustainable management of supply chains.

The sustainable supply chain management data warehouse architecture here presented need to be further tested and enhanced. While the proposed methodology may help organisations in a supply chain to define a common reference architecture for information integration, the developed reference architecture for sustainable management of supply chain is still in an early stage. More research is necessary in order to determine a commonly acceptable set of critical interoperability facts for sustainable supply chain management, and critical dimensions should also be further developed in order to grant the required analysis capabilities.

As a result of constructing a supply chain data warehouse, companies would be able to improve their sustainable supply chain management. On the one hand, because companies would be able to efficiently check supplier’s compliance with requirements. On the other hand, because the architecture may promote interoperability among clients and suppliers, and therefore along the whole supply chain. This situation may easily happen when a company’s suppliers understand CSR benefits and therefore start promoting CSR among their own suppliers

ABSTRACT

The use of renewable biomass for energy production is increasing in Finland. Moisture content in bio-mass is commonly seen as a major challenge. This study analyses the economic impact of moisture in different parts of wood biomass supply chain by making calculations covering the entire supply chain. The methodology of this article includes literature review, interviews and economic calculations. The results of this study indicate that total costs for moisture content in Finland is annually some 50 M€ higher when using wood bio-mass with 45 w-% instead of 30 w-% by. Roughly half of this increase comes from transportation and another half from weakening burning efficiency. Properly organised air-drying is the simplest and cheapest measure to decrease transportation costs and improve combustion. Large power plants are typically capable of utilising air-dried wood bio-mass with moisture levels between 30-50 weight %.

Keywords: renewable energy, biomass, wood, moisture, economic calculations, supply chain.

INTRODUCTION

The global discussion on carbon dioxide emissions on the climate change has greatly influenced environmental considerations and legislation especially in Europe (e.g. Schmalensee et al.; 1998; Hansen et al., 2008). Using renewable energy instead of fossil energy is crucial when attempting to reduce green house gas emissions (United Nations, 1997; Hoffert et al 2002; IPCC, 2008). Renewable energy can be derived from different sources such as hydroelectric power, wind, photovoltaics and biomass (e.g. Rosillo-Calle et al., 2007; O'Keefe et al., 2010). Worldwide electricity production in 2009 was 66 % from fossil fuels, 26 % from renewable sources, 8 % from nuclear power. Capacity increase during 2008-2009 originated: 53 % from fossil fuels and 47 % from renewable. (REN21, 2010).

Biomass can be used to produce bio-energy from renewable sources. Biomass is an organic material produced initially by photosynthesis. Biomass may include plant materials, agricultural residues i.e. animal manure, crop-wastes and any other material made directly or as a by-product during biomass processing. Bio-energy contributes 10-15 % of primary worldwide energy production, however, there are vast regional differences in the availability. (Kaltschmitt et al, 2002; Berndes et al., 2003; Parikka, 2004).

Finland has committed to increase the use of renewable energy to 38 % of total end-user energy consumption (Finnish Government, 2008). In Finland, the wood-based primary energy in 2005 was 76 TWh, including wood chips 6 TWh, small scale use of wood e.g. fireplaces 13 TWh, black liquour in pulp & paper industry 37 TWh, and industrial leftovers 20 TWh. The national goal for using wood-based biomass by 2020 includes increasing the use of wood chips to 25 TWh, bio-fuels for traffic to 7 TWh, wood pellets to 2 TWh (Pekkarinen, 2010).

The moisture of wood has an impact on both, its burning and transportation (e.g. McKendry, 2002; Demirbas, 2004; Demirbas, 2005; Fagernäs et al., 2010). Consequently, it is vital to consider where and how wood is dried (e.g. Hillebrand, 2010; Röser et al., 2010). There are different moisture measuring techniques available, including both on-line and sample analyses (Järvinen et al., 2007; Korpilahti and Melkas, 2010)

This study analyses the economic impact of moisture in different parts of wood biomass supply chain. This study makes a wide analysis on the significance of moisture for using wood-based fuels in Finland, founding on the national goals for increasing the use of wood chips. The calculations cover the entire supply chain, including collecting the wood, drying, transportation and combustion process. The above can be condensed into the following research questions:

RQ 1 What is the supply chain required for harvesting, collecting and transporting wood-based bio-mass?

RQ 2 What is the economic significance of moisture in different parts of the wood biomass supply chain?

RESEARCH METHOD / PROCESS

The purpose of this study was to analyse the economic impact of moisture in wood-based bio-fuels in Finland. Figure 1 illustrates the research process for this study.

Figure 1: Research process.

First a literature review was conducted to obtain adequate understanding over using wood-based bio-fuels to meet the national targets set for renewable energy. In addition, the physical significance of moisture for combustion was clarified.

Second, 10 expert interviews were conducted to clarify technical and practical details concerning the combustion process in power plants capable of using wood-based bio-fuels and sourcing of bio-energy. The interviewees were experienced bio-energy experts covering the studied topic in a versatile manner, including all the phases of the bio-fuel supply chain .

Third, the interviews were thoroughly analysed in order to obtain solid basis for economic calculations.

Finally, economic calculations were conducted to understand the impact of moisture in wood-based bio-fuels in Finland. The purpose was to clarify the magnitude of the impact, rather than to give very detailed exact figures suitable for all cases. The calculations cover the entire supply chain, including collecting the wood, drying, transportation and burning process. However, this study does not cover all the details of boiler house efficiency. Also, potential investments are excluded in this study.

RESULTS

Supply chain for wood-based biomass

This study indicates that the moisture in wood-based bio-mass ought to be assessed throughout supply chain. The supply chain typically consists of 1) harvesting, 2) local movement of wood, 3) local storing & drying of wood, 4) chipping, 5) transporting woodchips to the point of use, 6) optional thermal drying, and 7) burning.

Harvested wood biomass may contain of collecting branches and stubs left after ordinary logging. However, this is not enough to meet the wood biomass needs, and may include separate thinning of woods. Thinning of woods for the purpose of collecting bio-mass improves the wood growth as a positive side-effect. Moisture content during harvesting is always high and cannot be influenced. Consequently measuring the moisture content during harvesting is not feasible.

Harvested wood needs to be collected to small piles thus requiring to be *moved locally*. During local movements, measuring the moisture content is not feasible.

Local storing and drying of wood is an essential low-cost step in reducing the wood moisture content. Collected wood is transported and stored in larger piles and air dried for at least three summer months or alternatively over a year. These larger piles locate in places accessible by larger vehicles for the purpose of later transport to a power plant. The large piles are covered by a tarpaulin to enable better air drying. Also, proper air ventilation underneath the pile needs to be assured. The pile is constructed so that rain water runs of the pile. The purpose of this phase is to reduce the moisture content to a level that the wood can be used as fuel. However, measurement of moisture is not typically organised as

the number of piles to be measured is extensive. The benefits of measurements are not seen to exceed the costs. Should the air drying be conducted correctly the moisture level is expected to be acceptable.

Chipping of wood is organised at the site for local storing and drying. Wood chips are loaded directly to trucks by the chipping machine. The moisture content of wood chips is an important parameter for burning process. In addition, excessive moisture content increases transportation costs unnecessary when water is transported. Moisture content is, however, typically not measured during chipping.

Wood chips are typically *transported* by trucks that have weight-based maximum load limitations, up to 38 tonnes. The trucks are 100-140 m^3 in volume. The moisture content has a significant impact on transport costs.

Wood bio-mass may be *dried thermally* after transportation, if cheap excess energy is available. This type of drying is optimally timed to occur during summers when excess energy is available from industrial processes. During winters, this excess energy is more sensible to be used for heating local houses. Thermal drying is, however, normally not conducted as the burning processes have typically been optimised to use wood bio-mass with moderate moisture content.

Burning processes have been typically optimised to utilise wood bio-mass with moisture content of 35-45 %. Moisture content is typically controlled by analysing samples taken from arriving wood chip loads. Moisture analysis takes some twelve hours, making the feedback mechanism slow from the perspective of burning processes. However, instant online measuring methods are currently under development.

Analysis of the economic impact of moisture

Fuel value for wood can be calculated by following equation (1) (Alakangas, 2000; Kaltschmitt et al., 2002):

$$LHV_A = LHV_D * (1-M) - \Delta H_{vap} * M \qquad (1)$$

where,

- ΔH_{vap} is the enthalpy of vaporisation = 2.441 MJ/kg
- LHV is the lower heating value
- LHV_A is the lower heating value on arrival
- LHV_D is the lower heating value for dry wood
- M is the moisture content on arrival.

Coal and hydrogen are the components of wood that burn in practise. When hydrogen burns, water is formed, requiring energy for vaporisation resulting in weaker total efficiency in a similar manner as the moisture absorbed in the input wood. According Oulu Energy, LHV_D = 19.4 MJ/kg is a typical value. This value includes this phenomenon and is used in the calculations.

Table 1 summarises the influence of moisture in real fuel value of wood. The values in Table 1 have been calculated as described above using equation (1). When moisture content is 25 w-%, the wood is considered well dried.

Table 1: influence of moisture on fuel value.

Moisture w-%	LHV_A MJ/kg
25	13.9
30	12.8
35	11.8
40	10.7
45	9.6
50	8.5

Table 2 illustrates the influence of moisture on the number of required truck loads.
Table 2 estimates how many truck loads of wood chips are required to meet the national energy production goal of 25 000 GWh/a, set for wood bio-mass. The calculations acknowledge the fuel values (LHV_A) for wood bio-mass with different moisture contents as given in Table 1. The calculations assume a truck load to be 35 tonnes in weight. Additional wood % means the amount of additional dry wood required to compensate for the negative impact of moisture. Additional truck loads is the additional loads required to transport the additional wood. The required number of truck loads is calculated by using equation (2).

Truck loads = (25 000 GWh / (LHV_A/3.6 MJ/MWh)) / 35 tonnes (2)

Table 2: influence of moisture on the number of required truck loads.

Moisture w-%	Additional wood %	Truck loads #	Additional truck loads %
25	0	184 467	0
30	1	200 147	8
35	3	218 740	19
40	5	241 141	31
45	7	268 653	46
50	10	303 252	64

Table 3 illustrates the additional annual transportation costs to meet the national energy production goal caused by increased moisture content. Typical compensation received by a truck company 2 €/km for a 35 tonne truck (Oulu Energy, 2011; Hakeyhtymä Kankaanmäki, 2011). It is assumed that an average transportation distance is 80 km, resulting in a truck load to cost 2 * 80 km * 2 €/km = 320 €.

Table 3 also shows the cost of additional raw material required to compensate for the moisture in order to meet the national energy production goals. The calculations are based on raw material price level of 20 €/MWh. The additional cost for raw material can be calculated using equation (3).

Additional cost = National goal / LHV_A * Additional wood % * Price level (3)
where,
Additional cost Additional cost for raw material

National goal	25 000 GWh
LHV_A	The lower heating value on arrival (fuel value)
Additional wood %	Additional dry wood required (from Table 2)
Price level	20 €/MWh.

Table 3: Additional annual transportation costs & additional cost for raw materials.

Moisture w-%	Additional transportation cost M€	Additional cost for raw material M€	Total additional cost M€
25	0	0	0
30	5	6	11
35	11	14	25
40	18	23	41
45	27	34	61
50	38	48	86

In reality, moisture content ranges between 30 – 45 weight-%. Table 3 shows that the total additional costs for moisture content 45 w-% exceed those for 30 w-% by 50 M€. This 50 M€ is the biggest theoretical impact of moisture in Finland. The market value for the national goal for 25 000 GWh is 500 M€, when using the market price of 20 €/MWh for wood bio-mass. The calculations thus show how the significance of moisture is only 10 % of the market value of wood bio-mass, opposed to a common understanding.

Raw material moisture content has an impact on the burning process, thus measuring of moisture is essential for optimising the process. Developing measuring techniques to enable real time monitoring of moisture levels would be advantageous. The supply chain has a number of involved actors. The wood moisture content has significance on pricing of raw materials among the actors.

CONCLUSIONS

As a part of European strive towards increasing the use of renewable energy, Finland has committed to increase the use of wood bio-mass. The moisture of wood has a significant impact on both, its burning and transportation. This study analyses the economic impact of moisture in different parts of wood biomass supply chain by making calculations covering the entire supply chain, including collecting the wood, drying, transportation and combustion process.

This study shows that wood bio-mass supply chain typically consists of 1) harvesting, 2) local movement of wood, 3) local storing & drying of wood, 4) chipping, 5) transporting woodchips to the point of use, 6) optional thermal drying, and 7) burning.

Moisture content in wood bio-mass typically ranges between 30 – 45 w-% when delivered to a power plant. The results of this study indicate that total costs for moisture content in Finland is annually some 50 M€ higher when using wood bio-mass with 45 w-% instead of 30 w-% by. Roughly half of this increase comes from transportation and another half from weakening burning efficiency. When the national bio-energy goal is achieved, the total market value of wood bio-mass is 500 M€. The calculations thus show how the significance

of moisture is only 10 % of the market value of wood bio-mass, opposed to a common understanding.

Actors in bio-energy field should understand that wood moisture has true significant only for small power plants that are not capable of utilising moist raw material. Larger power plants are typically capable of utilising air-dried wood bio-mass with moisture levels between 30-50 w-%. However, it is desired that the moisture content remains at roughly constant level. Continuous moisture content measurement would ease the optimisation of combustion process. Properly organised air-drying is the simplest and cheapest measure to decrease transportation costs and improve combustion.

ABSTRACT

Today, as it is commonly recognized, energy patterns lead to an unsustainable future, that concerns not only natural energy resources narrowness and scarcity but is strictly linked to greenhouse gas emissions (GHGs), mainly CO_2 ones. Burning fossil fuels is one of the main causes of energy natural resources depletion and climate changes. After power generation one, transportation is the second sector that considerably generates these phenomena. As per the above, policy makers efforts are more and more focused on how to effectively harmonize growing energy demand and climate change mitigation. In these scenarios, a valuable option is the increase of renewable energy sources utilization. Among these sources a relevant role is held by biofuels intending any fuel derived from biomass, living organisms (algae) or their metabolic byproducts (bovine manure). Biofuels of so called "third generation" seem to be a promising possibility to convert a low-input and high-yield no food feedstock into biofuels, mitigating the transportation sector influence on energy demand and climate changes.
The objective of this paper is to investigate the role of the third generation biofuels, their impact on existing transportation sustainability and linked emergent markets.

Keywords: Biofuels, sustainability, microalgae, environmental critical innovation

INTRODUCTION

As it is commonly recognized today energy patterns lead to an unsustainable future, that concerns not only natural energy resources narrowness and scarcity but is strictly linked to greenhouse gas emissions (GHGs), mainly CO_2 ones. It is not possible to encourage further fossil resources increment because consequent climate changes lead to local and/or global environmental disasters. It is estimated that exceeding the CO_2 atmospheric concentration limit of 450 ppm means to overpass the point of no return towards global warming and non-reversible environmental changes (Hansen et al., 2008; Rockström et al., 2009). This means that the use of fossil fuels must stop prior to deposits depletion.

According to the previous concerns and considering that burning fossil fuels causes approximately 60% (18 million metric tons, Mt) of total CO_2 emissions (30 Mt), their contribution to energy demand is equal to more than 80% (9.8 million tons oil equivalent -

Mtoe), models of low fossil fuels energy or low carbon economy must be realized (ITF, 2010; IEA, 2010). Among energy sector issues, the fuels production has significant criticisms because it highly depends on fossil sources. This awareness makes policy makers more and more engaged to find the right way to effectively harmonize the growing energy demand and climate change mitigation. In this paper fuel sector means the economical activities finalized to producing and delivering "energy" for transportation, that is all those systems for moving people or goods (family cars, trucks, airplanes, boats). In order to achieve the goal of low carbon economy, the innovations or the options explored for the energy sector looked upon: energy saving, energy systems efficiency improvement, switching to less carbon-intensive fossil fuels, capture and storage of CO_2 emissions and a wider use of renewable energy sources. The latter is a strategic option because it improves domestic energy self-sufficiency and security (particularly for countries importing many energy carriers), the economic stability and sustainability of energy needs and above all their use decrease the CO_2 atmospheric emissions.

A renewable energy source with a relevant role is biomass because it suitable to producing biofuels, intending any fuel derived from biomass, included living organisms (algae) or their metabolic byproducts (bovine manure). It is interesting to note that biomass was at the origin of fossil fuel origins and today is one of the best promising options to solve their crisis. It is a matter of fact, that using biomass for biofuels production is not a novelty but the interest in its development is directly proportional to oil price, oil availability and environmental protection. Biofuels can be grouped in 'generation', according to the type of biomass feedstocks and technology used. Up today there are three biofuels generations. The first refers to biofuels, which are produced from food crops treated with technologies, today well established, including transesterification (biodiesel form oil crop), fermentation (bioethanol from sugar or starch crops) and anaerobic fermentation (biogas from organic residues). Second generation relates to biofuels produced from a wider range of no-food lignocellulosic crops feedstocks. Utilized technologies include different options such as enzymatic production of lignocellulosic ethanol and pyrolysis-oil and syngas gas based fuels. Second generation technologies are not yet economically and technical aspects are still under development. Third generation, also called oilgae or algae fuel, refers to the possibility to convert a low-input and high-yield no food feedstock, like algae are, into biofuels. Also in this case the technical aspects affect the diffusion and the convenience of this last generation.
These preliminary considerations summarize the principal reasons why the currently energy patterns, and particularly fuel sector, are unsustainable. It is commonly argued that environmentally technical innovations stimulate the change toward environmentally friendly and sustainable patterns. The innovation is environmentally critical if it causes large reduction in environmental risks, represents a significant technical advances and involves favorable ratio of social and private returns.

In particular, the reductions in environmental risks have to consider a large populations and significant categories of risks as human health and natural ecosystems modifications. It is beyond question the importance of human health but also the modification of natural assets is imperative because we do not have any alternatives to the services provided from the Nature (for instance the service of waste neutralization, freshwater generation, clean air, new soil). Among the critical concerns of natural ecosystems, the biodiversity losses are

the most important risks. Furthermore, the technical advances should introduce a method of production absolutely new and we cannot consider as a significant advance the simple increasing of efficiency of the current technology.

The objective of this paper is to investigate the role of the third generation biofuels, their impact on existing transportation sustainability and linked emergent markets.
The paper is split in different sections. After a brief introduction, a first part presents an overview on first and second biofuels strengths and weaknesses which make necessary to consider the third generation. A second section regards the state of technology in the different phases of third generation biofuels production chain. In the last part and based on the results obtained, the authors illustrate the related effects of the applied technologies, if they will be able to modify fuel generation patterns, if they will be environmentally critical technology related to CO_2 emissions and if they will represent a chance for the emergent markets of bio-chemicals.

THE CURRENT SCENARIO OF BIOFUELS PRODUCTION

The renewable energy sources, as above, have to play a relevant role in the near future and among them the role of biomass will be significant because it gives the possibility to produce biofuels intending any fuel (combustible materials) derived, directly or indirectly, from biomass such as living organisms (algae) or their metabolic byproducts (bovine manure). A wide range of biomass (energy crops, food, short-rotation crops, agricultural waste, etc.) sources can be used to produce bioenergy and the type of biomass used influence the energy yield.

The use of biomass to produce biofuels is not a novelty and several reasons, such as concerns about the adverse effects of increase greenhouse gases, the dependence on fossil fuels, the continuous increasing of oil price and instability in political situation, justify the expansion of biofuel markets and the interest related to it. In fact, biofuel can be a good opportunity to government worried about the stability of their fuel imports or the long-term future of global oil production. It is estimates that the world energy demand will increase of 36% up to 2035, from the current 12,300 Mtoe to 16,700 Mtoe; we know that about 30% of total energy consumption is related to transport sector and we can estimate that this consumption is going to expand in parallel with the enlargement of transport demand (IEA, 2011). Over the 2006-2030 period, transportation accounts for nearly 80% of the total increase in world liquids consumption (EIA, 2010). All these reason s show that it is necessary to re-organize transport sector and that it is important to free it from dependence on fossil fuels and on the continuing increases in oil prices which will make it untenable in the long run. That is why in these last years great attention has been paid on liquid biofuels for transportation, mostly produced using agriculture and food commodities as feedstock.

Biofuels can be classified according to source and type. They may be solid (fuelwood, charcoal, wood pellets), liquid (ethanol, biodiesel, pyrolysis oils) or gaseous (biogas). They also can be divided in: primary biofuels that are used directly in their natural form and secondary biofuels (charcoal, ethanol, biodiesel, bio-oil, biogas) that have a great application also for transport sector. Table 1 illustrates the different methods of biofuels generations.

Table 1: Methods of biofuels generations.

First generation biofuels	- **Vegetable oils** - **Ethanol** - **Biodiesel**
Second generation biofuels	- **Lignocelluloses ethanol** - **Enzymatic bioconversion of vegetable oils** - **Hydrogenation Biodiesel** - **Synthetic fuels**
Third generation biofuels	- **Energy crops for bio-alcohol** - **Hydrogen from algae** - **Oil from algae**

Source: personal elaboration by the authors.

The major liquid biofuels currently produced are ethanol, with approximately 76 billion liters in 2009 obtained by feedstocks containing significant amount of sugar or materials that can be converted into sugar, and biodiesel (16 billion of liters in 2009), generated by vegetable oils, with ethanol production being far greater at the global scale (Eisentraut, 2010; REN21, 2010; RFA, 2011). In fact, actually, biodiesel production is dwarfed by that of ethanol. The first generation biofuels are based on a well-established technology, which is widespread in the world. In Brazil, for example, ethanol from sugarcane replaces about 50% of gasoline for transportation.

Brazil and United State of America (USA) are the most important producer of ethanol respectively by sugarcane and corn, but in European Union (EU) it is estimated a future ethanol production approximately equal to 12 billion liters/year by 2012 (Eisentraut, 2010; REN21, 2010; RFA, 2011).

Brazil and USA accounted for 88% of global ethanol production in 2009. Ethanol production in USA was about 41 billion liters in 2009 (about 54% of global production) and corn-based USA ethanol displaced more than 360 million barrels of imported oil for gasoline production. Owing to the increase in sugar prizes and the adverse weather conditions, ethanol production in Brazil has decreased from over 27 billion liters in 2008 to 26.3 billion liters in 2009 (REN21, 2010; RFA, 2011).

Almost 80% of the world's production of biodiesel occurs in Europe where biodiesel plays an important role among biofuels consumption. France has increased its production by 34% in 2009 to surpass Germany, that was the leading country in manufacturing biodiesel from rapeseed in EU thanks also to a strict cooperation with automobile industry (RFA, 2011). The production of biodiesel has increased in percentage terms in countries such as Argentina, Austria, Colombia, Indonesia, Spain and United Kingdom while has decreased in other top countries such as USA, Italy and Belgium.

In order to incentive the use of renewable resources, in early 2008, EU has set a legal minimum of 10% renewable fuel share for all transportation fuels by 2020, which would amount about to 34 Mtoe or roughly 60 billion liters if all biofuels are ethanol. In addition to the target of 10%, in the EU for share of transport energy from renewable includes Belgium and Croatia (5.75% by 2010), France (10% by 2015) and Portugal (7% biodiesel by 2010).

Furthermore, only alternative fuels that meet established GHG savings and limits on biodiversity impacts will count towards the legal quota, thus limiting the import of biofuel blends not conformed to European quality standards.

PROS AND CONS OF BIOFUELS PRODUCTION

One of the parameter used to judge the opportunity to produce biofuel is the *fossil energy* balance, i.e. the ratio between the energy content of the biofuel and the fossil energy consumed in its life cycle. A fossil energy balance of 1.0 means that it requires as much energy to produce a litre of biofuel as it contains (no net energy is gained or lost); a fossil fuel energy balance of 2.0 means that a litre of biofuel contains twice the amount of energy as that required in its production. Conventional gasoline and diesel have a fossil energy balance of around 0.8-0.9, because some energy is consumed in refining crude oil into usable fuel and transporting it to the markets. So, we can consider the efficiency in biofuels and the reduction in the dependence from fossil fuels if the energy balance exceeds that numbers.

Just as different crops have different yields in terms of biofuel per hectare, wide variations also occur in terms of energy balance and greenhouse gas emission reductions across feedstock, locations and technologies. For example sugar-cane ethanol from Brazil has a much more favorable energy balance; for each ton of sugarcane, the fossil fuel energy input is equivalent to 210 MJ and the energy output close to 2,190 MJ, yielding an energy output ratio around 9; this depends on the fact that in that country ethanol is processed using biomass residues (bagasse) from sugar cane as energy input.

The net energy balance is an important consideration with regard to determining the net greenhouse gas emissions from the use of a biofuel, even if studies have not totally demonstrate that there is a point to point relationship between net energy balance and net greenhouse gas emissions. Lots of the considerations depend on system boundaries; for example, most recent analyses (Hill et al., 2006; Ghallagher, 2008; Howarth and Bringezu, 2009) show a positive benefit on net greenhouse gas emissions from using liquid biofuels, especially for producing ethanol from sugarcane or biodiesel from palm oil, if peat soil conversion and indirect land use changes are not considered.

The production of biofuels have shown, during the years, some limits that have changed the optimistic first impression that they could have been the perfect response to increasing demand of energy and the perfect candidate to replace gasoline and diesel fuels. Production of biofuels may have lots of environmental consequences: changes in the land use, expansion in agriculture, changes in agriculture practices, transportation of biomass used to make biofuels, conversion of the biomass into fuels and disposal of the remain waste

materials after fuels are made. Not less important is the effect, from an economical and social point of view, of the conversion of land on no-food agriculture.

Environmental concerns related to the production of biofuels have been discussed in lots of studies (Azar and Larson, 2000; FAO, 2008; Howarth and Bringezu, 2009) and now they represent the most controversial factors of biofuel production.

First of all, the reduction of greenhouse gas emission was the first and prominent objective of biofuel policies. All over the world ambitious reduction goals have been stated; for example UE had first fixed an objective of 45-60% by 2015 that it is now changed into 50% by 2017.
The basic question is whether the use of biofuels and thus the use of land for feedstock production saves more GHG emissions by displacing fossil fuel than that saved by leaving land in its existing use even while continuing to use fossil fuels. In particular this affect the forest land modification (Howarth and Bringezu, 2009).

As we mentioned before, GHG emissions are driving the production of biofuels and they are the major problem on which the most efficient refining technologies are based. The impact of biofuels on greenhouse gas emissions varies widely, depending on where and how the various feedstocks are produced, the logistics concerns, the technology and the type of energy used.
In any case, we might think that as biofuels are produced from biomass they should be carbon neutral as their combustion only returns to the atmosphere the carbon fixed by the plant during its growth. But, in reality, different biofuels can vary in the GHG balances when compared with fossil fuels and, sometimes, they can determinate more GHG than fossil fuels do. The agricultural practices, such as fertilizing, pesticide use, irrigation technology and soil treatment, influence net GHG emissions and can determine a balance that may not necessarily be positive or as positive as it is often initially assumed. For example a problem is the nitrous oxide (N_2O) that is realized by nitrogenous fertilizer as land conversion. A full consideration of N_2O emissions can transform the net GHG emissions of biofuels from positive to negative. Moreover, the land conversion itself can have some negative effects on GHG emissions that sometimes can double the GHG emissions respect to fossil fuels because of deforestation.

Secondly, large areas of land are necessary to produce adequate amount of biofuels to substitute a significant quantity of fossil fuels. For example, it is estimated that the 10% substitution of gasoline and diesel fuel requires 43% and 38% of current cropland area in USA and Europe respectively (Righelato and Spracklen, 2007). As even this low substitution level cannot be met from existing arable land, forests and grasslands would need to be cleared to enable production of the energy crops and this may place additional strains on the environment. Moreover, if we stress the opportunity to use sustainable practices for crops cultivation, needed area is larger.

Enlargement of land use can have immediately and direct environmental and social consequences: FAO report (2008) stated that while biofuels will offset only a modest share of fossil energy use in the future, they will have much bigger impacts on agriculture and food security.

The use of some food crops (maize, sugar, oilseeds, palm oil) for the production of biofuels has as consequence the increase of food prices. Between 2006 and early 2008, corn prices rose from $87 USD per ton to $217 USD per ton (FAO, 2008). The growth of some agricultural products, as new and significant source of demand for biofuels, contributes, with other factors, to higher prices in agricultural commodities. So, we can say that there is a strong competition between food and biofuels for raw materials appropriation and probably it is going to grow in parallel with the growth of biofuel production in lands suitable of food-agricultural production. This is one of the most controversial points to be analyzed when we want to weigh the pros and cons of no-food agriculture. In fact, from one side biofuel is viewed as an opportunity of promoting access to energy in rural areas and supporting developing countries agriculture sector and this is shown for example by the important role that ethanol production from sugarcane has for Brazilian economy. From another side there is the risk that higher food prices could threaten the food security of the world's poorest people that paid more the adverse effect in terms of lack access to energy, food, land and water.

Risks for biodiversity and environmental problems related to an intensive form of agriculture (water consumption due to irrigation, use of pesticide, no set aside) need to be discussed if we want to evaluate whether the benefits of devoting land to biofuel exceeds those of leaving that land in its existing use or potentially improving its existing use in other ways. To preserve biodiversity, EU provisions prohibit conversion of wetland to no-wetland and forest to other biofuels uses, but would permit harvest of forest or conversion of those unmanaged forests that do not meet standards for native vegetation to tree plantations.

It is estimated that, in the short term, the introduction of good agricultural practices and the conversion of large areas of land back to secondary forest provide other environmental services (such as prevention of desertification, provision of forest products, maintenance of biological diversity, regional climate regulation), whereas conversion of large areas of land to biofuel crops might place additional strains on the environment. Also the irrigation is an adverse effect of no-food agriculture, as the oil problems can be translated into the water problems (Service, 2009). All these problems show that we need to pay attention on cost-benefit analysis. Infact the efficiency of biofuels depends mainly on two factors: the net reduction in fossil carbon emissions arising from use of agricultural derived biofuels and the effect of alternative land-use strategies on carbon stores in the biosphere. Some studies showed that in a short term (30 years or so) it could be better to improve the efficiency of fossil fuel use, to conserve the existing forests and to restore natural forest and grasslands habitat on cropland that is no needed for food. Forestation of an equivalent area of land would sequester two to nine times more carbon over 30 year period than the emissions avoided by the use of biofuel (Righelato and Spracklen, 2007). According to this consideration, the emissions cost of liquid biofuels would exceeds than of fossil fuels and, sometimes, it is better to convert large areas of land back to secondary forest in order to provide other environmental services, such as prevention of desertification, provision of forest products, maintenance of biological diversity, regional climate regulation.

Together with the above-mentioned problems, the production of biofuels shows some other defects. One is related to the intrinsic characteristics of ethanol; ethanol is in fact corrosive and hygroscopic and these characteristics make difficult its storage and transport.

Also biodiesel shows some problems. For example, the presence of some fatty acid methyl esters tends to give it poor cold flow properties. Moving to non-oxygenated biofuels can overcome many of the issues of corrosion and cold-flow inherent in oxygenated biofuels.

Another important consideration concerns the small role of biofuel in the context of total energy consumption as they supplied only for 0.4% in 2006 (IEA, 2011). In terms of liquid fuels used for transportation, biofuel contributed 1.8% globally, with fossil fuels making up 92% of global use. In the 2030 scenario, it is forecast an increasing in the coal share at the expense of the oil while, for the some period, biofuels are projected to represent the still modest share of 3.0-3.5 % of global transport energy consumption (FAO, 2008).

According to these considerations, biofuels feasibility and economical convenience mainly depends on the political impulse towards this sector also in terms of incentives and subsidies and technological innovations, in order to eliminate critical states previous analyzed.

Actually, biofuel tax exemptions exist in ten EU Countries at last (Belgium, France, Greece, Ireland, Italy, Lithuania, Slovenia, Spain, Sweden, UK), in the OECD Countries Australia and Argentina and in several developing Countries (Argentina, Bolivia, Colombia, South Africa) (REN21, 2010).

The OECD has estimated that the elimination of all biofuel subsidies and mandates would reduce US ethanol production by roughly 20% on average compared to the level that ethanol would otherwise average in 2013-2017.

Technological innovation can lower the costs of agricultural production and biofuel processing. Investment in Research and Development (R&D) is critical for the future of biofuels as economically and environmentally sustainable source of energy.
In this sense, the tendency is towards new generation of biofuels able to balance economy and ecology. Since these fuels can be produced from biomass with much greater efficiency than for ethanol, less land is needed to produce an equivalent amount of energy. Greenhouse gas emissions and other environmental consequences associated with land conversions and intensive agriculture are reduced accordingly, as is the potential competition with food production.

The second generation biofuels use biomass not used for food production and, in this sense, represent a great opportunity to overcame lots of debates on pros and cons the use of first generation biofuels. In fact, lignocellulosic biomass is more resistant and it can be used completely as the entire crop is available as feedstock for conversion to fuel. On the other side, they have some problems related to the lack of highly efficient enzymes for converting cellulose. Moreover, lots of the species developed (jatropha curcas and switchgrass), although the advantage of not competing with the food market, are considered invasive or potentially ones and may have negative impacts on water resources. In any case,

investments are direct to the development of this biofuels; in particular international investors are rushing to establish large areas of jatropha cultivation in developing countries because of its great adaptability and potentiality.

In any case, as we mentioned above, the new tendency is towards third generation biofuels that refers to the possibility to convert a low-input and high-yield no-food feedstock into biofuels. Algae offer the potential for higher energy yield from lipids that would be cultivated using salt and/or fresh water in areas not currently used for food agricultural production so their use can reduce or eliminate food-fuel competition.

ALGAE BIOFUELS OUTLOOK

The term algae include macroalgae - seaweed- and a vastly diversified group of microorganisms known as microalgae. Algae can be aquatic or subaerial when instead to be immerged in the water they are exposed to the atmosphere. They show a good tolerance for a broad range of environmental conditions such as pH, temperature, turbidity, oxygen and carbon dioxide concentration. Due to these attitudes and to their carbohydrate (8-64% on dry matter), protein (6-71% on dry matter) and lipid (15-75 on dry matter) content algae are minor sources of foods, feeds and high-value nutraceuticals, pharmaceutical and other bioactive compounds (Bart, et al., 2010; Becker, 2007; Chisti, 2007). The growing interest in algae is, as just mentioned before, their potentiality to provide different types of biofuels including biohydrogen, methane from thermal gasification or anaerobic digestion of algae biomass; bioethanol by fermentation; bio-oil by pyrolysis and biodiesel by trasbesterifications of algae oil fraction (Figure 1).

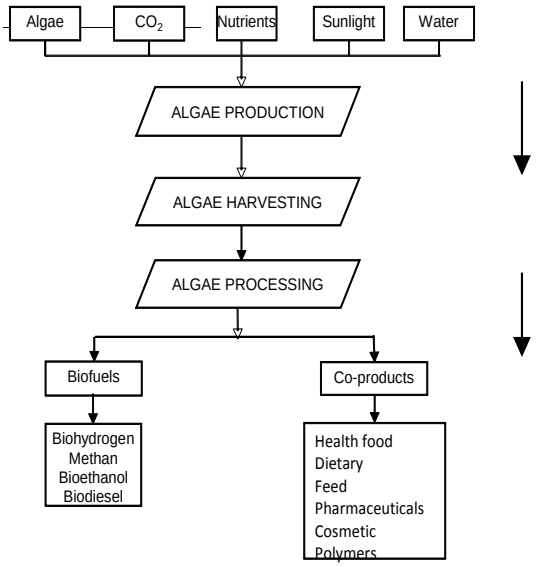

Figure 1: Integrated algae biomass processing (personal elaboration by the authors).

Biodiesel and bioethanol are the main promising options for the future sustainability of transportation sector but considering that fossil diesel is the fraction most used in transportation sector in this paper the authors focus their analysis on biodiesel. This choice

is based on worldwide diesel and gasoline consumption figures in 2009 equal respectively to more than 30 and 27 million of barrels per day, and because of the most commonly argued approach of algae exploitation is to obtained biodiesel rather than others biofuels (BP, 2010; Chisti, 2007; Lardon et al., 2009; Thurmond, 2011). Furthermore because of oil yield from macroalgae up today is less profitable than microalgae the authors in their analysis refer to microalgae (Bart, et al., 2010).

Microalgae are microscopic organisms that grow in fresh, salt or wastewater. The three most important classes of microalgae in terms of abundance are the diatoms (Bacillariophyceae), the green algae (Chlorophyceae), and the golden algae (Chrysophyceae). Microalgae seems to be a miniature biochemical factories, they are more photosynthetically efficient than terrestrial plants and they are efficient CO_2 fixers alike from atmosphere, from discharges gases (power plants) and soluble carbonates (Na_2CO_3 and $NaHCO_3$). To produce one ton of microalgae biomass approximately 180 t of CO_2 are required. Microalgae are able to double their biomass within 24 hours, so they show a very short harvesting cycle (1-10 days) allowing a higher oil yield compared with the best oil crops (table 2) (Andrate et al., 2011; Bart et al., 2010). Due to their just mentioned adaptability to a wide range of climate conditions, including wasteland and/or wastewater, they can be cultivated also in desert areas without competing with agriculture land use and food crops.

Table 2: Oil crop productivities.

Plant	Oil kg/ha	Oil L/ha
Corn	**143**	**172**
Soybean	**374**	**446**
Jatropha	**1,730**	**1,892**
Coconut	**2,260**	**2,689**
Oil palm	**5,000**	**5,950**
Microalgae[a]	**136,900**	**157,435**
Microalgae[b]	**58,700**	**67,505**

a) 70% oil (by wt) in biomass. b) 30% oil (by wt) in biomass.
Source: Burt et al., 2010; Chisti, 2007.

All these characteristics and considering that since 2007 the biodiesel demand has exceeded the vegetable and animal oil supply, the potentiality of microalgae has to be investigated despite technical and economic problems still affecting oilgae production and its costs.

Oilgae production chain is composed by several phases such as microalgae cultivation, harvesting, oil extraction and subsequent transformation in biodiesel. It is important to underline that up today the microalgae biomass production useful for biodiesel is obtained in pilot scale plants (from 10 meter to 2 hectares). This does not mean that there is no algae production, quite the contrary, worldwide algae production (few thousand tons of algae per year) are used in niche but profitable markets (up to 800,000 USD/t) such as health food, dietary, pharmaceutical or cosmetic ones (Bart, et al., 2010; Thurmond, 2011).

Sunlight, CO_2, water and nutrients such as nitrogen (N), phosphorus (P), and potassium (K) are the principal inputs needed to make microalgae growth. Silica and iron, as well as several trace elements, may also be considered important nutrients as the lack of one can limit their growth.

Different important factors influence the productivity of microalgae biomass first of all microalgae species (fatter and faster), light and insolation conditions (to improve the photosynthetic process) and the amount nutrients (determinant growth rate and chemical composition) (Pfromm, 2011). The key factors determining the growth algae rate are summarized in table 3.

Table 3: Factors influencing growth algae rate.

Algae species	**Algae species depend on the type of products you want to produce. "Fatter and faster" approach is at the base of the choice of high oil content algae with the faster growth rate.**
Aeration and CO_2	**The algae need aeration to fix CO_2 and to grow. To improve growth rate it is necessary a secondary CO_2 source for instance flue gas from power plant.**
Medium and Nutrients	**The composition of land and/or water determine growth algae rate. If water from farm-run off or waste water effluent are used, their high level of nitrogen stimulate the algae growth.**
Light	**Normally sunlight is needed for photosynthesis process. Artificial light sources are introduced to stimulate algae growth in same demonstrative pounds.**
pH level	**To grow optimally algae need a pH ranging between 7 and 9. This range could be influenced by CO_2 and nutrients inputs.**
Mixing	**Mixing is necessary to ensure that all algae cells are equally expose to light and to prevent sedimentation**
Temperature	**Warm temperature ranges are often required by several algae species to grow**

Source: personal elaboration by the authors on data by Thurmond, 2011.

They are cultivated in various types of ponds (such as closed or open raceway-ponds) and photobioreactors. Raceway open pond is the cheaper system, microalgae oil estimated production costs in open raceway ponds ranges between 2.4-4.5 $/L. Critics points of these systems are the vulnerability to contamination by other microorganisms (bacteria and/or other algae species) and the difficulty to control biocultural conditions (pH, light, carbon dioxide, temperature). Closed-ponds system is preferable but researches and studies show

the difficulty of producing large amount of algal biomass in such a plant and above all costs increase too much losing competitiveness with the photobioreactos. They, an enclosed and light culture vessel, are much more expensive systems than raceway open ones. Estimated oil production costs ranges between 5.2 -10 $/L (Thurmond, 2011). The principal technological goals during this phase are the improvement of microalgal biomass growth with high oil percentage and the development of the best and cheaper microalgae growing system able to achieve commercial success in sufficient quality and quantity to meet commercial scale viability in biofuels markets in the next 3-5 years.

The subsequent phase in oilgae production chain is harvesting and dewatering. Several options are available with different efficiency and cost level. Sedimentation, filtration, froth floatation, flocculation and centrifuges are commonly cited algae harvesting methods. Sedimentation is often the first step used in harvesting utilizing gravity to operate a preliminary separation of algae from water. Filtration due to dimensions of microalgae does not work well as froth floatation. Centrifuges systems are today the most used despite their capital and operating high costs (0.6 $/L) especially for energy inputs (3 kWh/L) (Thurmond, 2011; Schenk at al., 2008). The main problem of this method is the efficiency because algae are small portion of the total mixture centrifuged (1-4 g/L of mixture). When algae are harvested and dewatered oil extraction can be made by different methods such as traditional mechanical crushing, solvent extraction (with hexane and benzene), supercritical CO_2, microwave, ultrasonic cavitation and cellular decompression. Also in this case they differ for efficiency and costs. Hexane extraction system is the most used even if ultrasonic cavitation is the emerging trend in oilgae industry as it can accelerate the extraction processes. Microwave technologies are also considered a good option but its high capital and energy costs make it too much expensive to use. Like other vegetable oil, algae oil cannot be directly used in diesel engines above all because of its high viscosity. The algae oil obtained has to be transesterified to achieve the right standards parameters required in USA and/or EU for fossil diesel.

FINAL REMARKS

The sustainability of energy system represents one of the most important problems in the next future above all in transportation sector characterized by a high dependence from fossil fuels. To achieve this sustainability means to make compatible during the time, energy demand with energy supply without compromise natural equilibrium. Unfortunately there is not *one* solution rather than a *mix* of solutions by which to solve this kind of problem. Moreover, the mix has to be contextualized according to the realty, possibility and potentialities of specific situation. In this general context biofuels represent an innovative good options and in order to understand their role, in the first part of this paper, the authors have briefly described the evolution of biofuels of first and second generation highlighting pros and cons. Subsequently they focus on third generation with particularly attention on algae biodiesel. At the end of this review, authors have analyzed the contribution of biofuels innovation with the aim to verify if they represent environmental critical innovations able to get transportation sector towards sustainability. Based on the definition of environmentally critical innovation that is a type of innovation able to cause large reduction in environmental risks, to represent a significant technical advances and to

involve favorable ratio of social and private returns, the authors have been compared the three biofuels generations (Table 4).

Table 4: The role of environmental critical innovation in the biofuels production.

	Reduction in environmental risks	Technical advances	Social effects	Market developments
First generation	**Low**	**High**	**Negative**	**Low**
Second generation	**Low**	**High**	**Medium/low**	**Low**
Third generation	**High**	**High**	**Medium/high**	**High**

Source: personal elaboration by the authors.

Environmental critical innovation boosts shifting from the first to the third biofuels generation. The main limit of first generation biofuels is the social effects (food and cropland competition) followed by a low reduction in environmental risks. In fact several first generation biofuels input/output analysis are available and, despite the difficulties to compare final results, they often show that CO_2 fixed by the energy crop are equal or exceed CO_2 emitted during production and consume phases or in the same way energy inputs during all phases (agricultural, production and consume) are higher than energy value of biofuels produced. Second biofuels generation overpass the social effects but the feedstock logistic difficulties; high production costs mainly due to the investment and moderate reduction in environmental impacts still limit them. As concerning algae biodiesel (third generation) it seems to be the promising environmentally critical innovation. The state of the art and the medium term scenario available show that algae exploitation can accomplish two environmental problems such as CO_2 sequestration and wastewater reduction. Algae need CO_2 to grow and can be grown in wastewater reducing two important environmental risks. They show high yield rates, high oil content and they are not in competition with food production, cropland and freshwater sources. Quite the opposite algae cultivation in arid and deserted land could contribute to the social and economic development of those areas. Moreover, algae biodiesel is accompanied by joint production of several profitable co-products (Figure 1) already present on existing value added markets. As just mentioned in previous paragraphs, today algae production is finalized to obtain profitable products such as omega3, carotenoids and other useful bio-chemicals. Up today, in terms of values the much more profitable algae commodities are those at the top of a pyramidal scheme at the base of which there are low value products such as algae oil useful in biodiesel production. The paradox is that the by-products of these emergent markets are source for biodiesel industry and market, which are suffering a supply feedstock crisis. The role of these emergent markets is also important because bigger are their return bigger will be the capacity to invest in R&D in algae biofuels field improving their techniques of production and making lower their production costs. These markets could be the bridge to include algae biodiesel in the mix of options useful to transportation sustainability.

CONCLUSION

At the end of this analysis, the authors believe that in third generation biofuels field, innovations still present a large margin of action. The main challenger to exploit algae biomass could be summarized in these words *fatter, faster, cheaper and better*. Fatter and

faster because it is necessary to identify and/or modify genetically the algae species with high oil content able to be harvested daily rather than few time a week. Cheaper and better because costs and efficiency in algae biomass production have to be progressed in order to became profitable for companies and so available on fuels markets. In any case, it is necessary to remember that joint to environmental critical innovations, such as algae biomass, a concrete contribution to make sustainable the global energy problem arrives *faster and cheaper* from energy saving actions.

ABSTRACT

As firms move toward environmental sustainability, management must extend managements efforts to improve environmental practices across the supply chain. The selection of a suitable green supplier according to green supply chain management criteria (GSCM) is essential for the sustainable development of manufacturing firms. The objective of this study was to select an optimal alternative in the presence of incomplete information and linguistic preferences using multiple GSCM criteria. The goal of GSCM is to reduce a firm's pollution and other environmental impacts. In the proposed method, the weights of GSCM criteria and alternatives are described using linguistic preferences that can be resolved with fuzzy set theory. Subsequently, the rank of each alternative was calculated from incomplete information by applying a grey degree. Moreover, a case study was used to resolve the proposed method, and the results and managerial implications of the analysis are discussed in detail.

Keywords: grey degree, fuzzy set theory, firm's green supply chain management

INTRODUCTION

In recent years, environmental management has evolved to include boundary-spanning activities in the supply chain, and both upstream and downstream activities are included in green supply chain management (GSCM) (Sarkis, 1998; Lee et al., 2009). A limited understanding of GSCM has hindered the development of a widely accepted framework that characterizes and categorizes a firm's environmental activities. The European Union has established a variety of environmental policies, including RoHS (the restricted use of hazardous substances in electrical and electronic equipment) and WEEE (waste electronics and electrical equipment) Directives. These directives ban manufacturers, sellers, distributors and recyclers of electrical and electronic equipment from launching new equipment that contains hazardous materials on the market (Tseng, 2009a; Tseng 2010a). While WEEE directives are aimed at the life cycle of the product, RoHS is targeted at the

product design stage. Although environmental regulations and mandatory programs have been implemented, pressure to protect the environment also comes from other external stakeholders.

Currently, a wide variety of studies on GSCM can be found in the literature (Zhu et al., 2008; Srivastava, 2007). Srivastava (2007) defined GSCM as a combination of environmental and supply chain management (SCM) activities, including product design, material selection, manufacturing processes, final product delivery and end-of-life product management. Moreover, through GSCM, firms can select from a wide variety of suppliers and leverage resources throughout the firm to eliminate the environmental impacts of supply chain activities. Firms typically expect their suppliers to go beyond environmental compliance and develop efficient, green product designs. In addition, suppliers are expected to assess the life cycle of a product. Nevertheless, the firm's suppliers must satisfy GSCM criteria under the constraint of incomplete information and subjective human preferences (uncertainty); however, this phenomenon has not been thoroughly examined.

GSCM philosophy focuses on how firms utilize the supplier's processes and technologies, as well as the supplier's ability to integrate environmental concerns and enhance the firm's competitive advantage (Vachon and Klassen, 2008). However, to study and advance the body of knowledge related to GSCM, identification of appropriate measures is necessary. To effectively and empirically advance the theory, greater attention must be focused on employing multi-criteria evaluations, assessing the validity of criteria and modifying unacceptable criteria through extensive literature reviews (Tseng et al., 2009b; Lee et al., 2009). Hence, in this study, a number of different criteria that can be used to evaluate GSCM practices were integrated, and a literature review on supply chain and environmental management was performed. Firms can benefit from the development of reliable and valid criteria, and the practitioner can apply these criteria as benchmarks to attain continuous improvement. One objective of the present study was to assist firms in understanding the criteria and implementation. However, the uncertainties and incomplete information are often encountered in the implementation process. In the process of GSCM, the selection of green supplier is always encountered, the multi-criteria decision making (MCDM) tools are always proposed to be applied in the process (Tseng et al., 2008).

In real systems, MCDM is often based on subjective preferences or incomplete information. Grey theory is superior for the theoretical analysis of systems with imprecise and incomplete information within a system of evaluation (Tseng 2010b). Moreover, the evaluation system having incomplete information is so called grey system and the triangular fuzzy numbers in grey system represents a set of numbers with less complete information, the system is

always represented as lack of information. Hence, the grey possible degree is to evaluate the incomplete information. The principles of the available theories and modeling schemes for the prediction and diagnosis of an uncertain situation are summarized, and the practical applications of theories and linguistic preferences are reviewed. People often employ natural language to express thoughts and subjective perceptions; however, the meaning of words in natural languages is often vague. Although the meaning of a specific word may be well defined, when that word is used to define a set, the boundaries of the set can become uncertain. Hence, the proposed method uses fuzzy set theory to appropriately express the determination of human judgment in GSCM criteria. The second contribution of this study is the development of a hybrid approach for the establishment of GSCM criteria for the selection of an optimal alternative.

In an effort to determine the uncertainty in the proposed model, GSCM criteria were integrated and an optimal alternative was selected. This paper contributes to GSCM literature by developing valid and reliable criteria based on information obtained from GSCM literature and experts in the field. Moreover, this study developed an approach based on grey theory for the determination of linguistic preferences. In section 2 of this paper, a literature review of GSCM practices is provided. In addition, the methodology used to develop GSCM criteria was validated and is presented in Section 3. Section 4 presents the results of this study, and the implications of the results are discussed in section 5. The paper is concluded in section 6 by summarizing the results, implications, limitations and potential topics of future research.

PROPOSED GSCM CRITERIA

Contributions from industry and academia, along with the results of an extensive literature review, were used to establish 16 criteria of an optimal supplier (Li et al., 2006; Tseng et al., 2009b). Selection of appropriate suppliers in GSCM requires battery of evaluation criteria, which include such information as customer focus, competitive priority, green purchasing, information technology, and top management support of a firm. Srivastava (2007) described GSCM as combining environmental thinking and supply chain management and defines it as including product design, material sourcing and selection, manufacturing processes, delivery of the final product to the consumer, and end-of-life management of the product after its useful life. A firm must have outstanding competitive priority in order to perform well management in production, such as producing high quality products with excellent logistics arrangement. The competitive priority is closely related to top management support that requires strategic purchasing. As such, the present study will view GSCM a complex, interactive process of many different resources with multidimensional, interdependent

criteria (Sarkis, 1998; 2003).

To ensure that the profitability of the supplier (C2) is an important part of the firm's practices, GSCM has become critical in establishing value-added content (Kathuria, 2000; Johnston et al., 2004; Yao et al., 2007). Moreover, the reliability of delivery (C1), defined as the ability to meet delivery schedules or promises, and the ability to react quickly to customer orders, is critical to improving the firm's customer service. The product conformance quality (C5), defined as the ability of the firm to satisfy the customer needs, is critical to the firm's success (Chase et al., 2001). Tan et al. (1998) explored the relationship between supplier management, customer relations and organizational performance, and used purchasing, quality, customer relations and relationship supplier closeness (C3) to evaluate the suitability of a supplier selection model. Sarkis (1998) categorized environmentally conscious business practices into five major components including green design (green design (C8)), life cycle analysis, the total quality of environmental management and compliance with environmental standards such as ISO 14000 (C11).

Researchers have included internal green production (C12), clean production (C14) and the quality of internal service (C7) as GSCM criteria, and the supplier's purchasing perspective has also been addressed.. Carr and Smeltzer (1999) documented how firms with strategic purchasing plans foster long-term, cooperative relationships, and achieve greater responsiveness to the needs of their suppliers. Zhu and Geng (2001) studied Chinese firms and examined their methods of environmental development in business practices such as green purchasing (C9). Among the supplier selection models currently in use, environmentally preferable bidding and life cycle assessment (C10), which assesses the impacts of green purchasing and their financial consequences through the entire product life-cycle, are the most popular. However, supplier flexibility (C6) is a complex and multi-dimensional capability that requires firm-wide effort to increase the firm's responsiveness, reduce waste and limit the firm's environmental impact (Dreyer and Gronhaug, 2004). Chen, et al. (2006) identified many quantitative and qualitative factors such as quality, price and flexibility, and concluded that delivery performance must be considered in the determination of the optimal supplier. Humphreys et al. (2003) identified environmental criteria that influence a firm's management support services (C13) and developed knowledge-based environmental management system requirements (C16) to integrate the environmental criteria and support the supplier selection process.

GSCM capabilities are ‘‘complex bundles of individual skills, assets and accumulated knowledge exercised through production processes, that enable firms to co-ordinate activities and make use of their resources’’ (Olavarrieta and Ellinger, 1997). Moreover,

GSCM is essential to the competitive advantage of a firm. GSCM involves the flow of finances, logistics, and information, as well as the ability to integrate relationships and green technology (C4), and to reduce the use of hazardous products in the production process (C15). Figure 1 presents the hierarchical structure of the framework used to evaluate a firm's GSCM. The framework consists of a MCDM analysis based on fuzzy set theory and grey degree, and can be used to select optimal suppliers (Chen and Tzeng, 2004; Zhang et al., 2005; Li et al., 2007). Moreover, fuzzy set theory was used to eliminate the linguistic preferences of subjective judgment (Zadeh, 1965; Tseng et al., 2008; Tseng, 2010a). The proposed framework is based on the following criteria: (C1) reliability of delivery; (C2) profitability of the supplier; (C3) relationship to the supplier; (C4) green technology capabilities; (C5) conformance quality; (C6) flexibility of the supplier; (C7) service quality; (C8) green purchasing capabilities; (C9) life cycle assessment; (C10) green design; (C11) green certifications; (C12) internal green production plans; (C13) management support; (C14) green production; (C15) the reduction of hazardous materials in the production process; (C16) environmental management systems.

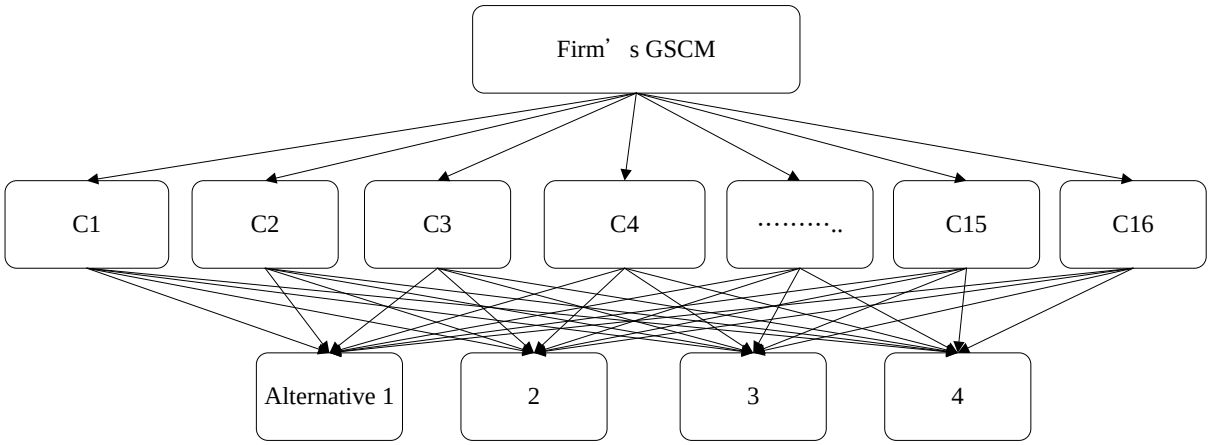

Figure 1. Hierarchical structure

METHOD

Researchers describe GSCM as a strategic, decision-making perspective used to improve the performance of a firm. This study focused on GSCM criteria and their relevant associations, as described below. The definitions of fuzzy set theory, grey theory and the procedures of the proposed approach are also briefly discussed.

Fuzzy set theory

Fuzzy set theory (Zadeh, 1965) is a mathematical theory designed to model the fuzziness of cognitive processes. It is essentially a generalization of set theory, where the classes lack sharp boundaries. The membership function $\mu_A(\mathrm{x})$ of a fuzzy set operates over the range of real numbers on the interval of [0, 1].

An expert's uncertain judgment can be represented by a fuzzy number. A TFN is a fuzzy number with a membership function that is defined by three real numbers (*a, b, c*), where *a*, *b*, and *c* are real numbers and $a \le b \le c$. This membership function is illustrated in Fig. 2 and described mathematically below.

In the proposed method, the linguistic preferences used to derive the priorities of the alternatives and the grey numbers used to establish the selection criteria were uncertain. The triangular fuzzy membership function employed in the proposed model is presented as follows (Lin et al., 2007).

Definition 1. A TFN $\tilde{\mathrm{N}}$ was defined as a triplet (a*, b, c*), and the membership function $\mu_A(\mathrm{x})$ was defined as:

$$\mu(x) = \begin{cases} 0 & x < a \\ (x-a)/(b-a) & a \le x \le b \\ (c-x)/(c-b) & b \le x \le c \\ 0 & c \le x \end{cases} \tag{1}$$

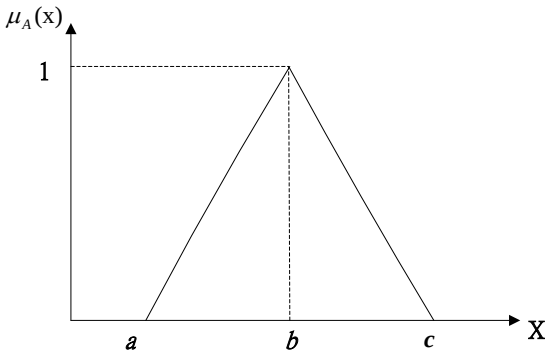

Figure 2. A TFN A= (*a, b, c*)

Therefore, *a, b*, and *c* represent the lower, mean and upper bounds of the TFN. The

membership function represents the degree to which any element (x) in domain X belongs to fuzzy number A.

Grey theory

Grey theory is a mathematical theory derived from the grey set and is an effective method used to resolve uncertainties in discrete data (Deng 1989). In this study, the basic definitions of grey systems, sets and numbers were applied(Tseng, 2008).

Definition 2. A grey system contains incomplete information and is represented by a set of TFNs. In the proposed model, X is the universal set, and G of X is a grey set defined by $\overline{\mu}_G(x)$ and $\underline{\mu}_G(x)$.

$$\begin{cases} \overline{\mu}_G(x) : x \to [0,1] \\ \underline{\mu}_G(x) : x \to [0,1] \end{cases} \tag{2}$$

$\overline{\mu}_G(x) \geq \underline{\mu_G}(x), x \in X, X = R, \overline{\mu}_G(x)$ and $\underline{\mu}_G(x)$ are the upper and lower membership functions of G after defuzzification, respectively. When $\overline{\mu}_G(x) = \underline{\mu}_G(x)$, G becomes a fuzzy set. Thus, grey theory considers fuzzy conditions and can handle fuzzy situations.

Definition 3. TFNs can be defined as a set of numbers within a grey system. For example, the rating of criteria and alternatives in this study are described by TFNs. The numerical interval contains uncertain information, and the TFNs are defined as $\otimes G, (\otimes G = G\Big|_{\underline{\mu}}^{\overline{\mu}})$. The lower and upper limit of G can be estimated, and G is defined as a lower limit TFNs.

$$\begin{cases} \otimes G = [\underline{G}, \infty) \\ \otimes G = (-\infty, \overline{G}] \end{cases} \tag{3}$$

Definition 4. The lower and upper limits of G can be estimated, and G was defined as an interval TFNs.

$$\otimes G = [\underline{G}, \overline{G}] \tag{4}$$

A set of TFNs is an operation based on sets of intervals rather than real numbers. In this study, the exact range of the corresponding operation was located on the interval

$\otimes G = [\underline{G}_1, \overline{G}_1]$ and $\otimes G = [\underline{G}_2, \overline{G}_2]$. Only the proofs of addition and subtraction were employed.

$$\begin{cases} \otimes G_1 + \otimes G_2 = [\underline{G}_1 + \underline{G}_2, \overline{G}_1 + \overline{G}_2] \\ \otimes G_1 - \otimes G_2 = [\underline{G}_1 - \underline{G}_2, \overline{G}_1 - \overline{G}_2] \end{cases} \quad (5)$$

Definition 5. The length of TFNs $\otimes G$ was defined as:

$$L(\otimes G) = [\underline{G} - \overline{G}] \quad (6)$$

Definition 6. For the two set of TFNs $\otimes G_1 = [\underline{G}_1, \overline{G}_1]$ and $\otimes G_2 = [\underline{G}_2, \overline{G}_2]$, the possible degree of $\otimes G_1 \le \otimes G_2$ was expressed as:

$$P\{ \otimes G_1 \le \otimes G_2 \} = \frac{\max(0, L^* - \max(0, \overline{G}_1 - \underline{G}_2))}{L^*} \quad (7)$$

where $L^* = L(\otimes G_1) + L(\otimes G_2)$. The positive relationship between $\otimes G_1$ and $\otimes G_2$ was determined as follows:

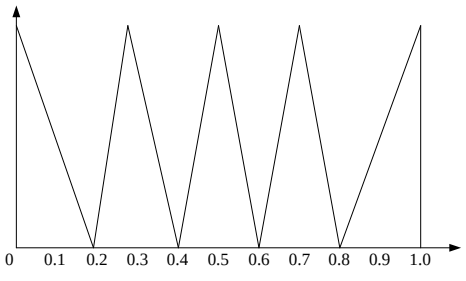
1. If $\underline{G}_1 = \underline{G}_2$ and $\overline{G}_1 = \overline{G}_2$, that $\otimes G_1 = \otimes G_2$, then $P\{\otimes G_1 \le \otimes G_2\}$ = 0.5
2. If $\underline{G}_2 > \overline{G}_1$, that $\otimes G_2 > \otimes G_1$, then $P\{\otimes G_1 \le \otimes G_2\}$ = 1
3. If $\overline{G}_2 < \underline{G}_1$ and $\overline{G}_1 > \overline{G}_2$, that $\otimes G_2 < \otimes G_1$, then $P\{\otimes G_1 \le \otimes G_2\}$ = 0
4. If $\otimes G_1$ and $\otimes G_2$ overlap, and $P\{\otimes G_1 \le \otimes G_2\}$ > 0.5, then $\otimes G_2 > \otimes G_1$. If $P\{\otimes G_1 \le \otimes G_2\}$ < 0.5, then $\otimes G_2 < \otimes G_1$.

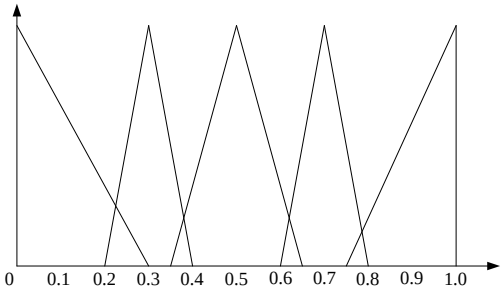
Proposed approach

In this study, fuzzy set theory and grey possible degree were applied to the evaluation of GSCM criteria. The objective of the study was to evaluate the application of fuzzy grey degree to the determination of GSCM criteria. To rank the suitability of the alternatives, grey theory was applied. In the proposed model, A = {A_1, A_2, …. A_m} is a discrete set of m possible alternatives, and C = {C_1, C_2,….C_n}is a set of n criteria and $\otimes w = \{\otimes w_1, \otimes w_2, \ldots\ldots\ldots, \otimes w_n\}$ is the vector of criteria weights. The weights and ratings of the alternatives were numbers located on the aforementioned interval scale. The procedures used to determine the optimal supplier are summarized as follows:

Step1. The fuzzy set theory was applied to determine the linguistic preferences of the proposed model. To this end, linguistic variables were defined for several levels of preference (Table 1). The TFNs used to represent the preferences are depicted in Fig. 2.

Table 1: Two linguistic variables for criteria and alternatives (importance and performance level).





(Criteria)	TFNs $\otimes G$	(Alternative)	TFNs $\otimes w$
VL	(0.00, 0.00, 0.20)	VP	(0.00, 0.00, 0.30)
L	(0.20, 0.30, 0.40)	P	(0.20, 0.30, 0.40)
M	(0.40, 0.50, 0.60)	F	(0.35, 0.50, 0.65)
H	(0.60, 0.70, 0.80)	G	(0.60, 0.70, 0.80)
VH	(0.80, 1.00, 1.00)	VG	(0.75, 1.00, 1.00)

A fuzzy weighted sum performance matrix (P) was derived for the criteria by multiplying the fuzzy weight vector by the decision matrix.

$$p = \left[\begin{pmatrix} a_1 & ,b_1 & ,c_1 \\ \dots & \dots & \dots \\ a_n & ,b_n & ,c_n \end{pmatrix} \right] \tag{8}$$

where *n* represents the number of criteria.

Step 2. Defuzzification. Defuzzification was conducted according to the method of Pan (2008); thus, TFN were used to transform the total weighted performance matrices into interval performance matrices, providing α_a and α_c for each criterion:

$$p_\alpha = \left[\begin{pmatrix} \alpha_{a1} & \alpha_{b1} & ,\alpha_{c1} \\ \dots & \dots. & \dots \\ \alpha_{an} & \alpha_{bn} & ,\alpha_{cn} \end{pmatrix} \right] \tag{9}$$

where *n* is the number of criteria.

$$\begin{cases} \alpha_a = \alpha \times (b-a) + a \\ \alpha_c = c - \alpha \times (c-b) \end{cases} \quad (10)$$

The last step of the defuzzification process was to convert interval matrices into crisp values by applying the Lambda function, which represents the attitude of the evaluator. Evaluators with optimistic, moderate and pessimistic attitudes take on maximum, intermediate or minimum Lambda values on the interval [0, 1], respectively:

$$W_j = \begin{pmatrix} W_j^1 \\ W_j^2 \\ ..... \\ W_j^k \end{pmatrix} \quad (11)$$

$$W_j = \lambda \times \alpha_c + (1-\lambda) \times \alpha_b$$

where W_j are crisp values corresponding to Lambda, λ=0.5, and were normalized to comparable scales.

Step 3. TFNs were used to obtain a rating of each criterion. The value of each rating was obtained from the following expression:

$$\otimes w_j = \frac{1}{K}\left[\otimes w_j^1 + \otimes w_j^2 + ... + \otimes w_j^k\right] \quad (12)$$

where $\otimes w_j^k (j = 1,2,.....n)$ are the weights of the K[th] expert and can be described by the TFNs $\otimes w_j^k = [\underline{w}_j^k, \overline{w}_j^k]$.

$$\otimes G_{ij} = \frac{1}{K}\left[\otimes G_{ij}^1 + \otimes G_{ij}^2 + ... + \otimes G_{ij}^k\right] \quad (13)$$

where $\otimes G_{ij}^k (i = 1,2,.....m;\ j = 1,2,.....n)$ are the weights of the K[th] expert and can be

described by the TFNs $\otimes G_j^k = [\underline{G}_j^k, \overline{G}_j^k]$.

Each expert group contains K experts. The criteria weights, w_j, were obtained from the following procedure:

Step 4. Establish the grey decision matrix

$$D = \begin{bmatrix} \otimes G_{11} & \otimes G_{12} & .. & .. & \otimes G_{1n} \\ \otimes G_{21} & \otimes G_{22} & .. & .. & \otimes G_{2n} \\ .. & .. & .. & .. & .. \\ .. & .. & .. & .. & .. \\ \otimes G_{m1} & \otimes G_{m2} & .. & .. & \otimes G_{mn} \end{bmatrix}$$

(14)

where $\otimes G_{ij}$ are based on TFNs.

Step 5. Establish the normalized grey decision matrix

$$D^* = \begin{bmatrix} \otimes G^*_{11} & \otimes G^*_{12} & .. & .. & \otimes G^*_{1n} \\ \otimes G^*_{21} & \otimes G^*_{22} & .. & .. & \otimes G^*_{2n} \\ .. & .. & .. & .. & .. \\ .. & .. & .. & .. & .. \\ \otimes G^*_{m1} & \otimes G^*_{m2} & .. & .. & \otimes G^*_{mn} \end{bmatrix} \quad (15)$$

For a benefit criteria, $\otimes G_{ij}^*$ was expressed as $\otimes G_{ij}^* = \left[\frac{\underline{G}_{ij}}{G_j^{\max}}, \frac{\overline{G}_{ij}}{G_j^{\max}} \right]$,

$G_j^{\max} = \max_{1 \le i \le m} \left\{ \overline{G}_{ij} \right\}$. For other criteria, $\otimes G_{ij}^*$ was expressed as $\otimes G_{ij}^* = \left[\frac{G_j^{\min}}{\overline{G}_{ij}}, \frac{G_j^{\min}}{\underline{G}_{ij}} \right]$,

$G_j^{\min} = \min_{1 \le i \le m} \left\{ \underline{G}_{ij} \right\}$. Normalization was conducted to preserve the property that the range of normalized TFNs was located on the interval [0, 1]

Step 6. By considering the importance of each criterion, the weighted normalized grey decision matrix was established as:

$$D^{*}=\begin{bmatrix} \otimes V_{11} & \otimes V_{12} & .. & .. & \otimes V_{1n} \\ \otimes V_{21} & \otimes V_{22} & .. & .. & \otimes V_{2n} \\ .. & .. & .. & .. & .. \\ .. & .. & .. & .. & .. \\ \otimes V_{m1} & \otimes V_{m2} & .. & .. & \otimes V_{mn} \end{bmatrix} \quad (16)$$

where $\otimes V_{ij} = \otimes G_{ij}^{*} \times \otimes w_j$

Step 7. The ideal alternative was established as the reference alternative. Thus, for m possible alternative sets, A = {A_1, A_2 ,...., A_m}, the ideal referential alternative $A^{\max} = \left\{ \otimes G_1^{\max}, \otimes G_2^{\max}, ... \otimes G_n^{\max}, \right\}$ was obtained from the following expression:

$$A^{\max} = \left\{ \left\lfloor \max_{1\le i\le m} \underline{V_{i1}},\ \max_{1\le i\le m} \overline{V_{i1}} \right\rfloor \left\lfloor \max_{1\le i\le m} \underline{V_{i2}},\ \max_{1\le i\le m} \overline{V_{i2}} \right\rfloor ..... \left\lfloor \max_{1\le i\le m} \underline{V_{in}},\ \max_{1\le i\le m} \overline{V_{in}} \right\rfloor \right\} \quad (17)$$

Step 8. The grey degree between compared alternatives (A = {A_1, A_2, ... A_m}) and the ideal alternative (A^{max}) was calculated, and the alternatives were ranked according to suitability. As $P\left\{ A_i \le A^{\max} \right\}$ decreased, the rank of A_i increased.

$$P\left\{ A_i \le A^{\max} \right\} = \frac{1}{n} \sum_{j=1}^{n} p\left\{ \otimes V_{ij} \le \otimes G_j^{\max} \right\} \quad (18)$$

RESULTS

To illustrate the utility of the proposed evaluation method, the model was applied to an actual firm. In the case study, the firm continues to improve its manufacturing processes and faces the challenges of environmental management and SCM. To deal with the requirements of supplier selection, the firm must implement GSCM criteria from relevant environmental regulations. To this end, the firm created an expert team consisting of four professors, two vice presidents and four management professionals with extensive experience.

Case information

Due to the prosperity of the electronic consumer products and network market, a plant was built in Taiwan to produce IC substrates and IC packing fields, to meet consumer demands in 2010. Currently, the firm is the largest professional printed circuit board (PCB) and original equipment manufacturer (OEM) in Taiwan and is the fifth ranked producer in the world. To offer the best services, the firm is continuing to develop next generation technology, enhance their competitiveness and satisfy customer demands. Moreover, due to the rapid replacement rate of electronic products, the firm continues to develop green products and new green technologies to comply with customer requirements. For the firm to sustain in a competitive market, proper GSCM is essential.

The chief executive officer wants to understand the role of GSCM, especially in the green market. Therefore, to develop the firm's GSCM criteria, this assessment was presented to the expert group. By complying with the requirement outlined in RoHS and WEEE directives, the firm benefited from this evaluation by acquiring purchasing orders from the USA and the European Union. In the case study, the firm's four green suppliers were analyzed. The expert group identified an analytical and systematic method of evaluating the management procedures of the suppliers. To select the optimal supplier, the experts should adopt an evaluation method from the proposed criteria. The analysis outlined in this paper would provide recommendations to the firm and would be useful for efficient and effective GSCM implementation.

Empirical result

In this study, the eight proposed steps were followed to analyze the data provided by the experts. The analysis was based on four alternatives A_i = (i =1, 2, 3, 4) and 16 criteria Cj (j = 1, 2, 3,….,16), as shown in Fig. 1. According to Eq. (8), the weights of the criteria were obtained from the group of experts and are shown in Table 2. The weights of the four suppliers were

obtained from Eq. (9), and the results are shown in Table 3.

Table 2: Criterion important weights.

Step1. In step 1, the expert's opinions on linguistic preferences of performance measures were collected and transformed according to the TFN membership functions provided in Table 1. The six definitions used to apply the following computational steps are denoted in Eqs. (1) - (6)

Step 2. 16 criteria and four alternatives were measured in the TFN. The defuzzification process employed Eqs. (9) - (10). The TFN was applied to transform the total weighted performance matrices into interval performance matrices, providing α_a and α_c .Using Eq. (11), W_j was transformed into crisp values corresponding to Lambda values on comparable scales.

Step 3. Using Eq. (12) and (13), TFNs for the ratings were calculated to obtain the criteria rating value, and the results are presented in Table 2 ($\otimes w_j$) and 3 ($\otimes G_{ij}$). $\otimes w_j$ was defuzzified into the weights and ratings of each criteria.

Step 4. In step 4, the grey decision matrix of alternatives was established according to Eq. (14).

Step 5. The grey decision matrix was normalized according to Eq. (15), and the resulting grey normalized decision table is shown in Table 4.

Step 6. According to Eq. (16), the weighted normalized grey decision matrix was obtained, and the results are shown in Table 5.

Step 7. The ideal alternative, A^{max} (the reference alternative), was calculated according to Eq. (17), and values of [0.614, 1.000], [0.574, 0.971], [0.547, 0.936], [0.486, 0.864] were obtained.

A 3	0.735	0.898	0.825	0.965	0.589	0.742	0.752	0.825	0.825	0.911	0.756	0.924	0.825	0.965
A 4	0.837	0.925	0.752	0.927	0.652	0.780	0.555	0.752	0.752	0.927	0.852	0.962	0.752	0.927

Step 8. The grey degree of the four alternatives, (A1, A2, A3, A4), was calculated from Eq. (18), and a ranking of the alternatives was obtained. The grey degrees of the alternatives were $P(A_1 \le A^{\max}) = 0.522$, $P(A_2 \le A^{\max}) = 0.555$, $P(A_3 \le A^{\max}) = 0.541$, $P(A_4 \le A^{\max}) = 0.552$. The smallest value indicates the best alternative; thus, A1 is the optimal supplier. Moreover, the following trend in suppliers was observed: A1>A3>A4>A2. Hence, to achieve the firm's GSCM criteria, supplier A1 is an important alternative.

MAMAGERIAL IMPLICATIONS

The framework can be used to evaluate the impact of various supplier selection activities and can provide a mechanism of monitoring and establishing evaluation platforms for firms in the green supply chain. In previous studies, the firm's GSCM procedures were highly variable; however, a clear link to the firm's decision was not observed. Indeed, the analyses presented in previous studies were based on only a few variables, and single variable models were not sufficient at explaining GSCM criteria. These results indicate that GSCM is a multi-criteria concept based on upstream or downstream selection in the supply chain. When evaluating the impact of a firm's GSCM activities, the overall enhancement in production and its effect on the organization must be considered.

By examining the 16 criteria, the proposed framework allows managers and researchers to better understand the differences in operations, activities and specific management interventions. The framework allows the firm to control and evaluate management practices and can describe the firm's supplier selection dilemmas. For example, in step 8, a value is placed on the overall importance of the evaluator's perception to the four alternatives. Here, the top five criteria and corresponding values were: 1. to reduce the use of hazardous products in the production process (C15- 0.833); 2. support of management (C14- 0.800); 3. quality of service (C7- 0.783); 4. the applicability of internal green production plans (C12- 0.767); 5. the presence of environmental management systems (C16- 0.750). The GSCM criteria were analyzed by the experts, and the performance of the supplier was determined primarily by the reduction of hazardous products in the production process and management support.

The results of the case study are similar to those of Yao et al. (2007), who found that management support and external influences are important determinants. Moreover, perceived benefits to customers or suppliers, and internal benefits affect the use of electronically-enabled supply chains. Tseng et al. (2009a) studied sustainable production indicators, and found that two major criteria contributed to sustainable production, including a reduction in waste generated by contracted service/material providers and a

reduction in the amount of hazardous waste generated by the supplier. In a broader sense, the framework can be used as an analytical tool to develop and construct a strategic environmental development plan and GSCM criteria for the firm. To achieve optimal results, managers should understand the firm's GSCM evaluation criteria, including the presence of linguistic preferences and incomplete information.

This study proved that the manager must be aware that the firm's GSCM is not just a black box. Through the proposed framework, managers are able to capture a fairly complete picture of the firm's GSCM. In other words, managers may find that the proposed framework for the assessment of GSCM criteria is a useful method for reviewing and improving strategic development plans and performance evaluations, which may lead to enhanced productivity and competitive advantage.

For firms that intend to evaluate suppliers with the proposed criteria, this study offers several benefits. The main contribution of this study is the hierarchical model presented in Fig. 1. This model provides a structured and logical method of synthesizing judgments that can be used for the evaluation of appropriate suppliers. The model is a useful guideline that helps structure a difficult and often emotional decision. The second benefit of this study is the development of criteria based on a comprehensive review. Moreover, the features of a firm's GSCM have been examined and identified.

The model developed in this study provides an overview of a firm's decision-making process in the presence of incomplete information. Moreover, firms can better understand the evaluation criteria of GSCM by applying the proposed model. The methodology outlined in this study is particularly useful for making decisions based on multiple criteria in the presence of linguistic preferences and incomplete information. Moreover, the framework can be customized and used for the selection of suppliers and management activities. To apply the proposed methodology, the evaluator must remove irrelevant criteria and include criteria that are applicable to their firm. Thus, a firm's GSCM can be based on many different types of criteria and can be modified and refined as necessary.

Furthermore, this study proposed a hybrid MCDM for selecting alternatives in the presence of uncertainty. However, the evaluator's judgment is often uncertain, and incomplete information cannot always be evaluated with exact numbers. An empirical example of green supplier selection was used to illustrate the application of the proposed criteria in an OEM firm. The experimental results indicated that the proposed approach is reliable and reasonable, and an optimal alternative was selected from the four possible choices. The proposed model can easily and effectively accommodate validated criteria. The proposed

model establishes a foundation for future research and is appropriate for predicting uncertain criteria. To improve the firm's performance and provide information that will have the greatest effect on reducing uncertainty, a firm can apply this model to evaluate and determine the optimal GSCM supplier.

A COMPARATIVE STUDY OF TWO COMMUNITIES OF PRACTICE IN A NON-PROFIT SETTING

Dr. Li-An Ho, Tamkang University, Taiwan
lianho@mail.tku.edu.tw

ABSTRACT

The present study aims to investigate the current status of two communities of practice: the network of knowledge chief managers (NKCM) of China Productivity Center (CPC) as well as iEARN Taiwan. The study adopts the qualitative method, using case studies to explore the development process of both communities. The data collection methods include documents analysis, file archives, observations as well as interviews. The results reveal that although the participants of both NKCM at CPC and iEARN Taiwan joined the communities for various personal interests, they all received organizational supports during their participations of community activities. However, the participants of CPC were more oriented toward the enhancement of professional development, cognitive interests, social relations, work improvement, organizational services, or marketing information collection. The participants of iEARN Taiwan were attracted to the community by exploring ways to improve their instructions as well as purpose sound instructional methods. The interactions for both communities were diverse and the content of interaction was broad. As for collaboration, the participants of iEARN Taiwan demonstrated higher motivation for collaboration than people in CPC group.

Keywords: community of practice, organizational learning, professional development

INTRODUCTION

In most corporate organizations, competitive advantages are characterized as people's tacit knowledge. As Kakabadse, Kouzmin and Kakabadse (2001) point out that knowledge, explicit or tacit, has emerged as one of the key strategic assets, although invisible, of organizations. It is obvious that tacit knowledge has integrated into people's daily conversations or life stories. Nowadays, even task skills can be disseminated in to daily dialogues or a work network, which makes it even more difficult to control, maintain or structuralize. Thus, Wenger (1998) suggests organizations begin to build up necessary policies and infrastructure in order to effectively manage knowledge, if organizations consider knowledge as one of their strategic assets.

Arther Anderson Business Consulting (1999), a well-known consulting company, points out that community of practice is an effective form to facilitate knowledge building. Cross, Parker, Prusak, and Borgatti (2003) believe that organizations may enhance networking for knowledge cooperation within organizations through various ways. Supporting community of practice appears to be one of the most effective ways for that effect.

The term, community of practice (CoP), was first introduced in 1991 by Lave and Wenger. According to Lave and Wenger (1991), CoP refers to a group of people have shared visions, questions or compassion through continuous activities. Their ultimate goal of people participating CoP is to acquire expert knowledge and obtain higher professional practices. Lave and Wenger claim that workers are part of social networks, in which they share their perceptions collaboratively. Also, the sharing process is dynamic rather than static. Thus, knowledge is not stored in each individual, but delivered and shared through interactions among individuals.

Since the recognition and popularization of community of practice, numerous studies have undertaken to explore its insights. However, considerate amount of researchers claim this area is a virgin territory waits to be explored, especially in the line of practical case studies. Compared to western literature, local studies lack documentations in regards to the development and implementation of community of practice. Consequently, the present study aims to investigate the current status of two communities of practice in a non-profit setting. They are the network of knowledge chief managers (NKCM) of China Productivity Center (CPC) as well as International Education and Resource Network (iEARN) Taiwan. A qualitative research method was used. By understanding the two cases, the present study aims to answer the following questions:

1. Why do people join a community of practice? (Motivation)
   Is there any difference between the members in the two communities of practice in terms of their motivation to participate in community activities?
2. How do communities of practice function? (Implementation)
   Is there any difference between the two communities of practice in terms of the members' interaction/communication, cooperation/collaboration and the organizational resource/support they receive?
3. What are the outcomes of communities of practice? (Outcome)
   Is there any difference between the two communities of practice in terms of advantages, disadvantages or challenges?

THEORETICAL FOUNDATION

The definition and scope of CoP

Since Lave and Wenger, the parent of CoP, in their book "situated learning: legitimate peripheral participation", first introduced the concept of community of practice, it has been the focus of attention (1991). According to them, CoP is defined a group of people who share interests, crafts and/or professions. The group may develop naturally resulting from the join members' common interests in a particular domain, or it can be created specifically with a purpose of advancing knowledge in a particular domain or field. Through the processes of information sharing and experience exchanging, the members of CoP are given the opportunity to develop themselves personally as well as professional. Hildreth and Kimble (2004) further point out that CoP is not only a theory of learning but plays an important role in the field of knowledge management. CoPs can be implemented through actual contacts, such as in a conference room at work, or via online mechanism, such as through discussion boards and newsgroups.

CoP can exist in various forms in terms of size of the group, duration of community, homogeneity or heterogeneity, Wenger (1998) suggests that CoP is examined through three levels: what it is about? How it functions? What capability it has produced. Wenger further addresses three elements that constitute a CoP. There are community, domain and practice, and suggests the successful implementation of a CoP involves mutual engagement, joint enterprose, and shared repertoire. Similar to Wenger's concept, Brown and Duguid (1991) propose that a CoP consists of three components: narratives, collaboration, and social constructivism. In other words, organizations depend on these informal relationships among groups to share and validate organizational knowledge. Through the processes of individual negotiation of meaning and insight and narratives sharing, organizational knowledge may evolve and become mature.

The development process of CoP

CoP exists in any organization. According to Wenger (1998), CoP is not bound by organizational affiliations, thus can be found (1) within businesses, (2) across business units, and across company boundaries. In addition, similar to team developmental process, CoP also move through various developmental stages which are characterized by different levels of interaction among members and by different kinds of activities. According to Wenger (1998), there are five stages in the CoP development process, namely potential, coalescing, active, dispersed and memorable stages (see Figure 1).

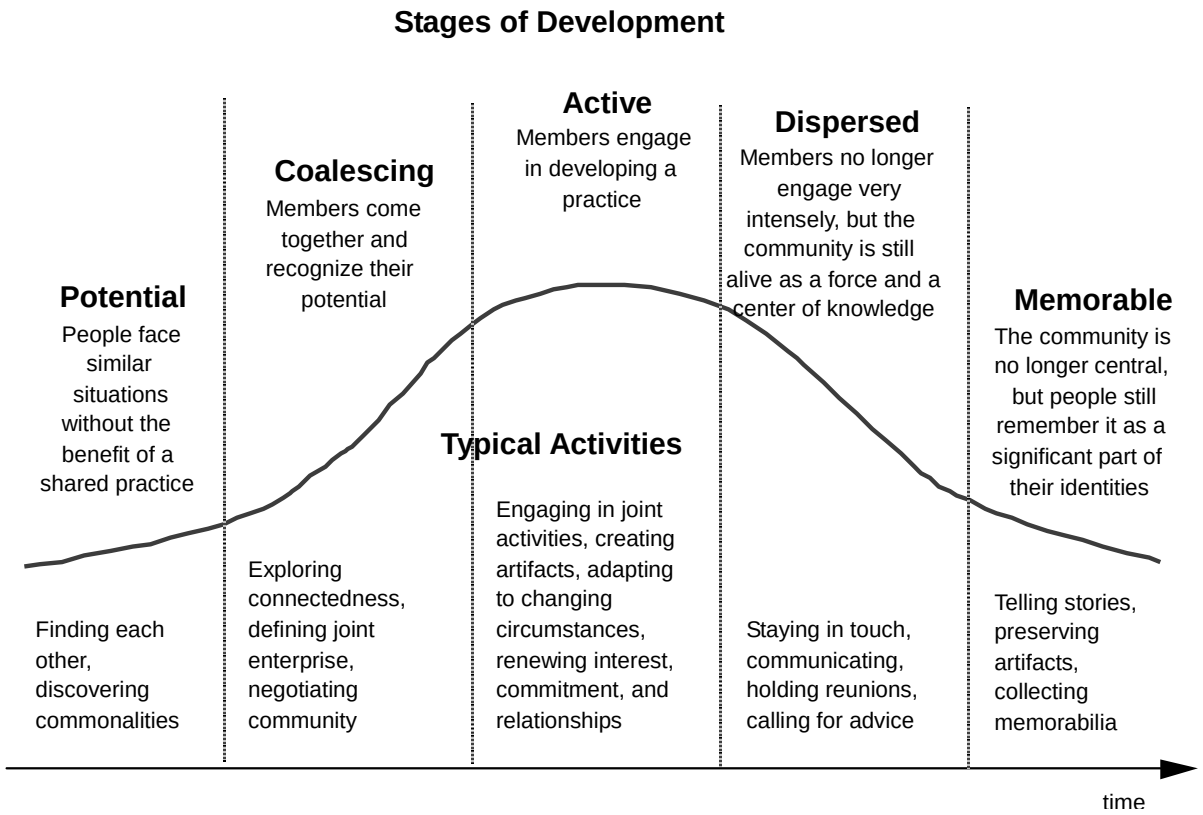

Figure 1: Stages of development for CoP (Wenger, 1998, p. 3).

Wenger, McDermott, and Snyder (2002) further conclude CoP very much like a living system which goes through a life cycle of born and dead. They divide the developmental process of CoP into five stages, including potential, coalescing, maturing stewardship, and transformation. Moreover, based on their IBM global experience, Gongla and Rizzuto (2001) propose a similar yet different view of CoP stages of development. Their study also divide the CoP development process into five stages which characterized different functions. Stage one is the potential stage, in which a CoP begins its formation and the main function is connection. Stage two is building in which community norms are established and the main function is memory and context creation. Stage three is engage, in which a CoP stabilizes and the maim function is access and learning. Stage four is active in which community members begin to understand and prove their values through knowledge management and community tasks and the main function is collaboration. The final stage is adaptive, in which communities and supporting organizations sustain their competitive advantages through knowledge development and the main function is innovation and generation. Gongla and Rizzuto further point out not all CoP move through all five stages of development. Most CoPs stay at stage three, engage stage; few enter stage four and none found in stage five.

The outcomes of CoP

Wenger, McDermott, and Snyder (2002) believe that CoP is the key for organizations to be successful in knowledge economy. Wenger, McDermott, and Snyder (2000) suggest CoP can "drive strategy, generate new lines of business, solve problems, promote the spread of best practice, develop people's skills, and help companies recruit and retain talent" (p. 105). According to Allee (2000), CoPs are beneficial for the business, for the community itself, and for employees (see Table 1 for details).

Table 1: Benefits of communities of practices (Allee, 2000, p. 8).

Categories	Benefits
Business	● Help drive strategy ● Support faster problem solving both locally and organization wide ● Aid in developing, recruiting and retaining talent ● Building core capabilities and knowledge competencies ● More rapid diffuse practices for operational excellence ● Cross fertilize ideas and increase opportunities for innovation
Community	● Help build common language, methods, and models around specific competencies ● Embed knowledge and expertise in a larger population ● Aid retention of knowledge when employees leave the company ● Increase access to expertise across the company ● Provide a means to share power and influence with the formal perts of the organization
Individual	● Help people do their jobs ● Provide s stable sense of community with other internal colleagues and with the company ● Foster a learning-focused sense of identity ● Help develop individual skills and competencies ● Help a knowledge worker stay current ● Provide challenges and opportunities to contribute

METHOD

Research Method and Research Structure

This study adopts a qualitative research method (i.e. case studies). The data collection methods include document analysis, observations, and interviews. Figure 2 presents the research structure for the present study.

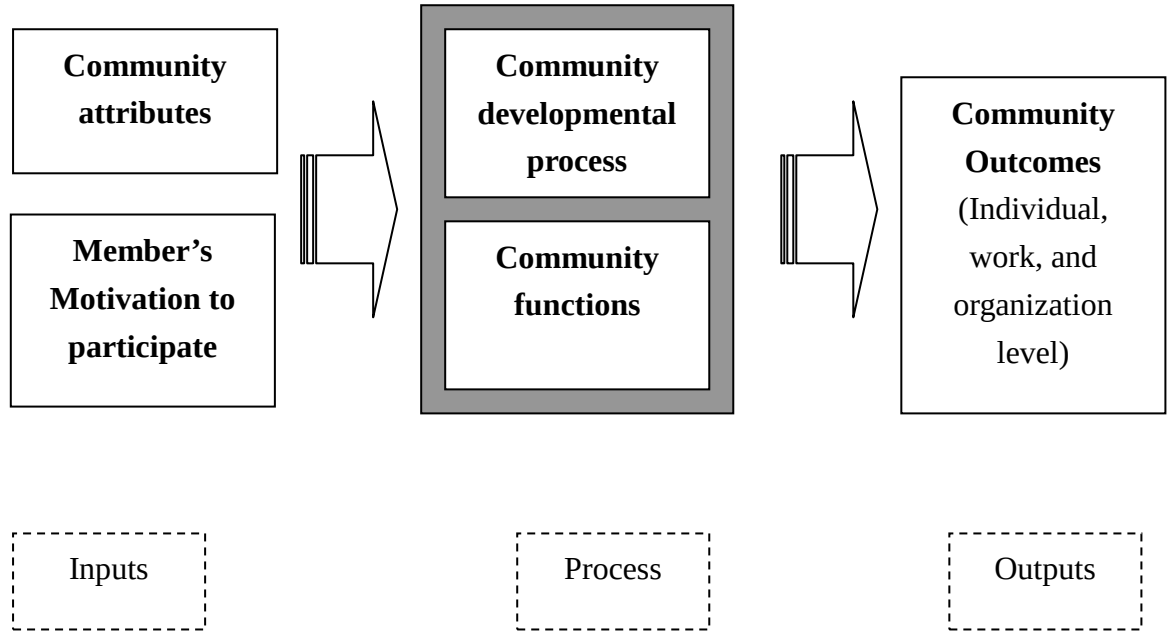

Figure 1: Research structure.

The Two Sample Cases

This study aims to explore two CoPs in a non-profit setting. The following briefly introduce the two sample cases: the network of knowledge chief managers (NKCM) of China Productivity Center (CPC) and International Education and Resource Network (iEARN) Taiwan.

First of all, iEARN is a non-profit organization made up of over 30,000 schools and youth organizations in more than 130 countries. iEARN empowers teachers and young people to work together online using the Internet and other new communications technologies. Over 2,000,000 students each day are engaged in collaborative project work worldwide. Since 1988, iEARN has pioneered on-line school linkages to enable students to engage in meaningful educational projects with peers in their countries and around the world. Additionally, iEARN offers both face-to-face workshops and online professional development

courses for educators seeking to integrate online global project work into their classrooms. Since 1988, iEARN has equipped more than 100,000 educators with the technical, collaborative and organizational skills needed to participate fully in a global, collaborative Internet-based learning environment.

Established in 2001, iEARN-Taiwan is a local chapter of iEARN, which works in conjunction with the Ministry of Education in Taiwan and the Taiwan Academic Network (TANet). iEARN-Taiwan provides local educators and students an opportunity to work on projects together using the Internet and other new communications technologies. Up till now, there are thirty local schools become the members of iEARN-Taiwan and the accumulated number of participating teachers and students has exceeded 3,000.

The network of knowledge chief managers (NKCM) is a group under the supervision of Taiwan's Industrial Development Bureau from Ministry of Economic Affairs (the controlling government agency). Since the Taiwan's government recognizes the trend of knowledge economy, the Industrial Development Bureau has made a series of plans (or stages) to facilitate organizations establishing their knowledge management mechanism since 2002. The NKCM was included in the action plan of the second stage. China Productivity Center (CPC) was designated to be the organizing unit of NKCM and has tried to recruit knowledge chief managers from various businesses in different industries to join the community. It is hoped that these knowledge chief managers can discuss their experience and knowledge in the area of knowledge management through real-life activities and online interactions.

Tested in 2006 and formed in 2007, the primary members of NKCM are from companies that received counseling from Industrial Development Bureau and technology service providing entrepreneurs. NKCM is a non-profit community which aims to provide a cross function interactive platform in order to promote national awareness of knowledge management, to facilitate interaction and collaboration of knowledge management practices, and direct the national trend of knowledge learning. A committee for NKCM was formed to discuss the constitutions of this community and roll out community activities.

Research Participants

This study adopts purpose sampling in conjunction with snowball sampling to recruit participants. A total of 28 participants, 16 from iEARN-Taiwan and 12 from NKCM, were invited for interviews. Triangulation and members check were used to improve the reliability and validity of our data.

RESULTS

The following present the similarities and differences between i-EARN Taiwan and NKCM based on our data (read table 2 to table 4).

Motivation

Table 2: The comparison of members' motivations to participate in a CoP.

	iEARN Taiwan	NKCM
Similarities	● Common interests (project-based learning) ● School's support and encouragement	● Personal interests (knowledge learning and management) ● Company's expectations
Differences	● An extension of personal educational concepts ● To emulate those better than oneself ● Broaden educational territory (or boundary)	● Professional development ● Accumulate social network ● Work Performance improvement ● Devote to organizational services ● Gather market information

Interaction

Table 3: The comparison of the interactions between the 2 groups.

	iEARN Taiwan	NKCM
Similarities	● They are a number of ways for its community members to interact (e.g. seminars, field trips, lectures, online discussion forum, etc) ● The content of communication is diverse. ● Members received high level of employers' support to participate community activities.	
Differences	● The collaboration level among member is comparatively high	● The collaboration level among member is comparatively low

Outcome

Table 4: The comparison of the outcomes between the 2 groups.

	iEARN Taiwan	NKCM
Similarities	● A common language in the field is built. ● Enhance knowledge sharing in a positive way ● Provide opportunities to learn ● Provide access to information ● Facilitate personal professional growth ● Broaden personal views ● Establish and accumulate social relations (networking)	
Differences	● Improve non-instructional abilities ● Accumulate project outcomes, which is useful for getting a job or getting in a school for future studies ● Improve teaching effectiveness ● Improve student learning outcome, especially in language	● Solving KM related problems at work ● Improve work procedure for better practice ● Strengthen KM field ability ● Provide consulting opportunities ● Provide business opportunities ● Getting help on product positioning

	and learning attitude ● enhance student learning motivation ● Students learn to share, appreciate, collaborate, and giving feedback	strategy ● Help implement KM platform ● Help set up KM related policies

CONCLUSION

The present study aims to investigate the current status of two communities of practice in a non-profit setting. The study analyzes two CoPs: NKCM as well as iEARN Taiwan. A qualitative research method was used to learn how the two communities different in three ways: motivation, interaction, and outcome.

First of all, the study learns that even people join a community due to personal interests or goals (agenda), more importantly; organizational support is a key issue for people to continuously participate in community activities in a long run.

Secondly, both communities appear to utilize various activities to enhance members' interactions. Both adopt face to face as well as online methods, although one may favor one of the methods over the other due to actual constrains (e.g. Geographical positions of members). The content of interaction shows freedom. It is not limited by the organizing unit of the communities. Community members demonstrate high level of enthusiasm on sharing knowledge. iEARN Taiwan shows a higher level of collaboration due to there were actual projects to be selected and to be worked on.

Finally, the study also finds both communities present positive outcomes not only on a community level, but also on an individual, work, and organizational level. Both communities were able to form a shared learning space using a common (shared) language in their particular field. Both communities turn knowledge learning into a positive force to help members to broaden their views and to develop professionally.

Based on our findings, all community members perceived CoP positively and were impressed with the outcomes from community activities. CoP demonstrates once again positive practices which bring many unexpected benefits which we think are worth further pursuit.

ABSTRACT

Organisational competences have become a major factor in gaining the competitive advantage. There is no consensus regarding the definition of this term, yet it is possible to determine the most popular attitudes presented in professional literature: the first perspective treats organisational competences in the context of the employees' own competences, whereas the second one focuses on the competitive advantage. Within the research perspective of competences, the following tendencies will be presented: resource-based, evolutionary, dynamic abilities-based, that of competence-based competition and a knowledge-based theory. The paper discusses the essence of organisational competency gap identifying the concept and methods of reducing it as well as the effectiveness perspective

The methods of reduction organisational competency gap will be discussed. The process of competency management through organisational learning is discussed.

The study also presents the results of quantitative research carried out in 56 Polish enterprises.

A description of the methods and procedures of competency gap management may significantly contribute to developing effectiveness of organization.

The present article aims at:

1) *presenting different views concerning organizational competencies,*
2) *suggesting a classification of competency gaps and the methods of their reduction,*
3) *presenting the results of empirical studies concerning the frequency of using particular methods of reducing competency gaps in different enterprises,*
4) *pointing at the practical implications of the discussed problem,*

Keywords: competency, organizational competency, organizational competency gap,

INTRODUCTION

In order to achieve a permanent competitive advantage in the changeable and complex global environment the functioning of organizations must be based on their effective application of the tangible and intangible resources they possess.

The results of scientific research concerning the sources of success and failure experienced by different enterprises suggest that internal factors, such as corporate culture, organizational structure, management systems, resources or abilities have a much more significant effect on the quality of company's functioning than the changes occurring in the environment.

One of the most vital determinants of the organization's successful functioning is its competences. They may be understood as a synthesis of resources and organizational abilities. Such competences are inherent in the processes, systems and structures of a particular organization and they are adopted by all or the vast majority of its members. The competences understood in this way remain an element of the organization even when its individual employees are leaving. Organizational competences are mainly based on routine activities which account for the fundamental organizational system of storing knowledge and establishing patterns of conduct.

There is usually a divergence between the competences of an enterprise and those that are necessary to accomplish its goals. It is defined as competency gap. There are different types of competency gap: current, anticipated, objectivized, perceptive, partial or total gap.

To function effectively, it is necessary for an enterprise to identify immediately competency gaps as soon as they occur, to assess and to eliminate them successfully. The reduction of competency gaps may be implemented with the help of the following procedures: acquiring tangible resources, acquiring financial resources, introducing elements of knowledge management, finding experts on the job market, acquiring competences from a business partner, collaborating with consulting companies, co-operating with scientific and research institutions, training courses (internal and external), learning in action, learning from rival companies and outsourcing.

The source of knowledge which made it possible to work on the present article was provided by the studied literature and empirical analyses.

Studying the literature on economics and sciences concerning organizations and management included the review, comparison and systematization of the definitions of the terms that were vital from the point of view of the issues discussed here, namely organizational competency, competency gap and the methods of its reduction. This led to adopting the definitions of the terms such as "organizational competencies" and "competency gap" that are used in the present work. It also provided a basis for developing the tools used for performing empirical studies.

The empirical research had also a quantitative character. It was conducted with the use of questionnaires in 56 enterprises that that had been intentionally selected. The aim of the study was to analyze and assess the determinants and frequency of choosing particular methods of reducing competency gap in the analyzed companies.

On the basis of literature studies it was stated that the issue of organizational competency was not new, as it was discussed already in the reference books published in the 1950s. However, it has not been fully recognized yet. The reason may be the fact that the structure of organizational competency was gradually evolving during the last few dozens of years.

The share of intangible assets was increasing while the significance of tangible and financial assets was diminishing.
The analysis of the existing knowledge on competency gap suggests that the issue has been the subject of a single research project so far. Thus, it may be treated as a *novum*.

THE RESEARCH PERSPECTIVE OF COMPETENCES

A belief that internal, knowledge-based resources play a significant role in acquiring and maintaining the company's competitive advantage finds an increasing number of supporters in the global environment. Such resources are known as organisational competences, although the term is not precisely defined. Managers and scientists have a rather vague idea of what it really means, yet both groups perceive competences as a decisive factor in reaching success in the contemporary economic system.

The term "competences" can be used in different meanings. Its manifold interpretations result from a large number of subjects to which it is referred, e.g. managers, human resources, organisations, as well as from different areas of interest in these issues, deriving from strategic management, quality management or human resource management.

The professional literature is dominated by two approaches concerning the analysis and description of organisational competences. The first approach treats organisational competences in the context of the competences of its employees. Individual competences of the staff create the potential of work, whereas the individual potential of an employee is composed of their abilities, health, knowledge, practical skills, moral level and motivation, all of which is their competences. Thus the competence potential of an organisation is the product of individual work potentials, expressed in the number of the employees and individual working time.

The other, more extensive, approach concerns the company's competitive advantage on the market, and the key issue here is the organisational competences. These are made of such elements as the unique, specific know-how and jointly created experience and abilities of the organisation which have contributed to its competitive advantage. Organisational competences often provide foundations for building its future strategy.

The latter approach has produced works referring to the role of competences, reflected in the dynamic development of a particular research approach known as the competence-based perspective. The advocates of this attitude focus primarily on analysing the organisation's interior, trying to find there the sources of its competitive advantage. They emphasise the heterogeneous character of the organisation's components and see the opportunity of gaining the competitive advantage in its unique composition of resources and talents which make it possible to receive some regular income on the basis of the competences possessed (Wernerfelt, B., 1984).

The competence perspective includes a series of theoretical models presenting the meaning of competence in gaining and maintaining an advantage over one's competitors (Escrig-Tena, A. B. and Bou-Llusar, J. C., 2005). It is derived from classical works by P. Selznic (1957) and E.T. Penrose (1959) discussing strategic management. The authors see an organisation

as a set of diverse resources, able to fully explain the differences between competitive positions taken in practice by particular companies.

The competitive perspective also includes the so-called resource-based view which is expressed by B. Wernerfelt, Y.Dierickx, K. Cool, R.M. Grant, J.B. Barney and others. This approach focuses on examining the properties, abilities and resources which are at the company's disposal and enable it to gain and maintain a permanent competitive position on the market.

Another component of the competence perspective is the so-called evolutionary perspective presented e.g. by R. Nelson and S.G. Winter in their studies. This attitude concentrates on examining the method used by a company to adapt itself to the environment and the changes that occur in it through trying to find randomly new, more advantageous procedures and routines.

The competence perspective also involves the so-called *dynamic capability theory* formulated by D.J. Theece and G. Pisano. This concept stresses the special, strategic meaning (the principles of superior order) of the ability to acquire, build and re-configure the competences that are present both inside and outside the organisation, which are necessary to adjust the latter to the dramatically changing environment.

On the other hand, the *competency-based competition* whose supporters include, among others, C.K. Prahalad, G. Hamel, R. Sanchez, N.J. Foss and S.G. Winter focuses on analysing such resources and abilities which make it possible to maintain the competitive advantage, as well as on the processes of acquiring and developing competences.

Finally, there is the *knowledge-based theory,* represented by B. Kogut, U. Zander, G.A. Hedlund, I. Nonaka and H. Takeuchi, which treats organisations as heterogeneous entities characterised by a unique composition of basic organisational knowledge.

The competence perspective, though promising as a platform of theory creation, still has not developed any adequate methods of how to make the theoretical constructs it uses operational. What is particularly bothersome, is a lack of objective standards which could measure organisation's resources and competences in a situation where all traditional indices based on the data from the sphere of finance and accountancy prove to be completely useless.

A common assumption underlying the competence perspective is giving the major role to the resources and competences which are unique to an individual organisation and based on the knowledge (mainly hidden), hard to communicate and distributed among the members of a given firm.

Organisational core competences

Since the beginning of the 1990s the popularity of the idea of organisation's core competences has been increasing. The concept was developed in strategic management within the resource approach. Unlike in the classical approach, where the source of the

company's success is considered to be its ability to adapt to external conditionings, the resource perspective emphasises the success factors inherent in the organisation itself. According to G. Gierszewska (2005), the most popular works in this area include the concepts of *core capabilities* by G. Stalk, P. Evans and L.E. Shulman, *core competences* by G. Hamel and C.K. Prahalad and *distinctive competences*.

G. Hamel and C.K. Prahalad (1994) introduced the idea of organisational competences which they defined as *„a unique combination of the business' specialisation and human abilities which reflect the organisation's typical character (…), the areas of knowledge and experience characteristic of a particular company"*. Since they affect the area of a business's competitive advantage, they were given the name of core competences.

Core competences are developed in the process of corporate learning. Learning and competences are mutually related. The learning process depends on the character of a company and involves collecting specific resources, skills and experiences and transmitting them onto new products and processes.

The process of core competence building is initiated by accumulating and exchanging information which may come from the knowledge generated in the company or from learning in action, in practice. The experience acquired results in developing an individual, unique for a given organisation, path of technical skill improvement and learning abilities. The information which has been acquired, stored and made available provides a basis to build the company's universal and hidden knowledge.
The next stage of core competence development is „experimenting". This means that the continuous improvement of the existing abilities and striving for more effective incorporating of new technologies enhance a certain creativity potential, which helps the company overcome its internal inertia and maintain its development impetus.

The final stage is constructing *dynamic routines* playing an important role in fostering new abilities and skills. The way the company supports dynamic routines of activities and learning inside and between organisational entities significantly influences the extent to which skills and abilities become rooted in the general social awareness of the organisation. In time, core competences become formalised and thus make a part of the world's system of knowledge creating. Having been fixed in the firm's social structure, competences become the sources of its competitive advantage.

The authors compare an organisation to a tree whose roots and stabilisers are made by competences, the role of the trunk is assumed by core products and these result in a system of business units which, in turn, bring about final products. However, just watching the final products is not enough to assess adequately the strength of the rivals. Core products make links between core competences and final products, a physical form of one or more core competences. Distinguishing core competences, core products and final products is vital, as each level is characterised by different principles of competing and the company may have a different market share in each of the areas. In order to build and maintain a competitive advantage for a long period of time the company should be the leader on each of the mentioned levels.

The most relevant features of core competences are listed by G. Gierszewska as (2005. pp.33-34):

- „invisibility", or remaining hard to be identified by competitors, e.g. through the techniques of benchmarking,
- being difficult to be imitated for competitors
- lack of substitutes
- durability, or building the enterprise's success and its development in a long time span, life cycle longer than that of ordinary competences,
- advantage over rivals' competences,
- making it possible to enter many different markets,
- ensuring cooperation with clients.

It is emphasised that core competences of a business are built on the basis of unique relationships between the resources, skills, strategy, goals, culture, management structure and methods, which makes them so difficult to be imitated by competitors. This, in turn, equips the company with a significant strategic power and increasing competitiveness, especially in the environment of global economy and quick technical advancement.

Imitating core competences is tough and requires that the copying one should perform the same set of „irreversible" investments and training. The organisation's competences are frequently impossible to copy, since the technology, learning process and skills are specific for the context of their development, used outside the company and may have no or hardly any value for the competitors. The particular "irreversibility" of the investment also leads to a certain dependence on the chosen path on which the existing strategy and method of organising the company result from its rare resources, business understanding and resources accumulated over a longer period of time, yet on the other hand they affect the evolution of skills and strategic opportunities in the future.
One step ahead is made in J. Kay's concept which is an expansion of the work by G. Stalk, P. Evans and L.E. Shulman. According to J. Kay (1996, pp. 99-102), core competences are: the ability to transform competences into specific benefits for the client, where the basic abilities of the company include architecture (internal and external relationships of the company with its employees, clients, suppliers and competitors), reputation (clients' opinion about the enterprise), innovations (product improvement, using more economic techniques and technologies) and strategic assets (natural monopoly, exclusive rights, irreversible costs).

A comprehensive analysis of core competences was performed by R.M. Grant and M. Javidan. They developed a model of "core competences" presenting the relationships between resources, abilities, competences and core competences. The lowest level is occupied by are material and non-material resources as the elements contributing to the chain of values yet are characterised by relatively lowest value for the enterprise. Among non-material assets eight basic categories were distinguished, related to technology, building a liaison with the client, methods of reaching an agreement, data processing (e.g. specialist software), human assets, marketing, company's location and goodwill. The level of making use of the resources, which at the same time determines the potential of a particular organisation, was called its abilities, whereas competences make a set of abilities

combined with know-how, and are a result of organising and coordinating individual links in the chain of values.

On the top level there are core competences which make the highest value for the business. They are a unique combination of resources and abilities in different areas of company's functioning. Core competences are created as a result of the synergy of the resources constituting the company's value and its unique resources, as well as the ability to coordinate and to make an effective use of these resources. A skilful manipulation with core competences (e.g. coordinating various manufacturing activities, integrating numerous technologies) results in new products and added value for the client.

The essence and characteristics of organisational competences

Despite numerous differences, there is a consensus that competences are one of the factors determining the company's success. Undoubtedly, competences make a conceptualisation of a new class of resources. However, it is necessary to distinguish competences, abilities and processes, though their hierarchical relationships are more important than accurate definitions.

M. Bratnicki (2000, p.13) distinguishes a concept of "*abilities*" which he assigns to human individuals, and that of "*competences*" which he refers to the level of the entire organisation. In his opinion competences mean integrating knowledge (the abilities of individuals and resources) in order to achieve a goal. Competences understood in this way are in fact the abilities of the people managing an organisation and having influence on making the most vital decisions. They are abilities to acquire adequate resources, including people, and to use them properly in order to carry out the adopted strategy.

Competences make a company distinct in its environment and give it the competitive advantage. Like in the case of other resources which are decisive for competitiveness, competences must be valuable from the perspective of the activities that are run, they must have the quality of rare goods and be difficult (or/and costly) to imitate.

Summing up the reflections referring to competences, the latter can be defined as a combination of knowledge and abilities which reflect both the resources of basic (hidden) knowledge and the abilities which are indispensable to perform necessary activities. Competences are based on the knowledge inherent in the skill sets of individual employees and the knowledge that remains at the disposal of particular organisational units.

In this context the major role is played by the knowledge and abilities accumulated by the company throughout a long period of its functioning. A quick imitation of this type of resources is difficult, bearing in mind the necessity to invest in time- and money-consuming process of learning.

In literature, competences are usually seen from a twofold perspective:

1) as assets, abilities or resources owned by the company and enabling its running systematic activities,

2) as the activities themselves, which can be performed by the company thorough its composing different sets of resources.

The latter approach emphasises what the company really does, rather than what it has at its disposal. Competences are manifested here as the effects of actual activities undertaken by the organisation. According to W.C. Bogner and H. Thomas (1994), both these perspectives lead to better understanding of the idea of organisation's competences. In their concept, organisational competences can be considered in the cognitive aspect depicting the knowledge and abilities owned by the organisation, and in the active aspect presenting the activities carried out by the firm. Hence, competences can be defined as the company's specific abilities to distribute its resources, as well as its cognitive abilities which enable taking up the activities necessary to achieve set goals.

Adopting similar assumptions, R. Sanchez (1996) defined three properties which should characterise organisational competences:

- they must have an organisational component, i.e. they should refer to coordinating and distributing resources;
- they must have an intentional component – they should result in well thought-out actions aimed at ensuring well-coordinated distribution of the resources;
- they must have a purposeful component – coordinating the resources should lead to reaching organisation's goals.

D. Turner and M. Crawford (1994) contrast organisational competences with individual ones. Individual competences include the experiences, knowledge, abilities and skills of individual people. Organisational competences make a combination of the abilities and knowledge belonging to the organisation as such. These competences are inherent in organisation's processes, systems and structure and adopted by all its members. Competences understood in this way are kept even when individual employees leave the organisation. Organisational competences are based primarily on sets of routine actions making the basic, organisational system of knowledge storage and setting regular routines. As claimed by R. Nelson and S.G. Winter, routine activities have the same role in the organisation as abilities and skills to individual people.

Considering the role of competences in acquiring and maintaining the competitive advantage, their four qualities should be noted: tacitness, robustness, embeddedness and the management's awareness of their existence (Wernerfelt, B., 1984):

- *Tacitne***ss** of competences reflects the range within which competences are difficult to codify or to communicate. As far as this criterion is concerned, competences can be arranged on a scale on which the beginning is marked by competences that are possible to articulate and the final point by hidden competences. Articulable competences may be given a form of instructions, procedures or principles which can be communicated orally or in writing, whereas hidden competences are based on intuitive knowledge and cannot be fully described or reported. Hidden competences are of particular value for maintaining competitiveness because they are directly dependent on the context of the company's functioning – consequently, they are difficult to imitate and make use of in a firm working in a different environment.

- *Robustness* of competences refers to their value and usefulness in rapidly changing conditions. Robust competences are hardly sensitive to changes in external conditions and will remain serviceable in a new situation. Non-robust competences, in contrast, are the ones that lose their usefulness when the environment is altered by changes which cannot be controlled by the organisation. Competences' robustness makes them more durable and resilient. Their presence increases the organisation's chances of gaining a permanent competitive advantage over its rivals.
- *Embeddedness* of competences reflects the ease or difficulty in transferring them to another organisation. This quality makes it possible to predict what will happen to the organisational competences when the employees using them leave the company. Such a property of competences results from their position in the organisation: if they are placed in some elements of a widely understood system of management or information they are easier to recreate after the employees have left. If they remain only in the memory and awareness of the employees they will be lost at the moment of the staff members quitting.
- *The level of awareness of organisational competences together with management's consensus* reveals how similarly the management of the top and middle levels perceive organisational competences and understand their role from the perspective of the firm's activities.

Even though the meaning of consensus in this area among top management has been extensively documented, the need to agree on the opinion in this respect with middle management is still underestimated. Middle-level managers are responsible for interpreting and communicating the visions and strategies formulated at the top level of management. If they manage to communicate also the agreed opinion concerning the most valuable resources decisive for the competitive advantage of the firm, its practical use will be facilitated and the organisation's efforts will be focused on priorities.

Summing up the analysis of competences, a few generalisations can be made:

- competences may be understood as a possibility or an ability to obtain a definite result, or a result on a definite level (the ability to perform definite tasks or reaching particular goals);
- their character is always relative and they must be referred to a certain standard, a goal or a task assumed. While analysing competences, it is necessary to start at some point of reference which is present in the question: "competences to do what? And/or in what area?";
- they are manifested through the ability to act adequately to the requirements of an individual situation.

COMPETENCY GAP

One of the main ideas to understand competency management is to define the gap.
To a contemporary manager, the role of competency gap is increasing and it becomes necessary to identify and reduce it. This results primarily from the fact that in contemporary global economy competences are a resource which decides about the business's success. The concept of *competency gap* may be understood as:

- „a lack or a deficiency of abilities" needed to: reach the organisation's goals and tasks; or to obtain results which are regarded by the management as "attainable" with the material and human resources of the company; or to obtain results attained by the leader or a group of the best companies in a given line of business.
- the difference between the desirable competences (according to the managers) and the existing ones, and between the structure and level of the competences owned by the management and the competences that are desirable or required.

It should be noted that contemporary managers have fewer problems identifying competency gap existing at a given moment. They have precise information regarding their competition on the market, and frequently are provided with the financial data in this respect. However, the major barrier is the recognition of the methods reducing such a gap and their effective implementation.

Competency gap is of a dynamic character and to reach the complex knowledge of this phenomenon it is necessary to adopt an analytical perspective taking into account not only the approach in the context of broadly understood organisational „resources" (or the potential of the organisation) but also in the context of their active use .

Competence management means identifying gaps and initiating actions aimed at their reducing. Functioning in a turbulent environment makes contemporary enterprises face a necessity to constantly adapt to new challenges, particularly to the intensifying processes of internationalisation and globalisation. Thus, it is necessary to adequately identify and analyse signals received from the environment, taking into account their influence on the current and future situation of the company, as well as anticipating, on the basis of such signals, the directions in which the environment is changing and some indispensable core competences which condition the functioning of the enterprise in the future.

RESERCH METHODOLOGY

The aim of the study is to determine the relationships occurring between competence gap management and improved effectiveness of an enterprise.

The following *hypothesis* has been formulated:
H 1. There are different methods of reducing competence gap in an enterprise, such as: acquiring natural resources, finding financial resources, introducing elements of knowledge management, finding specialists on the job market, acquiring competences from a business partner, collaboration with consulting companies, cooperation with scientific and research institutions, training courses (internal and external), building up company's own research and development potential, learning in action, learning from competitors and outsourcing. Among these, some methods are used particularly frequently in order to improve the company's performance.

We designed a research process consisting of two stages:

1) literature study,
2) empirical study – quantitative

Table 1.. Methodology of quantitative study.
Source: *Authors' own analyses*

Elements	Description
Type of analysis	Quantitative study
Research method	Selected methods used in statistical analysis
Research tools	Questionnaire, correlation analysis, factor analysis
Sampling method	Purposive sampling
Tools used to arrange and analyze the data	MS-Excel spreadsheet, CSS Statistica 6.0 package
Method of presenting study results	Charts, tables

Research results

The frequency of the effect exerted by the methods of reducing competence gap on individual effectiveness components was varied in the analyzed group of companies and it looked as follows:

1) Reducing the number of errors and flaws (33.33%),
2) Improved time of adaptation to clients' needs (32.13%),
3) Increased income from operating activities (29.31%),
4) Improved image of the company (29.15%),
5) Reduced time of process implementation (29.03%),
6) Increased client satisfaction (26.93%),
7) Increased creativity of the employees (26.16%),
8) Reduced costs of operating activities (23.52%),
9) Improved financial situation of the company (21.58%),
10) Reduced staff fluctuation (12.05%).

Similarly, the frequency of the effect exerted on the individual components of effectiveness by reducing competence gap was varied in the individual enterprises. Detailed information regarding this issue is presented in Table 2.

Table 2. Frequency of the effect exerted on the individual effectiveness components due to reducing competence gap.
Source: *Authors' own analyses*.

1.	Increased income from operating activities	29.31	21.93	27.87	52.08	30.83	16.67
2.	Reduced costs of operating activities	23.52	22.81	21.84	31.25	24.00	19.45
3.	Improved time of adaptation to clients' needs	32.13	32.46	26.44	51.04	32.33	29.17
4.	Increased client satisfaction	26.93	23.25	23.56	47.92	28.00	18.06
5.	Reduced time of process implementation	29.03	23.69	27.30	47.92	29.33	26.39
6.	Increased creativity of the employees	26.16	25.88	24.43	33.33	27.00	19.44
7.	Reduced staff fluctuation	12.05	11.40	11.50	15.63	12.67	6.95
8.	Improved financial situation of the enterprise	21.58	17.11	21.55	32.29	23.00	9.72
9.	Reduced number of errors and flaws	33.33	32.46	31.32	42.71	33.50	31.95
10.	Improved image of the company	29.15	26.75	25.86	46.88	29.17	29.17

While analyzing the frequency of applying the total of the methods used to reduce competence gap in order to improve particular effectiveness components in selected groups of companies, it was observed that:

- small enterprises most frequently used the methods of reducing competence gap in order to improve each particular effectiveness,
- medium-size companies least frequently used the methods of reducing competence gap in order to improve the following effectiveness components: increased income from operating activities, reduced costs of operating activities, improved time of adaptation to clients' needs, reduced number of errors and flaws and improved image of the enterprise,
- large organizations least frequently used the total of the methods for reducing competence gap in order to improve the following effectiveness components: increased client satisfaction, reduced time of process implementation, reduced staff fluctuation and improved financial situation of the company,
- non-market companies, compared to market-oriented enterprises, much less frequently used the total of the methods designed to reduce competence gap in order to improve the whole of effectiveness components, except for improving company's image, where the frequency of implementation was identical like in market-oriented firms.

Quantitative studies resulted in diagnosing the frequency of applying individual methods of reducing competence gap in order to improve the total of effectiveness components. Detailed information regarding this issue is presented in Table 3.

Table 3. Frequency of applying particular methods of reducing competence gap in order to improve the effectiveness in the studied companies.
Source: *Authors' own analyses*.

1.	Acquiring additional material resources	32.85	29.47	32.07	43.75	33.80	25.00
2.	Acquiring financial resources	31.42	24.74	29.66	53.75	32.00	26.67
3.	Introducing elements of knowledge management	33.40	36.32	25.86	53.75	33.80	30.00
4.	Acquiring specialists on the job market	29.64	25.79	26.55	50.00	30.00	26.67
5.	Acquiring competences from a business partner	18.75	16.84	16.55	31.25	20.40	5.00
6.	Cooperation with consulting companies	20.00	20.53	16.21	32.50	19.80	21.67
7.	Cooperation with scientific and research institutions	11.61	13.68	9.31	15.00	11.40	13.33
8.	Training courses	42.69	40.53	38.96	60.00	42.60	41.67
9.	Building up company's own research and development potential	17.48	11.58	20.34	21.25	19.00	5.00
10.	Learning in action	39.99	34.21	42.42	45.00	42.00	23.34
11.	Outsourcing	13.57	12.11	10.35	28.75	13.80	11.67
12.	Learning from competing companies	24,43	19,47	21,72	46,25	25,20	18,33

The results of the studies prove that the frequency of using the particular methods of reducing competence gap in order to improve the total of effectiveness components was varied. The most common method used to achieve this aim was organizing training courses. On the average 42.69% of the companies used this particular method to improve their effectiveness components. A popular method was also learning in action (39.99%). The least popular strategy of reducing competence gap in order to improve effectiveness in the studied enterprises was cooperation with scientific and research institutions, which was used by merely 11.61% of the analyzed companies. Outsourcing was not much more popular, as only 13.57% of the studied units were interested in applying it. Attempts to have positive effects in effectiveness, resulting from building up the company's own research and development potential (17.48%) or acquiring competences from a business partner (18.75%) were relatively rare.

It should be noted that small enterprises used all the methods leading to reducing competence gap in order to improve company's effectiveness more frequently than other groups of the organizations distinguished according to their size. Medium-size companies least frequently among groups of enterprises distinguished according to the criterion of their size used the elements of knowledge management, cooperation with consulting companies, cooperation with scientific and research organizations, training and outsourcing in order to improve their effectiveness. On the other hand, large companies were most

reluctant to improve their effectiveness by acquiring financial resources and specialists on the job market.

A large majority of methods used to reduce competence gap was applied more frequently in market-oriented enterprises, compared to non-market companies. The opposite tendency was observed only in case of cooperation with consulting companies and scientific and research institutions.

CONCLUSIONS

It turns out, however, that in the practice of Polish enterprises, despite the fact that the knowledge acquired in this way is indispensable to prepare a suitable strategy and to build consistently a set of adequate competences, in case of many businesses such knowledge does not make a basis for designing the directions for their future activities. The results of empirical examinations carried out by various teams suggest that the development of numerous businesses is a matter of chance, an unexpected opportunity, such as e.g. a possibility to purchase some extremely cheap fixed assets, a sudden offer to cooperate with a big company, using different relief funds offered by the European Union, finding a new investor, a company merger, favourable systemic solutions etc. (Sitko – Lutek, Skrzypek 2009) An opportunity of this type provides an impulse to act, though it depends on the company's competences whether and to what extent it will be able to take advantage of it.

Each of the enterprises studied came across such opportunities which affected, to some extent, its further functioning, and the success was determined by the company's ability to find and to use properly such an opportunity. Each of the enterprises identified in its own way the emerging competency gaps and initiated some activities in order to reduce them, which resulted in a consistent creation of the competences that helped the company's development.

The models of competence acquisition were different in the analysed companies, yet it can be concluded that he methods of identifying competency gaps they used were dependent, to a high degree, on the company's situation and the method of strategy building it adopted as a result:

- new opportunities implied an entrepreneurial approach characterised mainly by intuitive strategic choices; the aspirations of the owners/management were confronted with the opportunities and resources identified, with reference to the standards of the client, the competences owned were compared to the ones that were required to initiate and run a specific type of activity,
- using the adaptation approach consisting primarily of a flexible adaptation to emerging opportunities and threats, the enterprises were running systematic examinations of the market, analyses of the competition, analyses of customers' complaints, the reasons for clients leaving, marketing and financial indices; the clients requirements were considered and critical situations in the companies were analysed,
- using the developed procedures aiming at working out and consistent implementation of the adopted strategy, which is characteristic of the planned approach to formulate a strategy, Early Warning Systems were designed; benchmarking of domestic competitors and of the leader in a given branch were taken advantage of; moreover, similarly like in case

of the adaptation approach, market research was performed, as well as analyses of the competition and of customers' complaints, the reasons for clients leaving and the analyses of marketing and financial indices,

In the practice of the studied enterprises mixed forms of strategy building in an organisation were used, so the competency gaps found were identified in different ways.

Depending on the type of the competency identified, and also on a particular situation of the company, varied learning actions were undertaken:

- acquiring material resources – purchasing technologies, machines, construction investments etc.
- transfer of people – individuals or teams, having competences desirable in particular areas,
- acquiring knowledge through training courses, consultancy, cooperation with research institutes, as well as knowledge transfer within the company,
- adjusting to clients' requirements – mainly through meeting the needs of big clients, and also skilful defining the needs of individual clients,
- building their own skills,
- outsourcing.

In the context of organisational competence gap mangement, special role is played by *management's perception* which expresses, through the quality of the decisions taken, the way it views reality and, at the same time, plays a vital role in creating the portfolio of organisational competences (Sitko- Lutek, 2007).

The management's perception which is narrowed down or based on schemes suggests a decreased level of its competences (perception gap) and makes it impossible to see some relevant competency management activities. It can be thus stated that eliminating, or at least reducing, the perception gap occurring in a particular enterprise is the first and necessary step on the way to recognize other competency gaps that are taking place in it.

On many occasions competency management in a company is mutually related and, in specific conditions, lead to inertia routines.

The practice of companies' functioning proves that their managers come across serious difficulties in estimating quality categories among which there are organisational competences.

In case when competences are gradually completed when successive challenges emerge and they are properly handled, special meaning should be given to the process of "learning in action" which results in both an increase in the abilities of formulating an effective strategy of action and in its efficient implementation.

In the context of the strategy, competency gap can be analysed from the perspective of market environment in the form of emerging threats and opportunities. The reaction to threats may be different, depending on their strength and the chances to eliminate or to reduce the competency gap. On the other hand, opportunities in the environment offer

chances to become successful and the company tries to take advantage of those which remain in compliance with its competences or when missing competences can be relatively easily made up for.

Consequently, identifying competency gaps in companies is done intuitively and without taking advantage of the full range of methods and instruments. This poses a serious threat to the accuracy of diagnosing the competitive potential of the company. Therefore, one of the core competences in a company functioning in a turbulent global environment is developing effective practices in the area of analysing and assessing organisational competences and competency gaps.

Creating the awareness of existence, as well as identifying and eliminating competency gaps in the organisation can be implemented in the most effective way by means of corporate learning processes treated by the enterprises as their major philosophy and management practice.

A description of the methods and procedures of competency gap management may significantly contribute to developing an adequate methodology in the area of recognizing the need of corporate learning which occurs at the initial stage of the corporate learning cycle.
To sum up, organizational competency, competency gap and reducing the latter with the help of relevant methods may provide an interesting research problem. It should be also noted that organization's competencies make an important determinant of the company's success. For this particular reason, scientific research devoted to these issues may be of vital importance for economic practice

ABSTRACT

In this day and age, it is easy to see that small and medium enterprises (SMEs) play an essential role in the growth of the Thai economy. The rapid change in the world economy and its social repercussions has also influenced the aforementioned SMEs. In the case of Thailand, SMEs have faced many problems that affect business performance. An essential issue for Thai SMEs is the growing competition not only from inside the region but also from abroad. Consequently, SMEs must adapt and improve themselves in order to survive. A key challenge of modern organization is to develop a knowledge-based organization. As Drucker (1999) has proposed, the present competition is to shift from focusing on manual worker productivity or labor-intensive to a more knowledge-intensive-based form of work. The theories of organizational learning and innovation are widely used in modern organizations in order to accomplish their goals and build up their organizations. The purpose of this study is to develop a framework for organizational learning and innovation in the case of Thai SMEs from various standpoints including internal factors and external turbulences. The qualitative method was employed in a semi-structured interview technique used as the data collecting tool with the literature review also performed along the way. The results from the interviews were identified by conjunction with the literature. Seven interviewees from electronics, and automotive component companies were selected. As a result, the internal antecedents included leadership, culture, motivation, and information technology. The external antecedents were market turbulence and technological turbulence.

Keywords: Organizational learning, innovation, SME, Thailand

INTRODUCTION

Nowadays, one could say that small and medium enterprises have become an essential part in the growth of the Thai economy. According to the report of the Office of Small and Medium Enterprises Promotion 2010, the amount earned by Small and Medium Enterprises (SMEs) in Thailand was around 2.9 million or 99.8 percent of all private enterprises in the country. Moreover, they also helped generate the Thai GDP by as much as 37.8 percent of the national income. The hiring rate among SMEs was around 9.7 million workers or 78.2 percent of all enterprises. Therefore, it is fair to say that SMEs constitute the most important mechanism driving forward the Thai economy. Consequently, increasing the potentiality of SMEs is an important issue in Thailand. Both public and private sectors in Thailand recognize the importance of SMEs in improving the economy of Thailand, then

many organizations had been established with help from both sectors for the purpose of supporting and enhancing the performance of SMEs, such as the Office of Small and Medium Enterprises Promotion (OSMEP), Institute of Small and Medium Enterprises Development (ISMED), SME bank of Thailand, the Thailand Research Fund (TRF), and many commercial banks.

At the present time, the rapid change in the world economy has also influenced the SMEs. In the case of Thai SMEs, one challenge for them is the growing competition from both inside and outside the region. Moreover, free trade agreement with other countries such as USA, Australia and China will also affect the Thai economy and SMEs as well. SMEs must then adapt and improve themselves in order to survive. In recent years, SMEs faced many problems that affect business performance such as the uncertainty of the Thai political situation, natural disaster, high competition, high cost of labor, and lack in required knowledge. The ISMED 2008 categorized the current problems of Thai SMEs into eight issues, namely: marketing problem, labor problem, lack of capital, technology limitations, lack of modern management knowledge, insufficient support from public and private sectors, restrictions on access to the service of the public sector management, and restrictions on access to information.

To improve the SMEs' performance, one challenge of modern organization is to develop their knowledge-based organization. As Drucker (1999) mentioned, the present competition is to shift from focusing on manual worker productivity or labor-intensive to a more knowledge-intensive nature of work. To retain the useful knowledge within organization as long as possible, the theory of organizational learning, which is widely used in modern organization, was a focus of this study. Moreover, to survive in competition, innovative ability is also required in every organization. Hence, this study is focused on organizational innovation as well.

In addition, this study aims to develop a conceptual framework for internal and external antecedents towards organizational learning and innovation of SMEs in Thailand. Such a conceptual framework could provide a better understanding of the role of relevant factors and their influence. Furthermore, the qualitative method was also employed in this study. The semi-structured interview technique was used as the collecting tool. This paper is organized into four sections. The first section describes the nature and context of SMEs in Thailand from the literature review. The second section emphasizes on the methodology and sample of this study. The third section identified the internal and external antecedents of organizational learning and innovation, and its consequence. Moreover, the conceptual framework is constructed in this section. The final section is identified the limitation and further research of this study.

SME IN THAI CONTEXT

Each country defines SME differently. In the case of Thailand, the Institute of Small and Medium Enterprise Development described SME as follows: *"SME stands for small and medium enterprise that operates the business in production, trading, and service business sector."* According to the Small and Medium Enterprises Promotion Act of 2000, the type

and characteristics of SMEs can be categorized by the enterprise's fixed asset and number of employees as shown in Table 1.

Table 1: The type and characteristics of SMEs.

Type		Number of employees		Fixed asset (million Baht)	
		Small	Medium	Small	Medium
Production sector		< 50	51-200	< 50	51-200
Service sector		< 25	51-200	< 50	51-200
Trading sector	Wholesale	< 25	26-50	< 50	51-100
	Retail	< 15	16-30	< 30	31-60

First, the production sector includes the agricultural processing, manufacturing, and mining industries. Second, the trading sector includes the wholesale and retail businesses. Third, the service sector includes the service business such as hotel, restaurant, and spa businesses.

Some benefits of SMEs to the Thai economy (Ministry of Industrial, Thailand, 1999) are described as follows:

- To create jobs in every regions of Thailand: the SMEs were established in almost every region of Thailand in order to create jobs for the people in their regions. In other words, it is the distribution of income to the people in the rural area as well.
- To generate the high value-added of products: the SMEs can bring in benefits from exporting their products and also creating foreign exchange earnings. Moreover, they can also produce goods as import substitution which can prevent a lot of foreign goods being imported.
- To support and link large, medium, and small enterprises with each other in the form of primary production of raw materials or goods by manufacturing employment of subcontracting.
- To be a source of experience available to entrepreneurs, especially those who are in the start-up point of new businesses and investors can expand their business from small to ultimate growth.
- To link between the industry and other relevance such as trading, logistics, agricultural, and construction sectors.

METHODOLOGY

Theoretical framework typically originates from the data that could create new ideas or improve existing theories (Holloway, 1997). In this study, the qualitative method was employed in order to create the theoretical framework. Qualitative research usually focuses on human perception, behavior, and experiences with the purpose of improving theories or experiments (Stake, 2010). It has been applied and used in many research works in both the social and science fields. A semi-structured interview technique was used as the data collection tool. Moreover, a literature review was performed along with the whole data

collection and analysis processes, with the purpose of clarifying and comparing the evolving results.

For the sample of this study, five Thai SMEs companies were chosen based on our criteria. First, the selected companies are in the production sector and are located in the Bangkok metropolitan and perimeter areas, where there is high concentration of SMEs, and the premium business-infrastructures are provided in this area rather than the rural areas. Second, the medium size companies selected for the analysis each has the number of workers between 51 and 200 as well as the size categorization of ISMED. Then, there were in total seven interviewees who participated: three were two engineers and one technician from automotive and components companies; and four were two engineers, one technician, and one manager, who were willing to be interviewed for this study. Each interview was approximately 20-30 minutes. The questions were open-ended in semi-structured interviews. After a comprehensive literature review and semi-structured interview with Thai SMEs, a conceptual framework of organizational learning and innovation was developed as shown in Figure 1.

CONCEPTUAL FRAMEWORK

Organizational learning in SME

Even though the SME is a small or medium size business, the continuous performance improvement must be considered in order to keep pace with the rapidly changing economic conditions and global competition. Nowadays, the shifting from a labor-based economy to a knowledge-based economy, such that knowledge, which is an intangible asset, becomes an important weapon of organizations for competition. As such, management and sustaining of knowledge is a critical issue for organizations. One challenge for management of organizational knowledge is the organizational learning theory. It can be described as “a process that gathers information from both the external and the internal environments of organizations. This information is assimilated by organization members through collective struggle behavior which produces shared visions that can be used to make changes to lead to an organization’s success” (Chen, 2006). Many researchers focused on the research work of organizational learning in large companies rather than in SME companies including the research work of SMEs in Thailand.

Organizational Innovation

Nowadays, it is undeniable that innovation is an important driver in the improvement of performance, whether small or large organizations including SME. This requires an innovation process to improve and develop their organizations such as the development of product or process innovation. In the case of SME, their characteristics differ from large companies, for example, producing a variety of products in order to fulfill customers’ order, modern products or services. Moreover, not only can the needs of customers be changed all the time along with new technology, but also the external turbulence and competition lead SME to improve themselves such as the tools, machines, management system, and skilled and trained workers. In other words, innovation improvement is a critical issue of SME.

Antecedents of organization learning and innovation

After a comprehensive literature review and semi-structured interview, the four internal antecedents and two external antecedents were selected and described in this section. Internal factors consist of the following four: leadership, information technology, culture, and motivation as shown in Figure 1.

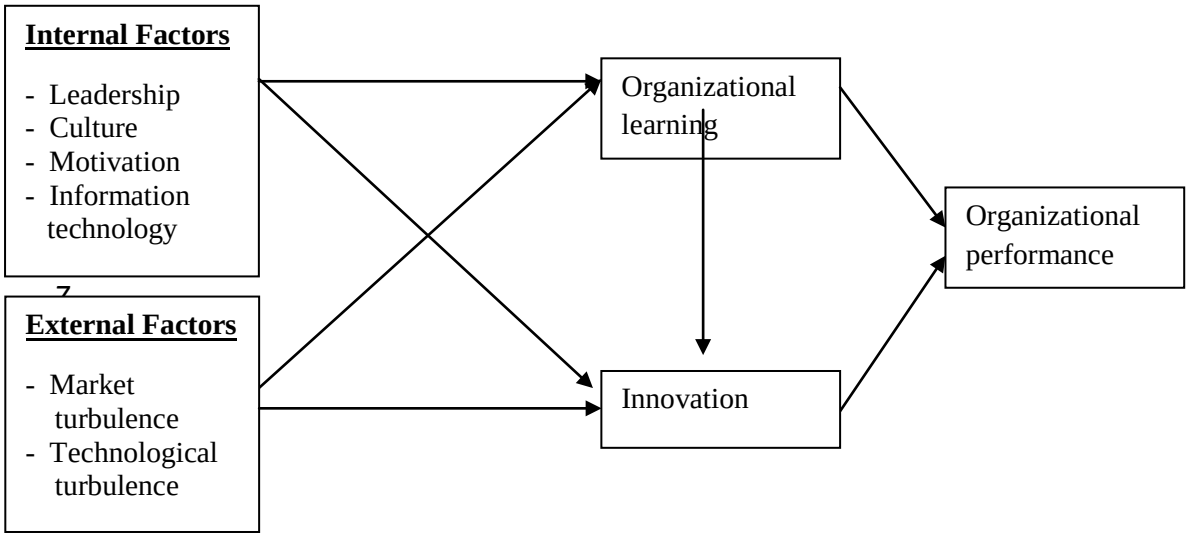

Figure 1: The conceptual model.

Leadership

Many decades ago, much has been researched on the theory of leadership with the purpose of developing the organization. The leader is also called manager in much of the literature. The roles of the leader include planning, hiring, motivating, and rewarding employees. However, the role of leadership does not only involve managing the organization but also encouraging, facilitating, and sustaining the innovation and learning (Yukl, 2009). Moreover, the needs of employees should be considered in order to have them integrated with the organizational system. The style of leadership, especially transformational leadership, could directly and positively influence organizational learning and innovation, all of which could be improved by processes such as training and mentoring (Jung et al., 2003; Vera and Crossan, 2004).

In this research, the researcher observed that the nature of Thai SME is such that the manager is the owner and thus contributes the tasks on a daily basis to all departments such as planning, controlling, R&D, hiring, motivating, organizing. Moreover, these SME managers have to face and solve problems on a day-to-day basis by themselves. One interviewee argued that:

> *"Our manager plays an important role in our company and he has to make the decision in almost all activities in the company such as hiring the staffs, providing our training course, and investing in new technology. … He is the central link and drives the relationship among staffs in our company."*

Additionally, Senge (1990) described that this new perspective of leadership could lead the organization to become a learning organization. On other words, poor leadership will instill a low capability for a learning culture in the organization. Furthermore, organizational learning can be enhanced by motivation such as pay incentive for creating new ideas for innovation, or building a climate and culture that lead to learning (Achua and Lussier, 2010). The engagement between staffs and manager will lead to SME development and continuous growth.

Culture

As Drucker (1975) mentioned, the management system is concerned with people, culture, and performance. One challenge of organizational development is organizational culture. Culture is traditionally referred to as intangible, a set of values, beliefs, and symbols that make the community an organization. Additionally, each organization has its own culture. Schein (1992), who is an expert in this field, defined organizational culture as "a pattern of shared basic assumptions that the group learned as it solved its problems of external adaptation and internal integration, that has worked well enough to be considered valid and, therefore, to be taught to new members as the correct way you perceive, think, and feel in relation to those problems" (p. 12). Moreover, Dwivedi (1995) mentioned that organizational culture also has influence on the attitude and behavior of employees that will lead to organizational improvement. In comparison, the strong organizational culture will lead to improving innovation, supporting teamwork, and increasing efficiency, quality, and productivity, while a weak organization culture could block the creating of new ideas, processes, and systems (Morgan, 1989).

In this study, the management system of Thai SMEs was the clan culture which was flexible and focused on the staff. One interviewee from an automotive component company mentioned that:

> *"Our company manages just as the relationship system. It has the munificence, and gives the opportunity for everyone to share ideas and make comment that is of benefit to our company."*

Increasing the robustness of organizational culture will lead to a learning organization (Chang and Lee, 2007). Moreover, the organization culture could be changed to organizational commitment by managing the relationship between leader and employee (Singh, 2007). Then, strong leadership will lead towards changing the organizational culture for the better.

Motivation

Motivation is an important role of the organization's manager: "Motivation is the set of forces that leads people to behave in particular ways" (p. 83). The theories of motivation were established by many theorist and researchers, for example, Maslow's hierarchy of needs theory included the physiological, security, belonging, esteem, and self-actualization

needs. Moreover, Herzberg's dual-structure theory consists of two essential factors, motivation factors such as achievement, recognition, and hygiene factors (e.g. pay and job security), and working conditions. Nowadays, there has been a tangible shift from the scientific management area which focused on the worker motivation by money to the human resource area with the focus on worker motivation and the contributions to the organization (Griffin, 2010).

In this study, the interviewees of Thai SMEs agreed that motivation was an important factor in driving the worker to pursue organizational learning and innovation. Some interviewees believed that if a comparison is made between the motivation source of large organizations and SMEs, most large organization provide better motivation than SMEs such as the pay incentives, rewards, and promotions at work. However, the primary remuneration and welfare such as social security are also provided in all SMEs.

> *"Our company has programs that give rewards to the idea that makes the most benefit such as part design improvement. …The training programs are provided for some staffs, not for all staffs in our company. However, I think they should provide training for all staffs as someone who is willing to learn is better than training according to the plan."*

Moreover, one of the interviewees recommended that the work environment and relationship between workers, colleagues and leader in the workplace were also important factors which could lead to motivate the worker's commitment to the organization. Moreover, sometime the innovation of SME could result from worker motivation such as giving rewards to new ideas.

Information Technology

Nowadays, information technology plays an important role in daily life and business. It has a lot of benefits to the organization such as enhancing the competitiveness and organizational performance (Potter and Millar, 1985; Croteau and Bergeron, 2001). The role of information technology in an organization includes controlling and storing data, learning and development. Moreover, the use of information technology to increase communication among members in an organization, as well as memorizing and storing information could also enhance organizational learning (Robey et al., 2000). Moreover, the high information technology capability of the organization will lead to a variety of profit- and cost-based performance measures (Bharadwaj, 2000).

In this study, from the interviews, all agreed that information technology is very important for their business because it can create many benefits and value added to their business such as transferring market data, communication with vendors and customers. Hence, they endeavor to apply and use information technology to develop their performance such as learning new knowledge from external sources, using electronic commerce or social networks to communicate with their customers and vendors.

> *"IT is needed for all part of our business. Communications via IT are very important activities both in terms of communication with customers and*

external persons but also between staffs. …However, the investment in IT is a decision to be made by our manager."

Moreover, the SME preferred to use the service from the computer agency in performing their business rather than employing a computer technician because the wage for the agency is lower than hiring a full-time computer worker. The amount of IT investment is based on the type of business and the decision making of the leadership while firm size is not an issue (Love and Irani, 2004).

External Factors

After the global economic crisis, every country faced its devastating impacts regardless of whether developed and developing countries. Thailand is one country that was directly affected in many sectors such as export, manufacturing, and service sector. These directly impacted the people, public, and their business, especially whether it could reduce the number of employment, production, and delay or reduce investment in Thailand, etc. One important factor characteristic of this situation is turbulence. Turbulence is defined as the change, uncertainty, instability in the external environment (Smith, 2005) and has both direct and indirect effects on organizational performance. Two types of turbulences were considered in this study, namely, market turbulence and technological turbulence.

Market Turbulence

Market turbulence (also called market dynamism or demand uncertainty) is defined as "the rate of change in the composition of customers and their preferences" (Hanvanich et al., 2006). Market turbulence can be categorized into five types such as customer, channel, competitor, macro-environment, and value proposition turbulence (Smith, 2005).

In this study, after the in-depth interview, the interviewees agreed that market turbulence was one factor that was difficult to control. One interviewee from the electronics company mentioned that:

"Our model has changed quickly due to customer needs…. Learning from external sources or benchmark with others….creating an innovation in our organization in order to increase the value-added to our products and make us different from the competitor. This will bring satisfaction to our customers and gives us the competitive advantage."

Organizational learning could be increased by forcing market turbulence (Hanvanich et al., 2006). And since customer preferences are unstable and change quickly, the innovation must be quickly changed in order to satisfy them.

Technology turbulence

Technological turbulence is defined as "the amount and unpredictability of change in production, process, or service technologies" (Srivastava and Frankwick, 2011). This is the factor that could determine the life cycle of existing products. For example, the products

with fast technological advances or high technological turbulence will have a short life cycle, while the low technological turbulence of products will perform in the opposite direction. Moreover, sometimes the product life cycle can grow and the new technology could occur in those cycles.

In this study, after the in-depth interviews, most of interviewees agreed that technological turbulence has an influence on their performance, especially among electronic companies, who seem to have been greatly impacted at least according to one interviewee from an electronic company:

> *"Technological turbulence comes around us all the time due to electronic products which have changed over time. Everything in our company also changed accordingly such as the machine, process, and knowledge about new technology. Then, we have to prepare ourselves in order to deal with it such as preparation of learning and training our staffs on the new technology. This way is quite better than hiring a new expert that requires a high investment. Moreover, this is the way to improve our staff ability as well."*

Even though many companies or businesses agree with the above, however, only one interviewee from the automotive part company seems not to agree:

> *"We did not get any effect from technological turbulence because we produced unique products of which we're the sole producer in Thailand. Moreover, our products do not need a lot of change because it is the foundational part of automobile."*

The requirement of technological development is an essential competitive strategy. Porter, (1985, p. 171) defined technological development as "raise or lower scale economies, make interrelationships possible where they were not before, create the opportunity for advantages in timing, and influence nearly any of the other drivers of cost or uniqueness". In other words, the products with low cost or are differentiated will lead the organization to be more competitive and could also create organizational innovation. Moreover, technological leadership will be required in order manage the costs of such learning activities and innovative technology (Porter, 1985).

Consequence of organizational learning and innovation

In this study, organizational performance was identified as the consequence of organizational learning and innovation. In order to know the current competency level of an organization, the measurement of the overall organizational performance should be recognized (Kaplan and Norton, 1996). The measurement of organizational performance is typically categorized into two types which are non-financial and financial measurement. A Tool for measuring non-financial performance is for example the balance scorecard, while the tools for measuring financial performance are the APC model and the MFPMM technique which were developed by the American Productivity and Quality Center. (Rao, 2006; Phusavat and Photaranon, 2006). The key performance indicators which are widely used in performance measurement include quality, cost, delivery, flexibility, creativity,

marketing, production, finance, innovation, and public relation (Kaplan and Norton, 1996; Cooper and Kleinschmidt, 1987; and Zhang et al., 2004).

CONCLUSION

The conceptual framework is illustrated in this study, is still in the first step and requires the further empirical investigation. As this study, the qualitative method was employed for construct the conceptual model, then further research, the quantitative method would be employed with the purpose of investigating the answer and reflecting the data. Moreover, the framework identified in this paper can be used as a guideline for organizational development to enhancing their learning and innovation ability. To sum, the conceptual framework identified the internal antecedents of organizational learning and innovation which included leadership, motivation, culture, and information technology. All of them were the internal factor of organization that could be focused on because they had been influenced on organizational learning and innovation. Moreover, the external antecedents included two factors which were market turbulence and technological turbulence. Both of them were the important factor of SME because they were the uncertainty factors and had the high risk.

LIMITATIONS AND FURTHER RESEARCH

The limitations of this study have to do with the sample which was selected from the SMEs in Thailand and all of them were in the industrial sector. First, the comparison across different sectors could be demonstrated. Then, these could provide a better understanding of the different industries with their different competencies. Second, the comparison across different countries could be considered. These could provide a better understanding of the different factors that influence organizational learning and innovation, such as the comparison between SMEs in Asian and European countries. Third, the comparison across cultures could be included. This could provide a better understanding of the different socio-cultural factors that influence organizational learning and innovation, such as the comparison between Japanese-Thai SMEs entrepreneurs and original-Thai SMEs entrepreneurs. However, the purpose of this study, which is to create a conceptual framework, will not be answered unless the hypothesis is constructed and tested in further research (Patton, 1989).

ABSTRACT

Trust is the essence of leadership. Leaders enable the creation of trustful workplace climate that gives support to innovativeness. The paper discusses and examines a highly timely topic of trust in organizations from the leadership perspective. The focus is on the role of trust in renewing human intellectual capital which is a crucial resource for sustaining innovations (Savolainen, 2011). Originality of the paper is based on the two ideas; First, defining leadership by trust as leader resource, skill, and intangible asset. Second, examining trust in leadership as enabler of the renewing of human intellectual capital. The paper provides a novel view into managerial leadership, since trust, leadership and the renewing of intellectual capital has hardly been examined integrated. The main point of discussion is crystallized in the suggestion that leading with trust enables the renewal and growth of human intellectual capital which is of utmost importance for sustaining innovativeness and competitiveness in business organizations. In the practices of renewing intellectual capital, sharing of knowledge is one of the key activities and processes. Trust is needed more in this context. The discussion paper advocates the idea that, in managerial leadership, it is important to understand antecedents, formation, and consequences of building and sustaining trust. The paper presents also real life examples from two case studies. They illustrate the practices of building and sustaining trust through leadership.

Keywords: intellectual capital, intra-organizational trust, innovativeness, intangible assets, leadership by trust, tacit knowledge, sharing, case study, qualitative

INTRODUCTION AND PURPOSE

Trust in organizations is an antecedent and a way to build innovative work environments in the knowledge era. In organizational renewal, co-creation, interaction, and relationships are stressed more and more. Trust is thus needed more but enacted less. Trust is a relational concept meaning that it develops in interaction and reciprocal activity between organizational actors. The main part of leadership work is about relationships, interaction, communication, sharing, and collaboration. As the service-dominant logic has permeated in global markets and exchanges (Lusch et al., 2007), services and processes undergo renewal.

For this organizational innovations and not only technology innovations are needed in private and public sector organizations. Leadership and HRM are the focal intellectual resources in the renewal activity.

Trust is hardly examined as intangible, forceful resource and asset in leadership. Although building trust is listed as one of the main elements and tasks of leaders (Yukl, 2010), the knowledge gap exists how leaders enact on trustful leadership and show trustworthiness in daily actions. Trust in workplace relationships is still scarcely studied, despite of the fact that leader-follower relationship is one of the key actor relationships in organizations. Recently the importance of trust in leadership has been widely recognized in the literature and practice. In Finland the Finnish Innovation Fund (SITRA) has raised 'new leadership by trust' as a paradigm for the future in the development program report "Elinvoimainen Suomi", Vibrant Finland (Nurmio & Turkki, 2010). Building trust in leadership has been prioritized nationally as the top theme in leadership education for sustaining our vitality and competitiveness.

The paper discusses of building trust which is also based also on real life examples. The purpose of the paper is to stimulate discussion and shed light into the importance of and issues related to trust in leadership for organizational innovativeness. Further, the objective of the paper is to increase awareness of the role, nature and consequences of trust and influence of trustworthy or untrustworthy leadership behaviour on people in workplaces. The topical question is: Do we want to nurture or hinder freedom, appreciation, openness, sharing, creativity and ideas? All of these elements are needed for innovativeness in current workplaces. The paper presents theoretical views of how trust, leadership and innovation are related, and, some examples and implications are presented of trust in intra-organizational relationships to support innovativeness.

As organizations become more knowledge intensive, event- and opportunity-oriented, the strategic challenge for gaining critical competitive advantages increases. Human activity builds on knowledge and knowing and their varied invocation. From this perspective, trust is a significant human intellectual resource, because it is formed through and between people.

THEORETICAL DISCUSSION

Concept of trust

Trust is looked as a relational concept in the paper (Mayer et al., 1995) and within intra-organizational, and leader-follower relationships. Trust has been defined in many ways. Yet, the concept remains without a generally accepted definition (McEvily et al., 2003). In this paper, *the relational definition of trust* is adopted from Mayer et al. (1995, 712) as follows: "the willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party". Mayer's model of trust integrates the factors of trust formation in organizations between actors, i.e., in a relational context. Theorists have suggested that trust evolves over time based on a series of interactions. Trust is a person's assessment of another's *trustworthiness.* Trust describes the

positive expectations of a person in relation to the object of trust behaving respectfully also in situations of risk. Risk taking is at the core of trust, not taking risk per se, but rather a willingness to take risk (Mayer et al., 1995). Cooperation and confidence are used as concepts closely related to trust (see Schoorman, Mayer and Davis, 2007).

Trust is combined of several components - rational (cognitive) and affective. The elements that underlie trust-based relationships are the individual's feeling of being competent, a feeling of safety and caring, a sense of autonomy and empowerment, consistency and fairness in social relationships, congruence in the values of an individual and the organization (Savolainen, 2009, 2000). Trusting relationships imply trustworthiness. Credibility, fairness, competence with good intentions, and benevolence belong to the widely recognized dimensions of trustworthiness (Möllering et al., 2004).

Trust as intellectual, intangible asset

In organizational renewal, trust is an internal motivational force for individuals to develop their intellectual capital. Trust is seen as a foundation for cooperation, and an ingredient for creativity and freedom. Trust is manifested in collaborative culture characterized by open communication. Human intellectual capital includes areas such as competences, motivations, communication, sharing of knowledge, and cooperation skills. Trust may become more powerful intangible asset in the development of collaborative workplace cultures. In e-, virtualizing and multicultural world, cooperation and co-creation will be the keys for innovations, and for sustaining competitiveness. It is the environments of 'coopetition' that seem to emerge and conquer the most inspiring workplaces to be. And they will be the ones that reflect trustful climate.

Trust is intangible resource for both individual and organization. In the workplace context, resources such as trust are used and "owned" by the organization, in principle. Trust is multi-level and reciprocal in nature. This means that the effects, means, and consequences of trust concern both the individual and organizational level. Interpersonal communication and norms create for people a sense of security and an opportunity to identify with a group (Mäkipeska & Niemelä, 2005). Rewards in work relationships are accumulated by individual players' stable relationships and bonds through consistent interaction, which makes it possible to maintain them. Over time and through mutuality the predictability of the other player's actions increases. Subsequently, in co-operation one party can trust the other that he or she will not act deceptively trying to gain short term advantage.

Intangible assets are managed by the organizations and are accumulated from the human capital. Human capital is connected to an individual and disappears with him or her in contrast for example to technological capital and information, which is accessible to all. Even though human capital is strongly grounded on the individual, it is also organizational. The individual builds and breaks trust, but the benefits and unfavorable effects spread to groups and organizations. When individuals build, maintain, or damage trust, they obtain benefits or losses. More broadly, the effects are seen in different structures and processes in the organizational and societal level. This especially applies ethical activities. An individual's unethical actions propagate detrimental consequences to the organizational level and even the entire society. The most blatant examples of this are the pyramid

schemes, in which one individual's betrayal of trust leads to very serious and vast negative consequences.

In short, intrinsically trust can be built or destroyed by an individual, but he or she alone cannot utilize it or carry its unfavorable consequences. They influence relationships and structures, socially and collectively. Individual trust can be invisible and even "tacit", easily breakable and fragile. On an organizational level it is usually more tangible and can be sensed for example in the culture and atmosphere as well as in various relationships of influence, say between a leader and a subordinate. In conclusion, the purpose of trust is essentially to facilitate and ease co-operation. Trust is invisible and intangible but its benefits and consequences are multifaceted within organizations and between actors.

Trust in organizations and leadership

Pertaining to intellectual capital leadership by trust plays two roles in organizations. First, trust is an influential force and human intellectual capital for leaders in enabling and building trustful climate. Second, leading with trust is a means and skill to develop human capabilities for the competitiveness of the organization. Considering that work today is largely expertise-based by nature and is strongly based on creating and sharing knowledge, development of human capabilities and the work environments for utilizing them become prioritized.

Trust is a psychological and functional state. An individual is going to take the risk of being vulnerable with the anticipation that he or she will have a positive expectation of the intentions and actions of another (Dirks & Ferrin, 2002; Rousseau et al., 1998). The person takes action based on his or her beliefs (McAllister, 1995) and may have to face disappointment when expectations are not met. Thus trust in work relationships is dynamic and varying. It grows from the basis of relationships depending on the character and functionality of those relationships. This is described for example in Laaksonen's (2010) research on trust formation in a team. It was observed that trust resembles wave like motion with its "surges, spatters, and calms". Trust can be seen as an opportunity to get an access to knowledge, political, economical, and relational resources which are controlled by individuals (Keskinen & Teräs, 2008). It is also an opportunity to create loyal relationships which do not deteriorate or break easily. In the long run, these relationships are human resources which become rooted in and stratify as social and cultural intangible capital.

Trust creates vitality for the organization

Organizations are in need for vitality in order to sustain innovativeness and competitiveness. Vitality is about energy, will, spirit, activity, influence, collaboration, courage and ability to see opportunities and make changes. Vitality is enabled by different resources such as social and cultural foundation and heritage. Trust as intangible resource belongs to them. Vitality is created by individuals and in collaboration between individuals. Leaders enable and create (or ruins) vitality in organizations. Trustworthiness is one of the essential leader traits

and skills gained and trained in interaction with people. The very concept of interaction is a common denominator for a number of leadership definitions (Yukl, 2010).

Trust building and maintaining in organizations create basic vitality and energy that *enables* revitalization of individuals and organizations, and effective, profitable performance, accordingly. Vitality is energy of the will, emotions and actions. It can be seen in people's motivation, enthusiasm, as well as fully utilizing their different skills, abilities and talents. One example is taking people through a change process in which they are able to take risks while continuously facing the unknown and unpredictable. Trust gives birth to vitality and vitality strengthens trust. Practically speaking, it means courage and readiness to deal with different opinions and perspectives. Conflicts and tension in an atmosphere of trust can also produce positive energy which results in active interaction and courage to make a difference (vrt. Nurmio & Turkki, 2010).

If an organization's vitality is depleted or is not maintained, these "feeble" organizations face unfavorable development, and even crisis. The organization's overload or premature aging can lead to its impotence (Probst & Raisch, 2005). This can be a result of overheated growth speed or respectively of slowness, in other words, of strong change resistance, clinging to old ways or the restrictions of a stiff culture. Conversely, the culture of trust is characterized by a readiness to follow and manage work environment, growth, and the operation structure of the leadership. It also means flexibility in facing changes, making decisions and maintaining an ability to function in a suddenly and unexpectedly changing environment. It takes creativity and flexibility to apply new ideas and decisions. A willingness to take risks is intrinsic for trustfulness. It can empower the organization to success just in a time of great uncertainty. When people trust their colleagues, their energy can be focused on the core activity, development, and performance instead of games, politics, and control.

In summary, trust building serves as influencing power and a device for leadership. It can give work places vitality and competitiveness, with which the future business life copes in the world of concerted, multicultural, and diverse global competition economy. Changing leadership requires new, deeper awareness of the significance and the necessity of positive influence in mutual interaction. It also includes an awareness of the effects of one's own actions, e.g., of trustful vs. distrustful actions. Continuous change also requires for leadership to have fresh understanding and new efforts to remove national, organizational and cultural as well as leadership obstacles from the way of trust-based leadership.

Trust building - a new focus in leadership

Trust in leadership work is embedded in the relationships between leaders and subordinates. Leadership by trust can be defined as a *leader's ability to enable interaction, co-operation, and productivity* (Savolainen, 2011). Enabling is central in this. It means both the removal of obstacles and supporting new ideas, solutions and implementations as well as inspiring and encouraging them. This is *the new focus of leadership.* Trust in leadership work aims at achieving functionality, co-operation, and performance in organizations. Trust grows in the soil of interaction and openness and can give birth to well functioning relationships between individuals, groups and networks. In everyday leadership, trust

provides readiness and ability for social influence. In daily work, it is shown in trustworthiness.

Work relationships are ever more important in a global expertise-based economy because creating new knowledge and innovation as well as development of competitiveness require them (Nurmio & Turkki, 2010; Savolainen, 2009). Leadership is currently undergoing major global transformation. Consequently, the significance of trust in leadership is inevitably connected to a larger change of working environments. For this reason the prerequisites of trust are highly emphasized. Intangible, human capital specifically makes a strategic skill resource in competition. Thus its conscious management is more and more important. In service economy, the goal is to increase interactive relationships and develop systems of co-operation. The challenges come from creating, sharing and interpreting knowledge.

As working life is facing tremendous changes, business models and relationships focus more and more on balancing and controlling the tension between competition and co-operation. The lack of managers weakens conditions and opportunities for interaction. That affects the level and maintenance of trust. The effects are also seen in an organization's openness and atmosphere as well as the motivation and commitment of the people. The benefits, effects, and results of trust are portrayed in the frequency and effectiveness of communication and interaction. This in turn is reflected in the practice of creating and sharing knowledge (Savolainen, 2008). In the end, the benefits are realized also in performance and results.

Because of the above mentioned changing factors it is reasonable to emphasize trust, and develop means to facilitate it in organizational leadership. The challenges of intangible capital renewal in a global scale are tremendous and they are primarily leadership based. Leadership does need renewing because many macro level factors influence the everyday activities of individuals and organizations. These are multiculturalism, environmental issues and technology among others. As a result operations are ever more complex, unsecure, and harder to control. Thus a sense of security is needed to maintain a capacity to deal with uncertainty and change. It is trust-oriented leaders that are needed to coach more teams in order to maintain and renew productivity and competitiveness as well as well-being and continual vitality.

The new kind of leadership seeks its role, because leadership cannot function any longer solely through an individual, position, or hierarchy. New competences and resources through which a leader gains his or her right to lead must be discovered and developed. Trust is a way of influence, which helps to build mutual co-operation and productive operation. Still, the manager's role is significantly more influential in how the subordinates want and actually do perform and what kind of results are achieved. Subsequently the subordinate influences the way he or she benefits the organization and how dependable his ability and performance are to the manager.

Trust building faces challenges

Trust building and maintaining are challenging at work places because so many situational factors influence them. Among the most common ones are *cultural structures* like deep convictions and customs as well as hindrances in communication. Trust is reciprocal and

cannot form one-sidedly. Trust "belongs" equally to each member of the work community or network. Everyone owns an equal part of it and is responsible to build it. It can be build upon the process and recommendations of good professional behavior. The significance of trust is emphasized in fields requiring creativity and innovation because they require freedom and favorable attitude and environment. Creativity never happens by force but in *freedom*. It develops through hearing different perspectives and views, freedom of discussion, and accepting differences. Creativity or trust for that matter do not happen in communities where there is room for only single opinion, view, truth, or interpretation. In large, multi-level and multi-unit organizations internal communication from top down is a very simple, everyday example. The content of electronic memo with instructions, schedules, and goals does not necessarily reach the target audience. It may not be understood, because the person receiving the information does not have a chance to interpret or check it. Electronic information overload may be a reason: one does not get answers, messages are ignored, or it is impossible to reach the right people.

In current business management, complexity is the approach characterizing daily operations and leadership. In intricate organizations varying views are crisscrossing, which manifest in contradicting interests and objectives. They are not accepted or dealt with in *fear of conflicts*, which is also an indication of the nature of culture and leadership style and the need for them to change. Human intellectual capital is renewed in complex and conflict situations - on one hand in interaction and on the other hand in simultaneous cross-fire of contradicting views and objectives. Conflicts and differing views, however, are strength, because they can produce constructive dialogue and profitable performance.

Furthermore, trust building and maintaining requires an investment in leadership capacity. Education is indispensable to gain skills. Intangible capital, like knowledge or trust can grow or disappear just like financial or other kind of capital. Despite of the fact that organizations aim to increase (tangible) capital which can be measured by financial indicators, strengthening co-operation between actors is among the most important attitudes and means to renew and increase internal, intangible capital.

Leadership role in renewing human intellectual capital

Especially in knowledge and expertise based operation in which critical assets are intangible, the leader cannot base his/her authority anymore on management position. Authority is rather based on the expert-subordinate's desire and ability to claim his status through being allowed to influence his own performance. Leadership has become emergent and has to be 'earned'. In the success of expert-based organizations this is a central factor. At this time trust and authority are re-evaluated. The organization's sources of authority are diversified and leadership is shared. The authority of an expert-subordinate is based on knowledge and know-how, while the authority of the leader is based on position, knowledge and ability. What happens if a manager lacks core competence required in leadership? How will position-based leadership work and influence the followers? If the manager wants to be trustworthy, competence cannot be disregarded.

Essentially, leaders are responsible for knowledge, guidance, motivating and commitment as well as creating a culture for learning needed for the renewing of human intellectual capital.

Gaining competence as well increasing performance and continuous individual development are reached through human intellectual capital. That is why ability-based management is central for strategic human resources. Human capital is both individual and collective. When the focus is in individual competence and ability as well as creativity and innovation, these qualities specifically are in demand in the information age. The ability to lead human capital is an important competitive factor for an organization. Knowledge may be unique or general but new knowledge is not created without encouraging creativity and innovative applications. This requires good leadership. The timeliest challenge in renewing human intellectual capital is thus renewal of already attained knowledge and ability.

When the understanding of intangible assets increased in the 1980s, it was observed that the organizational performance was greatly affected by its intangible capital (Sullivan, 2000). As a result, intangible capital began to be seen as an important issue in leadership. After Stewart (1997) defined intangible capital as mental, human and intellectual asset, it impacted the theories and practices of providing leadership for knowledge and know-how. From the point of view of leadership, it is important to understand human capital as multidimensional combination of mental, structural and relational resource (Edvinsson & Malone, 1997) that are also interrelated. While human capital is comprised of values, culture and philosophy, human capital also gains an organizational level character. It is easier for the leadership to influence the internal than external structures and relationships. Leadership is an internal structure but it influences the external relationships for example in customer relations management. Practically, the effects and connections can be seen for example in developing personnel's customer-based know-how. Thus human capital requires and utilizes interchangeably other intangible capital (Stewart, 1997; Roos & Roos, 1998).

Creating human capital is an integral part of an organization's leadership process. It describes activity, customs and processes (Roos & Roos, 1998), with which intangible capital is created for the benefit and success of an organization. Stewart (1997) points out the differences in leadership between different types of intangible capital. Different types of capital require varying leadership styles and. Taking care of knowledge and ability is central to the renewal of human intellectual capital. It is important that individuals and organizations are going in the same direction so that individual human capital would benefit the organization. Leadership is essential in this as vision, mission, and strategy direct the development.

Trust in renewing human intellectual capital

Because the organization is built upon the people and their talents as well as their knowledge and expertise the relational resources essential for trust formation are created by human activity. Generally, what is meant by relational capital are an organization's external relations to interest groups, such as customers and journalists. However, relational capital is more multidimensioanl than these, because it implies also internal interaction and relationships. This has not been specifically emphasized when evaluating relation-based intellectual capital.

Research shows the connection between trust and organizational performance (McEvily et al., 2003). Dirks and Ferrin (2002) studied the impact of trust on how talent, knowledge and

expertise are utilized in their full potential in an organization. According to their empirical research covering 40 years, trust plays an important role in the employee attitudes and behavior. It is seen in more positive work attitudes as well as in a willingness and ability to co-operate.

From the perspective of leadership by trust intangible capital is immaterial, governed by the organization, based on individuals' knowledge and know-how, capital created by internal and external interactive relationships, which add competitiveness in the market (Edvinsson & Malone, 1997). It includes individual process as well as cultural and operational structures which support the activities of groups and individuals. Among these are organizational structure, deep-rooted ways of operation and leading. Knowledge creation and sharing form the key processes in renewing human resources. Hence, trust provides a strong potential for renewing human intellectual capital. Therefore, it is worth nurturing and preserving. Trust has similarity to tacit knowledge because it is very unique personal knowledge and know-how and is embedded in relationships. Trust facilitates managerial routines, for example, sharing of information and knowledge. They manifest themselves in a positive, open behavior and communication.

Renewal of intellectual capital for competitiveness

The renewal capacity is a quality in the organizational management and HRM, which manifests in its procedures and processes. It is an ability to implement strategy and respond to changes. Currently, competitiveness is based on quick capacity for renewing and effective usage of opportunities and capabilities that are mainly human and intellectual. It is noteworthy that individual human capital may also include inherited and personal character traits such as intelligence, flexibility, and relatively consistent temperamental characteristics such as openness or introvertedness. These factors are relatively permanent, and usually cannot be much altered or developed. However, they may be foundational and important prerequisites for renewing and development of human intellectual.

Mobility of the work force is phenomenal in the global context. Kong & Thomson (2009) have found out that personnel and human capital are not as effectively and easily mobile as has been expected. Therefore organizations should create other means in their human resourcing, especially in addition to recruiting, to develop and include human capital for the sake of securing competitiveness. Häkkinen & Savolainen (2008) argue that mutual trust secures the effective use of know-how and expertise. This is an important observation for the sake of leadership because the effects of lack or failure in leadership can be serious and fatal for the organization's performance. There are examples of this in studies among crisis companies (Probst & Raisch, 2005). According to the researchers a too strongly centralized leadership structure can lead to the failure of a company or an organization.

To improve competitiveness more attention should be paid to maintaining trust than is done presently. A good example of trust building is personnel's job orientation. Häkkinen and Savolainen (2008) report on initiation in their study of trust in fresh leader-subordinate relationships. Job orientation is seen as one of the routine activities in HRM. The new staff member emphasized the significance of job orientation as a valuable and unique opportunity and situation for trust formation. When the newcomer is introduced to positive

interaction and sharing of information from the beginning, at best it leads to effective learning and socializing. It also becomes easier to apply good examples received in the orientation to one's own work. In the opposite situation when the initiation to work and organization is done poorly, consequences are mostly negative. The worst for the organization are underachievement and prognosis of lower performance. When know-how is not utilized from the beginning, or when a good example is not given of open knowledge sharing, the practice becomes permanent. Unfortunately this practice is often transferred to elsewhere in the work place.

EMPIRICAL FINDINGS AND EXAMPLES FROM CASE STUDIES

The practices of enacting on trust in leadership are presented next. They are based on the findings from the qualitative studies. The case study data were collected from the private sector organizations running business both in the service and industrial sectors, more specifically trade, retail, construction engineering, ICT, and metal industries (Malkamäki, 2010; Savolainen, 2008, 2009; Havukainen, 2011). The studies represent examples of trust development between actors and organizational units, trust in knowledge sharing and leadership. The aim of this section of the paper is to advance understanding of the role of trust in organizations and leadership, and present the ways of enabling and supporting organizational innovativeness.

Two case examples are presented and brief references made to the preliminary findings of the third case.

- Case A: Trust development within internal customer relationships between two organizational units and actors in a Finnish trade organization (Malkamäki, 2010).
- Case B: Knowledge sharing, trust and renewal of intellectual capital. From the service sector, a small Finnish construction engineering company (Savolainen, 2008, 2009).
- Case C: Trust and tacit knowledge in leader-follower relationships. A study of three companies in different industries (work in progress; Havukainen, 2011).

Case A – Trust building between organizational units and actors

Case company and methodology of the study

The study focuses on how two different functional units within a large, multi-unit and fast growing trading organization build mutual trust. The company has a wholesale unit and 69 retail sale units employing about 3900 people in all. In 2009 the net sales was 595 M€. A qualitative case study was made and the empirical data was collected by thematic interviews. A qualitative case study approach was chosen, as the research topic requires understanding the company holistically in the real context (Koskinen et al. 2005, 154). In the study, 'a case' refers to the leaders interviewed at different levels and positions by face-to-face interviews. The data consist of the individual interviews of six middle-level leaders. Leaders' perceptions and experiences of trust development were examined within internal customership between two units and through the concepts of customer relationship

management. The content of the transcribed data was analyzed using a thematic method and interpretation was theory driven.

Key findings

The key findings show that trust developed primarily towards the organization in the case organization. Yet, trust between people was also considered important. One of the main findings is the importance of the strategic management system in trust building between organizational units. Shared goals, clear allocation of responsibilities, as well as defined policies and procedures form the basis for productive and predicable co-operation. Transparency in leadership, based on management system, sharing of information, and control were seen as the most important pillars of trust building.

Interaction is an important element of cooperation. Electronic communication is the dominant tool for it, but direct interaction is also needed for sharing understanding and meaning. This research finding is supported by both customer relationship management and trust research literature. Moreover, a kind of unexpected finding that came up in the data was the importance of transparency and control in trust building, which differs from the views of the mainstream research literature (Malkamäki 2010, 92). More specifically, the literature is quite unclear on the point of control and trust. From a contextual-based approach it is suggested that the relationship between trust and control can be either complementary or substitutive in nature depending on the type of control (Das and Teng, 2001, quoted in Costa & Bijlsma-Frankema 2007, 398).

In this study, control and trust seems complementary. When all the members in organization are required to follow the rules and agreements, and the actions are controlled, it makes people to feel justice and equality in procedures. It is an important notion that the forms of control and procedures may vary but trust seems to develop despite of the variation (Malkamäki 2010, 93). This is supported by Costa & Bijlsma-Frankema (2007). Trust cannot be a control mechanism, if both trust and control are defined restrictively and not for increased clarity. Trust is defined as a positive expectation about others motives, and control as the process of regulating others' behavior to make it more predictable (Schoorman et al., 2007, 508).

Further, the findings reveal that time and forms of cooperation have an effect on trust development. Trust between actors not known well is seen more as trust in organization. Therefore, trust may not move into the deeper level towards the identification stage. Hence, structural and operational issues have a significant role in trust development in organizational level. As a result of the current study, setting goals and sharing them, and the management system supporting the common goals are the basic strengthening elements of trust. Interaction, knowledge sharing and business developments together are seen as glue between partners. *Transparency and control* are linked to the predictability. They are pillars of trust and trust building. An opportunity to be a mentor or an actor in the process of knowledge sharing is a tool for e-leadership. Trust building is strongly related to changes in the leadership system and especially in values and organizational culture. The findings thus suggest that the management system is an essential 'corner stone' of trust development. Organizational structure and systems support cooperation needed for reaching goals and

purposes (Malkamäki 2010, 92). The basis of trust is strongly based on *the functioning management system, organizational culture* as well as *structures and processes* by which it promotes development of trust in interpersonal relationships.

The results also seem to emphasize the significance of the management system as an antecedent of trust in leadership. The findings suggest that common goal setting, competence, reciprocity and predictability are the common features of trust building in leadership work. Furthermore, the experience of success enhances trust development (Malkamäki 2010, 89; see also Häkkinen & Savolainen, 2008). In leadership, the finding of the management system-based trust shows how transparency and control enabled and facilitated the clear distribution of work, power and responsibility issues, documentation practices, common goal setting and sharing, following performance indicators and information system with using intranet.

For interaction between actors in the units meeting practices and giving and receiving feedback are the concrete tools of cooperation and trust building, by which the attitudes can be changed. Change occurs through constructive feedback in interaction. Predictability by transparency and control strengthens trust, especially in the beginning stage of trust development. Time is needed for trust to be built and develop. Trust has to be earned and it is based on the experience of cooperation. The reciprocal following of rules and agreements create trust. Experienced fairness and equity by transparency and control are the key elements of trust building. In interaction, hearing, giving and receiving feedback and taking them into account in practical improvements facilitates trust development. In changing leadership, the leader's role as an example as well as keeping promises play an important role in creating trustful relationships (Malkamäki, 2010).

Conclusions and implications

Based on these findings of the specific organizational context, the inter-relation of trust at different levels seems worth further theoretical discussion and empirical studies. The interesting finding of the dynamics of trust development shows how trust develops simultaneously but differently depending on the levels, frequency of interaction, and time needed or available. Just as perceptions about an individual's ability, benevolence, and integrity will have an impact on how much trust the individual can garner, these perceptions also affect the extent to which an organization will be trusted (Schoorman et al. 2007, 345).

Trust is based on acquaintance but the study shows that in more complex organizations trust is built by the norms, reciprocity and networks (Koivumäki 2008, 80). In this case, trust development is based on the principle of reciprocity included in *the management system*, and the rights and the responsibilities of actors. The cooperation and interaction procedures in the target organization vary depending on the managerial level. Regular, individual interaction between actors of the other organizational units is restricted at the lower levels of organization. Therefore, in trust building, the quality of relationship between leaders and followers is linked to the organizational level in and between organizational units and actors.

In the study, trust formation in internal customer relationships between the units seemed interesting and worth further examination. It is even more so, as the inter-relation between the actor level, (inter-personal) and organizational level (inter-unit/organizational) trust emerged. Finally, the findings imply that the role of trust needs to be understood more deeply in 'coopetitive' type of relationships which may be multiplex in inter-personal, intra- and inter-organizational contexts.

The study increases understanding of how organizational level factors and inter-personal relationships between actors are intertwined by revealing differing developments by the levels. The findings imply that currently under-researched area of multi-level trust development (Rousseau et al., 1998) is what further research may need to look in real life cases and relationships processually and contextually.

Case B – Knowledge sharing, trust and renewal of intellectual capital

As important as tacit knowledge is for gaining competitive advantages for organizations, it is elusive in nature and, consequently, tends to remain inarticulated; It is difficult to understand, observe, acquire and share, and diffuse in the organization. In the conceptualization by Nonaka and Takeuchi (1995) of tacit and explicit knowledge, explicit knowledge is defined as easily identifiable, easy to articulate, detain and share. It is in written forms such as books, manuals and reports, etc. Tacit knowledge is defined as consisting of intuition, feelings, perceptions and beliefs. It is deeply embedded in the ways of thinking, talking, and working, and in relationships. It is complicated to articulate and express. Hence, it is difficult to convert, transfer and share between people. Due to the nature of tacit knowledge, people need good grounds, motives and support for sharing. Leaders are key supporters of sharing. Organizational culture and leadership form a foundation for people involvement and willingness to share knowledge.

That is why the examining the real life practices of sharing tacit knowledge is important This is also the point for presenting the empirical findings in the paper. The entire idea to studying the trust and tacit knowledge sharing is briefly: *unless shared tacit knowledge is not converted to explicit*. Trust develops and is embedded in relationships which enable discussions and sharing of ideas & knowledge between people. By definition tacit knowledge is shared trough people and is a social process.

A largely knowledge-based expertise in work today involves the acquiring, creating, sharing and utilizing of knowledge in groups and between individuals. This also comprises interactive practices, i.e., communication and coordination. They may specifically reveal how trust has been used in an organization as a human 'talent' and intangible resource. Only if each party invests in trust, the organization will benefit. Nahapiet & Ghoshal (1998) state that it is in the everyday routine of both leader-follower relationships as well as other work relationships where the skills to create and share human intellectual capital will be manifested. This is especially apparent in interaction and thus is behavioral-based. That is why a relationship perspective is so essential. In the renewal of human intellectual capital trust is thus a relational competence which on one hand enables creating, renewing, utilizing and sharing knowledge through interaction, and on the other hand strengthens and

maintains the cooperative relationships at the work place through interaction and continuous social activity.

In the context of project work, trust is seen as an important antecedent for collaboration in a project group. It should be noted, however, that although trust may frequently lead to cooperative behaviour, trust may not be a necessary condition for cooperation to occur, as cooperation does not necessarily put a party at risk and as mentioned above risk taking seems characteristics to trusting one another. Absence of trust in a project group, on the other hand, leads to seeking protection from risks and to tightening control with higher bureaucracy. Project culture provides opportunities for informal interaction between group members and for reinforcing the sharing of common values. This strengthens tendency to sharing tacit knowledge (Koskinen, 2001). Trustful working environments are mentally open appearing, for example, as appreciation of one another's expertise (Huotari et al., 2005), and also physically open, e.g., open-office lay outs.

Case study findings from a small construction engineering company

Methodology, data, and the case company

The second case example examines the role of trust in developing intellectual capital which involves largely the sharing of tacit knowledge in a project-based organization. What are *the factors related to and having influence on* the sharing of tacit knowledge (Savolainen 2009, 2008). Qualitative methodology was selected giving the scarcely studied topic and the purpose to gain more understanding of the abstract topic (Yin, 1994; Eskola and Suoranta, 1998). The case company's operations are entirely performed in projects and project groups. The company is a small construction engineering company with 19 employees in all focusing on structural design. There are approximately four project groups working in the company at the same time. The combinations of the groups may or may not vary between projects. Projects may last from 6 months to over a year.

The case study data was gathered by in-depth interviews. Six project workers were interviewed including a project manager. They formed a project group. Them interview method was used. All interviews were recorded and transcribed. The interview data was analyzed by thematic analysis of the content of interviews. The analysis was theory-driven based on the theoretical framework.

Key findings

Tacit knowledge is shared by several *methods.* Six main ways emerge as follows: interactive, verbal advising, modelling, joint problem-solving, guiding to learn, job enrichment, and initiation into the company. On significance of initiation in building trust with new employees see Häkkinen and Savolainen (2008).

Organization- and individual-related factors affect all of the stages in the process of sharing knowledge. They seem to appear in combination and as a whole. Sharing of knowledge is a chain of events starting from the identification of key knowledge needed and the individual needing knowledge, and proceeds to choosing methods of sharing. Sharing and receiving

knowledge occur in personal interaction and proceeds with utilizing of knowledge. Finally, internalizing of knowledge occurs if *willingness and motive* for knowledge storing on the individual's personal knowledge base exists.

Trust appears specifically in the functioning of group relationships and dynamics. The findings show that group relationships and managing group dynamics turn out to be the key antecedents and critical capabilities even for other elements of tacit knowledge to appear and evolve. Ability to collaborate and the functionality of relationships have an effect on daily work, success of projects, and goal achievements accordingly. Individuals can have influence on this by creating and sustaining the relationships in the project group through their behavioural choices such as keeping the 'deals' and promises, among others.

Summarizing the key findings

The results reveal four *forms* (types) of tacit knowledge:

- professional knowledge (sound expertise and quality of work)
- management of group dynamics (interaction skills and ability to collaborate)
- management of entities (ability to see the essence and relations between parts), and
- management of knowledge resources and knowledge base (recognizing and meeting the need for key knowledge).

A uniting factor for these four elements is *experience* and its importance in the evolvement of tacit knowledge. Tacit knowledge, evolving from experience, becomes evident as sound and fluent practical capability.

Tacit knowledge is *shared by several methods.* In practices of sharing six main ways emerge as follows: interactive verbal advising, modelling, joint problem-solving, guiding to learn, job enrichment, and initiation into the company. Havukainen (2011) has found out that the organized sharing of tacit knowledge involves practices and procedures such as mentoring, work in pairs, tutoring, sparring, and benchmarking. Moreover, stories and narratives are important and influential forms of sharing. E-mail is perceived as a 'hard' and straight forward form of conveying knowledge. Yet, tacit knowledge sharing is made through the electronic channels.

Tacit knowledge sharing occurs in an interactive *process* between group members. A personal, individual nature of the assimilation process of tacit knowledge is presented by Havukainen (2011). Several individual- and organization- & management-related factors are discovered that affect the sharing of tacit knowledge in the case company (see Figure1.)

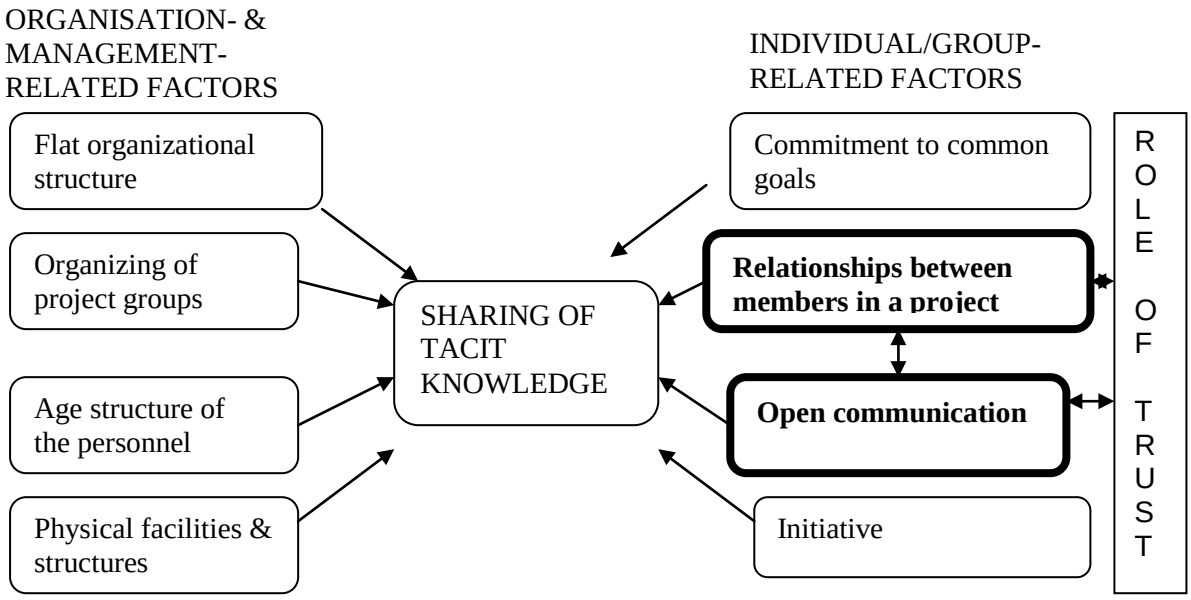

Figure1. Trust and factors related to the sharing of tacit knowledge in the case company (adopted from Savolainen, 2008, 2009).

An interesting finding is the dynamics of sharing; a process beginning by identifying the nedd for key tacit knowledge and the person in need for knowledge. The process proceeds from choosing appropriate methods and ways (tools) all the way into the actual sharing, receiving and possible internalizing of the knowledge in question. The processual nature of sharing has hardly been made explicit in prior studies. Interpersonal trust seems important. Trust supports the intra-organizational relational system where trust-based relationships are formed and maintained. This facilitates the actions of sharing tacit knowledge.

Conclusions and implications

The findings show that trust facilitates the activity of sharing tacit knowledge. The outcome is seen in work quality and performance. Creative project culture (cf. Koskinen, 2001) seems pervasive to the company studied. It becomes visible in multiple methods of tacit knowledge sharing, and the development of human intellectual capital, i.e., individuals' skills and knowledge. Leaders play an important role in skills and knowledge development. In conclusion, the group dynamics and workplace climate seem the most critical factors in sharing of tacit knowledge (see Figure 1.) They are shown by open communication and commitment to common goals, and functioning relationships between group members in a project group. Trust has an impact on both group dynamics and workplace climate. In practice, trust appears e.g, in a frequency of interaction, communication, keeping the deals and promises, and guidance to learn.

In conclusion, it is important to understand the role that interpersonal trust plays in the process of sharing tacit knowledge. As for trust in sharing knowledge, most of the issues and challenges related to sharing that emerge from the data are related to challenges of

interaction between people and dysfunctional work relationships (including preliminary findings from the third case; Havukainen, 2011). Trust creates openness and freedom and slackens control. It could be a more powerful intangible asset for collaboration and renewal of human capital - provided that knowledge is shared. Cooperation reinforces good workplace climate and makes knowledge sharing more effective. This improves operational work quality and performance in project-based organizations.

The main *implication from the case B* to managers is that trust is needed for developing intellectual capital and innovative 'spirit' in the group work. Leaders should especially pay attention to the maintaining trust in work relationships so as to assure functioning group dynamics. Leaders can build trust and support project groups by their openness and encouraging interaction and to developing communication skills. Moreover, supporting the sharing of tacit knowledge requires improving of leaders' skills, too. This means social and communication competencies for creating trustful working atmosphere and open culture. In daily practices, leaders should also communicate informally. They could show trustworthiness by small daily deeds through competence, fairness and credibility, among others.

Summary and managerial implications of the cases

Findings from the case studies show that trust in the organization and inter-personal relationships is important in utilizing intangible human resources, competences and professional expertise in an effective way. One of the interesting findings is that the functioning management system strengthens trust between organizational units (Malkamäki, 2010) and builds trust between actors. It is about transparency in leadership with regular sharing of information. Shared goals, clear allocation of responsibilities, as well as defined policies and procedures form the basis for informative, productive and predictable co-operation. Transparency in leadership is seen one of the most important pillars of trust building and occurs through the information management system and on the appropriate degree of control.

In tacit knowledge sharing the findings show that trust plays a main role in the group dynamics and functioning relationships between individuals in a project group (Savolainen, 2008, 2009). Moreover, trustful workplace climate characterized by open communication is the most critical factor affecting the sharing of tacit knowledge. Tacit knowledge in project groups is based on the individual's professional experience and knowledge base. As it is complicated to transform into explicit and share, the functioning relationships between group members are extremely important.

The case study findings imply for leaders that a transparent management system is important for trust, leadership and developing intellectual capital in which knowledge sharing plays an important role. Further, essential for leadership by trust is to enable, develop, and maintain work environments that nurture innovativeness. In other words, open culture and trustful climate support functioning relationships between actors and strengthen trust. This way social environment develop where innovativeness may grow and become prosperous. The practical implication for group leaders is how important it is to develop communication skills and functioning group relationships. In daily leadership work,

it is the small deeds that make a difference in leading with trust - not the great promises! Finally, concluding by Hamel (2007, 97) ”if the organization wants members to trust each other in all issues at the workplace nothing should be kept secret.”

LEADERS`S UNTRUSTWORTHY BEHAVIOUR DECREASES INNOVATIVENESS OF FOLLOWERS: WHAT KIND OF LEADERSHIP ORGANIZATIONS NEED TO ASSURE THEIR INNOVATIVE DEVELOPMENT?

M.Sc., Doctoral student, Sari Häkkinen, University of Eastern Finland, Finland
sari.hakkinen@uef.fi

ABSTRACT

This paper examines trustworthiness in leadership behavior as an inspirer of innovativeness. In managerial leadership, ensuring functioning new innovations is one of the major challenges in more and more complex organizations and competitive environment. While new innovations for all different kind of business fields from industry specific few to the education and consulting companies are found to be obligatory for organizations to catch on, is intra-organizational trust and leader`s trustworthy behavior as obligatory for succeed management, more specially managerial leadership. This research has been made by using qualitative methods.

Keywords: Trust, trustworthiness, managerial leadership, effects of trust, distrust, innovativeness, qualitative method, triangulation

INTRODUCTION

Trust forms a foundation for co-operation and is part of a social moral order in organizations and society (Rousseau et. al., 1998). Trustworthiness seems to be 'earned by daily deeds' and ways of actions of leaders (Häkkinen et.al.,2010). Trust has been shown to have influences on processes such as communication, cooperation, and information sharing (Burke et.al., 2007). Innovativeness is usually mentioned as an organizational behaviour. In this paper, innovativeness is discussed at individual level, which might be destroyed or harmfulled by leader`s distrustfully behaviour in leader-follower relationship in organizations. Distrust as a construct have been theorized as unidimensional or different construct from trust, and defined as low trusting or negative expectations of the other party and with a lack of confidence in the other, and belief that the other may not care about the other's welfare and may act harmfully (Lewicki et.al.,1998). Although trust has been widely studied in inter-organizational relationships recently (Ebert, 2009), the intra-organizational trust perspective is more scarcely studied despite the fact that it affects also the functioning and dynamics of inter-organizational relationships (Savolainen, 2010). How are these two perspectives interrelated? Recent research has called for research on trust at both the macro and micro levels (Schoorman et al. 2007). In this paper, at macro level trust is represent between organizations and at micro level trust (which is main topic in this paper) is represent between leader and follower. More specifically micro level trust is shown as a *trustworthy behavior*. Trust is a complex, multifaceted phenomenon, and different conceptualizations of the nature of trust exist in interpersonal relations (Möllering et.al.,2004).

Leaders show trustworthiness by building and sustaining or violating trust (Häkkinen et.al., 2010). The effects of leader trustworthiness are presented and discussed based on two real

life cases from small industrial companies. Both companies represented different kind of leadership styles; other might be describes democratic and the other authoritarian. In conclusion, the findings confirm the results in prior trust research that leader's competence (ability) is one of the key dimensions of trustworthiness (Peterson,1998) as well as leadership style. Findings show that the process of trust development is complex appearing as more meandering in nature. Tillmar (2007) conceptualizes trust and distrust as the endpoints of a continuum. Research results indicate, that when distrust exists between leader and follower, the follower has no interest to create new or develop itself or its work neither than feel innovative. Trust might also imagine as a "house with many doors", when it is possible to open a new door and going forward ignoring the disappointments; moving on. I might hesitate how far human might go without breaking down and giving up to even try to trust anymore? Every door you open, that heavier it will be to open the second one.

The study also shows that leadership style makes difference to innovative atmosphere at the organization. The style of management-by-fear broke the opportunities for developing and keeping quality and innovative workforce (Savolainen & Häkkinen,2011). Distrusting employees do not work effectively and share their knowledge, and tacit knowledge in specific (Savolainen,2008), which is extremely harmful for innovativeness atmosphere in organizations.

Methodologically this qualitative research is implemented by using triangulation. Narrative analysis, interviews and observation methods are combined in the study. Qualitative research methods have challenged to trustworthy development and leadership influences for subordinates and organizations (Cho & Ringquist,2007).

THEORETICAL DISCUSSION

Trust, Distrust and Trustworthiness

Trust has been classified in business research as an intra-organizational trust and an extra-organizational trust. Trust in different organizational and business relationships has been examined widely and multidisciplinary over the last few years (Ebert, 2009). Inter- and intra-organizational trust has been seen as a basis for all relationships and business interactions. Rotter (1967) defines *interpersonal trust* as an expectancy by an individual or a group that the word or promise (verbal or written) of another individual or group can be relied upon.

The importance of trust in leadership within organizational contexts has been recognized in the literature. Trust has been shown to have influences on processes such as communication, cooperation, and information sharing (Burke et.al, 2007, cf. Shamir& Lapidot, 2003). Distrust as a construct have been theorized as unidimensional or different construct from trust, and defined as low trusting or negative expectations of the other party and with a lack of confidence in the other, and belief that the other may not care about the other's welfare and may act harmfully (Lewicki et.al, 2006, 1998). Trust has been seen as a one of the main element of productivity in organizations (Bijlsma & Koopman 2003). In continuous change occurring in organizations, trust plays an important role in improving work welfare and business success (Seretin 2005, Mishra 1996). Innovativeness and good work welfare are walking hand-by-hand. Commitment to work and organization, and mental

well-being are related affecting the success of the organization. In this trust plays also a role (Coyle-Shapiro et. al., 2002). Commitment of employees is shown in acceptance of company values, pursuing goal achievement, and pride of working in the organization and willingness to stay (Coyle-Shapiro et. al., 2002). Trust appears at many levels, organizational or managerial, and is manifested in interaction between employees and/or organization (Joseph & Winston 2005, Serva, Fuller & Mayer 2005). At the organizational level trust is described as faith in the engagements of the employer. Employees believe that the actions of organizations are performed for public interests eventually (Lee 2004, Gilbert & Tang 1998). The more engaged followers are their work, that better they share their knowledge and innovative ideas to company`s credit.

Mental insecurity may be often a reason for atmosphere- related problems in workplaces such as teasing, conflicts, disputes and arguing. All of them affect the level of trust. Mental well-being is largely sustained by emotional support (appreciation, respect, openness, feedback, etc). Correlation of commitment for work and organization is reflected in employees work motivation and satisfaction, i.e., work welfare (Häkkinen, 2007). Leaders support is expected and their actions are seen as the most influential. In co-creation, trust is a basic element of functioning relationships in organizations (Savolainen, 2008). Employees in organizations create *trustworthiness* by their actions and behavior. Trust building has been listed as one of the most essential tasks in managerial leadership (Graen & Uhl-Bien 1995, Yukl 2010). Trust building and maintaining is complex, however (Ikonen & Savolainen 2010, Nurmio & Turkki 2010). Leader traits and behavior including styles and skills matter in *trust building.* By implication leaders mundane behavior seems to play the main role, i.e., trust is built and maintained by leaders 'daily deeds' (Häkkinen & Savolainen, 2010, Savolainen, 2009). Theoretically, various leader traits and leadership styles are related to trustworthiness shown in practice by the leader's behavior in dyadic subordinate-leader relationship. In conclusion, trustworthiness matters in emergent leadership (cf. Yukl,2010).

Managerial leadership and innovativeness

Theoretically, various leader traits and leadership styles are related to trustworthiness shown in practice by the leader's behavior in dyadic subordinate-leader relationship. In conclusion, trustworthiness matters in emergent leadership (cf. Yukl,2010). Leadership, management and managerial leadership, couching leadership etc., are often mixed metaphors. Northouse (2004) descriptive leadership as to explain how leaders help organizations to reach their purposes through concern for production (which is generally named as a *management)* and concern for people *(leadership*). Additional confusion for the term *leadership* is caused by the use of other imprecise terms as power, authority, management, administration, control and supervision to describe similar phenomena (cf. Yukl, 2010). Leadership includes following concepts: other term is management, reference to the past and future, dealing with change and managing stability, symbol of responsible and power, and also process of influence. Managerial leadership retains both terms: management and leadership, which means that processes and people will be lead at the same time. (Avery, 2004)

Innovative leadership or leading innovativeness retains those dimensions of leadership and for that reason, could be understood as a managerial leadership point of view. In the

development of trust and distrust in the organization, organizational culture is depicted as 'the other side of the coin of leadership' and is largely influenced by leaders' actions (Schein, 2004). In the case of very authoritarian management style, for example, employees become socialized into and adopt the way of actions of their leaders. As an indication of trustworthiness, trustful atmosphere, spontaneous sociality emerges between organization members (Fairholm & Fairholm, 1999). In the opposite case, distrustful atmosphere prevails which hinders communication and interaction (Savolainen & Häkkinen, 2010). Poor leadership underestimates employees' competences, which destroys innovativeness.

RESEARCH METHODOLOGY AND DATA

Methods of analysis

This paper adopts an explorative, qualitative approach to the study of trustworthiness within leadership. In the study, interviews, observation and narrative methods are used. The data were collected by means of thematic face-to-face interviews, open-ended interviews and observations. A few team leader-follower dyads in two organizations have been interviewed and observed. Methodologically, and from the philosophy of science perspective, this qualitative study is based on the constructionist paradigm and multi-source data. Narrative analysis, method of narrative accounts as well as interviews and observations will be combined in the study. Qualitative research methods have challenged the studying of trustworthy development and leadership influence on subordinates and organizations (Cho & Ringquist 2007). This paper answers the challenge by qualitative and longitudinal type of study using several data gathering methods.

Description of case company

Both companies are SMS companies and well recognized on their own business field and economically bandwagon. New innovations and product development were obligatory to the lean manufacturer.

- Company A, the first case (thesis) company, manufacturing and sale of valves and pumps, operating in worldwide.
- Company B, the second company, vegetable food supplier which main customers include mostly professionals in food, restaurant and catering companies in Finland.

Company A- The leadership style was pretty authentic and organization composition very hierarchy. Middle managers had responsibility, but it was somewhat apparent; GM made all decisions after all and his behavior was not steady handed nor neutral or equitable toward employees. Open dialogue between managers and subordinates was not potential. Also fear and qualm for GM`s attitude existed among the people. Co-creation between employees through the organization was insignificant.

Company B- The leadership style was democratic and participative management. Atmosphere in the organization was communicative and open to debate. Flexible job descriptions provided for diverse work and limitation of liability as well as authority. Co-creation between employees and managers was trivial and matter of course.

Main findings

The study shows that the factors most influential to the trust between leader and follower are: First leader: 1) equal behavior toward all employees and avoid divide or separate them for groups. Also avoid create too close relationship between any subordinates. 2) Showing and being trustworthiness when behaving stabile all the time, standing behind the values and leading democratic. 3) encourage followers to share their knowledge by asking their opinions and respecting their points of view. Second follower: 1) Avoid group together modeling cliques or clans inside the work community. 2) Distinguish work from leisure when adopting attitude for co-workers and leaders; understand the relevant behavior at work. 3) Share their knowledge to all co-workers and let information flow for tacit knowledge.

Furthermore, the study suggests that the most important phases influencing the strengthening of trust are reciprocity between an employer and an employee, competence of both parties and increasing of responsibility. On the contrary, at the organizational level, trust is not necessarily mutual and reciprocal (Schoorman et al. 2007). In other words, leader trustworthy behavior and untrustworthy behavior has effects on the organizational level trust. (Savolainen & Häkkinen, 2010)

CONCLUSIONS

In conclusion, the trustworthy behavior by subordinates might implement work related behavior and high commitment for company and work. Conclusively it can be stated that perceptions of the dyadic leader-subordinate trust about each other's ability, integrity and benevolence has effect on the extent to which an organization can be trusted (Schoorman et al. 2007). Thus, it seems that organizational and inter-personal trust are inter-related. Based on the research results, it seems evident that trust cannot be build without continuous interaction with leaders and followers, which has reciprocal effect on the interpersonal and organizational level trust, which is obligatory for people`s commitment and free will to create new and share their knowledge for benefiting organization. Overall, the study increases understanding of trustworthiness in leader behavior, leadership style and the consequences of trustworthy and untrustworthy behavior at both interpersonal and organizational levels.

The two leaders make an illustrative case for untrustworthy and trustworthy leadership reflected in different kinds of leadership features and behaviors. Most importantly, the differences in the cases show the favorable and unfavorable effects of trust in showing trustworthiness; in the first case trustful climate with enthusiasm, high commitment and effective communication and knowledge sharing prevail. In the second case, distrustful atmosphere, fear, low commitment, and lack of collaboration activity, and knowledge sharing appear respectively. As to leader behavior, in the case of authoritarian management style, employees become socialized into and adopt the very way of actions of their leader. Culture develops with unwritten daily manners by the influence of the leader. Lack of respect and appreciation stimulates development of distrust (Fairholm & Fairholm, 1999). The study implies that managers should learn more of trust and develop behavioral skills for showing trustworthiness. This way they may become more conscious of the role and consequences of trust and distrust in their actions of leadership. The style of management-

by-fear broke the opportunities for developing and keeping quality workforce (Peterson, 1998). Distrusting employees do not work effectively and share their knowledge, and tacit knowledge in specific (Savolainen, 2008; Juuti, 1999).

ABSTRACT

In recent years there has been a growing interest amongst both academics and business regarding business practices in Asia. There is a tendency that organisations are seeking to adopt relationship marketing with the expectation that it will help them retain customers and in so doing, deliver long-term and value-added customers. Relationship marketing aims to attract, develop, and maintain relationship with customers. Although many researchers point out that it should be considered to have long-term relationship with customers, companies have recognised the importance of relationship termination for saving budget and time in order to reduce the operation cost. Previous studies have indicated that when necessary, service suppliers should terminate relationships because not all customers are willing to engage in long-term and profitable relationships with banks. Senior bank staffs, from seventeen Taiwanese banks, were interviewed about their understanding and use of relationship marketing and their relationship termination strategies The aim of this research is intended to extend the understanding of the termination phase of relationship marketing within the consumer banking sector, especially with those relationships are not required on a continuous basis or one they have served their function. This research discovered that banks took more time to establish and enhance customer relationships, however, and at the same time they spend even more time in dissolving dysfunctional customer relationships. Banks also changes their service forms to reduce their operation costs. Moreover, banks may decide not completely terminated customer relationships but possibly continued to maintain guanxi with former customers.

Keywords: Relationship Marketing, Relationship Termination, Customer Relationship Management, Consumer Banking Sector, Banks.

INTRODUCTION

The concept of relationship marketing was first introduced to service marketing in the 1980s by Berry (1983). Since that, building long-term relationships with customers has created lots of interest among academics and practitioners, also in Asian (Leung *et al*., 2005; Adamson *et al*., 2003; Lee *et al*., 2001; Davies *et al*., 1995). Organisations have adopted this concept with the expectation that it will help them to improve profitability. However, relationship marketing might have not only been accused of being over-conceptualised and underdeveloped empirically but its appropriateness to all customers has been questioned (Colgate and Stewart, 1998; Fournier *et al*., 1998; Barnes, 2001). According business press reports, unprofitable customers account for up to 50% of some banks' customers (see for example, Ang and Taylor, 2005; Blömeke *et al*., 2010). In other words, many companies have faced the problem of having these unprofitable customers, so called of "the bottom of the customer pyramid" (Zeithaml *et al*., 2001), are often inactive in terms of buying behaviour and therefore generate very low profits, or are even unprofitable, since the cost of serving them in about equal to or even exceed their revenues (Shapiro *et al*., 1987). The segment at th bottom of the pyramid is often relatively large in number of customers, but generates very little or no profit due to inactive purchasing behaviours (Blömeke *et al*., 2010). The internal banking survey from the Chartered Institute of Banking by 1999 reveals that 56% of senior bankers are looking at methods of getting rid of unprofitable customers. The purpose of this paper is intended to extend the understanding of the relationship termination phase in the consumer banking sector, especial with these relationships are not required on a continuous basis or one they have served their function.

LITERATURE REVIEW

Relationship Marketing

Every marketplace exchange transaction involves a relationship. Some transactions are never repeated, so a relationship between a buyer and a seller could be momentary (Reddy and Czepiel, 1999). However, relationship marketing should be concerned with the nature of long-term relationship between business and customer which takes into account customer needs and values. Interest in the nature of relationship marketing has increased in B2B marketing as well as B2C marketing literature over the last three decades. Relationship marketing, according to Berry (1983), means attracting, maintaining and strengthening the relationship a company has with a customer in order to retain that customer. This definition became the foundation upon which most subsequent definitions built. For example, Christopher *et al.* (1991) define the function of relationship marketing as 'getting and

keeping customers'. Morgan and Hunt (1994) add the importance of trust, cooperation and shared values in order to maintain a successful relationship. Grönroos (2000, pg.39) defines relationship marketing as "*to identify and establish, maintain and enhance, and when necessary terminate relationships with customers (and other parties) so that the objectives regarding economic and other variables of all parties are met. This is achieved through a mutual exchange and fulfilment of promises*".

Moreover, it has been argued that the establishment and maintenance of any relationship will face the possibility of termination. For example, because of the cost involved, a company should not build a relationship with all of its customers. In fact, a few early academic papers have drawn attention to how considerable resources have sometimes been freed up and put to better use by dissolving unprofitable relationship (see for example, Storbacka *et al*., 1994; Blois, 1996). With this in mind, Moriarty *et al*. (1983) suggest the concept of relationship banking is based upon an acceptance that the bank can increase its earning by maximising the profitability of the total number of customer relationships over time, instead of seeking to acquire the most profit from any single product or transaction. In other words, the objective of relationship marketing is to create results in the long run through enduring and profitable relationships with customer; however, such relationships are usually, but not necessarily always long-term.

Relationship Termination

Relationship research has, however, indicated that termination may occur in any of the phases of a relationship's development (Halinen, 1997). It has become clear that dissatisfied customers may also exit the relationship (Ganesh *et al*., 2000; Halinen and Tähtinen, 2002). Thus, research indicates that insight into the nurturing of closer relationships does not guarantee the understanding of the termination process (Keaveney, 1995). Halinen and Tähtinen (2002, pg.166) characterise the relationship termination as a process where these links, ties and bonds are broken, disconnecting the former parties from each other. Hence, it is particularly important for the bank because the termination is likely to influence other connected customers and relationships and create changes in the relationship network (Anderson *et al.*, 1994; Halinen and Tähtinen, 1999).

In this paper, this study reviews and assesses previous studies concerning the ending of exchange relationships. According to Halinen and Tähtinen, (2002), relationship termination could be interpreted as a process where links, ties, and bonds (e.g. exchange of objects, personal relationships, contracts, bonds of trust and commitment) are disconnected. Although some authors may use different terms such as 'relationship break-up',

'disengagement', 'withdrawal', 'ending' or 'dissolution' (Tähtinen, 2001; Havila and Wilkinson, 2002) to explain the relationship termination, all these terms present the same meaning of termination which is understood as a situation where '*at least one partner no longer views the relationship as continuing or the interdependency has otherwise critically decreased*' (Tähtinen, 2001, pg.46).

Relationship Termination in Banking Sector

Not all customers want to engage in relationships and, in fact, it has been suggested that close customer relationships in banking are rare, and that relationships are being further weakened by the increases in self-service technologies (O'Loughlin *et al.*, 2004). The type of the relationship may also have important effects on its termination. For example, banks may promote one financial product or service with a particular purpose and/or time period, which then gives the client a natural break-out point straight after the project, has been accomplished. These services are not required on a continuous basis or once they have served their function (see for example, Dwyer *et al*., 1987; Hocutt, 1998). However, although the formal communication between the entities involved may no longer continue, personal bonds may be maintained between individuals from both companies (Havila, 1996; Tähtinen and Halinen-Kaila, 1997). For example, a bank may keep the former customer's name in its reference list if the ex-customer agrees to this arrangement (Tähtinen and Halinen-Kaila, 2000). Alajoutisjarvi *et al.* (2000) proposed this action as "beautiful exits" avoiding the future, potentially damaging effect when dissolving a relationship.

Termination is seen as a managerial activity as part of relationship management (see for example, Reinartz *et al*., 2004). Grönroos (1994) agrees that the objective of relationship marketing is to create results in the long run through enduring and profitable relationships with customers; however, such relationships are usually, but not necessarily always long-term. Therefore, applying this definition provides a good starting point for understanding business relationship terminations in general. However, relationship termination here does not mean that firms terminate all unprofitable relationship regardless of their potentials for development. It is merely accepting termination as one option in managing its relationships.

DATA COLLECTION AND ANALYSIS

Data collection took place between August 2007 and April 2008. Within Taiwan there are 41 consumer banks (Financial Supervisory Commission, 2006). All 41 banks were contacted by phone and email and asked to participate in the research. 17 banks agreed to take part and 34 in-depth interviews were conducted. All managers interviewed claimed to have

knowledge of their relationship marketing and relationship termination strategy, and typically occupied posts such as Marketing Manager or Vice President Personal Banking Division. An interview guide was used during the interviews which included questions asking what the interviewee understood by the term 'relationship termination', what circumstances bank will terminate to determine dissolution the relationship with customers? All interviews were taped, transcribed and analysed using thematic coding.

FINDINGS

Not Actively Terminating the Customer Relationships

Although Taiwanese banks are willing to terminate the relationship with unprofitable customers, all respondents from this study strongly indicated that they were not allowed to apply such a decision. Perhaps, bank employees still have certain constraints preventing them from exercising their initiative to terminate unprofitable relationships. This study classified all the descriptions into two possible reasons. First, The Taiwanese government policy limits the equity of the relationship termination in which the termination only occurs in certain conditions e.g. dormant accounts (i.e., no account activity for at least a year) or a bad debt (e.g. an uncollectible account or irrecoverable loans or credits). In other words, except for customers that have been proven to have committed illegal economic activities or bad debt (e.g. an uncollectible account or irrecoverable loans or credits), banks could not terminate the relationship with their customers actively. For example,

> "*We won't terminate the relationship actively because we are a service industry…our law or policy does not allow it to happen either*".

Second, considering the reputation and integrity, so the bank would not take steps to terminate the relationship. For example, one interviewee claimed,

> "*Banks should consider customers' feelings, so it is not appropriate for banks to terminate the relationship without common agreement*".

Therefore, banks particularly concerned about negative word-of-mouth advertising as a result of terminating relationships with unprofitable customers, so they will not actively terminate the customer relationships.

Maintaining Relationships and Changing Service Forms

The majority of respondents described their willingness to dissolve unprofitable customer relationships, but knew that this was not permissible. Thus, banks manage the discrepancies by putting these 'problem' customers on the touch-tone (e.g. ATM, Internet banking) or voice-mail support (e.g. telephone banking, call centres) to reduce the time and costs associated in engaging with such customers.

But do all customers be willingness to accept using technology? Not necessarily, as some customers, particularly elders still prefer face-to-face contact with banks. For example, one interview described that,

> "*72% of bank consumers, particularly older people...enjoy the social interaction of visiting a local bank branch, especially if they know the staff members who serve them and don't trust machines*".

Bank managers also believed that more time may be required to encourage customers to accept these kinds of self-service options.

***Guanxi* and Relationship Termination Decision**

Considering highly competitive consumer banking marketplace, especially, where competition is as high as it has ever been, where the customer base is saturated with offers from every other bank. Bank mangers strongly asserted that if it was possible, they were more likely to maintain *guanxi* (personal relationship) with former customers. This study also finds that sometimes a financial advisor or account manager may transfer to another bank, where a few of his/her customers may follow of *guanxi*:

> "*Customer relies on the trust of their financial advisor they know, rather than the bank. Every service staff member has his own Guanxi network which might contribute to us, but if he leaves, he may take the Guanxi with him and the bank loses business*"

G*uanxi* is an important cultural and social element in Chinese society. This Chinese term first appeared in the West in the 1980s to offer advice about cultural factors impacting on business relationships in China (Alston, 1989; Fan, 2002). The finding confirms and demonstrates this cultural influence on business operations in Taiwanese consumer banking sector. Banks may decide not completely terminated customer relationships but possibly continued to maintain *guanxi* with former customers, especially when some *guanxi*

relationships are too complicated to be ended abruptly. Interestingly, this result differ to those of Morgan and Hunt (1994), who argue that relationship marketing typically impersonal and mostly occurs at the organisational level. In other words, *guanxi* works at personal level and further extends to business performance.

DISCUSSION

This research discovers an interesting result that Taiwanese banks declined to terminate relationship although not all customer relationships are profitable and willing to engage in long-term. Different than Western studies (see for example, Grönroos, 2000; O'Loughlin *et al*., 2004; Helm *et al*., 2006), Taiwanese banks consider relationship termination with customers might have influence on their reputation, so banks would still hold the relationships but encourage these less profitable customers to use self-control services (i.e. ATM) in order to save cost and time. In addition, it is clear that it is necessary to consider the personal relationship (*guanxi)* as a feature of business performance in East.

Some authors (e.g. Grönroos, 2000; Tähtinen, 2001; Giller and Matear, 2001) indicate that ending the unprofitable relationship should be considered in order to reduce the operation costs and focus on the valued customers. However, this study suggests that although banks had recognised and agreed with this aspect, they are still more likely to continue these customer relationships. This strategy is different to western theories although many studies in relationship marketing illustrate the potential benefits in terminating these non-profitable or less profitable relationships. This type of research only shows part of the overall picture. Relationships with customers are complicated and dynamic, not static. This is particularly true of Chinese culture, where *guanxi* places lots emphasis on the continuity of the relationship. This study also extends the findings of the existing literature and provides some explanations as to why relationship termination is unlikely to occur within Taiwanese banks. Although business relationships might have been decreased, *guanxi* could still be remained.

ABSTRACT

This paper analyzes households' electricity market in Slovenia. While the number of suppliers in the households electricity market has increased and the initially increased market competition resulted in the process of switching of the consumers between the suppliers, the electricity price developments after the initial short-period of decline and stability has increased. This has raised the question whether the household's electricity consumers overpaid the electricity and whether electricity suppliers have to return for overcharged and overpaid households' electricity bills due to an oligopoly agreement on market supply division and electricity price settings. We find that consumption of electrical energy by households is positively associated with real income of households, which is expressed by real wages, but negatively associated, with real price of electrical energy for households at the higher tariff. It is also positively associated with real prices of substitutes for natural gas for households or for fuel oil as well as with a dummy variable for market liberalization of electrical energy market for households.

Key words: market liberalisation, households demand, electricity market, Slovenia

INTRODUCTION

Energy markets in Europe have been gradually liberalised with an aim to encourage competition and to increase market efficiency. We focus on electricity market liberalisation for households in Slovenia and its implications for households' electricity bills, electricity suppliers, and society. The gradual deregulation and liberalisation of the electricity markets in Slovenia has been completed since mid-2007. The initial deregulation in Slovenia has started in 2001 with the liberalisation of the electricity market for the largest industrial users of electrical energy. The deregulation has followed in the mid-2004 for the other electricity users, except for households, and in the mid-2007 also for the households' electricity users (Bojnec and Papler, 2006a, 2006b, 2010; Papler and Bojnec, 2006, 2007; Pollitt, 2007). The entry of new competitive suppliers and free trade, particularly possible import comptition, might contribute to the increased quality and price competition.

While the number of suppliers in the households electricity market has increased and the initially increased market competition resulted in the process of switching of the consumers

between the suppliers, the electricity price developments after the initial short-period of decline and stability has increased. This has raised the question whether the household's electricity consumers overpaid the electricity and whether electricity suppliers have to return for overcharged and overpaid households' electricity bills due to an oligopoly agreement on market supply division and electricity price settings. To test these hypotheses, we employ different empirical approaches. First, we present summary statistics on main households' electricity market developments in supply, demand, and real price developments. The market structure is measured by Lorenz curve and by Gini coefficient of market concentration. Second, we present issues of cartel agreement between suppliers and its implications due to overpaid electricity for consumers in the case of the typical standard consumer group during a controversial period of the overcharged electricity bills for households. On this basis we present welfare implications of the electricity market deregulation for a typical household in Slovenia on its electricity bill, implications for electricity suppliers, and for society. Third, we employ regression analysis (e.g. Kachigan, 1991; Norušis, 2002) to test the association between the household's electricity consumption and real price of electrical energy, real income and real prices of substitutes for electrical energy. In the estimation of the demand function for electricity consumption by households we estimate the sign of association and significance of the association of electrical energy consumption with direct price, income and cross-price elasticity. We find that consumption of electrical energy by households is positively associated with real income of households, which is expressed by real wages, but negatively associated, with real price of electrical energy for households at the higher tariff. It is also positively associated with real prices of substitutes for natural gas for households or for fuel oil as well as with a dummy variable for market liberalization of electrical energy market for households. Finally, we derive managerial implications for electricity suppliers, welfare implications for households' electricity consumers and society, and policy implications.

MARKET SHARES AT THE LOCAL ELECTRICITY MARKETS

Households are according to technical conditions for electricity use classified into three tariff groups I (connection power 3 kW), II (7 kW), and III (10 kW). In addition, the distribution enterprises have introduced the fourth package that is offered for above standard users with 23 kW of the installed connection power (Papler, 2008). The second group is the largest by the number of electricity users. In 2008, the average monthly consumption of electrical energy per households was 331.1 kWh. Moreover, households users of electrical energy by the size of annual electricity used are grouped into the five size groups: up to 1,000 kWh, from 2,501 to 5,000 kWh, from 5,001 to 10,000 kWh, from 10,001 to 15,000 kWh and above 15,000 kWh. The increases are for the largest users and decreases for the smaller users. The electricity consumption by households represents about one-third of the electricity consumption in Slovenia.

Since the electricity market liberalization, the new suppliers have entered into the markets. This has been reflected in the deterioration of the local regional supplier's market share, which have been taken by others non-local regional suppliers. Prior to the electricity market liberalization for households, they were dependent on the supply from one of the five regional distribution

enterprises in Slovenia. Electro Ljubljana had around one-third market share, Electro Maribor almost one-fourth, Electro Celje less than 18%, Electro Primorska around 14% and Electro Gorenjska a bit more than one-tenth market share. Since the market liberalization, into the electricity market for households has entered GEN-I and some other smaller suppliers, this has resulted in some changes in market shares, but they have not changed substantially (Ministry of Economy, 2009).

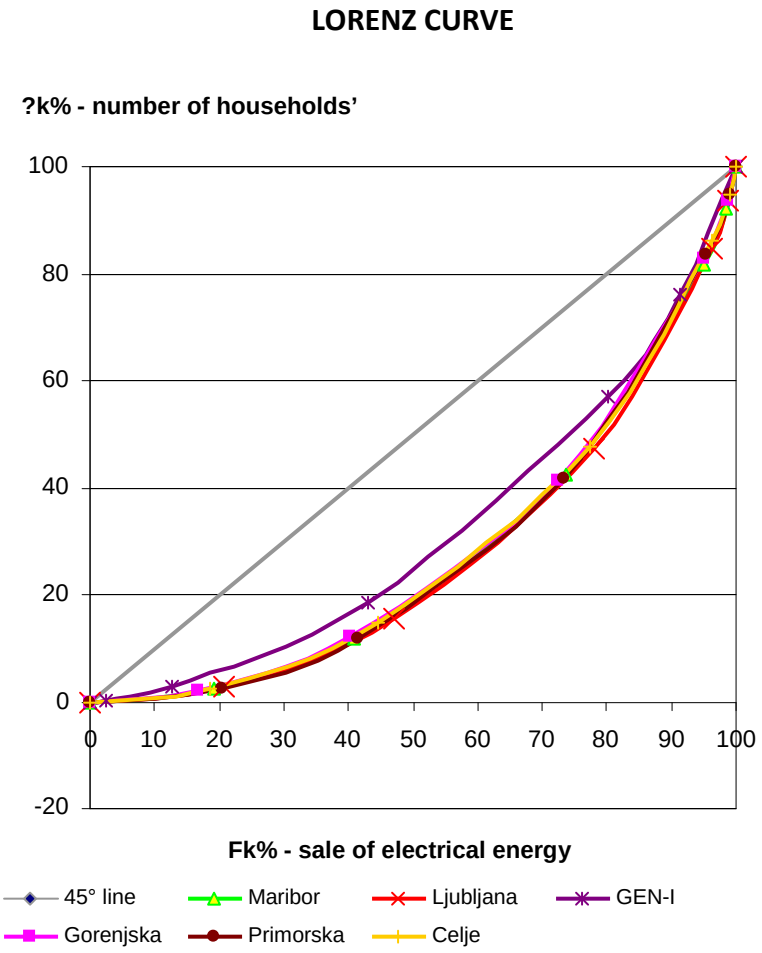

Figure 1: Lorenz curve for concentration of households users of electrical energy by suppliers in Slovenia, January – June 2009.

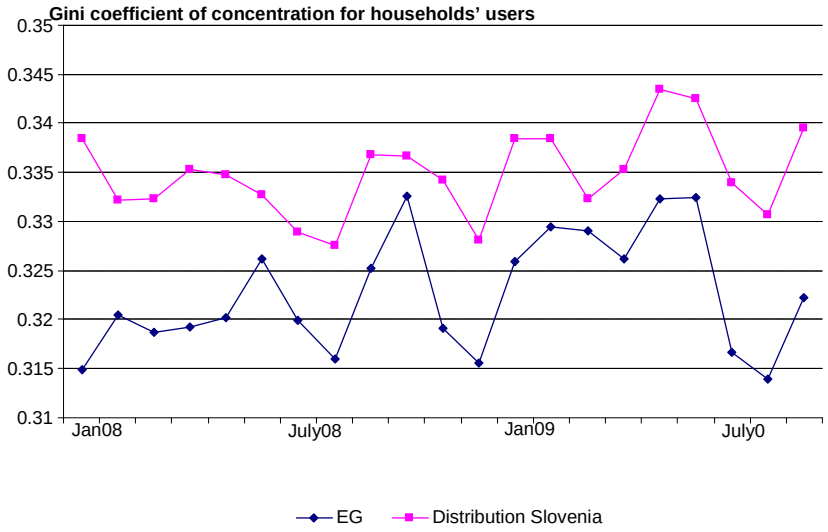
Among the most often used measures for presentation of distribution of appearance differences are Lorenz curve and Gini coefficient of concentration. We use these measures to present distribution of relative frequency in the sale of electrical energy. Figure 1 presents the relative frequency distribution in sale of electrical energy for households' users by the five electricity distribution enterprises and for the GEN-I. The concentration of Slovenian households' users is modest and rather stable over time. For example, for Electro Primorska and Electro Gorenjska around 40% of households' users spent around 72% of electricity or 83% of households' users spent 95% of electricity, which these to enterprises supplied to the

households' users. In the case of Electro Maribor is similar: 42% of households' users spent around 74% or 82% of households' users spent 95% of electricity, which is supplied to the households' users. Electro Celje and Electro Ljubljana sold to 48% of households' users 78% of electricity or 86% of households' users bought 96% of electrical energy, which these two enterprises sold to households' users. The new supplier GEN-I has more equal distribution of households' users.

GINI COEFFICIENT OF MARKET CONCENTRATION



EG – Electro Gorenjska.

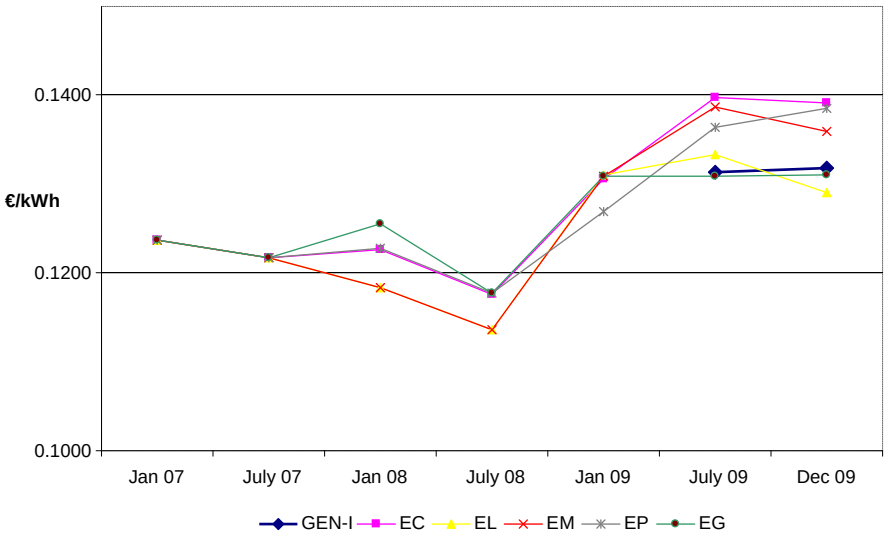
Figure 2: Gini coefficient of concentration of households' users for the EG and distribution enterprises in Slovenia, 2008–2009.

Figure 2 shows variations in the Gini coefficient of concentration of households' users by the electricity distribution enterprises and for the EG electricity supplier. This implies some changes in the suppliers market shares and market concentrations over time with the entry of the EG into the Slovenian households' electricity market.

PRICE DEVELOPMENTS

The retail price of electrical energy for households with the annual electricity consumption of 3,500 kWh (user group *Dc)* is the closest to the average Slovenian households by the electricity consumption. In March 2007 in Slovenia was introduced excise tax on electrical energy and prior to the electricity market liberalization for households in July 2007, the prices of electrical energy for households by the five distribution enterprises were uniform. However, since then there have started price differentiations with introduction of different packages and bonuses for households' consumers by the individual electricity suppliers, which is illustrated for the

average real price for the user group *Dc* for energy, for network grid, contributions, excise tax and value-added tax (Figure 3).



Note: EC – Electro Celje, EL – Electro Ljubljana, EM – Electro Maribor, EP – Electro Primorska and EG – Electro Gorenjska.

Figure 3: Real price of electrical energy for standard user group Dc for energy, network grid, contributions and taxes by different suppliers, 2007-2009.

OVERPAID ELECTRICITY BILLS BY HOUSEHOLDS IN THE CASE OF THE ELECTRO GORENJSKA

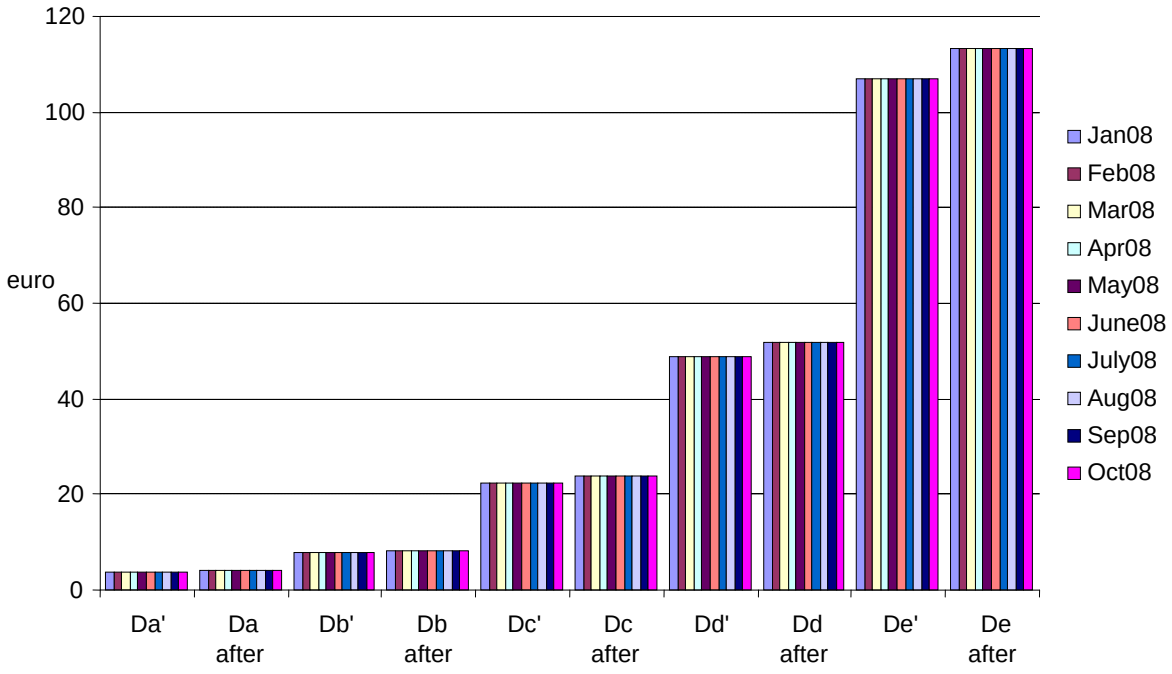
The subject of the return for the overpaid electricity bills by households in the case of the EG was the difference between the price of electrical energy from the start of price increase on 1st January 2008 up to the introduction of the new prices on 27th October 2008 jointly with the legal interest for delay from the date of an overdue invoice up to 30th September 2010. Due to a fact that the supplier did not disclosure evidence on the volume of electrical energy supply during this period, we calculate overpaid electricity bills by monthly amounts for typical standard households electricity consumers groups *Da, Db, Dc, Dd,* and *De*. According to the Eurostat (2011) standards, the standard households' electricity consumers groups consider the following criteria: *Da* – lights, radio and TV, fridge, small households' appearances (annual electricity consumption 600 kWh, power 3 kW; *Db* – as *Da*, but also washing or dish-washing machines (annual electricity consumption 1.200 kWh, power 3-4 kW); *Dc* – as Db, but also boiler (annual electricity consumption 3.500kWh, out of this 1.300 kWh during the night time; power 4-9 kW); *Dd* – as Dc (annual consumption 7.500 kWh, out of this 2.500 kWh during the night time, power 6-9 kW); *De* – as Dd, but also thermo accumulation electric stove (annual electricity consumption 20.000 kWh, out of this 15.000 kWh during the night time, power 9 kW). These characteristics of households' electricity consumption are considered in Table 1.

Table 1: Households' electricity consumption characteristics for standard consumption groups in Slovenia.

Symbol	Users group	Calculation power	Annual (monthly) consumption	Annual (monthly) consumption HT	Annual (monthly) consumption ST	Annual (monthly) consumption ET
		kW	kWh	kWh	kWh	kWh
Da	I degree – ET	3	600 (50)			600 (50)
Db	I degree – ET	3	1,200 (100)			1,200 (100)
Dc	II degree – 2T	7	3,500 (291.7)	2,200 (183)	1,300 (108)	
Dd	II degree – 2T	7	7,500 (625)	5,000 (417)	2,500 (208)	
De	III degree – 2T	10	20,000 (1,667)	5,000 (417)	15,000 (1,250)	

ET – one-tariff measuring, 2T – two-tariff measuring, HT – high tariff, and ST – small tariff.
Source: Ministry of Economy (2009).

The monthly bills for electrical energy consumption for standard consumer groups without value-added tax were the following: *Da* was 3.83 euro before the price increase, and 4.07 euro after cartel agreement; *Db* 7.66 euro and 8.14 euro; *Dc* 22.36 euro and 23.79 euro; *Dd* 48.83 euro and 51.96 euro; *De* 106.80 euro and 113.47 euro (Figure 4).



*After the cartel price increase
Figure 4: Monthly bill for households' electricity consumption for standard consumers groups prior and after the cartel price increase without value-added tax.

In January 2008, price of electrical energy in Slovenia increased on average by 6.0%. Between January and October 2008 the overpaid households' electricity bills by standard consumer groups without value-added tax were the following: *Da* 2.41 euro, *Db* 4.81 euro, *Dc* 14.12 euro, *Dd* 30.91 euro and *De* 65.57 euro (Table 2). The overpaid electricity bills in total households' monthly bills for electricity amount between 57.8% for De and 59.5% for Dd. The standard group Dc, which is the closest to the Slovenian household average, experienced the overpaid bills of 59.4% of monthly costs. The standard groups with the smallest electricity consumption Da and Db experienced the overpaid bills of 59.1% of monthly costs.

With the value-add tax, the overpaid households' electricity bills by standard consumer groups were the following: *Da* 2.89 euro, *Db* 5.78 euro, *Dc* 16.94 euro, *Dd* 37.09 euro and *De* 78.68 euro (Table 3 and Figure 5).

REGRESSION ANALYSIS FOR CONSUMPTION FUNCTION OF HOUSEHOLDS' ELECTRICAL ENERGY CONSUMPTION

The quantity of consumption of electrical energy by households (D_h) is explained by real households' income or net wage (Wage) or real households' expenditures for electricity, gas and water (E_h) and real price of electrical energy for households at the higher tariff rate (P_{h_HT}). Table 4 in the case of the EG indicates that the electricity consumption by households is positively associated with the real households' income variables and negatively associated with the real electricity prices.

Table 4: Consumption function of electrical energy in households on the higher tariff rate.

	ln(constant)	$\ln(H_h)$	ln(Wage)	$\ln(P_{h_HT})$	$AdjR^2$	F
$\ln(D_h)$	-3.764	0.288		-1.215	0.995	1,125.0
	(-8.713)	(2.659)		(24.97)		
$\ln(D_h)$	3.119		0.299	-1.219	0.996	1,155.4
	(-16.568)		(2.739)	(-25.008)		

ln – natural logarithm. t-statistic in the brackets.

Moreover, we estimate consumption function of electrical energy by households for the EG, which is additionally explained with real prices of substitutes and the changing market share variable and the Gini coefficient of concentration of households' users. Table 5 confirms that household's electricity consumption for the standard price group is negatively associated with the real electricity price, but positively associated with the real price of substitute, real wage and the Gini coefficient of concentration, but the regression coefficients, which are pertained to the latter three variables, are not significant.

Table 5: Consumption function of electrical energy in households for the standard price group.

	ln(constant)	ln(Psga)	ln(Psgb)	ln(Poil)	ln(Wage)	ln(Gini)	AdjR^2	F
ln(D_h)	16.978		-0.556	0.042	0.167	0.081	0.233	2.5
	(6.802)		(-2.422)	(1.106)	(0.499)	(0.211)		
ln(D_h)	16.610	-0.548		0.041	0.163	0.082	0.229	2.5
	(6.765)	(-2.401)		(1.086)	(0.486)	(0.214)		

ln – natural logarithm. t-statistic in the brackets.
Note: *Psg* – real price of electricity for standard households' group *a* and *b* and Poil – real price of fuel oil.

CONCLUSION

The electricity markets in Slovenia have been liberalized to become more competitive in the future. Electricity markets for households are still highly concentrated. The real incomes have played important role in demands by households, but significant role has played the price of electrical energy for households. The households are sensitive on the suppliers' price developments, which has so far encouraged a successful entry into the households' electricity market and an increase of the market share of the new GEN-I supplier with a favorable price and quality of supply.

The issues of cartel agreement between suppliers and its implications due to overpaid electricity for consumers in the case of the typical standard consumer group during a controversial period of the overcharged electricity bills for households are analysed. The overpaid electricity bills by households increased their costs of living, but with the return of the overpaid electricity bills they can potentially gains not only with this temporary return, but also with a greater transparency of electricity price formation in future, which is important for households and society welfare implications from the electricity market deregulation. At the same time this is also a clear signal for the electricity market participants, namely electricity suppliers and households consumers as well as institutions responsible for implementation of transparency of market competition that formal market liberalisation is not enough that free market forces can start to work in a perfect way as there might be persistence of formal and informal institutions and networks, which might reverse potential households and social welfare gains from electricity market deregulation and price liberalisation.

ELEMENTS OF SPACE STYLE AND MUSIC STYLE ON THE HIGH AESTHETIC, EMOTIONAL, EXPERIENCE QUALITY AND EXPERIENCE SATISFACTION STUDY

Dr. Kao, Yie-Fang, Fu-Jen Catholic University, Taiwan
012766@mail.fju.edu.tw

Chiu, Chuan-kung, Fu-Jen Catholic University, Taiwan
chuankung@gmail.com

ABSTRACT

The democratization of style and taste, and common people, from a variety of print media continue to discuss the economic and life style issues related to aesthetics, the subtle feelings and emotions triggered by the aesthetic elements and experience show that the elements of future trends. In the past, foreign and domestic are popular types of jazz music, the rapid development in recent years, stunning, particularly in the LIVE BAND PUB ubiquitous today. This study documented the elements of space music elements, high-end aesthetic elements, emotional elements and experience quality literature presented from the customer's point of view to find space for style and aesthetics of music style for the consumer perception, emotion, and experience the quality of relevance. Hope that by understanding customer perceptions of the actual store experience, to store the continuing or improving future business direction.

The samples were selected merchants for the Blue Note and Riverside Blue's mansion shop 2 live jazz restaurant, paid a total of 450 questionnaires.

Through this research are known: Jazz aesthetic elements and space elements are on the experience of satisfaction has an indirect positive impact of business improvement can be used as a reference. The level of spatial information is causing a sense of musical elements of their experience with the correlation of the reasons for the change, a sense of spatial information to increase customer associate degree this space music. High aesthetic elements and experience the satisfaction of this study is proportional to the new argument, so how to make customers feel that the very existence of the store is believed to be the new challenges of the future services.

Keywords: High aesthetic elements, Aesthetic elements of space, Jazz, Experience quality

INTRODUCTION

Study Background

In recent years, Taiwan society has showed some changes; for example, the public all fancy cute stuffs, nightclubs are almost everywhere, and people all love Wang. Regardless of price, style has become the mainstream and charisma prevails (Liu Wei-gong, Associate Professor; Social Science Department of Soochow University). The democratization of style and taste promoted by a variety of media through persistent discussion over the economic and life style issues has triggered subtle feelings and emotions, which reveal the future trend of aesthetic and experience elements.

With the rise of experiential society, "charisma competitive advantage" has gained more and more attentions. Unlike previous competition models which compete with volume, price, working hour, salary, and capital, today's competition is more about taste, style, content, texture, and unique characteristic.

Taiwanese enterprises often wonder why other competitors' products have gains more attentions from consumers while their product functions are no worse than those of competitors' products. Taiwanese enterprises normally have to use promotion to see effect. Why Taiwan's products cannot easily grab market attention during new product launches just like those of Apple, Lexus, and Starbucks and other brands? We attribute this result to Taiwan enterprises' ignorance towards charisma competitive advantages, which has led to Taiwan's current inferior status in today's experiential society.

Jazz, which used to belong to alien and non-mainstream music in Taiwan, has shown stunning development in recent years with significant record sales growth and growing fans as more foreign jazz musicians perform in Taiwan. Nowadays, live band pubs are everywhere, providing more chance for nationals to experience jazz in person.
To experience economic time's beauty is not the exclusive privilege of aesthetics. Communication through senses towards people, location, and object's outlooks instead of words will arouse the reflective communication art.

Beauty should be presented naturally instead of being said; beauty can automatically make people feel joyful without directing; the effect of beauty is immediate, visual and emotional. Although we may analyze the effect of beauty afterwards but the effect shouldn't be learnt through recognition.

Study Objectives

This study has sorted out relevant documents regarding elements of space, music, high-end aesthetic, emotional, and quality of experience and brought the following study objectives.

1) Based on customer's perspective, we find the relevance between the space style and music style in jazz live-band pubs (atmosphere) and consumer' aesthetic perception, emotion and quality of experience.
2) Understand customer's satisfaction level towards all sorts of experiences in Jazz live-band pubs (aesthetics, emotion, quality of experience)
3) Hope to give stores future direction of sustainability and improvement through understanding customers' perception of experience in Jazz live-band pubs.

EMPIRICAL CONCLUSION AND MANAGERIAL IMPLICATIONS

1) The relationship between the aesthetic elements of space (transparency and information sense) and high-end aesthetics
Transparency and information sense all positively contribute to high-end aesthetics. Information sense has bigger impact than transparency sense.
We suggest stores with live performance to smartly utilize interior design to increase transparency and visibility and cleverly design a theme to offset the crowded sense caused by the limited space in current modern unban society and to increase customers' appraisal towards such stores.

2) The relationship between Jazz music elements (improvisation, innovation, and localization) and high-end aesthetics.
Improvisation and localization have positive impact on high-end aesthetics while innovation doesn't have. Among the variables, localization has a bigger impact than improvisation.
We suggest stores with jazz performance can incorporate local elements into their music styles. For instance, it will help enhance store's quality by adopting domestic pop music. The most important element of jazz music is improvisation, but we believe more local elements will help show the store' irreplaceable uniqueness.

3) The relationship between space aesthetic elements (transparency sense and information sense) and emotion. Information sense has positive impact on emotion while transparency doesn't. We suggest night clubs with rock music performance should adopt interior design of Brooklyn graffiti or hang photos of rock stars such as the Beatles to resonate with customers. The most important thing for store with live performance is to arouse audience's emotions to make them feel high and relaxing, therefore it will not help the atmosphere on the spot without a matching interior design style and theme.

4) The relationship between Jazz music elements (improvisation, innovation, and localization) and emotion
Improvisation and localization have positive impact on emotion while innovation does not. Meanwhile, improvisation has a bigger impact than localization.
We suggest stores with Jazz music performance to increase special sessions of improvisation because Jazz music is so charming, relaxing, and renowned for its element of improvisation. Audiences always applauded performers' improvisation on spot with vibrant but relaxing emotions.

We also suggest Jazz music performers add some local elements; for example, they can link music with the life stores of local performers, which will help echo with audience' emotion.

5) The relationship between Aesthetic elements of space (transparency sense and information sense) and the quality of experience'

Information sense has a positive impact on quality of experience while transparency sense does not. We suggest stores design with layout that matches the store's theme. If customers are surprised and feel a sense of suspension, the information sense of the store's space is matching with its style, which will increase customers' learning inclination and participation.

6) The relationship between Jazz music elements (improvisation, innovation, and localization) and the quality of experience'

Improvisation, innovation and localization have positive impact on quality of experience with variable intensity: innovation> Improvisation> localization.

We suggest store with jazz music performance have certain degree of requirement for performance innovation because the higher innovation degree in Jazz music will easily arouse audience's surprise and learning along with their participation and immersion. Improvisation is one kind of innovation to Jazz music; hence it also has an impact on quality of experience.

7) The relationship between high-end aesthetics, emotion, experience, and experience satisfaction.

High-end aesthetic, emotion, and quality of experience have positive impact on experience satisfaction with the variables intensity as: emotion> quality of experience > high-end aesthetic.

We suggest restaurants with jazz music performance emphasize on high-end r aesthetic, emotion, and all sorts of quality of experience, among which emotion has the highest impact on experience satisfaction because as customers' satisfaction won't reach certain level without pleasant consumption. Therefore, the most important thing is to make customers feel it's worthy of spending.

8) The relationship between space aesthetic element and Jazz music element of different music styles and high-end aesthetic, emotion, quality of experience, and experience of satisfaction.

To let customers experience the best effect of the in-store music performance, the store's decor and layout have to be related to the music, otherwise the performances will be hindered by mismatching information sense. Meanwhile we suggest music performers make the audience feel more involved.

We suggest the Riverside to focus on store décor and layout and to create some reference to jazz style; for example more three-dimensional decoration instead of simply some drawings and photos.

We suggest Blue Note focus on customers' emotions; for example, it should require music performers to have more interaction with customers and to converse with them instead of focusing on their performance.

CONCLUSIONS

This study shows empirical evidence that space aesthetic elements (transparency sense and information sense) and Jazz music elements (improvisation, innovation, and localization) all have direct positive impact on experience satisfaction, therefore can be used as a reference for business improvement.

This study found new evidence that high-end aesthetic elements (uniqueness, persistency, organic) have a positive impact on experience satisfaction. Therefore, the new future challenge for service industry is to make customers believe the store has an existing value.

Study contribution

1) Academic contribution

This study defines transparency sense and information sense of space aesthetic through literature review. Jazz music elements include innovation, improvisation, and localization while high-end aesthetic elements include uniqueness, persistency, and organic concept. Our analyzed result also points to that our measuring indicators have credibility and effectiveness.

Based on literature review, this study discusses the transparency sense and information sense of space aesthetic elements. We use innovation, improvisation and localization of Jazz elements as the dependent variables and, high-end aesthetic, emotion, and quality of experience as intermediate variables, and experience satisfaction degree as the dependent variable to address their correlation. We found most assumptions are valid.
This study will use the different music styles of our investigated two stores as disturbing variables to conduct comparison analysis. We find the space's information sense can increase customers' imagination towards music space. Our empirical results can offer definition and measuring basis for reference to following consumer experience studies.

2) Practical contribution

The study's empirical results can be applied to related industry fields, including all performance services, music related services, catering services and store services.
Despite the real world's application might not as simple as this study presents, we believe our empirical evidence can be used as important reference for industry practice.

PREDICTING CONSUMER INTENTIONS TO PURCHASE GREEN CARS: AN EMPIRICAL TEST OF COMPETING THEORIES

Dr. Chi-Horng Liao, Ta-Hwa Institute of Technology, Taiwan
lchjerry@thit.edu.tw

ABSTRACT

The aim of this research is to find the key factors that would influence customer purchasing intentions for green cars. There is an increasing awareness that many of environmental problems are caused by human economic activities. For this reason, it is important to find and use a suitable model. "Theory of Planning Behavior (TPB)" was proposed by Ajzen in 1985 and is a famous and popular model to measure customers purchasing behavior intentions. Therefore, the researcher combined with other related aspects for the questionnaires. The rest of the research is organized as follows: The researches explore the TPB model and other related aspects by literatures in Section 2. Analyzing the past researches give us better picture on the behavior of the customer toward green cars. In the subsequent sections of the paper, the researcher focuses the expansion of research model. In Section 3 the existing approaches and relate to suitable aspects with TPB model would be discuss. The hypothesized models will be empirically test using the structural equation modeling (SEM) approach, supported by LISREL 8.8 software with maximum likelihood estimation.

Key words: Theory of Planning Behavior, Green Cars, Structure Equation Modeling

INTRODUCTION

There is an increasing awareness that many of environmental problems are caused by human economic activities. The activities not only consume huge amounts of resources, but also lead to the disposal of tons of pollutants into the environment at levels which nature can no longer absorb. This situation generates problems such as climate change, global warming, pollution, loss of biodiversity, and many more. Because of high-prices energy and conscious of environmental protection, green cars play an important role in cars purchasing. In the past research, many scholars focused designs of engines, fuel systems, and etc. The researchers always try to find out the way to decrease pollution. There are few research describing customer behaviors and purchasing needs of green cars. Thus, to find the key factors which would influence green cars buying intention is important.

There are some research pointed out that the primary task is to explore the needs of the customers and apply these needs in the development of green products (Baumann et al., 2002; Hart, 1995). These researches described that the designers have to consider what customers like and need, and put them together with production of green products. Many influencing factors such as characters of green products, customers satisfy, and customer relationship, were discussed in different research models. In this paper, the researcher tries to find out the purchasing intention of green cars. Turrentine (2001), Marcus (2009) and Ishioka (2009) sited that green cars are important in the green product industry.

The aim of this research is to find the key factors that would influence customer purchasing intentions for green cars. Base from the report, vehicle emissions contribute to the increasing concentration of gases linked to climate change (World Energy Council, 2009). In order of significance, the principal greenhouse gases associated with road transport are carbon dioxide (CO_2), methane (CH_4) and nitrous oxide (N_2O)(Marianne 2010). Road transport is the third largest source of greenhouse gases emitted in the UK, and accounts for over 20% of total emissions, and 33% in the United States. Of the total greenhouse gas emissions from transport, over 85% are due to CO_2 emissions from road vehicles. The transport sector is the fastest growing source of greenhouse gases (IPCC, 2007).

In order to reduce the greenhouse effect, for this reason, it is important to find and use a suitable model. “Theory of Planning Behavior (TPB)” was proposed by Ajzen in 1985 and is a famous and popular model to measure customers purchasing behavior intentions. Therefore, this research used TPB model to be a basis combined with other related aspects for questionnaires. The rest of the paper is organized as follows. TPB model and other related aspects by literatures is discuss in Section 2. Resorting to collect past researches could let the research model more complete. The development of green cars is discuss within this section. In the subsequent sections of the paper, we focus on the expansion of research model. In Section 3 we briefly discuss existing approaches and relate to suitable aspects with TPB model. The data collected by questionnaires will be analyze by the next research. The analysis method includes Principle Component Analysis (PCA), Analysis of Reliability and Validity, Regression Analysis, and One-way Analysis of Variance (ANOVA). By these results, we could know about the relationships among aspects and the key influencing factors for customers green cars purchasing behavior. The conclusions of this paper would be discussed of the implications of the use of the proposed research model to the manufacturing industry in the final section.

LITERATURE REVIEW

This research discusses the development and the consumer behavior toward green cars. Afterward, the development history of TPB model would be introduced by many researches. In the end of this section, we combined some related research with TPB model to built own research model for this study.

Green cars

A green cars or environmentally friendly vehicle is a road motor vehicle that produces less harmful impacts to the environment than comparable conventional internal combustion engine vehicles running on gasoline or diesel, or one that uses alternative fuels (RIC, 2005). Green cars are powered by alternative fuels and advanced vehicle technologies and include hybrid electric vehicles, plug-in hybrid electric vehicles, battery electric vehicles, compressed-air vehicles, hydrogen and fuel-cell vehicles, neat ethanol vehicles, flexible-fuel vehicles, natural gas vehicles, clean diesel vehicles, and some sources also include vehicles using blends of biodiesel and ethanol fuel or gasohol(US department of energy, 2010). Several author also include conventional motor vehicles with high fuel economy, as they consider that increasing fuel economy is the most cost-effective way to improve energy efficiency and reduce carbon emissions in the transport sector in the short run. As part of their contribution to sustainable transport, environmentally friendly vehicles reduce air pollution and greenhouse gas emissions, and contribute to energy independence by reducing oil imports (Green Student, 2010).

There are some attempts in the literature to define a green product (Elkington et al., 1988; Schmidheiny, 1992). Some studies focus on designing and marketing green products (Green et al., 1994; Roy, 1999; Vaughan et al., 1993). But it still confuses on what constitutes an environmentally friendly product, for consumers as well as for companies (Welford, 1998). Thought and needs form customers and companies are not the same, even they could be opposite to each other in some particular situations. Take fuel for example, customers always want characteristics of fuel include cheap and helpful to engine works. But some cheap fuel causes lots of pollution such as air pollution, and there is a duty for each company to maintain environmental protection. Thus, it is hard to get the balance between customers' needs and company's duty.

Fortunately, hybrid cars, solar-power cars, and other environmental protection vehicles have been invented in recent years. Not only cars' properties could be fit for environmental protection laws and terms, but also puts marketing essential factors like fashion into the car

design.

Many past researches focus on designs of engine and fuel systems. There are few researches to try to find the relationships between customers' needs and characters of green cars. Chang (2010) proposed a framework named "SEEDS" to describe the relationships amount "Supply Side", "Environment Protection Side", "Economic Side", "Demand Side", and "Substitute Side". Based on this framework, the author proposed some suggestions for different industries. Lantos et al. (2009) examined the felt need for new products in organizations, the usefulness of the new product development education, and the nature of the new product development discipline, for showing the paper's analysis of the death of the new product development courses in AACSB-accredited schools.

As the environment continues to worsen, the consumer has begun to realize the seriousness of the problem. Base on the needs of the consumer, businesses should design a green products to match the customers' demands. This paper could be seen as a pioneer in the research of green car design and customer behavior intention.

The theory of planning behaviors (TPB) model

The Theory of Planned Behavior was developed in response to a related existing model—The Theory of Reasoned Action (TRA) (Ajzen, 1988, 1991). Briefly, the Theory of Reasoned Action (Fishbein & Ajzen, 1975; Ajzen & Fishbein, 1980) places intention as the principal predictor of behavior. So conceived, the more one intends to engage in behavior, the more likely is the occurrence of the behavior. Determining intention are attitude and subjective norm. The attitudinal determinant of intention is defined as the overall evaluation of behavior. This overall evaluation, in turn, is composed of the salient beliefs: the perceived likelihood of particular consequences of the behavior occurring, weighted by an evaluation of the consequences. The subjective norm determinant of attitude is conceptualized as social pressure from significant others to perform or not perform the behavior. The subjective norm, in turn, is composed of normative beliefs: the perceived pressure from salient referents, weighted by the motivation to comply with the referents. The TRA has received support across a range of contexts (Sheppard, Hartwick, & Warshaw, 1988). A recognized limitation of the TRA is that it was developed to deal with behaviors that are completely under an individual's volitional control (Ajzen, 1988; Fishbein, 1993). Figure 1 is the structure of TRA.

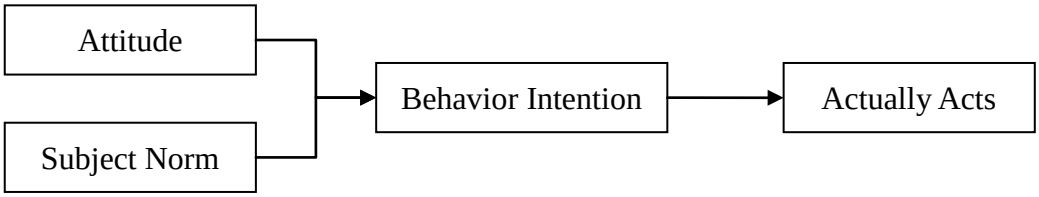

Figure 1: The structure of TRA.

In response to the aforementioned limitation of the TRA, Ajzen (1988, 1991) proposed an extension—the Theory of Planned Behavior. The TPB was designed to address behaviors not completely under volitional control. The model is identical to the TRA except that a perceived behavioral control construct has been added. Perceived behavioral control relates to the ease or difficulty of performing a behavior. Perceived behavioral control is affected by perceptions of access to necessary skills, resources and opportunities to perform a behavior, weighted by the perceived valence of each factor to facilitate or inhibit the behavior. In the TPB, perceived behavioral control is viewed as determining intention as well as behavior directly. The TPB has received strong support in predicting a wide range of intentions and behaviors (Godin and Kok, 1996; Sutton, 1998).

To understand the relationship between belief structures and antecedents of intention, several studies have examined approaches to decomposing attitudinal beliefs (Taylor and Todd, 1995; Chau and Hu, 2002; Chen et al., Jonathan, 2007; Riemenschneider et al.). Moreover, Shimp and Kavas (1984) suggested tha tthe cognitive components of belief would not be organized into a single conceptual or cognitive unit. According to Taylor and Todd (1995), in the TPB model, attitudinal, normative and control beliefs are decomposed into multidimensional belief constructs. The TPB model specified that, based on the diffusion of innovation theory (Jonathan, 2007), the attitudinal belief has three innovation characteristics that influence behavioral intentions are relative advantage, complexity and compatibility. Green technology can be considered a service innovation (Verhoef and Langerak, 2001). This study thus hypothesizes that the TPB model provides a more satisfactory explanation of behavioral intentions to purchase green cars..

The TPB (Ajzen, 1988 and 1991) extends the TRA (Fishbein, 1993), to account for conditions where individuals do not have complete control over their behavior. The TPB postulates that actual acts is determined by behavioral intention and perceived behavioral control. Behavioral intention is determined by three factors: attitude, subjective norms and perceived behavioral control. Each factor is in turn generated by a number of beliefs and evaluations.

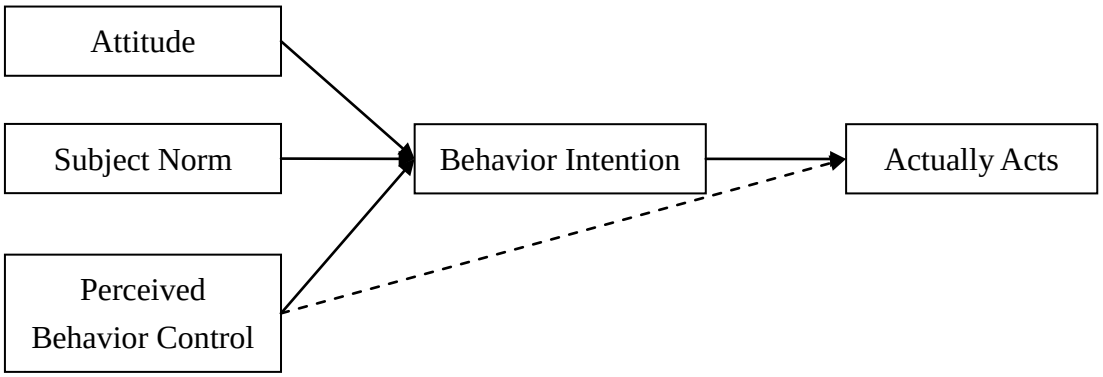

Figure 2: The structure of TPB.

"Behavior Intention" means personal volition and the volition would influence customers final decisions. Behavior Intention is impacted by two factors. One is an internal factor named "Attitude", and the other one is an external factor named "Subject Norm". "Attitude" is combined "Salient Beliefs (or Behavioral Beliefs)" with "Outcome Evaluation", and it means the feelings of customers when they try to do the specific thing. It could be good and bad, advantage and disadvantage, interesting and boring, or else (Ajzen, 1985). "Subject Norm" is combined "Normative Belief" with "Motivation to Comply", and it means people are under the pressure what they try to do something. The pressure is created by the people's parents, spouses, children, relatives, religious belief and etc. These individual suggestions would influence the behavior intention.

"Perceived Behavior Control" is combined "Control Belief" with "Perceived Facilitation", and it means when people try to do something, they would estimate how many the resources and opportunities they have and what kind of predicaments they might face to. "Perceived Behavior Control" could influence directly "Actually Acts" in some research, and some research shows the relationship between these two aspects is in-directly.

There is no past research using TPB model to measure green cars purchasing behavior intention. Thus, this paper could be the first research to estimate key influencing factors for behavior intention by using TPB model. With results of this paper, researchers could get valuable information from relationships among aspects.

THE RESEARCH STRUCTURE

In this section, we proposed a complete model for measuring influencing factors and green car purchasing behavior intention. We find and collect related research to create the structure. Based on past research, hypotheses would be proposed in objectivity. Some research results presented "Knowledge" would influence personal attitudes (Butler et al.,

1998; Hungerford et al., 1990; Limayem et al., 2000; Yan et al., 1999). People have different attitudes when they face to the same challenge because no one gets the same history of growing up and schooling. By these differences, people use own attitude to design what they like or what they want. Because of this, the hypothesis 1 is proposed as follow:

H1: Knowledge will have a significant impact on Attitude.

Clawson and Knetsch (1969) proposed product characteristics were the key factor that would influence customers' ability of perceived behavior control. Product characteristics include complexity, risks of purchasing, and etc. There is not much literature described relationships between product characteristics and perceived behavior control. Thus, we proposed the hypothesis 2 as follow:

H2: Characteristics of product have a significant impact on Perceived Behavior Control

Because TPB model offers a clearly defined model/structure that allows the investigation of the impact those attitudes, personal and cultural determinants and rational behavior control have on customers' behavior intention to buy environmental protection products, the model forms the theoretical structure of this study. TPB model was used to measure behavior intention of purchasing green products before (Alwitt et al., 1996; Chan, 2001; East, 1997; Diamantopoulos et al., 2003; Kalafatis et al., 1999). The hypothesis 3 to hypothesis 5 is described as follow:

H3: Personal Attitudes have a significant impact on Behavior Intention.

Consumers may perceive both difficulties and risk when considering buying green car, they can be expected to use their cognitive resources in forming beliefs toward the related attributes, which in turn may result in the development of an overall feeling (attitude) toward the behavior in question (refer to e.g., Antil, 1983; Zaichkowsky, 1985; Rossiter and Percy, 1987).

H4: Subject Norms have a significant impact on Behavior Intention.

Subjective norm, or the influence of others, has also been found to affect consumers' willingness to adopt a technology. Taylor and Todd (1995a, 1995b) reported that subjective norm positively affects consumers' adoption of innovative products. Green (1998) found that normative pressures have a significant positive effect on behavior Intention

H5: Perceived Behavior Control has a significant impact on Behavior Intention.

As the above-mentioned, TPB model is a perfect method to measure the key factors of behavior intention and causal relationships among aspects. The structure of this study is presented in figure 3 as follow. In the next section, we create questionnaires based on this model and past literatures.

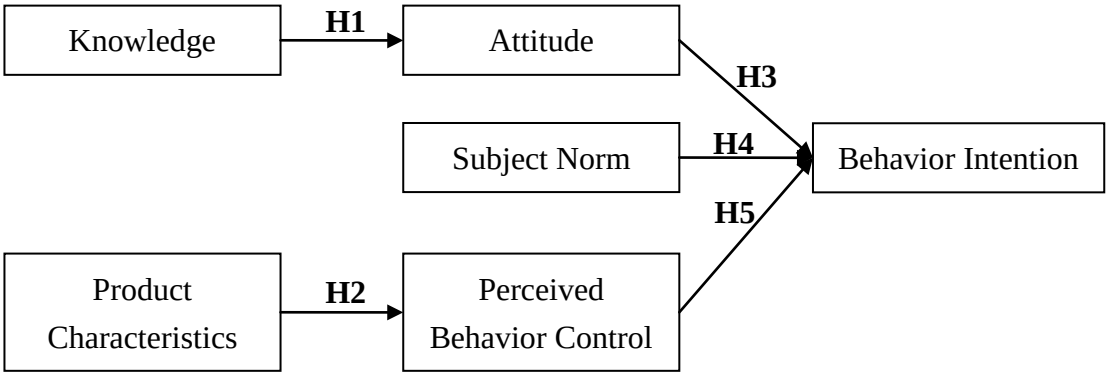

Figure 3. Research Model

RESEARCH METHODOLGY

Data collection

To empirically verify the proposed model, a comprehensive survey was conducted in Taiwan. Although English was initially used to develop the survey questionnaire, it was subsequently translated into Chinese to facilitate respondents' understanding. Linguistic equivalence between the English and Chinese versions was ensured by employing the back translation technique (Bhalla and Lin, 1987).

This study adapted the measures used to operationalize the constructs included in the investigated model from relevant previous studies, making minor wording changes to tailor these measures to the context of online shopping. The measures of actual usage, behavioral intention, perceived usefulness and perceived ease of use adapted from Davis (1993). The belief items for measuring compatibility, attitude, subjective norms, and perceived behavioral control were revised from Taylor and Todd (1995). Items for interpersonal influence and external influence were adapted from Bhattacherjee (2000), while items for measuring self-efficacy and facilitating conditions were adapted from Taylor and Todd (1995). All items were measured using a seven-point Likert-type scale (ranging from 1 = strongly disagree to 7 = strongly agree).

Data for this study will be collected as part of a larger mail survey of consumer perceptions

about green car purchasing. Participants were adults residing in Taipei, Taichung, and Hsin-Chu city. A three-page questionnaire was used as the research instrument. With the establishment of content validity, the questionnaire was refined through rigorous pre-testing. The pretesting focused on instrument clarity, question wording and validity. The pre-tested was performed in an iterative manner among a convenience sample of colleagues, students, and other consumers drawn from the general public. The 32 respondents of this test were asked to provide comments on the relevance and wording of the questionnaire items, length of the survey, and time taken to complete it. Based on the feedback, some of the questionnaire items were dropped. Further, the questionnaire layout was modified, and the wording of some of the questions was changed to improve clarity.

Multiple scale items, that were primarily adapted from Taylor and Todd (1995), were used to elicit respondents' salient beliefs, normative beliefs, self-efficacy, and attitude and intention towards green car purchasing. The instrument also included measures for assessing the level of green car purchasing and other relevant demographic indicators.

As a pilot test to gauge response rate, an initial mailing was sent to 120 of the randomly chosen sample. The survey package consisted of a cover letter, questionnaire, and pre-paid return envelope. A drawing to win one of NT$100 gift certificates, redeemable at shopping mall, was offered as an incentive to respond. As a reminder, a follow-up post-card was sent to all of the respondents a week after the initial mailing. Sixty one completed questionnaires were returned for a response rate of 56%. At the present time, 900 more survey was sent to the respondents via mail. After the collection of these survey questionnaires, the researcher will proceed to the statistical analysis.

Statistical analysis

The next stage, the hypothesized models are empirically tested using the structural equation modeling (SEM) approach, supported by LISREL 8.8 software with maximum likelihood estimation. Following the two-stage model-building process for applying SEM, the measurement model was estimated using confirmatory factor analysis (CFA) to test reliability and validity of the measurement model, and the structural model also analyzed to examine the model fit results of the proposed theoretical models.

OPERATIONAL PLATFORM FOR THE NORTHERN RESEARCH AND INNOVATION

Dr. Päivi Iskanius, University of Oulu, Finland
Paivi.iskanius@oulu.fi

ABSTRACT

Northern Research and Innovation Platform is an operational platform for promoting northern know-how and expertise in the field of 'the environment, energy and natural resources' with a strong geographical emphasis on northern and arctic aspects. The platform brings together key research actors; universities and research institutes, universities of applied sciences and companies, in addition to other public organizations, aiming to generate multidisciplinary research projects and speed up innovations especially in the mining and new forest and bio-energy industries, but also in the field of emerging environmental technology industry. The platform also aims to support research in preventing environmental changes in the northern regions and in man's operational prerequisites in cold climate conditions. Further, the platform aims to increase the awareness and visibility of northern and arctic research within the local and national sphere, as well as within EU authorities, and to strengthen the influence on national and EU programmes. The platform acts as a channel between the regional actors and EU authorities. This paper presents the development work of the Northern Research and Innovation Platform and shows how the platform can be used as a tool for the promotion of research and innovation activities. The platform is based on the European Research Area (ERA) and Northern Dimension (ND), and it follows the recommendations given by Finland's Strategy of Arctic Region. The development work of the Northern Research and Innovation Platform is coordinated by the University of Oulu, Thule Institute, and financed by the European Regional Development Fund.

Keywords: Northern research and innovation, Platform, ERA, European Research Area, Northern Dimension, Finland's Strategy of Arctic Region

INTRODUCTION

The international interest in Barents region, North-western Russia and the entire Arctic region has risen during the past twenty years. The economic potential of these regions which are associated with natural resources; oil, gas, minerals, and new transport routes which may open because of the climate change, may underline the strategic importance of the region. The world heavily relies on fossil fuels to meet its energy requirements - fossil fuels such as oil, gas and coal are providing almost 80% of the global energy demands (Korhonen and Savolainen, 2001). On the other hand presently renewable energy and nuclear power are, respectively, only contributing 13.5% and 6.5% of the total energy needs (Asif and Muneer, 2006). The global demand for energy is increasing, and the northern regions, with their new energy sources, may become a major energy reserve for European Union (EU).

The growing exploitation of natural resources and enormous investments in energy and mining industries offers new business possibilities for northern EU countries such as Finland.

Such possibilities abound, e.g., in the arctic shipbuilding and offshore industries, fields relating to the construction of infrastructures in cold climate conditions, service production and fields relating to security, energy, data transfer and the environment. The transport and logistics sectors have particularly great growth potential when the Northeast Passage opens. Also, renewable energy sector is growing fast. The development and use of renewable energy sources, such as wind power, solar energy, hydropower, biomass energy and geothermal energy, can enhance diversity in energy supply markets, contribute to securing long-term sustainable energy supplies, help reduce local and global environmental impacts and provide commercially attractive options to meet specific energy service needs, particularly in developing countries and rural areas, creating new employment opportunities (Asif and Muneer, 2006). Along with the forms of energy which are currently used, the prospect of using wood, peat, logging waste, agricultural waste, industrial waste, household waste and crop plants as fuel or a source of heat and power has also become a tantalizing business opportunity (Korhonen and Savolainen, 2001).

Sustainable use of natural resources, preventing the climate and environmental changes and international emissions trading, and protecting the livelihood and culture of indigenous peoples require new technological, social and political innovations. For sustainable development, it is essential that the natural resources of northern regions are exploited in a controlled manner, taking into account economic, social, cultural and environmental impacts. Promoting innovations; include product, process and organizational innovations of an enterprise as well as social and institutional innovations at the level of industry, region and nation (Morgan, 1997), is one of the most important regional development policy devices (Kitson, et al., 2004), also for rural, sparsely populated areas such as northernmost regions of EU representing.

Rapidly growing industries, related to the utilization of natural resources, need skilled employees, and global level experts. These industries are highly location-specific and far from the global markets, which increases the need for new knowledge, research, and technology. Special emphasis needs to be placed on developing technology and know-how which is compatible with the northern and arctic conditions, improving the business environment, and pursuing national and international collaboration. Supporting fields of business which show an upward trend, identifying new priority areas and interdisciplinary research targets, and producing state-of-the-art research data for the use of companies and business life in the region is a special challenge for the northern universities and research institutes. Further, research actors and companies have to be tied into a common innovation process. It is generally conceded that the innovative performance of regions is improved when companies are encouraged to become better innovators by interacting both with various kind of support organisations (Lawton-Smith, 2000).

Innovation is highly localized process (Asheim and Cooke, 1999; Maskell, 2001). Innovations, whether they are radical technological advancements or incremental social and organizational changes – are also often done in networks, where actors of different backgrounds are involved in the interactive process (Asheim and Cooke, 1999). Innovations are made inside complex innovation systems, which are formed by industries, universities, venture capital organizations, governments and other public organizations. This paper presents the development work of the Northern Research and Innovation Platform and

shows how the platform can be used as a tool for the promotion of northern research and innovation activities. The platform brings together experts from different scientific and industrial fields, from different regions, and different organizations; universities and research institutes, universities of applied sciences and companies, in addition to other public organizations. It is an open forum for collaboration, coordination and an increase of sense of community of northern research, with a strong geographical emphasis on northern and arctic aspects.

The development of the Northern Research and Innovation Platform has started in northern Finland in the field of 'the environment, energy, and natural resources'. The platform aims to generate multidisciplinary research projects and speed up innovations, especially in the mining and new forest and bio-energy industries, but also in an emerging environmental technology industry. Further, the platform aims to support R&D activities in preventing environmental changes in the northern regions and in man's operational prerequisites in cold climate conditions. The platform aims to promote northern know-how and expertise on environmental and energy issues and the sustainable use of natural resources for the benefit of the whole of Europe, and thus meet European needs, by combining the environmental and social dimensions into technological expertise.

METHODOLOGY

The aim of this paper is to present the development of the Northern Research and Innovation Platform and show how the platform can function as a tool for the promotion of northern research and innovation activities. The development work has started in northern Finland in the field of 'the environment, energy and natural resources', but an international aspect was already taken into account at the start. The aim of the Northern Research and Innovation Platform is to act as an open forum for northern research actors in Northern Scandinavia, including Finland, Sweden and Norway, and also Russia.

The empirical data for this study has been collected by analysing the publicly available documents, by arranging five workshops, and by interviewing several experts in the field. The development work has been carried out during the years 2009-2011. The research questions are:

1. How is the Northern Research and Innovation Platform developed?
2. How can the platform be used as a tool for promoting northern know-how and expertise in the field of 'the environment, energy and natural resources?

First, in this study, the current state of northern Finland in the field of 'the environment, energy and natural resources' is presented, based on the publicly available documents. The most significant changes which have happened in the operational environment of Northern Finland are presented. These major changes in the operational environment of northern Finland must be taken into consideration and will direct the development of the Northern Research and Innovation Platform. Also, based on the analyses of industries, the field of 'the environment, energy and natural resources' is positioned within the other clusters and industries.

Second, in this study, the initiatives that the European Research Area (ERA), Northern Dimension (ND) and Finland's Strategy of Arctic Region have recommended for northern research and cooperation are analyzed. The platform is designed, based on the five initiatives of the ERA related to 1) researchers, 2) research infrastructures, 3) knowledge sharing, 4) joint programming, and 5) international cooperation. The platform follows the ND policy recommendations that encompass cooperation among various stakeholders in the innovation system; universities, research institutes, parliamentarians and business. Finland's Strategy of the Arctic Region states the targets for Arctic and northern know-how. These targets have been taken into account in the development of the platform content. Further, several national and regional strategies on northern research and know-how have been surveyed. Based on the literature survey, the basis for the platform is formulated and the targets and tasks are defined.

Third, in this study, the key research actors in the field of 'the environment, energy and natural resources in northern Finland' were identified. Based on the identification, the research community for workshops was formed. Five workshops were then arranged (9.6.2010, 17.8.2010, 5.11.2010, 21.1.2011). Totally 80 experts from different regions of the Northern Finland, from different scientific and industrial fields, and from different organizations; universities and research organizations, universities of applied sciences and companies, in addition to financiers and support organizations, were participated in the workshops. The objective of these workshops was to examine and make forecasts of the developmental trends affecting the northern regions, to analyze the manner in which the northern regions should prepare for various possible future developments, by focusing and integrating activities, as well as by developing research and infrastructures, to evaluate and support the development of a northern research and innovation system, and to support the drafting of a common vision and research agenda for the northern platform. Based on the workshop process, the following content of the platform is formulated; future research needs, cooperation methods, and the vision, strategy, research agenda and joint operational programme for the platform. Finally, in this study, the Northern Research and Innovation Platform is formulated. In this paper, the vision, objectives and tasks of the platform are presented.

THE FIELD OF 'ENVIRONMENT, ENERGY AND NATURAL RESOURCES' IN NORTHERN FINLAND

The current state of northern Finland

Northern Finland is the northernmost and one of the most sparsely populated areas in the EU. According to Statistics Finland, the land area is 156 000 km^2, over 50 per cent of the national territory, and the population is about 700 000, 13.6 per cent of the country's total population. The average population density is 4.7 people/ km^2. The region covers both rural areas and several small and medium sized cities. Most of the people live in urban regions. FUR Oulu is the largest centre with 220 000 inhabitants. The following five largest FURs; Rovaniemi, Kemi-Tornio, Kajaani, and Kokkola, each have 50 000–60 000 inhabitants. The remaining localities each have 20 000 inhabitants or less. The regions are also quite different in terms of human and economic resources. In FUR Oulu, the investments in R&D are 12.8

per cent of the national R&D funding, while the remaining localities have barely any investments in R&D at all (Statistics of FUR Oulu). All in all, northern Finland is a region of opposites with a strong concentration of high-tech manufacturing in the Oulu city-region, but, at the same time, possessing a strong role of agriculture and forestry as well as tourism in most of the other parts of the region.

The main challenges of the region stem from its peripheral location, harsh climatic conditions and sparse and rapidly ageing population. Young people, i.e. future potential experts, move away from the region in particular. One exception in northern Finland is the Oulu region, with its youthful age structure and high birth rate. Only a few Finnish city-regions have the necessary research base and knowledge producing organizations to support the innovation of world-leading industries, but the Oulu region in northern Finland is one of these. Most of the regions lack strong research and innovation environments. However, instead, they have a relatively strong capacity in non-scientific practice-based innovation. In order to succeed, northern Finland must lead the way on a global scale in selected sectors of innovation activity. (Iskanius, et al., 2010)

Northern Finland has a rich stock of natural resources. Industries which are related to natural resources include fossil and slowly renewable natural resources (metal ores, industrial minerals, natural stones, soil and rock materials, groundwater and peat), resources related to agriculture and forestry (wood, meat, milk and fur farming), as well as natural products and experience management (mushrooms, berries, lichen, hunting, fishing, tourism, reindeer farming) (Suorsa and Iskanius, 2010). The energy branch includes the production, transformation and delivery of energy as well as the refinement of fuels. In northern Finland, the focus in the energy field is concentrated especially in hydro-, wind- and bio-energy, as well as in the refinement of industrial wastes. Northern Finland has also been promised to be the location for a new nuclear power plant. The environmental sector includes the treatment and recycling of wastes, water and the waste water supply and sewerage, as well as the protection of air. The maintenance of biodiversity is also considered to be an important issue of research in the northern regions (Aarras et al., 2008; Pohjois-Pohjanmaan liitto, 2005). The enterprises in northern Finland are small. That is especially the case concerning business in the bio-energy sector, as well as in soil and rock materials. The latter also suffers from a lack of leading focal companies, as well as international marketing and productisation. In mining, most of the owner companies are international, and the raw material is processed outside the region. Based on the analyses of industries, the field of ‘the environment, energy and natural resources’ is positioned within the other clusters and industries (figure 1).

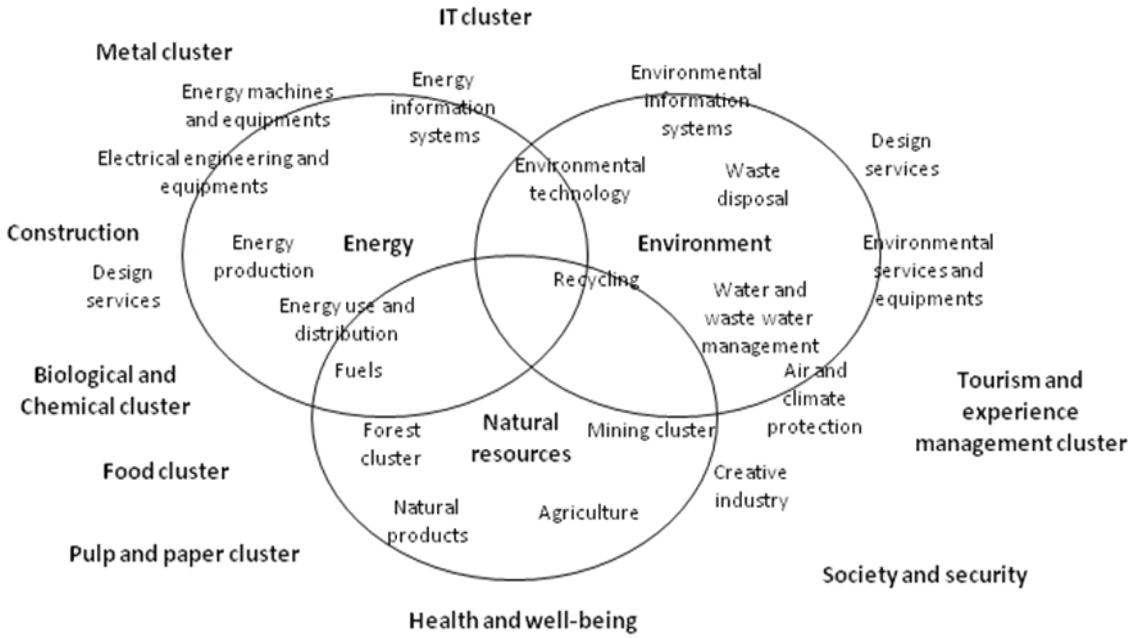

Figure 1: The field of 'the environment, energy and natural resources'.

Northern research

Northern research refers to research relating to the special conditions which are prevalent in the northernmost regions of the world. The primary special characteristics of the northern regions include a high sensitivity to the phenomena of global change, a cold climate, major seasonal variations in the amount of natural light, a low population density, a considerable diversity of cultures and identities, and rich natural resources. Northern research also looks at issues relating to global economy, society, social and regional development and their effects on the northern environment and communities (based on the Research Strategy Task Force of the Universities of Lapland and Oulu 2007 – 2008). Northern research is fragmented across various EU research programmes and research fields. Northern research has not been given due emphasis in the research policies of the EU. Northern research has been poorly coordinated in EU research policies, and EU funding for northern research has also been random and uncoordinated. According to Finland's Arctic Research Strategy (Korhola, 1999), the focus areas in the northern research are 1) Arctic natural resource research, 2) Global change and adaptation strategies in the arctic regions, 3) People and communities in the arctic regions, and 4) Arctic infrastructures.

From the viewpoint of the European research community, Finland possesses significant know-how and is the home to a large number of world-class research actors. Finnish northern and arctic expertise, know-how and research is internationally recognized. Finland possesses top-level arctic know-how in many sectors, eg. offshore industries, shipping industries, forest expertise, mining industry, metal industry, tourism, knowledge of traditional trades, low-temperature experise, winter testing, measurement technology, power and heat generation and distrubution, energy conservation and energy effidency, arctic wind power technology, arctic building and infrastructure, environmental engineering

and management of environmental impacts, sustainable social concepts, northern environmental expertise, northern health and well-being, waste management technology, informatioon technology and public e-services, innovation-oriented development, cold climate research, bio and nanosciences, risk analyses, oil spill prevention and response, material engineering (Finland's Strategy for the Arctic Region, 2010).

The research pertaining to nortehrn and arctic know-how and experiense is carried out in many universities and research institutes in Finland, however the universities of Oulu and Lapland, in particular, have been profiled as experts in northern and arctic research. Arctic Centre, University of Lapland, and Thule Institute, University of Oulu, have a leading position in the field. In August 2008, the universities agreed on a common strategy on northern research. It creates conditions for a regional (economic life, regional development organization), national and international network of northern research. In the annual negotiations between the Ministry of Education of Finland and the University of Oulu in April 2006, it was decided that; *"the university will focus particularly on northern global change research and on development of the Northern Research Platform of the European research area, thus supporting the EU's Northern Dimension Action Plan*".

Under the theme of global change in the northern regions, universities carry out top-quality research in the following sub-areas, which were supplemented by research concerning the Sami people in 2009:

- Natural systems: northern ecosystems, adaptation and climate.
- Environmental research and technology: natural resources, energy, land use, mining, tourism.
- The economy and judicial systems, societal and regional development: changes in the sources of livelihood, social structures and political structures.
- Art and culture: northern culture and history, minorities and indigenous peoples, northern art.
- Health and well-being: the significance of environmental factors and diet for health and well-being, indicators of health and well-being, social exclusion and special groups, special circumstances and adaptation.
- Methods and technologies: economical and judicial guidance, the interactions of art and technology, the identification and monitoring of change, remote sensing and geographic information systems, methodological and design-based research.

Research actors

Research is fragmented in the field of 'the environment, energy, and natural resources', both in terms of the themes and actors (figure 2). The northern research is carried out in two universities; University of Oulu and University of Lapland, but also in three university regional units/consortiums; Kajaani University Consortium, Kokkola University Consortium Chydenius, and Oulu Southern Institute; in five universities of applied sciences; Oulu, Kemi-Tornio, Rovaniemi, Kajaani and Central Ostrobothnia, and in several university research stations; Kevo Subartic Research Institute, Oulanka Research Station, Arctic Centre, Varrio Subarctic Research Station, Sodankylä Geophysical Observatory and Kilpisjärvi Biological Station. In addition, the northern research is carried out in several national research institutes; SYKE –Finnish Environment Insitute, METLA - Finnish Forest Research Institute,

MTT - Agrifood Research Finland, RKTL - Finnish Game and Fisheries Research Institute, GTK - Geological Survey of Finland, Evira - Finnish Food Safety Authority, VTT - Technical Research institute of Finland, STUK – Radiation and Nuclear Safety Authority, and Finnish Meteorological Institute (Suorsa and Iskanius, 2010).

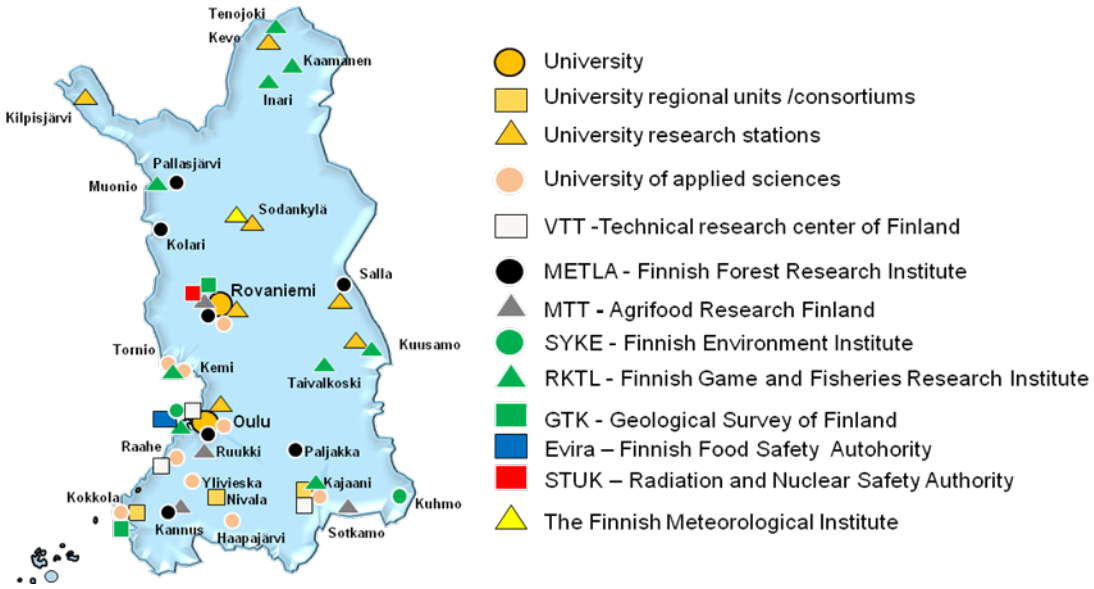

Figure 2: Northern research is fragmentated - over 50 different units/organistations.

In northern Finland, there are over fifty different research organisations/units in the field of 'the environnmet, energy and natural resources'. The research actors are small (staff <50) and they are located in various regions throughout northern Finland. However, small units tend to be more cooperative than large research communities. They are flexible in their decision-making and have a natural need for collaboration with others. The benefits which are reaped from collaborations are instantly visible as tangible increases in resources and know-how or as access to national and international research infrastructure environments or data. The research actors know each other, have few overlaps in their research efforts and already work together in various research networks. However, most future research needs are likely to involve more than one scientific discipline or field. Thus, greater effort should be made to increase interdisciplinary cooperation. For instance, the utilization of information technology in some of the more traditional fields might give rise to new innovations and business opportunities. Fragmentation creates specific challenges for multidisciplinary cross-scientific research, as well as research carried out in collaboration with business life. For strategic reasons, universities and other institutes of higher education have agreed on organization-specific responsibility areas in education and research, as well as on the forms of cooperation between the various research fields (based on the strategies of. Lapland University Consortium 2009 and the report of cooperation project of the universities of Oulu and Lapland 2007-2009). Also, in the NorNET- Northern Environmental Research Network cooperation, national research institutes aim towards a more coordinated research in the field of the environment and natural resources.

However, coordination, collaboration and the sense of community is still lacking. The collaborative networks of these research actors should be tightened, and their roles and responsibilities are in need of clarification. Particular attention should be paid to intensifying the collaboration between the public and private sectors, universities, universities of applied sciences and technology centers. Coordination is needed, and research activities should also have a clearer focus. While one cannot be an expert on everything, even relatively small competence clusters can represent top international expertise in a few carefully selected fields.

STRATEGIES BEHIND THE NORTHERN RESEARCH AND INNOVATION PLATFORM

ERA, European Research Area

The European Research Area (ERA) was launched in 2000 for composing of all research and development activities, programmes and policies in Europe which involve a transnational perspective. The ERA provides attractive conditions and effective and efficient governance for doing research and investing in R&D intensive sectors in Europe. It creates strong added value by fostering a healthy Europe-wide scientific competition whilst ensuring the appropriate level of cooperation and coordination. It is responsive to the needs and ambitions of citizens and effectively contributes to the sustainable development and competitiveness of Europe. Europe 2020 – Smart, Sustainable and Inclusive Growth Strategy is integrated into the development of ERA. The target is; that by 2020, all actors fully benefit from the "Fifth Freedom" across the ERA: free circulation of researchers, knowledge and technology. The EU Research Framework Programmes were designed to support the creation of ERA. ERA was established to address the weaknesses of European research activities, such as insufficient funds, the lack of a suitable environment for conducting research and exploiting the results, and the fragmentation of research activities and resources. The last two apply in particular to the northern regions. ERA aims at creating a unified, frontier-free zone, allowing a more efficient pursuit of research activities and the utilization of scientific resources for the ultimate goal of boosting employment and competitiveness in Europe. International cooperation, the free movement of competent researchers between countries, top-class research environments and research institutes, the sharing of knowledge, coordinated research programmes and an openness towards the rest of the world are important tools in creating a common research area. ERA aims to increase cooperation in five areas; 1) the careers, working conditions and mobility of researchers between different sciences, industrial fields and states; 2) the creation of world-class European research infrastructures, 3) the transfer of knowledge 4) the joint design and operation of research programmes and cooperation between public research and industry; and 5) the international cooperation in science and technology. (European Research Area, 2011)

ND, Northern Dimension

EU is closely linked with the northern and Arctic regions owing to political, geographical, economic and scientific factors. The impact of the EU's policies and decisions also extend to the northern regions. An example of this is the Northern Dimension (ND) policy, which was elaborated in 1999 with the participation of Norway, Iceland, EU Member States and the

Russian Federation. The USA and Canada hold observer status. The main objectives of the ND policy are to provide a common framework for the promotion of dialogue and concrete cooperation, strengthen stability and well-being, intensify economic cooperation, and promote economic integration, competitiveness and sustainable development in Northern Europe. Related to the northern research and innovation, The ND also encompasses the 'Arctic window', which means cooperation on issues concerning the whole circumpolar Arctic region. The core of the ND policy for research is the encouraging cooperation is mutual dependence between the EU and Russia in the joint border regions. Besides cooperation between governments, ND also supports the cooperation between universities, research institutes and politicians and industry. Also, Northern Dimension Institute was established for university networking to help coordination of research and education, and to get funding for research projects. (Northern Dimension, 2009)

Finland's strategy for the Arctic region

Finland has recently published Finland's Strategy for the Arctic Region, the main objectives of which are, related to the science, to give stronger support for northern research, the development of regional climate models and the long-term monitoring of the state of the environment as the basis for decision-making, and to reinforce the national coordination of research and monitoring. Finland's objectives are to strengthen Finland's role as an international expert in arctic knowhow by investing in education, research, testing, technology and product development, to make better use of Finnish experience of winter shipping and arctic technology in arctic sea transport and ship building, and to improve the opportunities of Finnish companies to benefit from their arctic knowhow in the large projects undertaken in the Barents Region by supporting the networking, export promotion and internalization of small and medium size enterprises, in particular. According to Finland's Strategy for the Arctic Region (2010):

- The arctic region has considerable economic potential. The increase in maritime traffic in the Arctic Ocean and exploitation of natural resources are an opportunity for Finnish expertice.
- Maintenance and further develpoment of arctic know-how, research and special experience require strategic choices and decisions on the part of Finland, and also relevant university-level education, correctly targeted investments and national and international cooperation.
- The development of know-how and technologies applicable to Arctic circumstances in the global operating environment highlights the importance of institutes of higher education.
- Competition is increasingly based on skilled labour and research resources in addition to market shares and capitals.
- The supply of new information and skills, and their diverse utilisation, will also lay the foundation for success in the future.
- The changes that have taken place in the operating environment require that universities accelerate their internationalisation efforts and resources are increased and focused on core strengths.
- International cooperation is a means of improving quality, eliminating overlapping activities, and gathering domestic and foreign resources for joint projects.

- Top-level competence is necessary when seeking interaction with leading global centres and actors.
- Finland has an extensive research infrastructure and a wide network of research stations.
- It is important that the national input into multidisciplinary scientific research continues.
- Guaranteeing broad-based Arctic research competence requires that universities and research insitutes emphasise their expertise in their strategies and activities and make use of the funding opportunities offered by the Academy of Finland and the EU Framework Programmes for research.
- Research and development bring economic benefits but also support environmental protection and the discovery and spread of best practices.

Essential targets of the northern research have been summarized based on the Finland's Strategy for the Arctic Region (2010):

- Owing to climate change and international emissions trading, environmental technology has the potential of serving as an engine in the expoert sector.
- Research plays a key role in adaptation to Arctic climate change and in the utilisation of opportunities offered by the Arctic region.
- The environment is fragile in the Arctic, including Northern Finland.The principal problems include climate change, the environmental impacts caused by increased shipping and exploitation of natural resources, reduced biodiversity, long-range transportation of pollution and issues pertaining to nuclear safety.
- The research carried out in Finland, especially in the monitoring of the state of the environment and in collecting long-term research material, has world-class relevance.
- The improvement of transport, communications and logistics links and simpler border formalities are key factors for the development of Northern Finland.
- The Sami in Finland are the Arctic indigenous people, whose status has been secured in the Constitution.

Finland's Strategy for the Arctic Region (2010) also promotes Finland's interests within the EU at a time when the EU is formulating its own Arctic policy, and specifies Finland's views in relation to the Arctic policies of other countries. According to the Communication from the Commission to the European Parliament and the Council – The European Union and the Arctic Region (2008), the European Community should maintain the arctic region as a priority area for research to close knowledge gaps and assess future anthropogenic impacts, especially in the area of climate change. The proposals for action include, for instance, developing further research programmes, assessing the state and evolution of the arctic environment, creating a new research infrastructure and enhancing monitoring and surveillance capabilities, and coordinating efforts in different research areas relevant to the arctic region, as well as developing arctic technologies.

Finland's Strategy for the Arctic Region includes a large variety of goals relating to the northern research and know-how. However, there are some important issues which are not covered by the strategy. The Northern Research and Innovation Platform aims to contribute to a part of these goals:

- Finland should make the northern regions a priority area for research, and additional resources should be earmarked for these activities in the governmental budget. Finland should also lobby for the European Union and other international actors to channel more resources into research carried out in the northern regions.
- Research should be integrated with environmental, foreign and industrial policies as this promotes collaboration between science and industry.
- New opportunities generated by interdisciplinary approaches should be exploited.
- Integration and the strategic development of northern infrastructures should be pursued.
- Networks should be created between regional research clusters, and a competence area focusing on northern know-how should be established.
- The knowledge and skills of people living in the northern regions, especially those of the indigenous peoples, should play a role in the development of the northern regions.
- Finland should shoulder its share of the global responsibility, i.e., be "a caring mediator".

NORTHERN RESEARCH AND INNOVATION PLATFORM

The Northern Research and Innovation Platform is based on ERA and ND (figure 3). The platform is formed by analyzing the five areas of ERA; 1) researchers, 2) research infrastructures, 3) the transfer of knowledge, 4) joint design programmes, and 5) international cooperation in science and technology. Further, the platform follows the ND policy recommendations that encompass cooperation among various stakeholders in the innovation system. Finland's Strategy for the Arctic Region includes a large variety of goals relating to the northern research and know-how, which has been taken into account in the development of the platform content. Also, there are some important issues which are not covered by the strategy. The platform aims to contribute to a part of these goals.

The Northern Research and Innovation Platform is a platform for promoting northern know-how and expertise in the field of 'the environment, energy and natural resources' with a strong geographical emphasis on northern and arctic aspects. The platform brings together key research actors; universities and research institutes, universities of applied sciences and companies, in addition to other public organizations, aiming to generate multidisciplinary research projects and speed up innovations, especially in the mining and new forest and bio-energy industries. Further, the platform aims to support research in preventing environmental changes in the northern regions and in man's operational prerequisites in cold climate conditions. The platform also operates in the field of emerging environmental technology, focusing on, e.g., material and energy efficiency, renewable energy solutions and waste management, as well as water and waste water treatment, air protection, environmental measuring, monitoring, and analysis, environmental law and sustainable economy, and climate-friendly and cost-effective processes, automation and services.

The Northern Research and Innovation Platform will develop know-how and expertise on the environmental and energy issues and the sustainable use of natural resources for the benefit of the whole of Europe, and thus meet European needs by combining the

environmental and social dimensions into technological expertise. The platform also aims to increase the awareness and visibility of northern and arctic research within the local and national sphere, as well as within EU authorities, and to strengthen the influence on national and EU programmes. The platform can act as a channel between the regional actors and EU authorities.

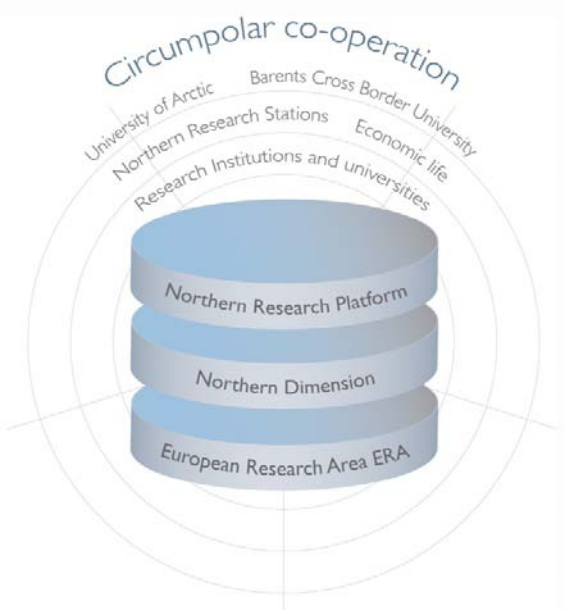

Figure 2: Northern Research and Innovation Platform.

Based on the ERA, ND and Finland's Strategy for the Arctic Region, the Northern Research and Innovation Platform is formulated:

1) The platform is an open forum for new partnerships between research actors, companies and the public sector in northern Finland. The platform encourages people living in the northern regions, especially those of the indigenous peoples, to share their knowledge and skills in the development of the northern countries. The platform encourages researchers and other experts to circulate and to cooperate across scientific, organizational, regional and national borders and to create transnational, multidisciplinary research groups.
2) The platform supports the development and operation of common research structures in northern Finland. The platform aims to make the northern regions a priority area for research, and recommend that additional resources should be earmarked for these activities in the governmental budget. The platform develops an infrastructure of electronic communication and promotes international networking.
3) The platform provides access for northern know-how and experience and promotes the collaboration between science and industry. The platform disseminates the results of publicly funded research to make them more exploitable, allowing them to be refined into new products and services.
4) The platform increases collaboration, coordination and the sense of community in a fragmented field of research actors. The platform actors participate voluntarily and variedly in defining, developing and implementing a common strategic framework for northern research. A shared vision on how the great societal and scientific challenges should be addressed serves as the platform's foundation.

5) The platform promotes collaboration in northern research and also creates new connections to neighbouring countries, while strengthening those that already exist. In collaboration with international partners, the platform will actively participate in addressing the challenges which are typically present in the northern regions. The platform strengthens the northern negotiation power to have an influence on the contents of national and international/EU programmes. The platform is a channel between region and EU and other international actors to channel more resources into research carried out in the northern regions. The platform develops recommendations, detailing specific tasks, approaches, participants and the necessary infrastructure for the national and EU programmes, such as FP 7 and the forthcoming FP 8.

Northernmost Europe's future growth, competitiveness and sustainability objectives are dependent upon major research, innovations and technological advances in the medium to long term. The platform will promote the creation of new partnerships between universities, research institutes and companies, draft, in the first stage, a co-operation strategy for research and development from the regional and national starting points and links it with international strategies. The platform will play a key role in ensuring an adequate focus of research funding on areas with a high degree of industrial relevance, by covering the whole economic value chain and by mobilizing public authorities at national and regional levels. In fostering effective public-private partnerships, the platform has the potential to contribute significantly to the renewed Lisbon strategy and to the development of a ERA of knowledge for growth. As such, they are proving to be powerful actors in the development of European research policy, in particular in orienting the national and international research programmes better meet the needs of industry in the field of environment, energy, mining and forestry.

CONCLUSIONS

The Barents region, North-western Russia and the entire Arctic region offer extensive business opportunities especially in the sectors of shipbuilding and offshore industries, sectors associated with the building of infrastructure, and in the sectors of the environment, security, energy, and telecommunications. For sustainable development, it necessary to pay increasing attention to environmental protection, and thereby, also to the preservation of healthy living conditions for indigenous peoples and other inhabitants in the northern regions. Environmental issues are not just a separate sector of their own; instead, they are an important element of a wider whole. Because climate change and other environmental hazards are not contained by national borders, international cooperation for prevention is vitally important. The environmental problems in the northern regions must be identified and tackled in the close cooperation among all actors in the northern regions, by launching transnational, multidisciplinary research projects, and by making the implementation of international treaties more efficient.

There is a strong increase in the demand for northern and arctic know-how and technologies. The feasibility and use of technological solutions and tools related to the sustainable use of northern natural resources and the preventing and adapting to climate

and environmental change must be studied. Economic, technological and social innovations arising from this process must be developed. Controlling northern environmental issues contains business opportunities which offer an important way to solve these issues. The need for problem-oriented multidisciplinary research has increased, and solving research problems requires more and more cooperation these days. The need for international centers of excellence is on the rise. The small number of businesses is a weakness for northern Finland. This creates a need for new methods of action to transform research-generated ideas and inventions into commercial profits. The productisation of northern know-how has also become a high priority.

Issues which are related to the sustainable use of 'the environment, energy, and natural resources' are usually politically and emotionally charged. Furthermore, different sources provide conflicting information, e.g., on how non-polluting the various production processes are, how sustainable the use of various natural resources is, and what the practical implications of climate change actually are. More impartial information and open discussions are required on these topics to allow an economically, environmentally and socially sustainable use of natural resources in the northern regions. People who live in the region tend to see the close proximity of, e.g., mines, waste incineration plants or nuclear power plants as a threat to their personal health and well-being or the region's other businesses, such as tourism. This is why we need information about the true impact of different industries and should also be on the lookout for possibilities to develop production methods and make them more ecologically sound. This is important in order to avoid pitting the region's different businesses (industry, reindeer management, tourism etc.) against one another.

The northern research actors are small compared to their Central European competitors, which encourages cooperating and networking. Improving coordination of northern research will add interest in this horizontal area of research on a national and international level. This will provide northern research with more resources which can be targeted on research benefiting the economic life and developing new innovations. Thus, northern research will offer better support for regional innovation activity and regional entrepreneurship, and promote equal regional development.

The Northern Research and Innovation Platform is not ready, but it has already adopted some specific characteristics when compared to the other actors in the northern research and innovation community. The activities will stretch over the entire circumpolar belt, and connect universities and the regions, from Canada to Sweden, from Japan to Russia, and Iceland, Finland. Compared to the other research actors or networks in the north, the platform is market-driven, down-up processes, and is also more focused to how research results can benefit the business world around the research institutes. In summary, the Northern Research and Innovation Platform supports the following activities:

- Scientific collaboration between various scientific disciplines, research institutes and industries should be increased.
- Scientific and infrastructure collaboration (logistic arrangements, research-related infrastructures) with other research institutes in the northern regions (Norway, Sweden, Russia, Canada, Iceland, Greenland, the Faroe Islands) should be increased.

- EU subsidies and programmes targeted at the northern regions should be exploited more efficiently.
- The European Union should be made aware of northern research needs.
- Existing networks and projects, and the results generated by them, should be utilized more efficiently.
- Impartial information (concerning different forms of energy in particular) should be generated and disseminated.
- Regional strengths (minerals, geo-energy, water, ICT) should be utilized better, and their true potential should be explored.
- More emphasis should be placed on value chain thinking: the possibility to establish new networks and adopt a perspective of sustainable production and product development.
- Education and know-how should be increased and developed by educational institutions as well as the exploiters of research and education (companies, decision-makers, officials) – targeted training based on regional needs, training for top experts/researchers, the ability to accept new information.
- Educational collaboration should be increased both internationally and between various northern organizations.

The Northern Research and Innovation Platform strongly supports the action proposal of Finland's Strategy of Arctic Region, i.e., that the Academy of Finland should launch an arctic research programme with a special emphasis on multi- and interdisciplinary research and international collaboration, in order to safeguard Finland's extensive competence in arctic research. Finland's Arctic Research Strategy is from the year 1999. Responding to today's changing circumstances and financial situation through research requires an update to the new national northern research strategy and the adoption of a new approach based on Finland's Strategy for the Arctic Region. Vital important is also to influence on matters relating to research and know-how in the coming EU Arctic Strategy and commit the action proposals of the Northern Dimension policy. The Northern Research and Innovation Platform may create a certain kind of EU Gateway status for the Barents region, North-western Russia and the entire Arctic region related to the northern and arctic research and innovation.

SUPPORT FOR INNOVATIONS IN HIGHER EDUCATION IN POLAND UNDER SELECTED OPERATIONAL PROGRAMMES SINCE 2004

Dr Joanna Rakowska, Warsaw University of Life Sciences-SGGW, Poland
joanna_rakowska@sggw.pl

ABSTRACT

The paper refers briefly to main definitions and categories of innovations defined in literature. Next it synthesizes rationale for supporting innovation in education expressed in OECD, EU and Polish strategic documents and presents goals of these strategies towards combined key elements of knowledge triangle: innovation, research and education. Empirical part of the elaboration presents findings of qualitative and quantitative analysis of innovative projects carried out by tertiary education institutions (TEI) under selected operational programmes over 2004-2006(2009) programming period. Selected TEI innovations were categorised, classified and grouped according to criteria defined in literature. Quantitative analysis focuses on financial effects of discussed projects. Author also discusses directions of support for innovations under sectoral operational programmes over on-going 2007-2013 programming period.

Key words: innovations, higher education, sectoral operational programmes.

INTRODUCTION

Development of many EU countries has advanced to innovation-driven stage. Hence, investment in innovations – next to research and technology - is essential to economic growth (Varis, 2007). However, it is people – human capital - who generate innovative knowledge and ideas, and it is people who implement and apply all kinds of novelties in the workplace and in society (OECD 2011). That is why support for innovative economy should begin with support for innovative education.

Human capital is formed basically by formal education. Especially higher (tertiary) education is indicated as an element playing crucial role in the process of building innovative society. And it should be stressed that tertiary education institutions such as academia and universities take here a double role. Firstly, in the process of education they produce human capital which is able to create and/or absorb and disseminate innovations. Secondly, these institutions still remain main research centres, on one hand providing innovations and on the other hand providing information on changes in this field, because they carry out research both *on*[1] and *in* innovations (Meek et al., 2009).

The above has been acknowledged by many international organisations, EU institutions and EU Member State governments, including Poland. However Polish tertiary education has to

[1] 'It is not surprising that research on innovation has gained importance: it has become essential to understand why and how certain enabling environments encourage innovation and help optimize its various benefits. Among other things, research can identify how knowledge translates into innovative action and how diversity can drive positive change'. (Meek et al., 2009)

face not only challenges of innovation-driven economy, but also those resulting from long-lasting negative effects of centrally-planned economy and next from difficult transformation process. That is why Polish tertiary education does need support to become an engine for innovative society and knowledge-based economy.

After accession, EU funds became very important for the development of Polish research and tertiary education. According to the opinion of Polish Ministry of Science and Higher Education (2010) these funds are at present the main support for innovation and research, for creating modern infrastructure of science, for modernising universities and improving the education process.

METHODS

The presented analysis was based on data provided by the Ministry of Regional Development, which is the main national institution responsible for implementation of Sectoral Operational Programmes (SOP) in Poland. The basis comprises of 87909 records describing the value, thematic field, action and sectoral operational programme for each project carried out over 2004-2006(2009) under all seven SOPs. As no detailed data is disseminated for 2007-2013 programming period, this part of elaboration is based on general reports of the Ministry of Regional Development and the Ministry of Science and Higher Education.

The applied research method consisted of both qualitative and quantitative data analyses. First stage comprised of the standard method of qualitative data analysis e.g. data coding, categorisation, sorting and reduction (Miles and Huberman 1994). All applied criteria were *a priori criteria*, e.g. criteria classifying innovations as product, marketing, process and organisational ones emerging from the innovation theory [Oslo Manual, 2005] or criteria defining soft and hard projects, presented in literature (Crawford and Pollock, 2004). Coding used at all stages was based on main categories (*non-hierarchical (flat) coding).*

The research process began with selection of projects meeting the main criterion: they had to be projects carried out by tertiary education institutions (TEI) as beneficiaries of Operational Programmes over 2004-2006.

The next stage focused on selecting projects resulting in implementation of innovation.

The list of selected innovation projects carried out by TEI was sorted into groups of projects under specified operational programmes. Thus obtained and categorised research sample was coded according to Oslo Manual criteria. Based on the results of coding, the projects were categorised again into four groups: product, process, organisational and marketing innovations.

Quantitative analysis focusing on the financial effects of the support for innovations in education was the last stage.

THEORETICAL FRAMEWORK AND PRACTICAL BACKGROUND FOR INNOVATIONS

Definitions and categories of innovations

There are numerous definitions of innovation in academic literature. Each of them reveals different important aspects of innovations, but the most applicable ones - from the point of view of this elaboration - are those presented below.

The classical definition by Schumpeter (1934) says that innovation is an introduction in the market of a new product or process which provides new distinguishing elements versus the existing ones. Schumpeter identified innovation as the critical dimension of economic change.

In 'Green Book on Innovation' (1995) European Commission referred to the term of innovation as 'renovation and expansion of the range of products, services and the corresponding markets', 'renovation of the methods of production, supply and distribution' and 'changes in management, working organization, working conditions and qualifications of workers'. Such approach seems to reflect quite closely the definition of OECD and Eurostat.

Oslo Manual (OECD, Eurostat, 2005) defines innovation as the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organisational method in business practices, workplace organisation or external relations. Thus, all innovations must contain a degree of novelty. And according to the criterion of novelty the innovations can be classified into three groups:

i) innovations new to the firm (diffusion of an existing-in-the-market innovation to a firm),
ii) innovations new to the market (the firm is the first to introduce the innovation on its market) and
iii) innovations new to the world (the firm is the first to introduce the innovation for all markets and industries).

Oslo Manual also defines four other types of innovations. These are:

- A product innovation, which is the introduction of a good or service that is new or significantly improved with respect to its characteristics or intended uses. This includes significant improvements in technical specifications, components and materials, incorporated software, user friendliness or other functional characteristics. Product innovations can utilise new knowledge or technologies, or can be based on new uses or combinations of existing knowledge or technologies. Product and/or service innovation entails activities such as design, research and development, acquisition of patents, technology licenses, trademarks, and tooling-up industrial engineering.
- A process innovation, which is the implementation of a new or significantly improved production or delivery method. This includes significant changes in techniques, equipment and/or software. Process innovations can be intended to decrease unit costs of production or delivery, to increase quality, or to produce or deliver new or significantly improved products.
- A marketing innovation, which is the implementation of a new marketing method involving significant changes in product design or packaging, product placement,

product promotion or pricing. Marketing innovations are aimed at better addressing customer needs, opening up new markets, or newly positioning a firm's product on the market, with the objective of increasing the firm's sales.

- An organisational innovation, which is the implementation of a new organisational method in the firm's business practices, workplace organisation or external relations. Organisational innovations can be intended to increase a firm's performance by reducing administrative costs or transaction costs, improving workplace satisfaction (and thus labour productivity), gaining access to non-tradable assets (such as noncodified external knowledge) or reducing costs of supplies.

European Commission suggested another classification of innovations, based on findings of evaluation of Employment and ADAPT Programmes. These are:

i) process-oriented innovations: development of new and/or improvement of already existing methods, instruments and approaches;
ii) target-oriented innovations: setting up new objectives and approaches in order to identify new possibly successful qualifications and creating new jobs on the labour market;
iii) context-oriented innovations: developing political and institutional structures in the labour market.

Innovation can occur in any sector of the economy, including government services of which education is of special focus herein. Although the theoretical framework applies mostly to business innovations, its elements can also be used to define and classify the concept of innovations in education.

Plaza (et al., 2010) analysed the concept of innovativeness in the context of university education. They came up with the following examples:

i) product innovations: creating new teaching materials (books, lecture notes, educational software) and/or improving the existing ones, ICT (Information and Communication Technologies) play an important role;
ii) process innovations: novelties in the teaching-learning process (updating teaching methodology);
iii) organisational innovations: as there are different levels of organization at universities (faculties, departments, areas, lecture rooms, etc.) the innovation may involve improvements in the human resources management, infrastructure, internal organization, etc.

Although not mentioned in the above discussed elaboration, in Poland we can observe also marketing innovations at some universities competing for and trying to attract prospect students. This is caused by negative demographic change and decrease in the number of young people.

Innovation rarely occurs in isolation; it is a highly interactive process of collaboration across a growing and diverse network of stakeholders, institutions and users (OECD, 2010) and education is of major importance in this growing and diverse network.

International, European and Polish rationale and strategies for innovations in education

The advent of the information and knowledge-based society is a major event for innovation (Council, 2011), but it is a challenge as well.

If higher education is to play a role of instrument creating innovative attitudes among young people, then its statistics are vital. In OECD member countries one-third of 25-34 year-olds have a tertiary education now, however young people graduate in social sciences, business and law increasingly, while there is a decline in the share of science and engineering graduates in a number of countries, including Poland. This phenomenon is definitely limiting the future innovative potential of human capital. Educationally inactive youth, tertiary drop-outs and poor literacy levels suggest that OECD countries still have a lot to do to raise educational attainment (OECD 2011) and so has Poland.

To address these challenges, OECD (2010) elaborated five main policy principles for innovation:

i) Empowering people to innovate (education and training systems should equip people with the foundations to learn and develop the broad range of skills needed for innovation in all of its forms, and with the flexibility to upgrade skills and adapt to changing market conditions. To foster an innovative workplace, ensure that employment policies facilitate efficient organisational change);
ii) Unleashing innovations;
iii) Creating and applying knowledge;
iv) Applying innovation to address global and social challenges;
v) Improving the governance and measurement of policies for innovation.

Very similar attitude to innovation as a driver of economic growth and a way to address global and social challenges is taken by EU. Innovation, together with research and education make three central and strongly interdependent drivers of the knowledge-based society and are referred to as the 'knowledge triangle'. The convergence of higher education, scientific research and innovation systems which have now become strategically interlinked in terms of their objectives and modalities generates synergy (Plaza et al., 2009). These three key concepts creating knowledge triangle should be better linked together to reach the objectives of Lisbon Strategy and of Strategy Europe 2020 (European Commission, 2010).

Goals of EU's Lisbon Strategy aim to deliver stronger, lasting economic growth and to create more and better jobs thus making EU the **'**most dynamic competitive knowledge-based economy in the world'**.** Innovation is indicated as an instrument enabling to achieve these goals through contribution to creating new jobs and industries.

Strategy Europe 2020 puts forward three mutually reinforcing priorities, among which smart growth priority aims at developing economy based on knowledge and innovation[2]. The

[2] 'Europe's education and training systems need to provide the right mix of skills and competences, to ensure a sufficient supply of science, mathematics and engineering graduates, to equip people with basic skills and the motivation and capacity to learn, to foster the development of transversal competences, including those

Commission also proposed the following EU headline targets that should be achieved by 2020:
– 75 % of the population aged 20-64 should be employed;
– 3% of the EU's GDP should be invested in R&D;
– the "20/20/20" climate/energy targets should be met (including an increase to 30% of emissions reduction if the conditions are right);
– the share of early school leavers should be under 10% and at least 40% of the younger generation aged 25-34 should have a tertiary degree;
– 20 million less people should be at risk of poverty.
It was highlighted (Council, 2010) that measures taken in the education and training sector will contribute to achieving the targets in other areas, such as increasing employment rates, promoting research and development, and reducing poverty.

To achieve the above goals and progress under each priority theme the Commission put forward seven flagship initiatives, of which 'Innovation Union' is meant to improve framework conditions and access to finance for research and innovation in order to ensure that innovative ideas can be turned into products and services which create growth and jobs.

Boosting innovative ability in Europe can be done by bringing together enterprises and research centres or universities, developing systems of education and training, emphasising the local and regional level, fostering mobility among students and research workers or disseminating "technology watch" results (Council, 2010).

Since its accession to EU in 2004, Poland faces the same challenges as the whole Community and is obliged to aim at achieving the same educational, research and innovation targets strengthening knowledge triangle. But the social and economic situation of Poland differs significantly from those in old Member States. The deep development disparities result from both unfavourable inheritance of centrally planned economy and from difficult transition process.

Comparing Polish economy to economies of other EU countries proved that if Poland wants to make up the economic gap separating it from richer EU States, it will have to considerably increase innovativeness of its economy. It was assumed in government documents that global economy based on knowledge and ITC technologies demands teaching new skills in all professions, both the traditional and new ones. Thus 'education today must teach for the economy tomorrow', and this means that it should strengthen analytic skills, develop innovation talents and entrepreneurship (Ernst&Young and IBnGR, 2010b; KRASP 2009).

Polish tertiary education institutions are not ranked satisfactorily in international ranking lists, where research achievements are one of the main criteria. It results mainly from the government policy implemented over the last two decades, where the priority was to educate more and more people to improve catastrophically low indices of scholarisation

---

that enable the use of modern digital technologies, to promote sustainable development and active citizenship, and to encourage creativity, innovation and entrepreneurship' (Council, 2011).

inherited after the previous system[3]. This 'quantitative' approach was realized in conditions of dramatically low and still decreasing national budget expenditure on R&D. Now there is an urgent need to reform Polish higher education system in order to assure its better quality through its adjustment to the needs of knowledge-based economy.

The same need has had to be addressed by most industrialized countries, who have been obliged to address the double challenge of providing wider access to tertiary education as well as training and ensuring adequate investment in high-level research. Governments pursue reforms to build world-class system of higher education, to assure quality in both research and teaching.

According to ongoing discussion and public debate in Poland, the new reformed tertiary education should perform three main functions: generating knowledge (research), transferring knowledge (education) and applying knowledge (innovations). Thus implementing the idea of knowledge triangle and becoming a more effective part of the European Research Area and European Higher Education Area (Ernst&Young and IBnGR, 2010a). The reform also aims at promoting reinforced cooperation between higher education institutions, research institutes and enterprises with a view to strengthening the knowledge triangle as the basis for a more innovative and creative economy (Council, 2011). However the issue of lack of funds necessary to improve innovations in educational system in Poland still remains unsolved.

STRUCTURE AND NUMBER OF STUDENTS IN TERTIARY EDUCATION INSTITUTIONS AND CHANGES OVER 2004-2009

According to the data from the Central Statistical Office of Poland, there was a significant change in the number of tertiary education institutions and their students between 2004 and 2009 (the latest available data). In 2004 in Poland there were 420 TEI which educated 1.91 million students, in 2009 the number of TEI increased to 454 (i.e. by 8.1%) while the number of students decreased to 1.88 million (i.e. by 1.7%).

The structure of TEI changed significantly over that period. The number of universities increased by two (to 19 in total), but they lost 3.5% students when compared to 2004. The same trend is observed in case of higher technical schools: 23 in 2009 (increase by one) and decrease in the number of students by 6.7%, which is a very undesirable tendency from the point of view of EU's educational objectives aiming at the increase in the number of graduates from technical tertiary schools. Next there was increase in the number of pedagogical TEI (to 18), while the number of their students decreased by 20.2%, and similarly in case of 15 theological TEI (increase by one) which in 2009 were educating 29% less students than in 2004.

[3] Paradoxically enough, some authors argue (Ernst&Young and IBnGR, 2010b) that ageing of the society may cause desirable changes in higher education as decreasing number of young people will force universities to compete for students, offering a high quality education, hopefully. The number of young people aged 18-24 is forecast to decrease till 2020 by 1.5 million, while the number of students will decrease by 600-800 thousand, assuming that scholarisation index remains on the same level.

Another group consists of two categories of TEI, economic and agricultural ones. The number of economic TEI decreased by 13% (from 93 in 2004 to 80 in 2009) and the number of their students decreased by 20.1%. There are also two agricultural TEI less (7 in 2009), and the number of their students decreased by 24.5%.

Although the number of medical (9) and physical training (6) academies did not change, they educate more students: medical academies 26% more and PT academies 5% more in 2009 than in 2004.

The most numerous is the group of 254 Public (State) Higher Education Vocational Schools which had 407.4 thousand students in 2009. They replaced Higher Education Vocational Schools which had 207.1 thousand students in 2004.

EFFECTS OF SUPPORT FOR INNOVATIONS IN HIGHER EDUCATION IN POLAND UNDER SELECTED OPERATIONAL PROGRAMMES 2004-2006(2009)

Over 2004-2006(2009) public and private tertiary education institutions (TEI) carried out 928 projects classified as innovative, under four Sectoral Operational Programmes, namely:
- Development in Human Resources (DHR),
- Increase in Enterprises' Competitiveness (IEC),
- Fish and
- Integrated Regional Development (IRD).

TEI did not carry out any projects under three remaining SOPs: Transport, Agriculture and Technical Assistance.

Most projects (583, i.e. 63%) were carried out by public TEI, while the remaining 345 (37%) by private ones (Table 2).

Under SOP Development in Human Resources (DHR), TEI carried out 317 innovative projects, of which 60% (190) were those carried out by non-public TEI (see Table 1). All these projects can be classified as soft projects, mostly aimed at creating new educational products, e.g. as many as 71 post graduate studies and 7 MBA programmes. Other educational products were different kinds of vocational trainings, language courses, new qualifications and skills and distant-learning courses in different fields. TEI also created such new products as labour market diagnoses, vocational consultancy, actions promoting equal chances in the labour market, etc. TEI did not carry out any other types of innovative projects (eg. process or organisational) under this SOP. It results from the programme framework and legal basis strictly defining what kind of projects can be carried out and co-financed, thus determining in a way also the scope of produced innovations. Applying European Commission's criteria of defining innovations, the outcomes of projects carried out under DHR can be classified as process-oriented innovations, because they are a development of new and/or improvement of already existing methods, instruments and approaches; as target-oriented innovations for they set up new objectives and approaches in order to identify new possibly successful qualifications and creating new jobs on the labour market and last but not least as context-oriented innovations, developing political and institutional structures in the labour market.

TEI realised 7% of the total number (4488) of projects under SOP DHR, and they absorbed 5% of total EU funding spent under this SOP. However there were significant differences between beneficiaries: the top five beneficiaries who carried out in all either the comparatively largest number of projects or projects of the highest costs are some of the best-known and renowned technological schools (polytechnics) and universities in the country, e.g. University of Bialystok 2 projects of the highest value (46.4 million PLN) in this group, next Wroclaw Technological School 6 projects which cost 21.2 million PLN and Warsaw University, which carried out 23 projects of the total cost of 18.3 million PLN,

Analysis of SOP Fish reveals that TEI carried out 29 projects, of which 25 can be classified as product innovations and 4 as marketing innovations. The first group mostly consists of new research, while the latter one includes four actions promoting fish consumption. All these projects were carried out by public TEI.

The share of TEI in total number (4128) of projects under SOP Fish equals barely 1%, but they absorbed 3% of total EU funding spent under this SOP. The cost range of projects realised under this SOP was between 140 thousand PLN for the research by Agricultural Academy in Szczecin (the minimal cost in this group) and 2.5 million for a project by Maritime Academy. Agricultural Academy in Szczecin was the main beneficiary in the discussed group, as it realised 21 projects for 18.8 million PLN, under SOP Fish.

According to the findings, SOP IEC was supportive to mostly public TEI (61 projects out of 62 total), as only one non-public TEI carried out a project under this programme. Most (47) projects were hard projects aimed at building, modernising or equipping laboratories. They are classified as organisational innovations as well as those soft ones (9) aimed at creating technology transfer networks. Only 9 projects in this group were product innovations providing foresight and improving quality of research.

The share of TEI in total number (15514) of projects under SOP IEC equals barely 0.4%, but they absorbed 3% of total EU funding spent under this SOP.

Table 1: Basic data for innovative projects by TEI.

Under SOP	Number of projects by TEI	Share of projects by TEI in total No of projects *in %*	Share of total EU funding absorbed by TEI *in %*
DHR	317	7	5
Fish	29	1	3
IEC	62	0,4	3
IRD	520	3,8	7

Source: author's elaboration.

TEI carried out most of their innovative projects (520 of 931 total) under SOP IRD. Public TEI realised 366 (70% out of 520 total) projects, while non-public TEI realised 154 (30%) projects. In total number, as many as 284 project were classified as organisational innovations, of which 123 were results of soft project implementing a wide range of novelties: strengthening cooperation with other institutions, knowledge transfer systems,

scholarhips for students, organising trainships, creating innovation networks, supporting innovation activities of students, etc., and 161 were effects of hard projects aimed at building new or modernising/ extending/ equipping already existing laboratories, research centres, digital libraries, ICT systems, music halls (Musical Academy), gallery (Academy of Arts), etc. The remaining 227 projects (44%) resulted in product innovations, very similar to those obtained under SOP DHR, those are: postgraduate studies, innovative research, trainings and vocational consultancy.

The share of TEI in total number (13597) of projects under SOP IRD equals 3.8%, and they absorbed 7% of total EU funding spent under this SOP. The biggest projects were carried out by public renowned TEI, e.g.: Politechnics of Gdansk (new building for the Faculty of Electrics and IT) 53 million PLN, University of Silesia (new building for the Faculty of Neophilology) 52 million PLN, Warsaw School of Economics (new building for teaching and research) 45.6 million PLN, Jagiellonian University in Cracow (Auditorium Maximum, second stage of construction) 45 million PLN.

Table 2: Classification of analysed projects according to Oslo Manual Criteria.

Under SO Programme	**Number of project carried out by tertiary education institutions:**		
	total	public	non-public
Development in Human Resources total	**317**	**127**	**190**
product innov.	317	127	190
Fish total	**29**	**29**	**0**
product innov.	25	25	0
marketing innov.	4	4	0
Increase in Enterprises' Competitiveness total	**62**	**61**	**1**
organisational innov.	9	9	0
product innov.	6	6	0
process innov.	47	46	1
Integrated Regional Development total	**520**	**366**	**154**
organisational innov.	123	112	11
product innov.	227	120	107
process innov.	161	131	30
other*	9	3	6
Total	**928**	**583**	**345**

*could not be classified due to insufficient description.
Source: author's elaboration.

The total value of analysed projects (see Table 3) equalled 2133721 thousand PLN, of which EU co-funding made 63% (1343719 thousand PLN). These values show considerable financial transfers over a relatively short, two-year time span, resulting in the increase of innovations at TEI, although it may be argued that the earlier analysed share of TEI in absorption of EU funds was rather insignificant: from barely 0.4% of total EU co-funding under SOP IEC up to 7% under SOP IRD.

Table 3: Financial effects of analysed projects.

Tertiary education institutions	Total value of projects *in thous. PLN*	Total EU funding *in thous. PLN*	*in %*
Non-public total	**383806**	**253829**	**66**
under SOP:			
DHR	198006	139132	70
Fish	0	0	0
IEC	366	270	74
IRD	185434	114427	62
Public total	**1749914**	**1089890**	**62**
under SOP:			
DHR	222689	154061	69
Fish	34539	25309	73
IEC	203553	135867	67
IRD	1289133	774653	60
All TEI total	**2133721**	**1343719**	**63**

Source: author's elaboration.

Still, the fact is that none of the past, analysed programmes or actions within were aimed at TEI as the only or main beneficiaries and innovations for education were not the main objective of any of them either.

That was also the first programming period, or rather a two-year part of it, when Poland could use EU funds. This required elaborating new procedures, carrying out evaluations (which in Poland were a new process itself), training both institutions implementing these programmes and prospect beneficiaries.

In these circumstances, the above presented results can be assessed as satisfactory.

SUPPORT FOR INNOVATIONS IN HIGHER EDUCATION IN POLAND OVER 2007-2013

The experience of the past programming period and still increasing urgency to support innovations in higher education in Poland resulted in elaborating and approving a special Sectoral Operational Programme Innovative Economy (IE) for 2007-2013.

The overall objective of SOP IE is to develop Polish economy based on innovative enterprises. This objective will be achieved through implementation of the following specific objectives:

i. Improvement of innovativeness of enterprises.
ii. Improvement of competitiveness of Polish science.
iii. Strengthening of the role of science in economic development.
iv. Increasing the share of innovative products of the Polish economy in the international market.
v. Creation of permanent and better workplaces.
vi. Growth of the use of information and communication technologies in the economy.

Scientific and research centres, including TEI, are listed as prospect beneficiaries of this programme, especially of Priority I 'Research and Development of Modern Technologies' and Priority II 'Infrastructure of R&D'. The Programme has been co-financed from resources of the European Union and the state budget. The allocation for the IE amounts in total to EUR 9,711,630 thousand including EUR 8,254,885 from the European Regional Development Fund.

This is the biggest so far implemented programme supporting innovation in all fields, including tertiary education and its institutions as beneficiaries. Although other on-going programmes support TEI in carrying out innovation projects as well. SOP Infrastructure and Environment offers support for TEI within Priority XIII titled 'Infrastructure of higher education'. Its objective is to develop modern universities and academies, especially those educating student in fields most desirable from the point of view of knowledge-based economy, i.e. mathematical, technical, natural and medical sciences.

Water Centre at Warsaw University of Life Sciences-SGGW – example of project under SOP Infrastructure and Environment 2007-2013

Scientific and Educational Centre of the Faculty of Civil and Environmental Engineering – so called "Water Centre" of the Warsaw University of Life Sciences is located at the main university campus in Warsaw, in Ursynow district, at the intersection of Nowoursynowska and Ciszewskiego Streets. The project takes the area of around 14600 m^2. It includes educational facility with the development area of 1954.8 m^2 and the total area of 5565.3 m^2, usable area of 4557.4 m^2 and cubage of 28167 m^3. In the building there are 19 laboratories equipped with the most modern scientific and research equipment. In Scientific and Educational Centre there are 19 laboratories: Water Monitoring Laboratory; Groundwater Flow Monitoring Laboratory; Water Quality Laboratory; Water Chemistry, Sewage Sediments, Soils and Plants Laboratory; Fluid Mechanics Laboratory; Sedimentation Laboratory, Irrigation and Drainage Laboratory; Laboratory of Water Ecosystems Ecology; Laboratory of Ecotechnology; Meteorological Data Control and Atmospheric Processes Modelling Laboratory; Physics of Porous Media Laboratory; Geoinformation Systems and Environmental Modelling Laboratory; Geoinformation and Geodesy Laboratory; Physical Properties of Soil and Rock Laboratory; Mechanical Characteristics of Soil and Rock Laboratory; Dynamics Characteristics of Soil and Rock Laboratory; Geosynthetics Testing Laboratory; Physical Processes in Construction Laboratory; Strength of Materials and Building Constructions Laboratory. They have 310 sets of modern scientific and research equipment and 51 computers together with specialist software and equipment.

In the building of the Scientific and Educational Centre, next to the laboratory rooms, there are exhibition rooms which present and popularise research fields of the modern water and sanitary engineering. The permanent and periodic exhibition is intended for secondary school students and visitors to Warsaw University of Life Sciences. Drinkable water source with artesian water from the Oligocene (Tertiary) and Pleistocene (Quaternary) water deposits as well as from urban waterworks (from surface water intakes) are one of the most distinguishing elements. They also enable conducting selected water quality research.

The educational establishment called Water Park is situated in the area surrounding Scientific and Educational Centre. It is a model of a watercourse connected with trophic reservoirs, with its outlet in the ultimate water reservoir. The whole water system represents water circulation in the environment. The system is divided into two parts; one which represents a mountain catchment basin and the other which represents lowland river catchment basin. The water system is fitted with models of hydrotechnical buildings, situated along the river course and on reservoirs (trap, tower spillway, weirs). The models present sample construction solutions for the hydrotechnical building industry and make it possible for the students and PhD researchers to acquaint themselves with modelling systems of hydraulic and hydrobiological conditions. In the reservoir, there is a dock ending with a glass wall and lighting, which allows to descend into the water reservoir and observe the development of the coastal area of the water region. Water in the system of Water Park flows in a closed circuit thanks to the system of pumps feeding water from the ultimate reservoir to the initial station - a ground object built in gabion and landmass construction. The quality of water is maintained mainly through a natural reed bed treatment plant which is a part of the water system.

The mentioned structure is the only in the country. It will be used in the educational process, to transfer general knowledge, to illustrate water circulation in nature and to teach principles of designing and carrying out hydrotechnical undertakings. A meteorological station will be situated in the surroundings of the Centre. It will monitor the quality of atmospheric air and selected meteorological parameters measured on multiple levels. The station will operate within the air monitoring network of the Voivodship Inspectorate for Environment Protection. Both the building and Water Park have been equipped with amenities meeting the educational and work needs of the disabled.

The main aim of the project is to improve the quality of education and research at the Faculty and to support economy through the transfer of knowledge, which necessary for creating knowledge-based society.

It is assumed that the project will result in increase in the number of students and PhD researchers, consequently in the number of researchers, scientists and specialists whose professions based on modern technologies and engineering are most crucial for economic development of the country.

Total cost of the project 52.7 million PLN, of which 41.95 million PLN of EU funds (79.6% of total cost).

The project began in 2008 and was completed in 2010.

CONCLUSIONS

The above presented findings based on analysis of innovative projects carried out by Polish TEI over 2004-2006(2009) programming period and outlines of support available under SOPs 2007-2013 confirm the important role that EU funding granted under selected operational programmes plays in supporting higher education in Poland.

The first programming period resulted in 928 projects carried out by TEI under four SOP which did not aim particularly at supporting such units. In this context the effects may be assessed as satisfactory. However analysis of the list of beneficiaries indicates that the biggest projects were realised by the biggest, best-known TEI who are situated in the largest cities of Poland. These TEI also appeared to be the most active in carrying out projects co-financed by EU, some of them carried out as many as 23 projects (e.g. Warsaw University) over one brief programming period of 2004-2006. Thus the allocation of funds among smaller TEI, especially those operating in areas distant from big cities, seems insufficient to support them in implementing innovations. The main problem of smaller TEI when applying for EU funds is the necessity to cover a part of costs of the project by the beneficiary. Thus, in the situation of shortage or lack of their own funds they realise either relatively smaller projects or none.

TEI realised a wide range of different projects, both those enhancing their educational and scientific facilities and infrastructure and those extending educational offer and research.

The new programming period 2007-2013 offers a new instrument – SOP IE - targeted in whole at improving and increasing innovativeness of Polish economy and tertiary education institutions meant as innovation engines paying a double role of creating innovations through research and creating innovative human capital through education process. Together with other SOPs, namely Infrastructure and Environment and Human Capital, they make so far optimal tools to achieve targets set up in EU and Polish policies and strategies promoting knowledge triangle.

ABSTRACT

This paper aims to demonstrate the Thailand Higher Education Classification Model (THEC-Model) based on research performance, and to compare the results of it with the university classification by the Office of the Higher Education Commission(OHEC) whereby universities can be classified as National Research Universities (NRUs).The classification, conducted by using empirical data and a statistical approach, was initiated to develop the THEC-model as a multi-dimensional classification and to link the classifications to rankings. The results of the hypothesis test showed that the criteria in four classification dimensions included; (1) Research funding, (2) Instructional programmes and curriculums, (3) Instructors and research staff body, (4) Student body. These criteria have influenced the research performance in three dimensions; (1) research output (2) citations, and (3) research awards. It was found that six universities were classified as NRUs, and this result is consistent with the classification by OHEC. The findings provide important information, for example, classification criteria, outstanding and disadvantageous criteria would enable the policy-makers to manage higher education effectively to elevate universities to become word-class, and increase competitiveness.

Keywords: Higher Education Classification; National Research University; Performance Indicators; Management in Education; Thailand University; global competitiveness

INTRODUCTION

Schwab (2009) stated that two fundamental factors are crucial to enhance long-term competitiveness and sustainable development. One is 'higher education and training' which is important to propel efficiency-driven economics. Another is 'innovation' which is necessary to drive the economy progressively. This is consistent with Schultz (1961); Lucas (1988);Becker (1993); Hedin *et al.*, (2005); Burke *et al.,*(2009); and Ramoniene and Lanskoronskis (2011) who stated that 'higher education and training'is vital to any country because firstly, it increases the value chain beyond simple production processes and products; secondly, it produces well-trained workers who are adaptable in changing environments; and lastly, it produces a healthy workforce which has the potential to improve national productivity and competitiveness. In addition, Romer (1990); Grossman and Helpman (1991); and Aghion and Howitt (1992) stated that the standard of living in the long run can be improved by innovation. Ramoniene and Lanskoronskis (2011) added that innovation could result from the higher education system. Similarly, innovation may not occur without high quality scientific research institutions, a highly

skilled workforce including scientists and engineers, and sufficient research and development (R&D) investment.

The situation mentioned above has led many countries and governments to recognize and drive 'research universities' as essential for improving competitiveness and bringing forth sustainability in countries (Liu and Cheng, 2005; and Deem *et al.*, 2008). Furthermore, Lee *et al.,* (2007) stated that organizational flexibility, long-term enterprise development, and a country's competitiveness depend primarily on graduates and university education. Consistent with the Commission on Higher Education or (CHE) under the Ministry of Education in Thailand[1], the Scopus International Database indicated that between 2004 and 2008 over 90% of research stemmed from universities, indicating that the university is the largest source of research and researchers in a country.

However, in Thailand, there are almost 200 public and private accredited universities. The number of universities has doubled over the past decade.This has resulted in greater diversity and more complexity in the higher education system. Four major factors[2] have impacted the higher education system, including (1) politics, for example, decentralization and local administration, (2) economics, for example, autonomous universities, and globalization, (3) society and demography, for example, a reduction in population, life-long learning, social networking, retirement, and lastly (4) technology, for example, e-learning. As a result, the question how to classify and evaluate the university as a "research university" is raised. Several researchers, for example, Amano and Chen (2004); McCormick and Zhao (2005); Liu and Liu (2005); Phusavat and Chansa-ngaveg (2007); Phusavat (2008); Bartelse and van Vught (2009); and Shin (2009), reported that higher education classification has become a crucial strategy to deal with diversity in the higher education system because it allows us to understand the nature and characteristics of HEIs under the same criteria and parameters. At the same time, a ranking system allows a HEI to reflect on estimated quality and recognition, especially in the research dimension.

Under the crucial role of the higher education system that has influenced competitiveness, the research question is how the HEIs should be classified on a research basis to improve research competency, which is fundamental to enhance global competitiveness. To answer the research question, this paper primarily aims to develop the THEC-Model based on research dimensions that are useful for classifying the research university.

BACKGROUND

This section describes the following three areas of the background. Firstly, HEI classification is analyzed in terms of the criteria and parameters used to classify the research university. Secondly, HEI ranking is employed to analyze the criteria and parameters used to evaluate the research dimension, and lastly, the NRU classification is used to compare the outcomes of the developed THEC- Model and the NRU classification by OHEC. The detail is shown below:

Higher education classification

According to Bailey (1994), classification is an organizing or grouping process where the same properties are grouped together. The Carnegie Foundation for the Advancement of Teaching (CFAT)[3]stated that HEI classification in educational terms is employed to recognize the similarities and differences for individual institutions under the required criteria and parameters. This is consistent with McCormick (2008) who stated that classification is more likely to identify the similarities and differences of HEIs than the ranking of HEIs.The result is that classification fails to reflect university quality and recognition, and only identifies the nature and characteristics of the university (Phusavat and Chansa-ngavej, 2007). HEI classification has been popular worldwide, particularly in the U.S.A. where CFAT has been in practice for over three decades. Subsequently, it has been used as a basic framework for HEI classification in many countries, for example, the Chinese HEIs by Liu and Liu (2005), the European HEIs by Bartelse and van Vught (2009), and Thailand's HEIs by Phusavat (2008). The detail of higher education classification is as follows:

The US Higher education classification system by CFAT

The US higher education classification system by CFAT[4] was initiated in 1973, and there have been many revisions since in 1976, 1976, 1994, 2000, 2005, and most recently in 2010, so that it could be employed consistently with changing situations and the greater complexity and diversity of U.S.A.'s HEIs. Changes have occurred in the labels used, definitions, and technical parts. However, the core HEI classification remains the same, based on the research and teaching objectives, the degrees offered, the number of comprehensive programs and size.

Research-based HEI classification demonstrated that all of the versions of the US higher education classification system focus on the research dimension. In the1976 version, the dimension based on research was categorized into C1 under the name "C1: Doctoral-Granting Institutions", and was subdivided into four subcategories (SC) including SC1: Research Universities I (implying that 50 or more doctoral degrees awarded and received annually $40 million or more in federal support.), SC2: Research Universities II (implying that 50 or more doctoral degrees awarded and received between $15 million and $40 million per year.), SC3: Doctoral-Granting Universities I (implying that at least 40 doctoral degrees annually awarded in five or more disciplines.); and SC4: Doctoral-Granting Universities II(implying that at least ten doctoral degrees awarded in three or more disciplines or 20 or more doctorates per year total). In the 1994 version, four subcategories were re-categorized into four major categories which highlighted the research dimension. The 2000 version, which also focused on the research dimension, was divided into two categories; C1: Doctoral/Research Universities Extensive (implying that 50 or more doctoral degrees per year awarded across at least 15 disciplines) andC2: Doctoral/Research Universities Intensive (implying that at least 10 doctoral degrees per year awarded across three or more disciplines, or at least 20 doctoral degrees per year overall).

A significant comprehensive overhaul[5] was the result of the 2005 version of the US higher education classification, namely, single classification was replaced by multiple classifications.

The previous single classification was updated and renamed “Basic Classification” which became a set of multiple classifications in the 2005 version. Not only the research dimension, but also a multi-measure research index was established. The research-focused area was categorized into C2 (Doctorate-Granting Universities) in ‘Basic Classification’, implying at least 20 research doctoral degrees awarded during the update year. In addition, C2 was subdivided into 3 subcategories (SC) including SC1: Very High Research Universities (RU/VH), SC2: High Research Universities (RU/H), and SC3: Doctoral/Research Universities (DRU). Research activity-based subcategories involved research & development (R&D) expenditure in science and engineering (S&E); R&D expenditure in non S&E fields; S&E research staff; doctoral conferrals in humanities fields, in social science fields, in STEM (science, technology, engineering, and mathematics) fields, and others (e.g., business, education, public policy, social work). Moreover, like the 2005 version, the 2010 version values the research dimension, and also gives significance to educational management under the ‘Community Engagement Classification’.

The Chinese higher education classification system

Liu (2007) and Ma (2004) stated that the HEI classification in China was of interest to the government, HEIs, and the academic community. The Chinese HEI classification was based on work by Shanghai Jiao Tong University (SJTU)[6] and by Liu and Liu (2005), both placing significance on the research dimension. The former is based on student profile, consisting of two categories; C1: universities with an engineering or technology orientation (implying that over one-third of all graduate students enrolled in engineering fields) and C2: universities with a medical orientation (implying that over one-third of all graduate students enrolled in medical fields) while the later, which is also based on the research dimension, was categorized into C1, which consisted of the following two subcategories; SC1: Research Universities I, and SC2: Research Universities II , where the criteria are the following; (1) Number of doctoral degrees in excess of 193. (2) Ratio between doctoral and baccalaureate degrees more than 0.09 for SC1 and between 0.06 and 0.09 for SC2 (3); the amount of government research funding over 44 million Yuan., and (4) the number of SCIE and SSCI articles per capita (at least 0.7).

European higher education classification system

Bartelse and van Vught (2009) stated that the establishment of the European higher education classification was to satisfy the five following stakeholders: students, HEIs, businesses and industries, policymakers, and researchers. It consisted of four phases: Phase 1 to develop the conceptual model and set dimensions and indicators; Phase 2 to test the classification model developed following phase 1; and Phase 3 and 4 to conduct analysis and fine-tuning which was in-process during phase 1 and was taken into consideration in this paper. Bartelse and van Vught (2009) grouped the HEIs into five categories and 14 dimensions. The research-focused group was categorized into C2: Research and Innovation, consisted of 2 dimensions with measurement criteria for each dimension as follows: D5: Research intensiveness has two criteria:(1) Number of peer reviewed publications per FTE academic staff and (2) The ISI based citation indicator, normalized per field, also known as the “crown indicator”. D6: Innovation intensiveness has four criteria: (1) Number of start-up firms, (2) Number of patent applications

filed, (3) Annual licensing income, and (4) Revenues from privately funded research contracts as a percentage of total research revenues.

Thailand's higher education classification

In 2006, the HEI classification was applied to Thailand HEIs by the Office for National Education Standards and Quality Assessment (ONESQA)[7], aiming to evaluate external quality assurance at the second round between 2006 and 2010 to see whether and how much HEI operation was executed consistently with the mission. Consequently, the HEI operations were carried out in accordance with the core HEI mission and were divided into four categories:(1) university focusing on graduate production and research, (2) university focusing on graduate production and social development, (3) university focusing on graduate production and art and cultural development, and (4) university focusing on graduate production only.

In 2008, the Ministry of Education divided the HEIs into four categories; including C1:community college, C2: baccalaureate colleges, C3: specialized institutions which consisted of two sub categories (SC) as follows: SC1 universities focusing on graduate degrees , and SC2 universities focusing on undergraduate degrees , and lastly C4: advanced research universities, and doctoral universities, resulting in the ONESQA changing higher educational classification in the light of the external quality assessment for the third round (2011-2015) in accordance with the Ministry of Education's announcement. However, C1 added two subcategories, including SC1 graduate production and research-based university, and SC2 graduate production and social development-based university.

The outcomes of HEI revision by the ONESQA showed that all versions of HEI classification have focused on the research dimension, but no specific criteria have been defined, just the broad scope is provided so that each institute can choose the HEI classification in accordance with its philosophy, goal, and mission. One more important issue is that HEI classification by ONESQA has followed the Framework of the Second 15-Year Long Range Plan on Higher Education in Thailand)[8](2008-2023), ONESQA's classification of research university and graduate university have been outlined with the following scope, (1) it focuses on research-based postgraduate programs, doctorate programs and post-doctorate programs, (2) it is located in the capital and cities, (3) 100% doctorate professionals (4) Science and Technology students and Social Sciences students ratio (90:10). This kind of university has a mission and role on national competitiveness; the graduates are expected to be global prime movers and cognitive leaders.

Higher education ranking system

Phusavat and Chansa-ngavej (2007) and Salmi and Saroyan (2007) stated that a ranking system was used to rank higher education institutions. The ranking reflected the quality and recognition of the HEIs, especially in the research activity dimension. These studies analyzed the common criteria that have been used in the international ranking system: SJTU[9]and Times Higher Education QS World Universities Ranking (THE-QS)[10], and quality assurance system for

higher education. Common criteria were found which comprise three parts; (1) publications in science-oriented indices, science and nature, social science oriented indices, and other indices, (2) citations include bibliometrics (counting publications and citations), highly cited publications, citations in engineering publications, citations in social science oriented indices , and research citation per head of academic faculty (3) research award, prestige, and patents issued including national research awards, international research awards, number of patents issued, alumni of institution winning Nobel prizes and fields medals, academics peer review, and employer reputation. The results are consistent with Bowden (2000); Dill and Soo (2004); van Dyke (2005); and Williams and van Dyke (2005).

NRU Classification by the OHEC

In 2009, the Royal Thai government (RTC) had an urgent policy urging that the OHEC develop the NRUs objectively, moving university development toward 'world-class universities', and public service universities which play important roles in problem-solving in the social and manufacturing sectors. Such a policy is consistent with the Framework of the Second 15-Year Long Rang Plan on Higher Education of Thailand) (2008-2023) formulated in 2008 by the OHEC[11]. Under this framework, the university is divided into four categories. The research dimension is assigned into C4: Research University and Graduate University.

The NRU eligibility criteria[12] consist of the following: firstly, it must be one of the top 500 universities ranked by THE-QS in 2008, whose ranking criteria are based on four pillars: (1) research quality, (2) teaching quality, (3) student employability, and (4) international outlook. Research quality was measured by two indicators: an academic "peer review", and the number of research citations per head of academic faculty. Teaching quality was measured in terms of student-teacher ratio. Student employability and the international outlook were measured by two indicators, international teacher and researcher ratio, and the proportion of international students. To qualify, a university has to have demonstrated any of following work results, (1) Scopus articles of no less than 500 publications in the last five years (2004-2008), (2) distinctly international researches at least 2 of 5 THE-QS fields; Arts & Humanities, Social Sciences, Technology, Life Sciences & Biomedicine, Natural Sciences; , and (3) more than 40% of overall instructors are doctorate professionals. Secondly, there must be a clear direction and uniqueness of a NRU, and lastly, there must be quality, accuracy, and modernity in the university.

NRUs selection criteria[13] shall be based on a development plan, an operational plan, and a budget plan to move a university (1) to become 1 of 400 universities that has never been ranked before, or to improve the ranking to be among the previous 400 universities for an overall rank and field rank, (2) to establish a national and international research center that is linked to industry, or is consistent with the national strategy, (3) to hold an international conference in expertise fields, increasing the number of students and foreign instructors, and the availability of international programs.

Many people of various backgrounds such as administrators, staff, and research fellows of HEIs have a strong interest in this project and hope that their own institution will be selected as a NRU. There are nine universities classified as NRUs. They include Chulalongkorn, Kasetsart, Mahidol, Khon Kaen, Chiang Mai, Thammasat, Suranaree University of Technology, King Mongkut's University of Technology Thonburi, and Prince of Songkla University. However, academics, researchers, students, and many people in various occupations discuss and criticize the method, criteria, and the results for selecting NRUs and the role of NRUs.

METHODOLOGY

To achieve the research objectives, processes have been set which are divided into three phases (see Figure1).

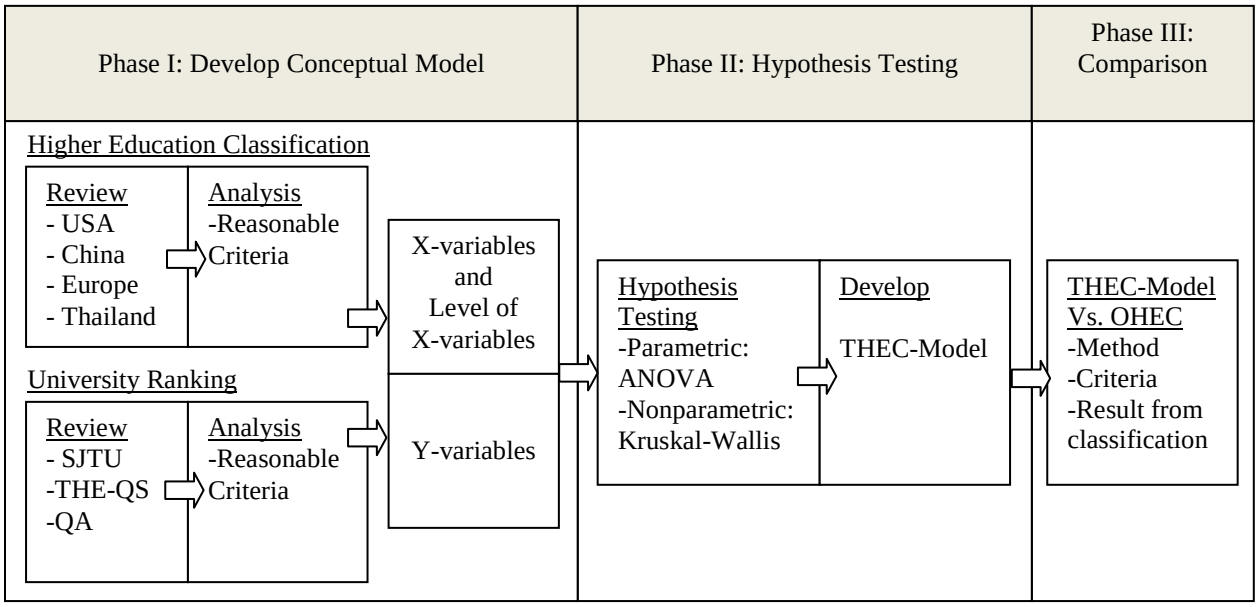

Figure 1: The Three phases of the methodology framework.

Phase 1: develop conceptual model

The methodology consisted of the following three steps. The first step is to review the classifications in such locations as the US, China, Europe, and Thailand to analyze the dimensions, criteria, and specific conditions of categories as input or 'X-variables' which would be used to perform the hypothesis test at Phase 2. The second step is to review the international rankings: SJTU and THE-QS educational quality assurance criteria to identify the evaluation criteria for research dimension as output or'Y-variables' to further perform the hypothesis test at phase 2. The third step defines 'X-variables', level of 'X-variables' and 'Y-variables' that are appropriate for Thailand's higher education context.

Phase 2: hypothesis testing

Phase 2 consisted of the two following steps. The first step was to conduct a hypothesis test to analyze whether or not the 'X-variables' have significant impact on 'Y-variables'. That is to say, the hypothesis test was designed to see which criteria could be applied to classify higher education significantly. A total of 50 independent samples were used, consisting of twenty-three public universities, and twenty-seven private universities, to test the hypothesis where the database was derived from the OHEC and ONESQA (June 1, 2009- May 31, 2010). The detailed hypothesis test consisted of the three following steps; (1) to test the relationship among Y-variables; Y_1, Y_2, and Y_3 by using 'Pearson's correlation coefficient. (2) to test the assumptions for 'Parametric', including two tests 'Normality Test' to determine if y-values for each population have a normal distribution. The 'Shapiro-Wilk'was employed to test the assumption under null hypothesis or H_0: the population is normal and the alternative hypothesis or H_a: the population is non-normal (see detail in, D' Agostino and Stephens, 1986 and Shapiro and Francia, 1972). Another kind of hypothesis test that was used was 'Homogeneity of Variance' to determine if y-values for each population have equal variances. The 'Levene's tests' was used to perform the hypothesis test under H_0: equal variances versus H_a: not all variances being equal. (3) 'Parametric' or 'Nonparametric' statistics were used for the hypothesis test. For this step, the assumption results for 'Parametric' were as follows; if H_0 was accepted for two tests, the 'Parametric' would be used through 'Analysis of Variance or ANOVA' under H_0: all population is equal, and H_a: at least one is different from the others (see detail in Johnson and Wichern, 2008). On the contrary, if H_0 was rejected only one test, the'Nonparametric'would be used through 'Kruskal-Wallis' under H_0: all of the population medians are equal and H_a: at least one of the medians is different from the others (see detail in Gibbons, 1976).The second step was to develop the THEC-Model; the results of 'ANOVA' or 'Kruskal-Wallis' in the case of rejecting H_0 at alpha.05 would be used to develop the THEC-Model.

Phase 3: comparison the classification results

Phase three compares the classification results for NRUs by using the THEC-Model and OHEC in the year 2009 based on the viewpoint of method, criteria, and classification results particularly in the category of 'Research-Intensive Universities'.

RESULTS

This section represents the results for each respective phase with the following detail:

Phase 1: develop conceptual model

The outcome of the review and analysis of the higher education classification showed six dimensions as follows: D1 Research funding, D2 Instructional programmes and curriculums, D3 Instructors and research staff body, D4 Student body, D5 Size, Location, and campuses, and D6 University-industry collaboration in research. The criteria of each dimension/X- variable and the specific conditions of categories/levels of X- variables were selected for Thailand HEI classification. In addition, the review of the international ranking SJTU and THE-QS, and criteria for higher education quality assurance based on the context of research activity evaluation as outputs or Y-variables found that the following three dimensions were common to assessments; D1research output, D2 citations, D3 research awards. A Y-variable in each dimension was selected for Thailand's HEI evaluation based on the research dimensions as follows:'Y_1' refers to the percentage of research and innovations published or registered as intellectual property or patented or utilized at the national or international level in proportion to the number of full-time faculty, 'Y_2' refers to the percentage of research articles cited in the refereed journals or national or international databases in proportion to the number of full-time faculties, and Y_3 refers to the percentage of full-time faculties who have received academic or professional awards at the national and international level, in D1, D2, and D3 respectively (see the Table 1).

Table1: The X-variables and the Y-variables to test the hypothesis.

Dimensions (D)	Criteria or X-variables	Specific Conditions of Categories (C) or levels of X-variables	No. of Hypo.		
			Y_1	Y_2	Y_3
D1 Research funding	X_1 The amount of internal and external grants for research and innovations in proportion to the number of full-time faculty (FTF)	C1 ≤ 80,000 Baht C2 80,000-180,000 Baht C3 ≥ 180,000 Baht	H1	H21	H41
D2 Instructional programmes and curriculums	X_2 Medical programmes	C1 Universities have no medical programme C2 Universities have medical programme	H2	H22	H42
	X_3 Engineering programmes	C1 Universities have not engineering programme C2 Universities have engineering programme	H3	H23	H43
	X_4 The percentage of graduate programmes in proportion to total programmes	C1 ≤ 30% C2 30-50% C3 ≥ 50%	H4	H24	H44
	X_5 The percentage of doctoral programmes in proportion to total programmes	C1 ≤ 10% C2 10-15% C3 ≥ 15%	H5	H25	H45
	X_6 The percentage of doctoral programmes in proportion to bachelor programmes	C1 ≤ 30% C2 30-50% C3 ≥ 50%	H6	H26	H46
D3 Instructors and research staff body	X_7 Number of FTFs and research staff	C1 ≤ 400 people C2 400-1,000 people C3 ≥ 1,000 people	H7	H27	H47
	X_8 Number of FTFs who are qualified as thesis advisors	C1 ≤ 200 people C2 200-500 people C3 ≥ 500people	H8	H28	H48
	X_9 The proportion of the number of faculty members holding bachelor, master and doctoral degrees or equivalent to the number of FTF	C1 (1) doctoral degrees 1-29% or (2) doctoral degrees 30-49% but bachelor degrees >5% C2 (1) doctoral degrees 30-49% and bachelor degrees < 5% or (2) doctoral degrees ≥ 50% and bachelor degrees >10% C3 (1) doctoral degrees ≥ 50% and bachelor degrees ≤ 5%	H9	H29	H49
	X_{10} The proportion of the number of faculty members holding doctoral degrees or equivalent to the number of FTF	C1 ≤ 30% C2 30-50% C3 ≥ 50%	H10	H30	H50
	X_{11} The proportion of the number of faculty members holding the position of instructor, assistant professor, associate professor, and professor to the number of FTF	C1 (1) A combination of Asst Prof., Assoc Prof., and Prof. 1-29% or (2) A combination of Asst Prof., Assoc Prof., and Prof. 30-49% but Assoc Prof. combine with Prof. <30% C2 (1)A combination of Asst Prof., Assoc Prof., and Prof. 30-49% and (2) Assoc Prof. combined with Prof. >20% or (1) A combination of Asst Prof., Assoc Prof., and Prof. ≥ 50% and (2) Assoc Prof. combined with Prof. <20% C3 A combination of Asst Prof., Assoc Prof., and Prof. ≥ 50% and (2) Assoc Prof. combined with Prof. ≥ 20%	H11	H31	H51
	X_{12} The proportion of the number of faculty members holding the position of associate professor and professor to the number of FTF	C1 ≤ 5% C2 5-15% C3 ≥ 15%	H12	H32	H52
	X_{13} The number of faculty members holding the position of professor	C1 ≤ 10 instructors C2 10-20 instructors C3 ≥ 20 instructors	H13	H33	H53
	X_{14} The percentage of FTFs who actually function as thesis advisors in proportion to the number of those who are qualified	C1 ≤ 70% C2 70-80% C3 ≥ 80%	H14	H34	H54
D4 Student body	X_{15} Number of full-time equivalent students or FTES.	C1 ≤ 10,000 students C2 10,000-20,000 students C3 ≥ 20,000 students	H15	H35	H55

	X_{16} The percentage of graduate students in proportion to the number of total students	**C1 ≤ 10% C2 10-20% C3 ≥ 20%**	**H16**	**H36**	**H56**

Table1: Cont.

Dimensions (D)	Criteria or X-variables	Specific Conditions of Categories (C) or levels of X-variables	No. of Hypo.		
			Y_1	Y_2	Y_3
D5 Size, Location, and campuses	**X_{17} The proportion of the number of full-time equivalent students to the number of full-time faculties and research staff.**	**C1 ≤ 20 C2 20-25 C3 ≥ 25**	**H17**	**H37**	**H57**
	X_{18} Location and campuses	**C1 City location/one campus C2 Suburban or rural location/one campus C3 City location/multiple campus C4 Suburban or rural location/ multiple campus**	**H18**	**H38**	**H58**
D6 University-industry collaboration in research	**X_{19} The percentage of FTF who are involved in providing academic services as consultants, thesis committee members outside the institution, academic or professional committees at the national or international level in proportion to the number of FTF.**	**C1 ≤ 40% C2 40-60% C3 ≥ 60%**	**H19**	**H39**	**H59**
	X_{20} The percentage of academic and professional service activities/projects responding to the needs for development and strengthening the society, community, nation and the international community in proportion to the number of FTF.	**C1 ≤ 40% C2 40-60% C3 ≥ 60%**	**H20**	**H40**	**H60**

Phase 2: hypothesis testing

To be consistent with the methodology, this section presents the results of phase 2 with an explanation which consists of the following two steps. The first step shows results from a hypothesis test where the detail consists of the three following steps; (1) The results of the relationship test for Y variables. (2) The results of parametric assumption tests and (3) The results of 'ANOVA' or 'Kruskal-Wallis' test. The second step show results from developing the THEC-model. The detail is shown below:

The results from the first step: test hypothesis

(1) The results from the relationship test

A relationship test for each pair of Y variables, $Y_1 - Y_2$, $Y_1 - Y_3$, and $Y_2 - Y_3$ was performed using Pearson's correlation coefficient, the results indicate r_{12}=.607, p-value = .001, r_{13}=.446, p-value = .002, and r_{23}= .655, p-value=.001, respectively. Because all p-values were smaller than .01, it is evident that the correlation was not zero for alpha.01. However, to determine what the extent of the relations for each pair of Y variables was by means of the percentage of the variance accounted for R^2, it indicated R^2 = 36.84 for r_{12}, representing the relationship by 36.84% (account for 36.84%), r_{13}, R^2 = 19.89, representing the relationship by 19.89%, (account for only 19.89%), and r_{23}, R^2 = 42.90, representing the relationship by 42.90%. In this paper, the hypothesis test selected the independent Y variables Y_1, Y_2andY_3 for analysis. The result was that the hypothesis test for X variables (X-variables; X_1-X_{20}) and Y-variables (Y_1, Y_2,andY_3) was

independent, respectively. A total of 60 hypotheses included H_1-$H_{20}$for eachX variable (X-variables; X_1-X_{20})and Y_1, H_{21}-H_{40} for eachX variable (X-variables; X_1-X_{20}) and Y_2, and H_{41}-H_{60} foreachX variable(X-variables; X_1-X_{20}) andY_3(see Table 1).

(2) The results form test assumption of 'Parametric'

The test assumptions for 'parametric' were performed to test 'Normality' with the 'Shapiro-Wilk Test', and test 'Homogeneity of Variance' by using Levene's test. It was found that only 3 of 60 hypotheses could apply the 'parametric' conditions including, H14 (hypothesis test betweenX_{14} andY_1), H37 (hypothesis test betweenX_{17} and Y_2), and H54 (hypothesis test betweenX_{14} andY_3) while the other remaining hypothesis applied the 'Nonparametric' for further analysis in the third step.

(3) The results from 'ANOVA' or 'Kruskal-Wallis' test

The 'ANOVA' or 'Kruskal-Wallis' test was employed to determine which hypothesis has differences between the categories or level of each X-variable and has significantly statistically influenced the differences in each Y-variable at alpha.05 (see Table 2).

The results showed that (1) the H1-H20 for each X variable (X-variables; X_1-X_{20}) and Y_1 showed that 7 of 20 hypotheses; H1, H6, H9, H10, H12, H16 , and H20, or 5 dimensions and 7 X-variables (D1 consisted ofX_1, D2 consisted of X_6, D3 consisted of X_9, X_{10}, X_{12}, D4 consisted of X_{16}, and D6 consisted of X_{20}) where H_0 was rejected because these hypotheses provided a p-value <.05, it was interpreted that the level or categories of these variables resulted in the differences in Y_1 variables. In respect of H21-H40, the test between X-variables; (X_{21}-X_{40}) and Y_2 indicated 8 of 20 hypotheses, including H21, H24, H25, H26, H29, H30, H32 ,and H36, or 4 dimensions with 8 X-variables (D1 consisted ofX_1, D2 consisted ofX_4, X_5, and X_6, D3 consisted ofX_9, X_{10}, X_{12}, and D4 consisted ofX_{16}, where $H_0$was rejected because these hypotheses provided a p-value <.05, it was interpreted that the level or categories of these variables resulted in the differences in Y_2 variables. In respect of H41-H60, the test between X-variables; X_{41}-X_{60}) and Y_3 indicated 18 of 20 hypotheses, where H_0 was rejected because these hypotheses provided p-value <.05, it was interpreted that the level or categories of these variables resulted in the differences in Y_3 variables.

In the step H1, for example D1 Research funding consisted of X_1 where X_1 referred to the amount of internal and external grants for research and innovations in proportion to the number of FTF, consisted of three categories (C1 ≤ 80,000 Baht, C2 80,000-180,000 Baht, and C3 ≥ 180,000 Baht) (see data in Table 1). With 'Kruskal-Wallis', the hypothesis results showed p-value =.014 where H_0 was rejected at alpha.05, indicating that the level or categories of X_1 variable resulted in the differences in Y_1 variable (see data in Table 2). Other hypotheses could be explained in the same way.

The results from the second step: Develop the THEC-Model

To classify the HEIs as 'research universities', the last category for each X variable (in Table 1) was applied. For example, X_1 consisted of C1, C2 and C3 respectively, and then C3 was taken into consideration for classifying 'research universities'. This paper demonstrates both 'single dimensions' and 'multiple-dimensions' for research university classification. This was to allow diversification under the interesting criteria at statistical significance at alpha .05. In the case of a 'single dimension', each dimension was taken into consideration for each hypothesis. For example, for D1 in H1, a different classification was found under X_1 criteria which resulted in differences in Y_1criteria. When the results of these 'single dimensions' were taken into consideration, there were 11 research universities classified as follows: Chulalongkorn, Kasetsart, Khon Kaen, Chiang Mai, King Mongkut's University of Technology Thonburi, Suranaree University of Technology, Thammasat, Mahidol, Prince of Songkla University, King Mongkut's Institute of Technology North Bangkok, National Institute of Development Administration (see detail in Figure 2).

Table2: The results from hypothesis testing in the case of reject null hypothesis.

Figure 2: The results of research university classification by THEC-model.

Note. 1 NIDA has only graduate students, so criteria of X_6 in D2 were not taken in consideration.

On the other hand, if 'multi-dimensions' (two or more dimensions) were taken into consideration, for example, a combination for dimension 1 in H1 (test between level or categories of X_1 and criteria of Y_1), along with dimension 4 in H16 (test between level or categories of X_{16} andY_1criteria) as shown in Figure 2, indicating that 'multi-dimension' for such pairs under combined criteria, it would include six research universities, including Chulalongkorn University, Kasetsart, Chiang Mai, King Mongkut's University of Technology Thonburi, Mahidol, and National Institute of Development Administration. Similarly, research university classification could be possible under the combination of other dimensions.

However, regarding the THEC- model development for classifying the research-intensive universities to produce potential personnel in different disciplines that meet the needs of the community, industry, and innovation development, leading to competitiveness for NRUs, this paper presented the development of the THEC-model based on 'multiple-dimensions', employing a combination of criteria for each X variable that has influenced the differences in all Y-variables, namely Y_1, Y_2, and Y_3. Such combinations showed that with 5 X-variables in 4 dimensions, namely; X_1 inD1, X_6 in D2, X_9, X_{10}, andX_{12} inD3 and X_6 inD4, there were a total 6 universities classified as research-intensive universities including Chulalongkorn, Kasetsart, Chiang Mai, King Mongkut's University of Technology Thonburi, Mahidol, and National Institute of Development Administration (see Table 3). The results were then compared to the NRUs classification by OHEC in phase 3.

Phase 3: comparison the classification results

This section presented the results of comparison for classification between the developed THEC-model and OHEC-based NRU classification. The comparison was made in three areas; method used, criteria used, and national research universities (NRUs) as described in Table 4.

DISCUSSION

The THEC-model, which is based on research dimensions, was developed to classify the research universities and NRUs in Thailand. The HEI classification conducted by using empirical data and a statistical approach was initiated to develop the THEC-model as a multi-dimensional classification and linked the classifications to rankings. Phusavat (2008) stated that Thailand's higher education system has been growing rapidly while the HEI classification in previous versions was based on a single dimension, and connects with quality assurance insufficiently and ineffectively. This is consistent with McCormick (2007) who added that in 2005 the HEI classification by CFAT changed from a single classification to multiple classifications.

Thailand's HEI classification has been of interest since 2006 when ONESQA classified the HEIs to evaluate external quality (2006-2010). However, each institution was allowed to choose the categories in a way that was consistent with its own goal, philosophy, and mission. Thus, to classify HEIs by using the THEC-model provides HEI administrators and policymakers with important and useful information to compare the classification results with the institution-

selected classification, and to analyze the strengths and weaknesses of the developed HEIs, and to benchmark with other HEIs in the group.

Table 3: The results of national research university classification by THEC-model.

The outcome of NRU-focused HEI classification by using the THEC-model appeared to be similar to that of the OHEC classification. It included the following five universities - Chulalongkorn, Kasetsart, Mahidol, Chiang Mai, and King Mongkut's University. Only one, the National Institute of Development Administration, was classified as "NRU" by the THEC-model, but it was not classified as "NRU" by OHEC. Furthermore, four institutions were not classified as "NRU" by the THEC-model, but they were classified as "NRU" by OHEC, they included Khon Kaen, Thammasat, Suranaree University of Technology, and Prince of Songkla University.

Table 4: Comparison of the developed THEC-model and the OHEC-based NRU classification.

Issues	Classify NRUs by THEC-model	ClassifyNRUsby OHEC
Method	The THEC-model used statistical principles with a hypothesis test to determine which levels of X-variables have significantly statistically influenced the differences in Y-variables. It was constructed in multi-dimensions. It linked the classification with ranking and educational quality assurance.	NRUs classification[14] by OHEC selected the HEIs with requirement; namely being ranked as Top 500 of THE-QS Ranking. On contrary, it was out of the Top 500 of THE-QS Ranking, it's required to demonstrate the research publications for at least 500 articles publicized in the international journals within 5 years (2004-2008), and outstanding national research for at least 2 of 5 fields of THE-QS and 40% of its academic staff must have doctoral qualifications.
Criteria	The criteria used to classify the NRUs in the context of 'multi-dimension' which was caused by the combination of X-variable criteria that have influenced the difference in 3 Y-variables; Y_1, Y_2, and Y_3. - Criteria of X-variables, as follows: D1 Research funding; $X_1$the amount of internal and external grants for research and innovations in proportion to the number of FTF. D2Instructional programmes and curriculums; X_6 the percentage of doctoral programmes in proportion to bachelor programmes. D3 Instructors and research staff body; X_9 the proportion of the number of faculty members holding bachelor, master and doctoral degrees or equivalent to the number of FTF X_{10} the proportion of the number of faculty members holding doctoral degrees or equivalent to the number of FTF, and X_{12} the proportion of the number of faculty members holding the position of associate professor and professor to the number of FTF D4 Students body; X_{16} the percentage of graduate students in proportion to the number of total students -Criteria of Y-variables, as follows: D1Research output; Y_1 the percentage of research and innovations published or registered as intellectual property or patented or utilized at the national or international level in proportion to the number of FTF D2 Citations; Y_2 the percentage of research articles cited in refereed journals or national or international databases in proportion to the number of FTF D3 Research awards; Y_3 the percentage of FTF who received academic or professional awards at the national and international levels.	The NRUs selection criteria[15] applied the THE-QS ranking which contemplated the published researches in the Scopus database and indicators representing Thailand context. The criteria used included as follow: D1Research Quality; (1) number of published international publications, (2) number of published publications to number of FTF, (3) number of corresponding authors to number of total publications, (4) number of patents earned domestically and internationally, (5) experts' opinion, for examples Club Professor, (6) research identity (Targeted Niche, e.g. identity), D2 Teaching Quality; (1) The proportion of the number of FTES to the number of FTF, (2) number of faculty holding doctoral degrees, (3) number of professors, (4) graduated to total FTES ratio. D3 International Outlook; (1) number of foreign students, (2) FTF to foreign researcher ratio, (3) Joint research with corresponding authors in Thai people, D4 Graduate's employability and satisfaction (1) satisfaction evaluated by employer, (2) Public private partnership (PPP).
No. of universities	6 universities including Chulalongkorn, Kasetsart, Mahidol, Chiang Mai,King Mongkut's University, and National Institute of Development Administration	9 universities includingChulalongkorn, Kasetsart, Mahidol, Khon Kaen, Chiang Mai, Thammasat, Suranaree University of Technology, King Mongkut's University of Technology Thonburi, and Prince of Songkla University.

In regard of the criteria, it was found that (1) Khon Kaen and Suranaree University of Technology failed to meet only one requirement for D4 Students' body in criteria. X_{16} refers to the percentage of graduate students in proportion to the total number of students, accounting

for 19.29% and 11.22%, respectively. But Khon Kaen University was close to the THEC-model criteria (20%); (2) Thammasat did not meet the requirement for two criteria, the criteria X_{16}, accounted for 19.86%, close to the target 20% for NRUs and D2 in criteria X6, which refers to the percentage of doctoral programmes in proportion to bachelor programmes, accounting for 24.74%, which is some way off the THEC-model criteria (≥ 50%), (3) Prince of Songkla University did not meet the requirement for four criteria. Of the four, two criteria were similar to that of Thammasat; X_6 and X_{16}or 44.01% and 12.48%, respectively, and other two criteria - D3 Instructors and research staff body consisted of X_9 which refers to the proportion of the number of faculty members holding bachelor, master and doctoral degrees or equivalent to the number of FTF, accounted for 48.89% for doctoral degree and 5.63% for bachelor degree, close to the THEC-model criteria (see in Table1), and X_{10} refers to the proportion of the number of faculty members holding doctoral degrees or equivalent to the number of FTF accounted for 48. 89%, close to the THEC-model criteria (≥ 50%). In conclusion, the THEC-model and OHEC results were consistent.

However, to classify HEIs by using empirical data under a statistical approach, which was initiated to develop the THEC-model, limitations on information and data were found. For example, only 50 of 200 universities (one fourth of HEIs in Thailand) were selected. Some criteria were incomplete or had insufficient data, so they failed in the'parametric' conditions. In this case, the'nonparametric' test was used, resulted in less accuracy. Importantly, the HEIs had no common data set, for example, national and international publications were not separated, resulting in restrictions in selecting the hypothesis test criteria.

IMPLICATIONS

The developed classification model benefits academic researchers, HEI administrators, and policy-makers for many reasons. Firstly, it meets the academic researcher's need for information in the classification system to determine the important variables for HEI explanation in different areas. For example, Shin and Milton (2006) analyzed the variables connected to tuition. Henderson and Buchanan (2008) analyzed the variables pertaining to faculty teaching and research. Burke *et al.* (2005) analyzed the faculty salaries. Secondly, the information obtained from HEI classification enables higher education administrators to deal with the strengths and weaknesses in terms of educational quality, and allow them to understand the position of the institution and develop the strategy to maintain their position or elevate it to a better position. Thirdly, since the THEC-model criteria were generated by reviewing the classification system in different locations, such criteria could be applied extensively at domestic and international level. Fourthly, the policymakers understand the information reflecting the reality of individual HEIs, especially in the research dimension. For example, they can know which NRUs are distinctive or disadvantaged in any area. This enables them to manage higher education in the right direction and move the HEIs toward world class universities. Lastly, the developed THEC- model is based on a statistical approach and empirical data improved the reliability and would be beneficial to the CHEs in Thailand for further improvement on research-focused HEI classification criteria in the future.

FUTURE STUDIES

Future work should take the following areas into consideration: firstly, improvement of common data set to enable more effective HEI classification; secondly, to standardize the figures on educational management in each section to allocate resources better, especially in the NRUs; thirdly, it should investigate the strategies for reposition, for example, from research universities to NRUs by using SWOT Analysis to understand the strengths and weaknesses of the institution, and opportunities and threats in environmental, political, economic, social, demographic, and technological contexts. Finally, it should designate the combination sets in other types in pursuit of the desired classification objectives, for example, developing a research-based model, and further examining the weight for each dimension.

CONCLUSIONS

The THEC-model was designed to classify Thailand's HEIs, focusing on 'research universities', particularly, NRUs. The THEC-model development stemmed from linking the classification criteria where nature and characteristics of HEIs are identified, with the ranking criteria based on research performance that reflects the HEI's quality and recognition. The classification criteria were generated by reviewing the existing popular classification systems in different locations such as the US, China, Europe, and Thailand. On the other hand, the ranking criteria were developed by reviewing the criteria used in SJTU, THE-QS, and educational quality assurance. Criteria were derived from both reviewing the classification and ranking systems, and were aligned consistently with the higher educational context in Thailand.

HEI classification consists of the following six dimensions (1) research funding, (2) instructional programmes and curriculums, (3) instructors and research staff body, (4) student body, (5) size, location, and campuses, and (6) university-industry collaboration in research. The HEI Ranking consists of three following dimensions (1) research output (2) citation, and (3) research awards. Such criteria have been statistically used for hypothesis testing and categorization. The criteria affecting the research performance, and the results of hypothesis tests will then be applied to classify HEIs in multiple dimensions, namely, the criteria affecting the research performance in three dimensions were taken into consideration.

As a result, the HEI classification criteria for NRU consisted of four dimensions (out of 6 dimensions), including (1) research funding, (2) instructional programmes and curriculums, (3) instructors and research staff body, (4) student body. Such classification criteria showed that six universities were classified as NRUs, including Chulalongkorn, Kasetsart, Mahidol, Chiang Mai, King Mongkut's University, and National Institute of Development Administration. The results were consistent with NRUs classification by OHEC. The findings provide useful information for policymakers to develop plans and deal with the higher education system corresponding to the mission and excellence for individual institutions, especially in enhancing the HEIs to research universities, NRUs, and world-class universities. Universities are important sources of well-educated workers and a source of innovation, Schultz (1961); Lucas (1988); Becker (1993); and Hedin *et al.*, (2005); Burke *et al.,*(2009); Schwab (2009) and Ramoniene and Lanskoronskis

(2011),who are important for the business sector to propel enterprise development in terms of global competitiveness enhancement.

EFFICIENCY AND EFFECTIVENESS OF PUBLIC SPENDING ON HIGHER EDUCATION INSTITUTIONS

Dušan Lesjak, University of Primorska, Faculty of Management Koper, Slovenia
dusan.lesjak@fm-kp.si*corresponding author

Duša Marjetič, Ministry of Higher Education, Science and Technology, Slovenia
dusa.marjetic@gov.si

ABSTRACT

European higher education systems are facing numerous changes and are becoming increasingly internationalised, deregulated, liberalised and market-oriented, which has its advantages and disadvantages, proponents and opponents. These trends have, among other things, resulted in an increasing financial autonomy of higher education institutions (HEIs) in the member states of the EU. However, the recent economic downturn has revealed numerous weaknesses of mechanisms of higher education (HE) funding.

This paper presents key characteristics of HE funding in the member states of the EU. In particular, it focuses on the characteristics and effectiveness of Slovenian higher education where an emphasis is given to HE funding and resources managed by HEIs.

The purpose of the paper is to show how complicated it is to search for the answer to the question of rational use of (public) funding in (Slovenian) higher education. There is no simple and unambiguous answer to the question of whether public funding in higher education is being used rationally. The aim of every member state of the EU is to provide the necessary conditions for effective and efficient higher education which provides equal opportunities, quality education and adequate employment opportunities for graduates, as well as supports the sustainable development of the society, country (and the EU). Therefore, HEIs, governments and other actors must be aware of their roles in the "knowledge society", and take responsibility for ensuring the expected economic, social and cultural prosperity.

Keywords: effectiveness, efficiency, public funding, higher education, Slovenia

INTRODUCTION

In the EU, higher education (HE) is a **public responsibility and public good** with high expectations of higher education institutions (HEIs) which are required to respond to societal needs and fulfil their three main missions: teaching, research and the transfer or exchange of knowledge (EPC, 2010) by:

- creating and maintaining an advanced knowledge base, and encouraging research and innovation,
- transferring knowledge to students to prepare them for their career and active citizenship in a democratic society, and to promote their personal development,

- and through the social dimension involving the impact of research and knowledge creation and diffusion on society at large, as well as equity in access independent of the socio-economic background.

The development of HE in EU countries in the past decade is an interesting subject for research, because of the numerous changes it has undergone. Among major factors that consequently influenced the behaviour and development of HE(Is) we can state:
- Bologna process: introduction of new HE structure (bologna three cycles),
- changes in funding of HEIs for teaching,
- demography and changes in the student body,
- development of private HEIs,
- establishment of (national) agencies for quality assurance in HE together with international ones ENQA and EQAR.

In 2009 Leuven Communiqué, the Bologna Process highlighted that **HE funding** had a direct impact on HE, and made it its priority with the need for new methods and instruments of HE funding and for a bigger diversity of funding sources.

When thinking about the future of HE, also global situation and trends in HE and other areas that influence the policy making must be taken into account. Among the major international events or trends influencing HE in the EU are:
- growing demand for HE and increase in % of generation that enters tertiary education,
- new learning technologies that put under reconsideration traditional course structure,
- internationalization of HE and development of transnational HE,
- global recession and financial crisis in 2008.

The efficiency of the use of HE funding has become very important due to the development of the HE system in recent years, an increasing number of people participating in it and consequently growing financial needs on the one hand, and limited public funding on the other. This issue was addressed in Study on the efficiency and effectiveness of public spending on tertiary education (St Aubyn et al., 2009). The study analysed the relationship between productivity, employability and expenditure on education, since the efficient use of resources depends on the effectiveness of the relationship between these elements. While some countries are efficient according to all the criteria (the UK, the Netherlands), the countries characterised by lower efficiency are countries of Southern and Eastern Europe unexpectedly, Italy, France, Germany, and also public HE in the USA.

In its Communication Europe 2020, A Strategy for Smart, Sustainable and Inclusive Growth, of 3 March 2010 (Europe 2020), the European Commission proposed to the EU members states to include among their national targets a goal of increasing the share of the population aged 30-34 with completed tertiary education from the current 31% to at least 40% by 2020. In Slovenia, in 2005 the share of this population was 25%, compared to 31% in 2008. Since public and private funds are very limited, this objective can only be achieved through their **careful allocation** and **efficient use**.

European HE systems are facing numerous changes and are becoming increasingly internationalised, deregulated, liberalised and market-oriented, which has its advantages

and disadvantages, proponents and opponents. These trends have, among other things, resulted in an increasing financial autonomy of HEIs in the member states of the EU. However, the recent economic downturn has revealed numerous weaknesses of mechanisms of HE funding.

In recent years, HEIs in Slovenia have been given considerable financial autonomy due to the transition to lump sum funding of study activities in 2004. HEI's increased institutional and financial autonomy gives them greater flexibility in managing resources (financial and others) which should result in a more efficient use of public funds. However, it requires from the recipients of funds **more knowledge and responsibility** when spending the funds received.

This paper deals with **efficient** use of public funds in HE (education) at the national level and in the relation state – HEI, it being understood that HEIs are part of the HE system and in pursuit of common national goals, and that at the national level efficient use of resources in HE, i.e. achieving the optimal ratio between the inputs and effects, must be considered together with the **effectiveness** of achieving the objectives and results for which the funds were intended.

DEFINITIONS AND TRENDS

Efficient and effective use of public funds

In accordance with the principle of efficiency, efficient use of public funds is achieved through the optimal ratio between the inputs and effects. Effectiveness, on the other hand, is measured by comparing specific objectives and planned outcomes, and refers to the achieving of the objectives and results for which the funds were intended.

This topic is especially demanding because of the differences in understanding the concepts of efficiency, economy, effectiveness and sound management in public and private sector.

The Rules on the Guidelines for a Coordinated Functioning of the System of Internal Control of Public Finance (Official Gazette of the RS, 2002) determine that sound management is at the same time economical, efficient and effective. Therefore, sound financial management includes (Guidelines for Auditing Sound Financial Management, 2006):

- the principle of efficiency, concerned with the optimal relationship between resources used and results achieved (in a similar manner as in economics),
- the principle of economy which requires that the resources used by organisations for the pursuit of their activities are made available at the right time, in appropriate quantity and quality and at the best price, and
- the principle of effectiveness which refers to attaining set objectives and achieving the anticipated results.

Sound financial management is achieved when organisations are economical, efficient and effective at the same time, i.e. a process or programme which is assumed to be economical with regard to invested resources, efficient with regard to their use and management and which successfully attains the anticipated results, is described as sound or that it brings

good value for money. These definitions are taken from the Council Regulation (2002), applicable to the general budget of the European Communities.

With HE policy measures, states can encourage or inhibit the efficiency and effectiveness of HEIs. Efficiency refers to the management of limited resources through the efficient work with students and achieving the best quality of studies given the financial limitations, as well as to the relevance of study programmes offered by HEIs. The latter refers especially to the connection with potential employers of HE graduates.

Financial challenges and HE reforms

In recent years, we have observed numerous reforms and changes in the European HE area. European HE systems are becoming increasingly market-oriented, deregulated, liberalised and privatised (OECD, 2008). The extent of reforms varies between countries, but none of them avoided them. These reforms have many common characteristics (Eurydice, 2008; Kaiser, 2002; Strehl, 2006; CEGES, 2007; Lepori, 2007; EUA, 2008):

- A share of GDP devoted to HE (and related social transfers), and the growth in expenditure on HE (at least until the 2009 economic crisis).
- Due to the limited public funding, the share of private funding is increasing.
- There is a general trend towards an increased autonomy in public funds spending and an increased accountability within HEIs.
- Increasing efforts for efficiency and effectiveness (also of public and private funds spending).
- Efforts to introduce and use the full-cost method in carrying out HE activities.
- Funding in terms of coordinating the available resources with national priorities, and guiding the development of HE and achieving national HE objectives through the systems and mechanisms of HE funding.
- A move towards a greater transparency and simplicity of funding, through the systems and mechanisms of funding – from the historical component and input, to the achievements or output of education and.
- the cost of education should not be covered by a single actor or the state.

As noted in the EUA's report University Autonomy in Europe I (Estermann and Nokkala, 2009), funding of study activities of tertiary education institutions in Europe is characterised by the following trends:

- Allocation of public funds by using the method of lump sum funding which is often based on the results or their target values.
- In most European countries, universities can collect tuition fees from at least part of the student population. However, there are differences in the methods of determining tuition fees and what expenses they should cover.
- In most countries, universities are still restricted in their operation in financial markets. Money borrowing is quite common, while investments are often possible only through "satellites" of legal persons established by universities.
- There are also significant differences in the ownership of property, where formal ownership does not necessarily mean the right of free disposal.
- In most countries, universities have the autonomy in human resource management (recruitment/dismissal), but they are usually limited when it comes to determining

wages, since their employees are civil servants or national frameworks exist within which their wages must be determined.

These and other trends reflect the problems regarding HE funding at the EU level which have also been emphasized by the European University Association (EUA) in its report (EUA, 2008). According to the EUA, due to the increasing costs of HE activities, the primary question of universities in the 21st century concerns the risks related to the sustainability of their mission.

With the above and other aspects of HE reform, society faces the challenge of ensuring more efficient study and research, referring to:

- the shortening of the length of study – in the EU, full-time undergraduate studies on average take 6 years (Key Data on Higher Education, 2007); in Slovenia, academic higher education studies on average take 6.9 years and professional higher education studies 5.9 years (Euroštudent, 2007),
- a more rational use of financial resources for study and research activities.

Despite the anticipation that the economic recession and financial crisis will increase the problems of insufficient public funding of HE by further reducing public expenditure on HE (Varghese, 2010), it is interesting that the OECD in second research which was carried out over the summer of 2010 and in which 25 OECD member states participated at the time of economic recovery and fiscal consolidation, shows that education systems have not been dramatically affected by the overall budgetary costs, and governments seem to be rather successful in protecting education spending, some of them by increasing social measures to contain education costs. (Damme, 2010) Rather opposing are the results of the EUA's continuous monitoring of the effect of the economic crisis on funding and its trends which show that European HE systems have been affected very differently and at different stages of the crisis. HEIs in most countries report being faced with uncertainty and expect further – and possibly deeper – cuts to come in the year following 2010. (Estermann, 2011)

National mechanisms for funding HE and HE policy

Funding mechanisms vary between countries. There are four mechanisms for allocating public funds to tertiary education institutions: negotiation, growth/supplement, a formula and a contract.

It is becoming increasingly obvious that countries do not sufficiently connect their funding mechanisms and HE policy, which significantly contributes to the inefficiency and ineffectiveness of public (and private) expenditure on HE. Furthermore, in such case, HEIs are not motivated and stimulated enough to actively monitor their economic and social environment and trends, and to consolidate their position as key economic and social factors.

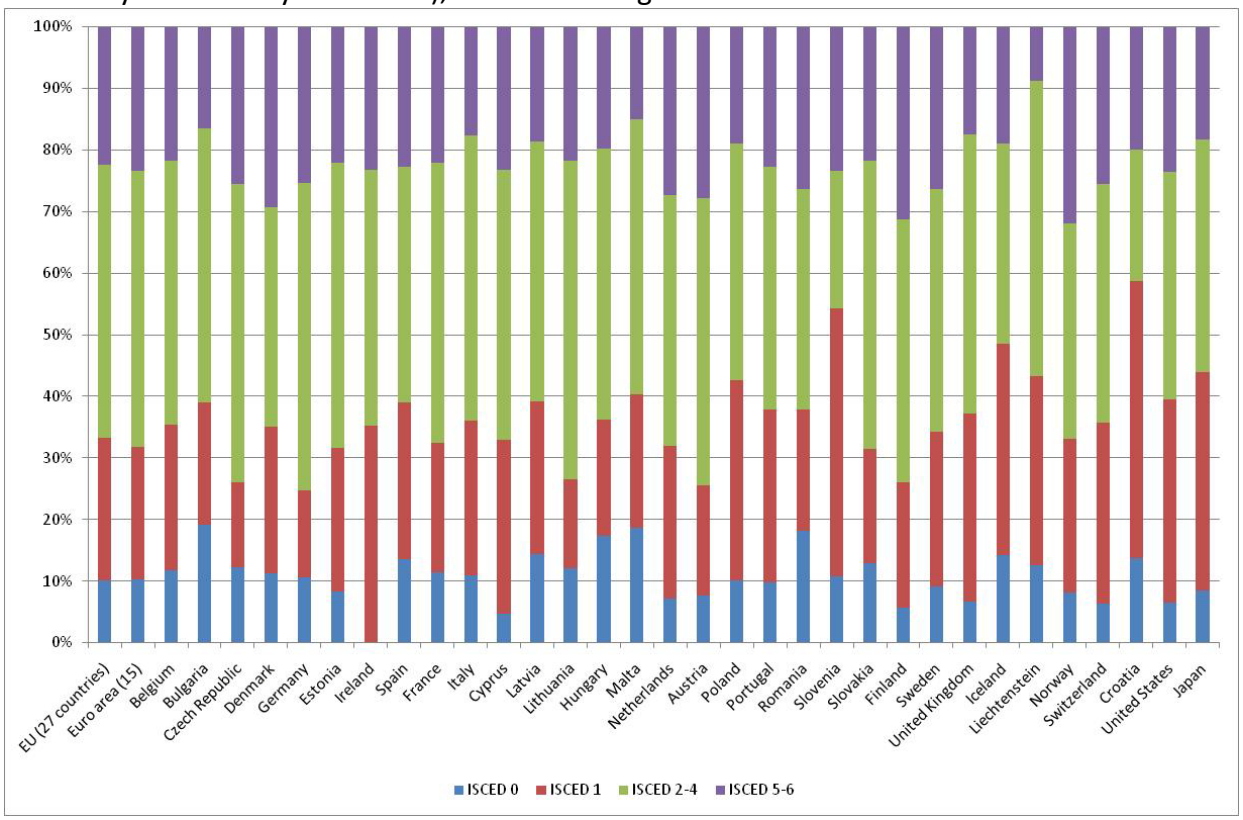
When defining systems of HE funding, at least the following goals of HE policy should be pursued:

- to achieve a greater responsiveness of HEIs to the needs of society (social and economic),

- to ensure a transparent and rational use of (budgetary) resources,
- to ensure quality HE, accessible to everybody, so that each student has the opportunity to start and complete their studies regardless of their social and economic status.

Public funds for education - international comparison

When examining the efficiency of using public funds in HE, we should look at how much budgetary resources is allocated to each segment of education (preschool, primary, secondary and tertiary education), as shown in Figure 1.



Remark: ISCED 0: pre-primary level and not allocated, ISCED 1: primary level, ISCED 2-4: secondary level, ISCED 5-6: tertiary level

Figure 1: Structure of public expenditure on education by levels of education in 2007 (Eurostat, 2011)

As demonstrated in Figure 1, the biggest relative share of total public expenditure on education in Slovenia is allocated to primary education (43.5%) and the smallest to secondary education (22%), which is almost the opposite of the EU average. Tertiary education in Slovenia is allocated just over 23% of public funds for education, which is slightly higher than the EU average and comparable to the average of the euro area.

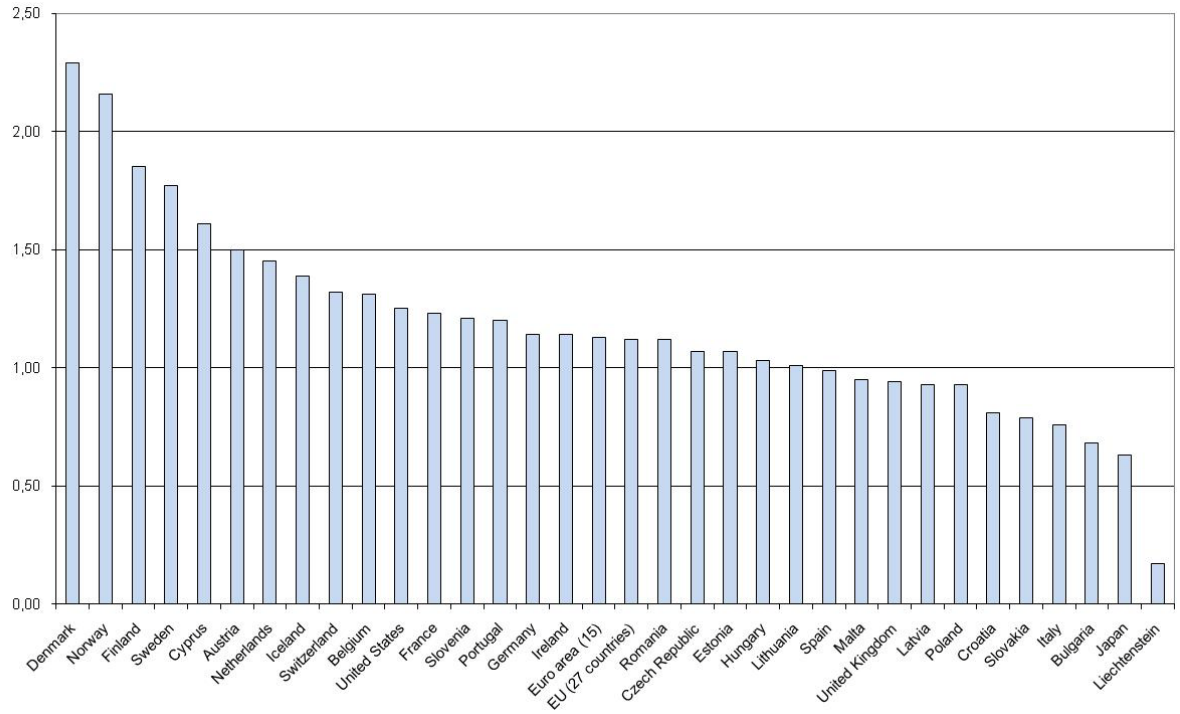


Figure 2: Expenditure on tertiary education as % of GDP in 2007 (Eurostat, 12 April 2011)

The Lisbon Strategy has set a target for countries to allocate 2% of their GDP to HE (public and private sources) by 2010. The target share of GDP from public sources has been met by the majority of EU member states, the EU 27 average being 1.12%. With 1.21% of GDP allocated to tertiary education from public sources, Slovenia is above the EU average (Eurostat, 2007).

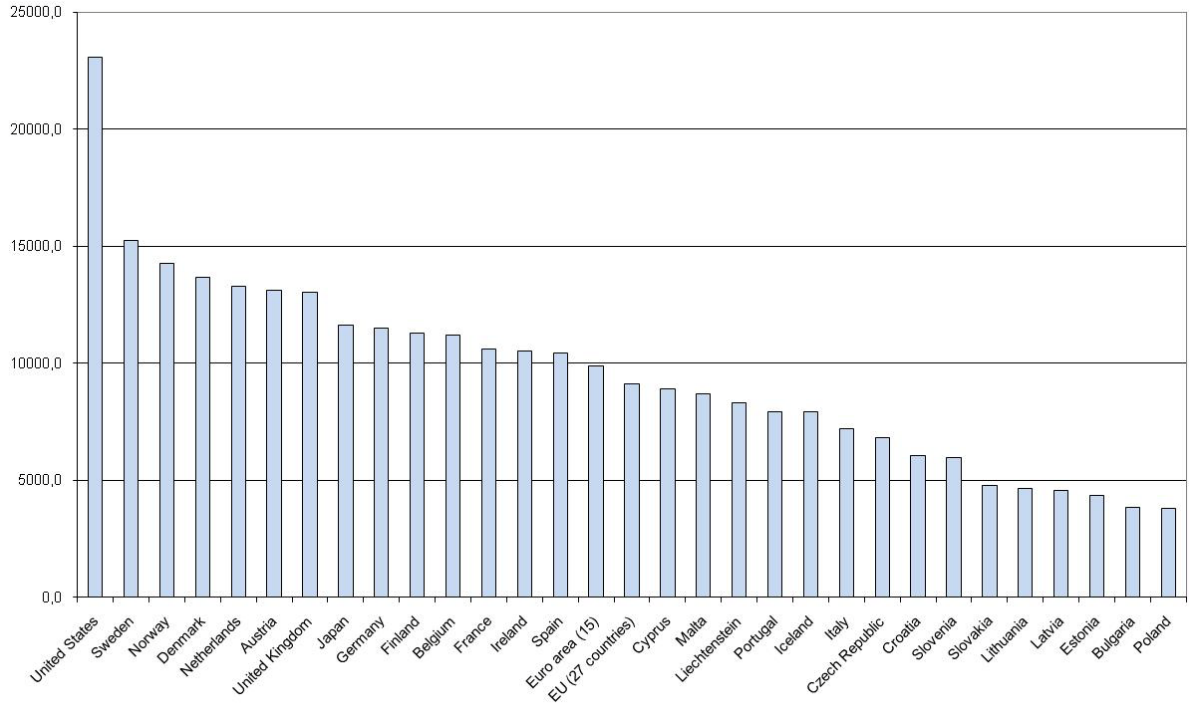

Figure 3: Expenditure on public and private tertiary educational institutions in PPS[1] per student in 2007 (Eurostat, 12 April 2011)

According to the share of GDP allocated to tertiary education, Slovenia is above the EU average, as shown in Figure 2, while according to the expenditure per student (even if expressed in PPS), it is at the tail of the EU member states. This is to some extent due to a high level of enrolment of the population in studies and the inefficiency of studies, i.e. students study considerably long and often do not complete their studies (approx. 35%, compared to the OECD average of approx. 30%) (OECD, 2009).

Measuring the efficiency and effectiveness in higher education

Until recently, the main performance indicator of the functioning of the HE system was the share of GDP allocated to HE by the state and the number of people enrolled in HE, rather than results of education and research and their impact on society. The 2008 global economic crisis, which resulted in drastic budget cuts, highlighted the issue of the efficiency of investments in HE. Measuring the effectiveness of HE and the efficiency of public spending is increasingly putting at the forefront monitoring of HE results, and is looking for the ways of measuring its impact on society. The Europe 2020 strategy (ET 2020) expects the EU member states to ensure at their national levels the efficiency of investments in educational systems, improve the outcomes of education, enhance the openness of educational systems (including a better matching of the outcomes of education and the needs of the market), and improve the transition of young people to the labour market. One of the five key indicators for measuring progress by 2020 is the increase of the share of the population aged 30-34 with completed tertiary education from the current 31% to at least 40%.

In a crisis, states must allocate their resources to the mechanisms that will contribute to the development of the economy, creation of added value and GDP growth. Since investments in education return only in the long run, they might be underestimated in short-term measures. This is highlighted in the OECD study with a suggestive title The High Cost of Low Educational Performance (OECD, 2010) which compares PISA results with the economic growth. The study found that even a relatively small improvement of the knowledge and skills of the workforce could have a significant impact on the future welfare of society, a key factor being the quality rather than length of education.

The study St. Aubyn et al. (2009) analysed cost-efficiency of HE systems using data envelopment analysis (DEA) and stochastic frontier analysis (SFA). In conclusions the study emphasized inefficiency in spending as an important issue when it comes to public tertiary education. An important group of countries was found to be operating under inefficiency conditions irrespective of the methods used (South and Eastern European countries, France, Germany, Italy, US public tertiary education), while on the other hand countries like the UK and the Netherlands appeared at the top of the efficiency ranking irrespective of the method or models used. As an important factor related to efficiency of TE was identified the

[1] PPS – Purchasing Power Standard.

quality of secondary education (using PISA results) and factors pertain to HEIs features, namely:

- The funding rules followed in each country. When funding to institutions depends more on outputs (e.g., graduations and publications) and less on historical attributions or inputs, efficiency tends to increase.
- Evaluation systems. Efficiency tends to be higher in countries where institutions are publicly evaluated by stakeholders and/or independent agencies.
- Staff policy. Institutions' autonomy to hire and dismiss academic staff and to set their wages is correlated with higher efficiency.

The study on progress in higher education reform across Europe (Jongbloed et al., 2010) identified four mechanisms used by EU states to encourage efficiency and cost reductions through targeted funding to HEIs over the period 1995–2008:

- Encourage mergers and amalgamations of institutions,
- Encourage reduction in the time students take to complete a degree,
- Encourage an increase in student success rates (i.e. reducing drop outs),
- Reward institutions that bring funding from the private sector.

Targeted funding in identified cases was allocated on the basis of:

- Competition (tendering) between HEIs,
- Negotiations between the government and (a selected number of) HEIs,
- Equal allocation of funding across HEIs.

The study then tried to measure HE systems performance of its key activities (teaching, research and knowledge transfer) through eight dimensions with selected indicators shown in Table 1.

Table 1: Performance dimensions and indicators.

Performance dimensions	**Indicators**
1. Access	Net participation rate
2. Mature learners	Mature (> 30 years old) enrolment rate
3. Graduation	Share of population with tertiary degree
4. Employability	Relative graduate earnings
	Graduate employment
5. Research output	Scientific articles
6. Capacity to attract funding	HE R&D income from business;
	Private (households') expenditure on HE
7. International student mobility	Incoming EU+ students
	Outgoing EU+ students
8. Cost effectiveness	Expenditure per student in Euro

Observed 33 HE systems of EU countries were divided into four groups on basis of the values of indicators in reference years 2002 and 2006:

- 'moving further ahead' – countries that are doing well in 2006 and that have further improved over the period 2002-2006,
- 'losing momentum' – countries that are still doing well in 2006 but have improved less over the period 2002-2006 then the average for the 33 HE systems,

- 'catching up' – countries that have improved more than other countries in period 2002-2006, but are still performing below average,
- 'falling further behind' – countries that in 2006 are performing below average and that over the period 2002-2006 have shown a change that is less than the average for the 33 HE systems.

The comparable analysis of performance of HE systems was done with the use of the performance quadrants (for case of Slovenia see Figure 5).

In 2010 European Commission, Economic Policy Committee published a working document on Efficiency and effectiveness of public expenditure on tertiary education in the EU in which approaches the tertiary education governance, efficiency and effectiveness observing the three missions of HEIs: teaching, research and the transfer or exchange of knowledge as interactive activities. An efficient and effective HE system should perform well in all three fields.

The document touches the open subject that HE is neglecting teaching in favour of research, while also recognizing that research and teaching are mutually sustaining. This study also identified as important elements for efficient HE: HEIs autonomy to select students, their financial autonomy and staff policy autonomy.

MEASURING THE EFFICIENCY AND EFFECTIVENESS OF SLOVENIAN HE

Overview of HE in Slovenia

As on 30 June 2010, the register of HEIs included (Marjetič and Dobnikar, 2010):
- 86 HEIs; of these 5 universities (with a total of 51 faculties, 2 professional colleges and 3 academies) and 30 single HEIs (15 faculties and 15 professional colleges), and
- 663 study programmes (48% undergraduate – first-cycle, 40% master – second-cycle and 12% doctoral study programmes), 84% of which were offered by public HEIs.

In 2009/10, as on 31 December 2009 (Statistical Office of the Republic of Slovenia), 114,873 students or 5.6% of the population were enrolled in tertiary education, of whom 98,279 in HE. In 2006/07, Slovenia had the highest share of the population aged 20-24 enrolled in tertiary education (46.1%; the EU27 average was 28.4%), i.e. 56.5% of the population of women and 36.3% of the population of men.

In 2009/10, 74% of HE students were enrolled in full-time study programmes, 92.4% (67,410) of them in undergraduate and 5.9% (4,289) in master (second-cycle) study programmes. 19.2% (14,061) of full-time undergraduate students were absolvents.

In 2009, there were 18,103 tertiary education graduates, 5% more than the previous year and 72% more than a decade ago. The average length of study in undergraduate study programmes in 2008 was 6.3 years, i.e. 6.8 years for academic and 5.9 years for professional higher education programmes (Komljenovič and Marjetič, 2010).

HE funding in Slovenia

In Slovenia, HE funding consists of the funding of HEIs and financial assistance offered to students who are considered part of the household in which they are financially supported by their family. Students who are not employed or registered at the Employment Service as active job seekers are, regardless of whether they are enrolled in full-time or part-time education, entitled to compulsory health insurance through their parents and may receive a child allowance up to the age of 26. Other transfers which aim to bridge socio-economic differences between individuals and thereby increase the accessibility of studies include state grants and subventions for food, transport as well as accommodation in student residence halls and private accommodation. Students can also apply for Zois scholarship (for talented students) and sponsorships by future employers.

In addition to public expenditure on educational institutions (346.6 million EUR in 2008), public expenditure on tertiary education also includes transfers to households and other private entities which represent almost a quarter (23%) of total public expenditure on tertiary education (104.8 million EUR in 2008).

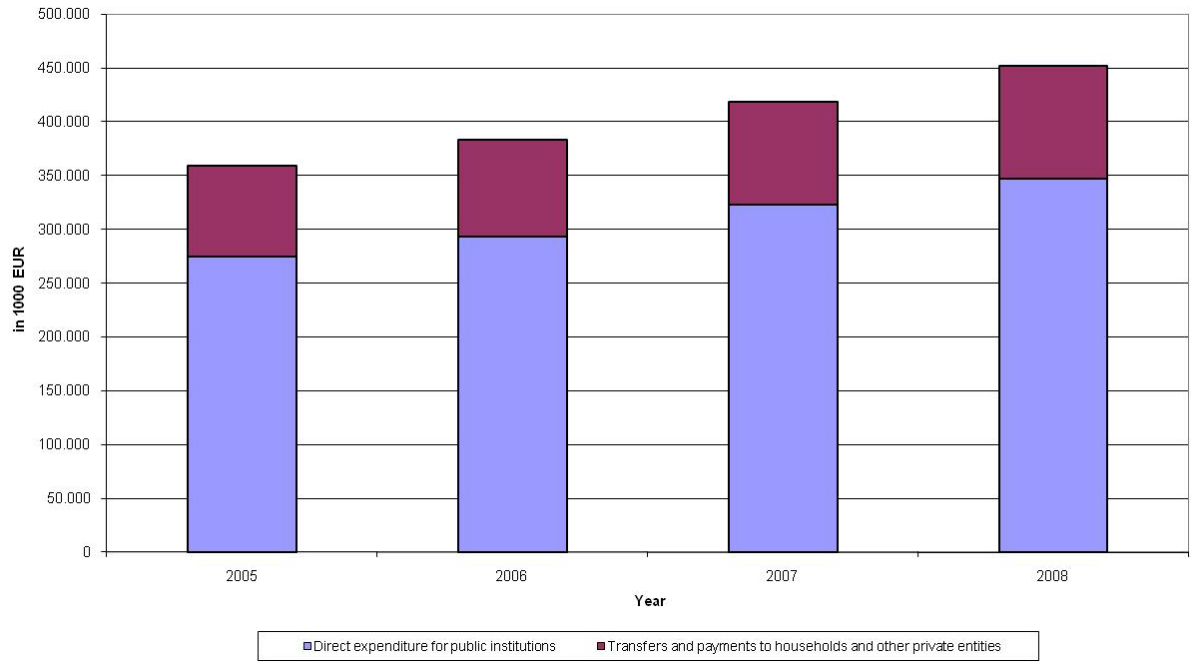

Figure 4: Public expenditure on tertiary education by purpose in the years 2005-2008 in 1,000 EUR (Statistical Office of the Republic of Slovenia, 2011).

Slovenia is among the countries with the dual system of tuition fees in which students who on a basis of their matura examination results enrol in full-time first- and second-cycle studies (if a graduate acquires a higher level of education), which are funded by the state, do not pay any tuition fees, while part-time students are charged tuition fees which are paid by them or by their employer. The state finances study activities by directly allocating funds to HEIs carrying them out – in addition to public HEIs, they also fund study programmes of certain private HEIs for which they have acquired a concession. In 2010, the concessions were allocated 4.1% of all public funds for study activities.

In 2004 Slovenia introduced a lump sum financing of teaching at HEIs, which was supposed to cover salaries (for teaching staff and administration related to teaching activities), and material costs for full-time studies at undergraduate and second-cycle master study programmes. Lump sum included historically based fixed part (60% in 2010) and normative part, which was calculated in dependence of the number of students, graduates, six tariff groups with different factors.

Table 2: Number of undergraduate and master full-time students and graduates of full-time undergraduate studies taken into account in the lump sum formula.

(Budget) year (Y)	**2003**	**2004**	**2005**	**2006**	**2007**	**2008**	**2009**	**2010**
Academic year	**2002/03**	**2003/04**	**2004/05**	**2005/06**	**2006/07**	**2007/08**	**2008/09**	**2009/10**
Undergraduate students	49.818	50.568	51.873	52.462	53.229	53.848	52.679	52.803
Master students (2. cycle)	-	-	-	-	112	675	1.685	3.635
Students total	49.818	50.568	51.873	52.462	53.341	54.523	54.364	56.438
Graduates (Y-1)	7.460	7.789	7.585	7.845	8.048	8.150	8.105	8.098
EUR per student*	3.228	3.445	3.574	3.725	3.781	4.058	4.670	4.455

Remarks:
* Estimated funding per student is calculated on the basis of public funds allocated to HEIs for study activities.
Source: Lesjak et al, 2010.

One of main reasons the system remained in use (with a few changes) until 2010 is in the fact that the budget for lump sum was increasing annually – in period 2003–2010 by 156%. It was only in 2010, when the funds for lump sum were for the first time nominally the same as in previous year that the full effect of normative part of the lump sum formula showed. Due to the decrease in the number of undergraduate students as a consequence to (Bologna) HE reform and demography the operations of Slovene's universities could be seriously endangered. On one hand they were not able to attract more public funds through normative part of lump sum formula and on the other hand they did not prepare themselves for the loss of income from private sources namely tuition fees for undergraduate part-time studies and scientific master programmes, which were abolished in 2009. On national level it was expected that HEIs will develop a market for (so-called) HE lifelong learning short study programmes.

Consequently new lump sum financing system for teaching at HEIs for full-time studies (1^{st} and 2^{nd} cycle) was introduced in 2011. In comparison with the previous financing system, the new lump sum represents 100% of value from 2010, which can be increased or decreased by 3% each year. This variable part is calculated through three indicators which measure the improvement of value compared to the previous year in:

- completion rate of current generation of students that should graduate taking into account the duration of study programme plus one year,
- progress of students from first into second year of studies, and
- international incoming and outgoing mobility of students.

The main limitation at setting the indictors was the availability of data on the level of student. The data exists on HEIs, but not on national level. It is expected that the new information system on HE will solve this problem within next two years.

Example of measuring the performance of Slovenian HE

Figure 5 shows how Slovenia is placed in the described matrix. Slovenian HE is definitely very accessible, but we doubt that we are the leaders with regard to HEI's capacity to attract funding for research and development from businesses. Particularly problematic is the fact that we lag behind in cost-effectiveness and the employability of graduates which are crucial for the effectiveness of HE.

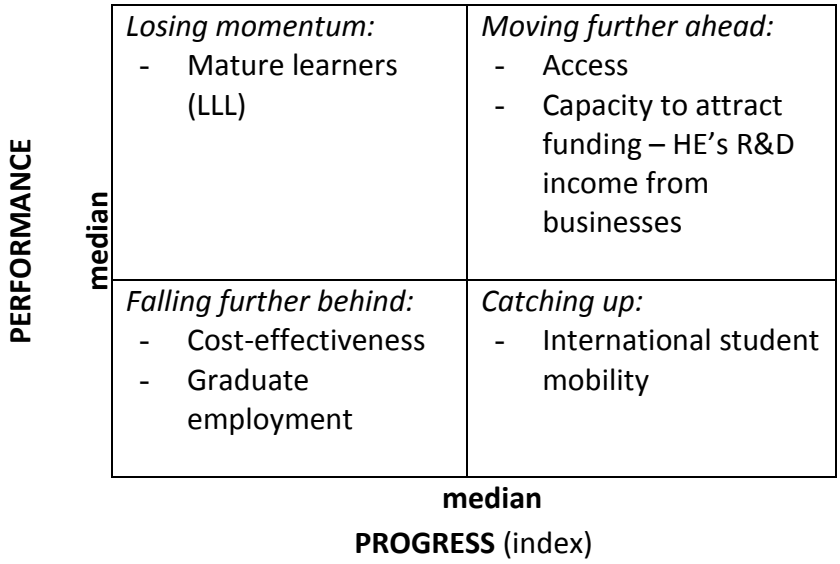

Figure 5: Placement of Slovenia regarding the effectiveness of HE performance (Jongbloed et al, 2010; Lesjak and Marjetnič, 2010)

Mechanisms for ensuring good governance of public funds in HE

To ensure efficient and effective operation of the HE system and HEIs in Slovenia, a number of mechanisms and institutions have been established. Table 2 presents some of the more important mechanisms, which we divided into direct and indirect, and preventive and control mechanisms in terms of the implementation of higher education activities by HEIs.

Table 3: Mechanisms for ensuring good governance of public funds in Slovenian HE.

Mechanisms	Direct	Indirect
Preventive mechanisms	- Accreditation of HEIs and study programmes by SQAA - National Register of HEIs kept by MHEST - Matura – national external secondary school leaving exam - Government's approval of the call for enrolment in HE - Publication of the call for enrolment in HE - Centralised application and selection procedure at the undergraduate level - Internal evaluation carried out by HEIs - Field and international accreditations (e.g. EAEVE, EQUIS, FIBAA)	- Administrative board of public universities - Annual work programme of HEIs - Annual report of HEIs - Internal audit and internal control of public funds of HEIs - Certification of management systems (ISO 9001 etc.) - Participation of HEIs in projects co-financed by EU funds
Controls	- Evaluation of HEIs and study programmes by SQAA - MHEST controls - International university rankings (Shanghai ranking, THE-QS, WEBOMETRICS, etc.)	- Budget Supervision Office of the Republic of Slovenia - Court of Audit of the Republic of Slovenia - Labour Inspectorate of the Republic of Slovenia - Corruption Prevention Commission - Market Inspectorate of the Republic of Slovenia - Inspection of the Public Sector Salary System (formerly the Ministry of Public Administration and departmental ministry)

Legend: SQAA – Slovenian Quality Assurance Agency for Higher Education, MHEST – Ministry of Higher Education, Science and Technology

With the introduction of lump sum funding, the state to a large extent entrusted the implementation of the HE policy strategy to HEIs. Therefore, it has become even more important that the state has an established methodology and system for monitoring the efficiency of using public funds in HE on the basis of the outcomes of HEIs (e.g. the length of study, study completion rates, employability of graduates, publications in renowned journals, citations of authors, cooperation with the economy and wider environment) and indirectly through the factors affecting the efficiency of HE (e.g. the quality and level of knowledge of secondary education).

If we continue to derive from the study of the efficiency and effectiveness of tertiary education (St Aubyn, 2009), the efficient use of resources has a positive impact on the total factor productivity and technological progress[2]. The first results of the continuation of this study, which compares the efficiency of tertiary education in the EU member states, show that Slovenian tertiary education operates **below its capacities**. Slovenia has relatively high investments in tertiary education which probably means that it does not use them best according to the indicators of HE performance, i.e. a large number of students who study for

[2] Total Factor Productivity is calculated as the difference between the growth of productivity and the growth of the employment of all production factors (capital, work, material costs).

a long time or never complete their studies, and the low efficiency of research given the small impact of numerous papers, as measured by citations.

CONCLUSION

This paper shows how complicated it is to search for the answer to the question of whether (public) funds in Slovenian HE are used efficiently, as there is no simple and unequivocal answer to this question. Furthermore, it is even more difficult to answer the question of whether we use the funds wisely, that is, if we realise the aims of the HE policy, and effectively, referring to the employability of graduates, their salaries and their contribution to society.

Efficiency is one of the key factors of effective HE, as are quality, excellence, etc. All these factors should contribute to achieving the HE development strategy included in countries' strategic documents – in Slovenia, mostly in the Master Plan for Higher Education.

We must keep in mind that in the field of HE governments face numerous, often conflicting, challenges, e.g. how to ensure:

- equal access to HE,
- HE funding and its fair allocation, and
- the accountability of HEIs in terms of the quality of education, and dedicated and efficient use of resources

without infringing on HEI's autonomy.

The eternal challenge of the state (government) is to find the right balance between HEI's autonomy and the necessary regulation of HE. The challenge of HEIs, on the other hand, is how to balance their autonomy with appropriate accountability to all stakeholders in HE.

The aim of the state is to provide the necessary conditions for effective HE which allows for equal opportunities, offers quality education and supports sustainable development of the country (and the EU). Therefore, HEIs, governments and other actors must be aware of their roles in the "knowledge society", and take responsibility for ensuring the expected economic, social and cultural prosperity.

ABSTRACT

This research deals with business relationship coordination during extended project supply process in service intensive project business. The focus of the research is to describe and explain problems faced in relationship coordination between project buyer and seller along different stages of the project supply process. In order to acquire a more complete understanding of the phenomenon a theoretical framework combining IMP-related interaction research and project supply process research is created and empirically grounded. According to the empirical findings, the main challenge of coordination is the fluctuating interaction between project stages, reflected in high employee turnover, communication problems and challenges in controlling customer responsibility. This research contributes to the micro level interaction research, by building a pattern between coordination processes and stages of the extended project supply process. Managerially findings are interesting, because they reveal fundamental problems in relationship coordination, followed by practical solutions into overcoming them.

Keywords: interaction, coordination, project supply process, relationship discontinuity, service intensive project business.

INTRODUCTION

The research on project business can be divided into studies on the understanding of project business characteristics (e.g. Artto & Wikström, 2005; Söderlund, 2004), project-based firm as a type of organization (e.g. Hobday, 2000; Whitley, 2006) and to research that aims to understand business relationships in this specific context (Bansard, Cova & Salle, 1993; Cova & Holstius, 1993; Hadjikhani, 1996; Alajoutsijärvi & Tikkanen, 2000; Skaates & Tikkanen, 2003; Cova & Salle, 2006). The lastly mentioned research stream, which is the focus of this research, emphasizes the distinctive features of project marketing, namely discontinuity, uniqueness and complexity of projects (Mandjak & Veres, 1998, Hadjikhani, 1996) resulting in specific types of business relationships. Majority of this research has been IMP related, highlighting interactive relationships and networks as the core phenomena (Ahmed, 1993; Alajoutsijärvi, Möller & Rosenbröijer, 1999; Cova, Mazet & Salle, 1996; Skaates & Tikkanen, 2003; Skaates, Tikkanen & Lindblom, 2002; Welch et al., 1996).

Research into interaction between project buyer and seller can be further divided to three broad categories. The first stream of research is concerned with managing individual projects from beginning to end. At this level research has concentrated on mapping the activities of the project supplier in different stages of the project supply process (Cova & Holstius, 1993; Cova, Mazet & Salle, 1994; Cova, Ghauri & Salle, 2002). These studies give a detailed view of the tasks project supplier needs to accomplish in order to acquire a project, but les attention is given to activities following project contract and especially project completion (Mandjak & Veres, 1998). The second stream of research deals with interaction during multiple sequential project deliveries and projects are regarded as "episodes" within long-term development. This IMP-related research has contributed our knowledge on the development of project business relationships. However, stages of the project supply process are overlooked, as projects are viewed merely among other episodes (Håkansson, 1982; Ford, 1990). The third research stream aims to understand discontinuous interaction after project completion by studying social dimension of business relationships. Accordingly, maintaining a structural relationship after project completion is viewed problematic (Skaates, 2000) due to absence of contractual obligations, which has given birth to concepts such as sleeping relationships (Hadjikhani, 1996), milieus (Cova, Mazet & Salle, 1996) and ritual approach (Cova & Salle, 2000). However, this kind of thinking is becoming quite obsolete, as project business involves increasingly service business characteristics (Artto, Wikström, Hellström & Kujala, 2008; Tyler, Patton, Mongiello & Meyer 2007; Skaates & Cova, 2005). Today, economic exchange rarely dissolves after project completion and many project-based companies are actually earning more revenues from project-related services than from project deliveries (Gebauer, Edvardsson, Gustafsson & Witell, 2010).

From the literature review it comes evident, that the previous research does not describe adequately interaction between project buyer and seller during the different stages of the project supply process, not to mention research that would consider different aspects of interaction. However, previous research has pointed out challenges in relationship coordination, resulting from information break up points between project stages (Skaates & Tikkanen, 2002, 399). This is also inline with difficulties pointed out in the temporary project organization literature (Engwall, 2003; Lundin & Söderholm, 1995; Packendorff, 1995). It has been also shown, that albeit interaction tends to fluctuate along project supply process, each stage can be associated with certain interaction characteristics, which appear generic into some extent (Ojansivu, Salo & Alajoutsijärvi, 2011). This implies, that the main problem of relationship management is not fluctuating interaction as such, but coordination between stages. Following the previous reasoning, this research proposes the subsequent research questions: 1) how does fluctuating interaction between project stages affect relationship coordination, and 2) what type of managerial actions can be taken to overcome the resulting challenges?

The empirical setting of this research is build around a single case study of a content management systems (CMS) supplier. These systems are supplied as projects requiring approximately 50% customization depending of the customer. Project completion is followed typically by service exchange ranging from basic maintenance to state of the art R&D. In general, CMS-systems are used in large organizations for creating and maintaining electronic services online. All to-

gether, supply of CMS-systems can be considered to be a typical service intensive project business by nature. In this research the term "service intensive" is used in order to describe project business, where service exchange accounts for a significant part of the turnover. According to the empirical findings, relationship coordination is strongly affected by the fluctuating interaction during extended project supply process. This can be seen in the high employee turnover in customer surface, communication problems and challenges in controlling customer responsibility. Furthermore, an empirically grounded framework anchoring certain coordination characteristics to each project supply stage is put forward

This research includes five sections. After introduction, the theoretical foundations of the study, comprising project supply process models and interaction processes and modes in the context of service intensive project business, are discussed and the theoretical framework is put forward. The third section describes the research design and methodology of the study. The fourth section, presents the empirical findings of the research. In the final section, the findings of this research are discussed and an empirically grounded framework is put forward. The limitations of the study are also considered and further avenues for the research explored.

BUSINESS RELATIONSHIP INTERACTION AND COORDINATION

Interaction processes form the backbone of business relationships. Generally speaking, interaction in buyer-seller relationship can be described with three basic processes: exchange process, coordination process and adaptation process (e.g. Håkansson, 1982; Möller & Wilson; 1988). Exchange processes are at the core of the interaction. Exchange is described usually with four types of elements: product or service exchange, information exchange, financial exchange and social exchange (Håkansson, 1982, 16). Adaptation processes refer to actions that interacting parties perform in order to benefit more from the exchange relationship. These actions can include modification of resources, skills, operations and even goals, attitudes and managerial values (Möller & Wilson, 1995, 27). If adaptations require investments that are relationship-specific, this may lead to increased relative dependence and high switching costs between the interacting parties. Non-retrievable investments are relationship-specific commitment of resources that cannot be recovered if the relationship ends (Lohtia & Krapfel, 1994; Wilson, 1995). Coordination processes have to do with mechanisms that facilitate the control of exchange processes. These mechanisms include decisions, rules and procedures as well as the "terms of trade" that all contribute to the efficiency of the relationship (Möller and Wilson, 1995, 27).

When project suppliers and buyers interact in specific way for a certain period of time, different interaction modes develop (Campbell, 1985; Möller & Wilson, 1988, 1995) and by viewing these modes in longitudinal setting, it is possible to understand the long-term development pattern of the relationship (Alajoutsijärvi, Möller & Rosenbröijer, 1999). Broadly speaking, project supplier and buyer may follow four "extreme" interaction modes: cooperative, competitive, command and submission (Campbell, 1985; Möller & Wilson, 1988, 1995). Business relationships represent seldom these four "extreme" interaction modes, but tend to be combinations of

them, which is why Alajoutsijärvi et al. (1999, 25) propose a "diamond" framework that views the four alternative relationship modes on a diamond-shaped space divided to two continuums; competition-cooperation and the buyer's versus seller's dominance. Each of these modes can be linked to certain relationship characteristics, which epitomize the behavior in the project supplier-customer relationship. According to this framework, relationships develop through interplay of different modes, which can be depicted as a shift on the diamond surface. Development requires, however, project supplier and buyer to have a quite similar mindset; otherwise the relationship becomes soon dissolved.

"Diamond" framework has proven successful in describing and explaining cyclic interaction between a paper mil and paper machine manufacturer in the context of multiple project deliveries (Alajoutsijärvi, 1996). It has been later modified by Ojansivu et al. (2011) to describe and explain interaction during single project delivery viewed in extended setting in the context of service intensive project business. According to their findings, albeit interaction tends to fluctuate along project supply process, each stage can be associated with certain interaction characteristics, which appear generic into some extent. This implies, that the main problem of relationship management is not fluctuating interaction as such, but coordination during transition from one stage to another. This research further elaborates the empirically grounded framework from Ojansivu et al. (2011) in order to focus on relationship coordination along the extended project supply process in service intensive project business (Figure 1).

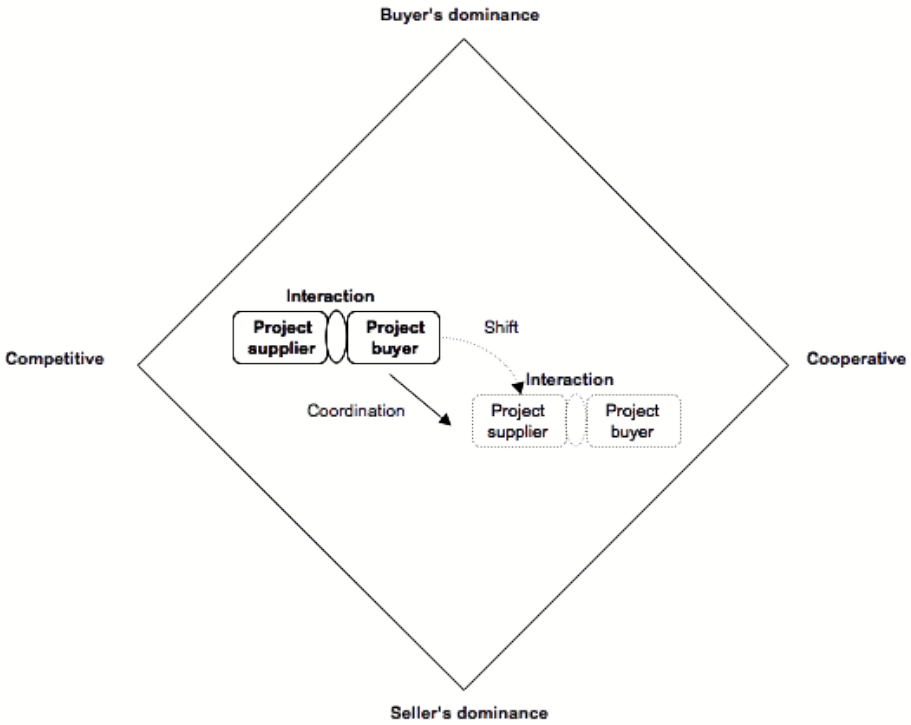

Figure 1: Theoretical framework: relationship coordination during a shift in the interaction processes and modes along stages of the project supply process.

In the framework an "extended" view to projects is adopted (e.g. Artto, 2001; Mandjak and Veres, 1998) in order to describe and explain coordination during the entire project supply process. Consequently, project is split to three general periods: pre-project, project and post-project. Pre-project stage starts from the first contacts between the parties directed towards cooperation. Signing the project supply contract means beginning of the project stage. When the project is delivered to the customer, so that it can start to use the system, project moves into post-project stage. From this point onwards further exchanges are viewed as service exchanges, not as incremental projects. Post-project stage continues until the supplied project is replaced with another one.

When project progresses from one stage to another, content of the interaction processes and modes changes along the way, which is reflected as a shift in the diamond surface (Ojansivu et al, 2011). Different tasks take place between project supplier and buyer during separate project stages requiring particular content of interaction processes. Therefore progress in the project creates changes in exchanges, coordination and adaptations between the parties. For example, if interaction mode turns into competitive and submission, exchanges are dealt on short-term basis, coordination is bound to turn formal and adaptations are minimized. It has been shown, that project stages represent possible information break points in the relationship, because the organizational structure in the supplier company becomes adjusted (Skaates and Tikkanen, 2002, 399). Coordination is needed, in order to facilitate the transition between stages.

RESEARCH DESIGN AND METHODOLOGY

The methodological choices of this research are guided by the basic aim of expanding existing knowledge of relationship coordination during extended project supply process the context of service intensive project business. Due to the novel nature of this phenomenon and the complexity of project business in particular, single case study has been chosen as the method of this inquiry (Stake, 2000, pp. 435-454). The author collected all the data specifically for the purpose of this research. The main data source through which the relationship coordination will be described consists of semistructured interviews (Kumar, Stern & Anderson 1993; Arksey & Knight, 1999) of employees of the supplier firm and its main three public customers (see table 1). The choice of informants was premised on the principle that information is best elicited from people who have knowledge of relationship coordination. Although other respondents working in the same company could have offered additional viewpoints on this subject, a key informant from each company was chosen based on the understanding, that he was actively involved in the relationship and thus able to provide explicit and definite insight into it. All the interviews were taped with the interviewee's permission and then transcribed and analyzed accordingly. Qualitative data analysis was employed in order to thematize the material (see Miles & Huberman, 1984). Documents, minutes of meetings, industry reports and company visits were used to triangulate the respondents' answers, as suggested in literature (Patton, 1987; Denzin, 1978). Data triangulation was first used to compare the different perspectives presented by each of the interviewees and, subsequently, to compare the interviews with other sources, such as industry reports, in order to validate our observations and interpretations (Denzin,

1978). The results are presented in the next section. The identities of the companies or the respondents are not revealed for reasons of confidentiality.

Table 1: Interview data.

Company	Position	Date, and duration of the Interview
Alpha	Business unit manager	May 2006 (1 h)
	Chief executive	December 2005 (2 h)
	Chief project manager	July 2006 (2 h)
	Project manager (a)	May 2006 (2 h)
	Project manager (b)	June 2006 (2.5 h)
	Leading application designer	June 2006 (1.5 h)
	Sales manager	December 2005 (2 h)
City	IT Project manager	July 2006 (2 h)
Uni	Application designer	June 2006 (2 h)
Edu	Development manager	June 2006 (2 h)

BUSINESS RELATIONSHIP COORDINATION: A SINGLE CASE STUDY

The empirical setting of this research is build around a single case study of a content management systems (CMS) supplier. The goal of the empirical research was to increase understanding of challenges related to relationship coordination during extended project supply process. Besides of the company representatives working in the customer surface, also three main public customers of Alpha were interviewed to achieve customer perspective to coordination and data triangulation. These customer are a medium size town in Finland referred onwards as City, an University called Uni and an educational federation of municipalities namely Edu. The supplier company of the case study, Alpha, was founded in 1997 to develop web-technology based systems and digital user interface design. The main product of Alpha, and the subject of exchange in the case relationships, is a content management system (CMS) referred onwards as AlphaWeb, which customer receives through the ownership of a license, but whose intellectual property rights (IPR) holds the supplier. AlphaWeb projects can be described as fairly unique and complex requiring on average 50 percent tailoring. Alpha functions in typical service intensive project business as it provides a variety of services ranging from basic maintenance services to more sophisticated development, education and consulting services. Yearly revenue for Alpha is around 4,36 million euros.

Coordination in the pre-project stage

Typical AlphaWeb delivery begins long before the formal competitive bidding process by informal social networking between the sales and marketing people from Alpha and its potential customers. It is also typical that the customer orders first a minor application from Alpha to check its reliability. Thus, when the bidding process begins, Alpha has already a social relationship to the provider of the bid. No ties are yet formed and interaction is restricted mostly to information and social exchange between the sales people of Alpha and its customer candidate. In this stage buyer has typically dominance over the competing suppliers as long as the contract

remains plank. However, if a social relationship exists, dominance becomes lesser and bidding process might even represent a "show" just to play by the book. Coordination at this stage is formal and customer applies arm's length approach to keep the distance to the suppliers and make them compete for the winning bid. Challenges begin to appear after project contract has been signed and the actual project delivery begins, because promises made by sales persons have to be met on technical level during the project. Project management of Alpha was suffering from the unrealistic promises as pointed out by Alphas leading project manager: *"On one occasion sales person had been visioning stunning and extremely expensive ideas and was thus able to acquire the customer. After this it was the project manager's responsibility to keep the unrealistic and overhyped promises from the sales person as best he could with his technical knowhow."* This communication problem related to the organizational structure of Alpha. Project managers felt that they were a "lover rank" in the company hierarchy because they did not have permanent function as sales and marketing had. Project managers went from a project to another one quickly and were involved with customer only during the active implementation. Project managers felt that problems faced in project specification were neglected and project management was not in the position to complain as Alphas project manager B stated: *"After all you feel that because sales division is higher in the company hierarchy than project management, so we are just, we are just ordinary mortal."* Sales people on the other hand did not know much about the technical details, as they were more interested of the potential sale than the following delivery. One of the concurrent problems was timing of the project that was seen by sales people very optimistically, which was causing delays in delivery, stress for project managers and unhappy customers. This created tension between these two professional groups as clarified by Alpha's leading project manager: *"At the moment our sales people don't have the required technological know how. They know the small talk and are thus able to bring the customers in, but when thinking of customer responsibility, well it's another thing. Basically sales people bring the customers in, but afterwards everything is unclear, and the same stuff goes on today."*After Alpha had won the competitive bidding process and acquired the customer, sales people and possibly upper management involved in the negotiations stepped aside from the relationship and moved customer responsibility to the project manager and project team.

Coordination during the project stage

Project stage began by Alpha setting up the project team including at least an application designer, graphic designer, software developer and a project manager. It was project managers task to continue from where the sales people had left after contract signing. This was challenging, because project implementation required more cooperative interaction with the customer, because all the necessary details had to be discussed and the system tailored according to the customer preferences. From the customer perspective, this was the time when most of the social interaction took place and the project team members of Alpha became known, as highlighted by the development manager of Edu: *"Of course in the development phase and during the system implementation we knew all software developers who were working for us and we almost acted like…well, we didn't gave them direct assignments, but nevertheless they were present in meetings so we could communicate with them directly about problems in hand and*

guidelines for product development." The important role of the project team shifted the power balance to Alpha that was obligated to deliver according the project contract. At this stage, depending of the project characteristics, adaptations started to take place between the interacting parties and coordination was needed to adapt schedules and work routines as expressed by Citys IT project manager: *"We could pay a visit to Alpha at anytime, talk things through in the phone and do rapid adjustment or updates…and when we had an emergency they would speed up their processes."* When project delivery came to an end and project team was dissolved, setting the customer responsibility proved to be difficult. Sales representative that had acquired the customer had stepped aside after contract signing and the project team members including project manager were already working on other projects, so it was challenging to held anyone directly responsible. However, project managers had often built a social friendship to the customers and they knew the customer specifications by heart, so they felt responsible for the customer as Alphas project manager B pointed out: *"As far as I understand the roles right, responsibility for the customer should stay with me after the project. I take care of all the practical things and the sales responsibility stays with the sales person. I don't know how it should be, but I personally feel responsible for the relationship. I can't just disappear after the project has ended. After all, I'm the one customer is calling after the project. This can be confusing for customers and I know occasions when customers have been struggling to find their primary contact person."* Customers were told not to contact directly any productive resources such as application or software designers after project ending. However, customers saw this as a strange arrangement, as they had formed personal relationships to these people during the project. Some customers persisted to contact software developers and application designers regardless of the advice from Alpha just to discover they were not there anymore.

Coordination in the post-project stage

In service intensive project business, post-project stage marks the end of the project supply process and beginning of the service supply process. From this point onwards Alpha viewed further exchanges as service exchanges, not as incremental projects, because post-project stage was seen to continue until the system is replaced with another one. Generally speaking, two opposite interaction modes were apparent during post-project stage. In the first one, business relationship continued as exchange of maintenance services**.** These services were very basic and did not require much interaction. However, due to the proprietary technology AlphaWeb contained, they had to be acquired from Alpha, which increased its power in the relationships. This type of interaction mode was not very cooperative as these services were delivered without direct contact with minimum inconvenience and therefore coordination was handled through electronic means. Actually most of Alpha's customers were in this stage as explained by Alphas project manager A: *"When we are dealing with a basic small customer, like an association or a small private sector company, business with them is usually active only during the implementation of the system. After this it turns pretty much to a maintenance type relationship and we don't have any project like activities going on with them anymore."* The second post-project interaction mode resource exchange is build upon development services, which require a more cooperative interaction mode. These services often included consulting and develop-

ment activities and marked sizeable profits for Alpha. In addition, Alpha was able to further benefit from this interaction mode, as it was able to build simultaneously its own technological capability. It was, however, difficult to find customers who had the resources to invest heavily on R&D, so if a potential customer appeared, it gained more power in the relationship. In this stage coordination was most concerned with relationship continuity, as Alpha tried to keep the cooperative service exchange going. Alphas leading application designer highlighted the important role of project managers in this stage: *"It is part of our unwritten guideline and success that project managers have known their customer's situation perfectly. So, they have been able to offer services, such like development and further development services and played the role of a consulting person…It has been our strength, as it builds the size of the delivery, and then we are not just selling licenses anymore."* Problems appeared when customers that had been involved only with basic maintenance services begin to develop their system. At this point their know project managers could have moved away and be replaced with new ones that did not possess all the necessary knowledge of the relationship history as described by Alphas project manager A: *"It was challenging to build relationships to customers that were accustomed to another person, who had been responsible for the original project. It was especially hard, because these customers had been on a maintenance stage for long, much longer than I had worked for the company."* This phenomenon appeared to be a continuing problem in Alphas customer relationships and one of the reasons for the interaction to turn from active development back to passive maintenance. The application designer of Uni pointed out the frustration regarding this issue: *"Of course certain things have been left unfinished, or we have agreed things with the previous person and then the next one has not been aware of these because information has not been passed from a project manager to another project manager."* Alpha's project managers explained that this was not a straightforward issue, because project manager's resources were scarce and customers were plenty. That was the reason why project managers had to priories and decide which customers earned more attention than others as explained by Alpha's project manager A: *"Communication with maintenance customers depends on the heaviness of their system use. Of course it makes a difference whether the customer has only a small and basic website where only topical information is maintained or an active environment where 250 people are involved in updating the website every day."* It seemed that there was no simple solution for the customer responsibility problem along the different project stages. General impression was that sales people in the pre-project stage should be replaced with persons possessing wider understanding of project business and technical details of projects as the leading project manager of Alpha pointed out: *"One should get rid of the sales representative and replace him with an account manager type of person, who would understand business, technology and the product to be sold."* It was considered important that same person would stay in the relationship from the beginning so that customer responsibility would not be transferred between project stages. Therefore using an account manager only after project completion was seen unwise, because then all the customer specific information would be jeopardised as project manager B of Alpha pointed out: *"I don't think that using an account manager for all the old customers would solve anything. According to my knowledge, it's best to have one project manager responsible for the customer from the project implementation onwards, so that responsibility is not shifted again to another person."*

ANALYSIS

The single case study reflected challenges in business relationship coordination along different stages of the project supply process. In the pre-project stage main tasks of coordination related to creating and maintaining social relations to potential customers and after project negotiations got underway interaction changed to more formal consisting of information exchange and buyer's dominance during the competitive bidding. Sales people and upper management from Alpha were in charge of the contract negotiations and formal meetings. Main task of coordination was to create technically realistic bids that were at the same time compelling for customers. The role of the sales people in the pre-project stage was questioned, because they did not posses the required technical knowledge of the product and were therefore causing problems for the subsequent project stages. Educating sales people of project business special characteristics and improving their knowledge of the supplied system could improve the situation.

Project stage was more or less a rapid specimen of project team's skills to implement the system, which shifted the relationship to a more cooperative setting and increased supplier's power in the relationship. Exchange included information, social, economic & technologic aspects needed to finish the project on time and budget. Coordination activities were dependent on project characteristics, with more complex and unique projects demanding wider organizational interaction. The main challenge was to implement the often abstract and highflying sales speech that could be misleading with reality. Improving communication between sales and project people was seen as a possible solution, but would be difficult to accomplish, because the company hierarchy that highlighted sales departments position in the organization over project management. This made sales people reluctant to care about business relationships after customer had been acquired and contract signed.
Post-project stage proved to be an evolving one, with interaction activities moving from development to maintenance and vice versa. For the period of development activities communication was intensive and kept personal. These activities required interaction between various organizational levels and professionals and therefore relationship turned into a more cooperative setting. Relationships were generally neutral or buyer dominated, which occurred if the customer had exceptional resources. Most of the adaptations were formed during development activities when system was tailored and new applications created. Interestingly, customer responsibility was often unclear as it was dependent on project characteristics, but it usually involved project or sales manager. Not surprisingly, the main challenge of coordination was to improve communication between sales and project people. This was needed to achieve a more consultative approach towards customers integrating sales knowledge with technological understanding. Alpha was not able to continue this stage perpetually as relationships turned finally into maintenance.

During maintenance activities relationships were passive and communication was organized non-personally by using electronic CRM. Relationships tended to be competitive and supplier dominated, because customers did not have a choice due to earlier relationship specific investments. Maintenance activities did not cause other than psychological ties at most, because

interaction and further investment were kept minimal, but the previous structural ties remained unchanged. The main problem of coordination was to disconnect customer from the project team members and project manager after project implementation or active development activities. This was necessary, because project team members were working already on other projects and therefore busy. This was bizarre in a sense, that it was Alpha's best inters to continue active development activities as long as possible, but at the same time there was not enough resources to keep active interaction going, if customers were not involved with development activities. As a way out of this problem it was suggested, that project managers should be kept in charge of the relationships after project implementation permanently. This would however require more resources for project managers that were already tremendously busy. Table 2 summarizes the findings of the case study.

Table 2: Summary of the findings: relationship coordination during extended project supply process.

Project stages	**Pre-project**	**Project**	**Post-project Maintenance**	**Post-project Development**
Persons involved with coordination	Sales & upper management	Project manager & project team	Non-personal electronic ways	Unclear
Tasks of coordination	Social interaction & winning bids	Successful project implementation	Problem solving with minimum inconvenience	Further service sales & relationship continuity
Challenges of coordination	Creating tempting but realistic bids	Implementing the abstract sales speech	Disconnect customer from the project team members	Interaction between sales and project management
Proposed solutions for coordination	Educate sales people of project business characteristics	Improve communication between sales and project people	Keep the project manager in charge of the relationship	Replace sales speech with consultative problem solving

DISCUSSION AND CONCLUSIONS

In the present study relationship coordination during extended project supply process in the context of service intensive project business has been explored. The Focus of this research has been to find out, how fluctuating interaction between project stages affects relationship coordination, and what type of managerial actions can be taken to overcome the resulting challenges. Based on the literature review, a theoretical framework was constructed, portraying relationship coordination during a shift in the interaction processes and modes along stages of the project supply process. Based on the findings of the single case study, an empirically grounded framework for relationship coordination in service intensive project business in proposed in the figure 2.

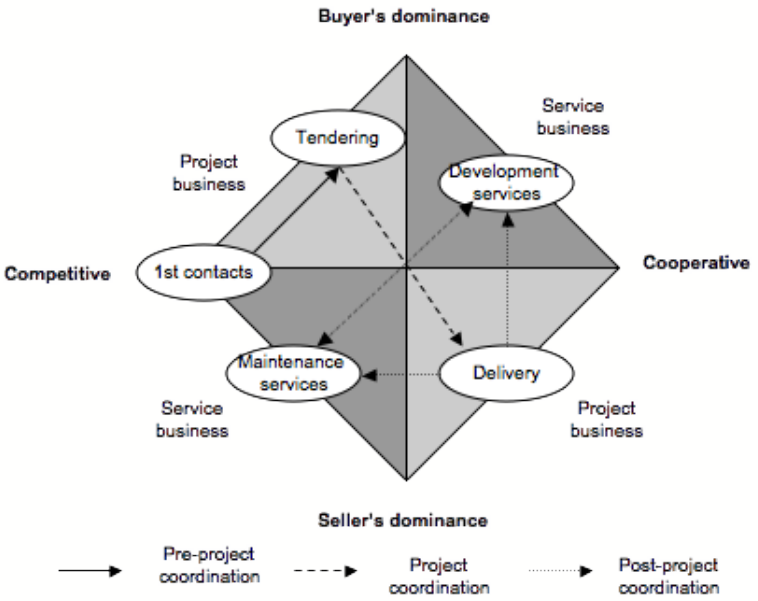

Figure 2: Empirically grounded framework for relationship coordination during extended project supply process.

In the framework the diamond shaped surface in divided to four sections, which each hold resemblance to a separate stage along the extended project supply process and require particular type of coordination depicted with specific arrows. It is acknowledged, that while business relationships goes through these stages, interaction processes and modes evolve concurrently. Each of these sections, however, reflects specific relationship characteristics predictable in advance. During the pre-project stage (the left upper quarter of the framework), interaction is limited to information exchange between sales people and customer and relationships are buyer dominated and competitive. In the project stage (the right bottom quarter of the framework) more cooperative setting is required in order to finish the project, yet the power balance shifts to the supplier who holds the written contract for the delivery. At this stage interaction is wider and coordinated by the supplier's project team. First minor adaptations take place, as the interacting parties adjust their work processes and schedules. This stage represents the first information break point in the relationship as the responsibility of the project is passed from the upper management to the project team (cf. Skaates & Tikkanen, 2002, 399).

After project has been completed, interaction revolves around service exchanges. Post-project stage resembles the second possible information break point in the relationship, as the project team becomes dissolved (cf. Skaates & Tikkanen, 2002, 399). In the framework, two opposite interaction modes for post-project stage are suggested. In the first one, business relationship continues after project completion as exchange of maintenance services (the left bottom quarter of the framework). These services are very basic and do not require much interaction between the parties, i.e. the relationship shares similarities with the sleeping relationship (Hadjikhani, 1996) with the exception of the continued economic exchange. These services are easy to produce, and if the supplied project requires proprietary technology they need to be acquired from the original project supplier (Ojansivu & Salo, 2010), which shifts the power to the suppli-

er. This type of interaction mode is competitive and passive as these services tend to be delivered without direct contact with minimum inconvenience.

In the second post-project interaction mode resource exchange is build upon development services, which requires a cooperative interaction mode (the upper right quarter of the framework). These services can include consulting and R&D and mark sizeable profits for the supplier. In addition, supplier can further benefit from this interaction mode, as it is able to build simultaneously its own technological capability (cf. Wynstra, Axelsson & van der Valk, 2006). It might be difficult, however, to find customers who have the required resources, so if a potential customer appears, it will most likely gain the power over the supplier. Depending of the service characteristics, adaptations create structural dependency between the interacting parties. Especially if the technology in the supplied project is proprietary (Teece, 1986; West, 2003) and the system is highly customized, high switching costs may appear (Lohtia & Krapfel, 1994; Wilson, 1995).

Interaction modes evolve during the post-project stage and therefore cooperative development service exchange may turn into competitive and passive maintenance service exchange and vice versa. It is managerially challenging to predict these changes and coordinate relationship accordingly. In the next section, these problems are addressed both theoretically and managerially.

Theoretical and managerial contributions

This research contributes to the IMP-related project business research, by deepening our understanding concerning business relationship coordination during extended project supply process in service intensive project business. Based on the literature review it was suggested, that the previous research does not depict interaction processes, not to mention coordination, during different stages of the project supply process. Therefore an “extended view” to projects was adopted to overcome the limitations of the previous research. Thus, project stages were not restricted to time before project contract like the previous supply process research had assumed and view of the project was not limited to an “episode” as the interaction research had assumed. Consequently, this research proposed a framework for relationship coordination during a shift in the interaction processes and modes along stages of the project supply process in figure 1.

Based on the empirical findings, relationship coordination is strongly affected by the fluctuating interaction during extended project supply process. This can be seen in the high employee turnover in customer surface, communication problems and challenges in controlling customer responsibility. Accordingly, an empirically grounded framework anchoring certain coordination characteristics to each project supply stage was put forward in the figure 2. Results support the previous findings of the information break points during project supply process; information accumulated during project negotiations from sales people and upper management has to be passed to project team during project stage and after project team becomes dissolved custom-

er specific information needs to be transferred to the next responsible person in the post-project stage.

Fluctuating interaction during project supply process is challenging managerially, because it affects relationship coordination. By connecting project stages into certain coordination characteristics, relationships are made more transparent and therefore manageable; managers can expect specific behavior from their counterpart along each project stage and review their own behavior accordingly. To translate the theoretical findings into practical ones, three aspects of fluctuating interaction require further examination relating to relationship coordination. First, sales people need to have knowledge of project business characteristics and they need to understand technological details of the supplied system. Secondly, relationship coordination is difficult when project progresses from one stage to another, and therefore replacing project managers during project should be avoided to the last resource and project managers should be kept in charge of the relationship starting from project implementation. Thirdly, customer specific knowledge derived from sales people, project managers and upper management during different stages of the project supply process should be secured in company databases and actively used. To conclude, long-term relationships require management attention and the supplier needs to be on tiptoes, because both ideas for product development and resources for product development arise from customers.

Limitations of the study

Business relationships are strongly embedded in their specific environment and therefore generalizations are challenging. In fact there exist only few models appearing as general relationship development frameworks (cf. Dwyer, Schurr & Oh, 1987; Ford, 1980). Current research is qualitative in nature and provides insights into service intensive project business, and especially CMS projects. Thus, results should be generalized with caution to other type of project business, while future research is needed to validate the findings in broader context. The role of this research was to open up new avenues for project business and project-related services research.

ABSTRACT

This paper discusses the meaning of business ecosystem in business development, especially in value creation and offering development. The discussion is based on literature and a case study of service business ecosystem. Results are literature review, a case description of service business ecosystem, and critical analysis of ecosystem thinking in developing a new business. In this paper, a framework for modeling a business ecosystem was developed. Framework was also tested and a map of a service business ecosystem was presented and analyzed. Key findings were the actual roles of actors of the ecosystem and relationships between the actors. Few actors were controlling most part of value creation and revenue streams while most of the actors were only focusing on a niche portion of the ecosystem.

Keywords: Business ecosystem, value chain, value network, business model, service business

INTRODUCTION

Networked business is the reality for most companies in any industry. Business ecosystems are composed of hundreds of and even thousands of organizations globally. (Dittrich and Duysters 2007; Iansiti and Levien 2004b) Individual companies are dependent on success of the whole aggregate and thus face a vast challenge in their business development. To thrive sustainably in competition between rival ecosystems, development and innovation efforts of companies must benefit the ecosystem as a whole.

Ecosystem metaphor emphasizes network members' symbiotic relationships and dynamic nature of business network. Moore (1996) defines business ecosystem as "an economic community supported by a foundation of interacting organizations and individuals - the organisms of the business world." In a business ecosystem, companies co-evolve capabilities around new innovations by working cooperatively and competitively to support new offerings, satisfy customer needs and eventually discover innovations (Moore 1993).

This paper contributes scientific discussion of business networks by studying revenue streams and offering structures in developing a new business ecosystem. The study focuses on a single business ecosystem, which is considered as a closed system for the simplicity's sake. This system consists of three types of actors: consumers, businesses and operators. The research question is: ***How can the business models of actors be exploited in developing a new business ecosystem?***

For the background literature is reviewed. As a main contribution, a business ecosystem is modeled based on inside information of service business industry. To ensure the privacy of stakeholders, data discussed in this paper is reduced and disguised. Main managerial implications and conclusions are discussed from the viewpoint of business development in a business ecosystem. The main implications contribute on how business model approach can leverage the development of a new business ecosystem. The actors in ecosystem can utilize the model in positioning themselves in the ecosystem. In addition, external organizations can exploit approach described in this paper to model current state and determine potential development paths within the ecosystem they are involved.

THEORETICAL BACKGROUND

Modeling business models and ecosystems are fundamentally based on the mechanics of value chains and value networks. Therefore, theoretical elementary of value chains and networks are described first. Then business models and business ecosystems are introduced and finally theoretical background is synthetized.

The idea of value chains is introduced as industry level approach where each actor, or a firm, adds value to the product (Porter 1985). In a value chain, organizations are horizontally linked to each other and each provides products or services to the next operator in the chain (Porter 1985). Value chain can be considered as a group of sequential activities, which can be connected through information and resource flows. The ultimate goal of a value chain is to provide value to the end customer of the value chain.

In contrast to value chains, in value networks the value created is not only for the customer, but also for firms and societies participating in the network (e.g. Parolini 1999; Bovet and Martha 2000). In value networks, resource and information flows can run vertically and horizontally. These flows can be simultaneous and multidirectional. Therefore, the value network could be rather described as a web than a funnel like value chain. The value network can be as a network structure where actors are linked, vertically and/or horizontally, to each other through value exchange activities. The ultimate goal of a value network is to provide value to the end customer and actors participating in the network.

While value chain and network approaches focus on value creation, value capture functions are ignored. Therefore, it is essential to broaden our approach to business models to understand the role of value capture in an ecosystem. Next business model literature is introduced and summarized briefly.

Business model elements and components

Business models are actively discussed topic in literature during last fifteen years. As a consequence, dozens of various business model concepts and frameworks exists including up to fifty different business model components (Morris et al. 2005; Mäkinen and Seppänen 2007; Shafer et al. 2005). For this study couple of various and comparable business model definitions and frameworks is chosen for review. Those frameworks form a representative sample of literature that is presented at table 1. in terms of main elements and components.

Afuah (2004) defines a business model of a firm as a framework for money-making and explains business models as a strategic management approach. This framework is conceptualized through five main elements and embodies money-making aspects of strategies. According Osterwalder and Pigneur (2009) a business model describes the rationale of how an organization creates, delivers and captures value. Furthermore, Osterwalder and Pigneur (2009) explain the business model being like a blueprint for a strategy to be implemented through organizational structures, processes, and systems. It is broadly used model that is conceptualized through four main elements and nine building blocks. Shafer et al. (2005) define business model as a representation of a firm's underlying core logic and strategic choices for creating and capturing value within a value network. This descriptive study is an example of many attempts to define business model by integrating and synthesizing earlier literature. According Suikki et al. (2006) business model describes the offering, the value chain or network, and revenue model of a firm. Suikki et al. (2006) designed their framework for describing and building business models in telecommunications industry. It provides an example of using business model for research purpose in industry settings.

Table 1: Business model elements and components in literature.

Author	**Main elements**	**Components**
Afuah (2004)	Positions	Customer value, market segments, revenue sources, price, relative position (vis-à-vis competitive forces)
	Industry factors	Competitive and macro forces, co-operative forces and industry value drivers
	Activities	Decisions of: Which activities to perform and which not, how to perform activities and when to perform activities?
	Resources	Resources (or assets: tangible, intangible and human), competences (or capabilities)
	Costs	Cost drivers of: industry, resource, activity and position
Osterwalder and Pigneur (2009); *Osterwalder* (2004)	Offer	Value proposition
	Customers	Customer segments, channels and customer relationships
	Infrastructure	Key resources, key activities and key partnerships
	Financial viability	Cost structure and revenue streams
Shafer et al. (2005)	Strategic choices	Customer, value proposition, capabilities/competences, revenue/pricing, competitors, output (offering), strategy, branding, differentiation and mission
	Create value	Resources/assets and processes/activities
	Value network	Suppliers, customer information, customer relationship, information flows and product/service flows
	Capture value	Cost, financial aspects and profit

Suikki et al. (2006)	Offering	Composition, customer and sales approach
	Value creation system	Structure, players and size
	Revenue model	Basic logic, cost and pricing structure, market and share of value

Mäkinen & Seppänen (2007) concluded that literature of business models is diverse and lacks unified taxonomy and conceptual groundings. Besides differences in naming and in hierarchical classification, there is divergence also in actual content of business models. Inside a firm, business model concept is linked with and somehow positioned between strategy and operational level in which activities and processes are carried out (e.g. Osterwalder 2004). It is being argumented whether business model includes competitive strategy, value capture aspects of strategy or is like a blueprint of strategy (Afuah 2004, Chesbrough and Rosenbloom 2002, Osterwalder and Pigneur 2009). Furthermore, Osterwalder and Pigneur (2009) and Suikki et al. (2006) exclude strategy from business model itself. Relations to external environment and actors outside a firm are variously described and included in business models. Besides customers, perception varies which actors should be included in business model by default. In addition, approach to value creation varies from value network to be based on resources and activities. Relation to environment is overextended in Afuah's (2004) business model framework compared to others. Especially, the main element of industry factors and its components are not built into others' business model frameworks. This study distinguishes industry factors from business model because those factors are not describing how an organization creating and capturing value.

Description of business ecosystem

Ecosystem metaphor emphasizes network members' symbiotic relationships and dynamic nature of business network. Moore (1996) defines business ecosystem as *"an economic community supported by a foundation of interacting organizations and individuals - the organisms of the business world. In a business ecosystem, companies co-evolve capabilities around new innovations by working cooperatively and competitively to support new offerings, satisfy customer needs and eventually discover innovation*s (Moore 1993). " Iansiti and Levien (2004b) describe business ecosystem as "*loose networks – of suppliers, distributors, outsourcing firms, makers of related products or services, technology providers, and a host of other organization – that affect and are affected by the creation and delivery of a company's own offerings*." Originating from biology, an ecosystem provides a rich analogy for understanding business networks. Those, as well as biological ecosystems are characterized by a large number of loosely interconnected participants who depend on each other for their mutual effectiveness and survival (Iansiti and Levien 2004a).

These (biological) ecosystems has some specific features - the structure, the relationship among members, the kind of connections among members, and the differing roles played by their members (Iansiti and Levien 2004a). According Corallo et al. (2007) parties in a co-evolutionary relationship activate selective pressure on the other, and consequently affect each other's evolution. Economic and social aspects are emphasized in business ecosystem; its evolution is due to competitive and cooperative interactions of its members. Differing behavioral roles exist in every business ecosystem: very few keystones, few dominators,

large amount of niche players and few special members. In a business ecosystem, network is a key activity of members. Members share the total value that the ecosystem creates. Each organization adds one or more distinct aspect of offering value to the value generated by the ecosystem (Corallo et al. 2007)

Business model elements to describe ecosystem

In a simplified manner, *business model describes how a firm is creating and capturing value* (c.f. Shafer et al. 2005, Osterwalder and Pigneur 2009). Studied business model frameworks identify customer and firm's offering that proposes value to customer. The offering is the source of revenue. Value creation is built into all business models but emphasis is given on different aspects of it, such as resources, activities, value network and its participants. Costs are very basic element of all business models. Costs result from other business model elements. For example, using and maintaining capabilities and resources, making acquisitions from value network and delivering an offering cause costs for a firm. Main actors in business model frameworks are a firm and customer. In addition, different kind of co-operators, namely suppliers, partners and players in value network are mentioned in literature. As a summary and integration of business model frameworks, this study lists elements and components of business model for describing a business ecosystem in Table 2.

Table 2: Business model elements and components for describing business ecosystem.

Elements	Components
Actors	A firm, customer, co-operator
Value creation structure	Chain or network
Capabilities	Capabilities, activities, processes
Resources	Resources, competences
Offering	Offering
Revenue	Revenue logic, share of value
Cost	Cost of: resources, capabilities, position, downstream

Elements and components of business models include describes business ecosystem several ways. Offering and revenue are the basic elements for describing business relation between a firm and customer. To create value to offer and to deliver offering, a firm has own resources and capabilities as well as with the support of co-operators in value network. This approach on business models used in this study is depicted in Figure 1.

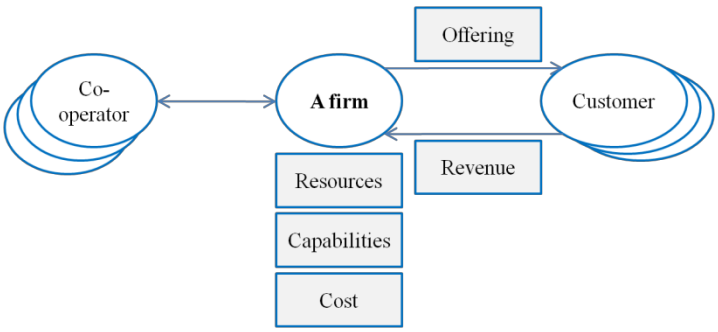

Figure 1: Business model framework and main components.

Utilizing the framework in Fig. 1, a view on business ecosystem based on actors' business models can be drawn as theoretical construction.

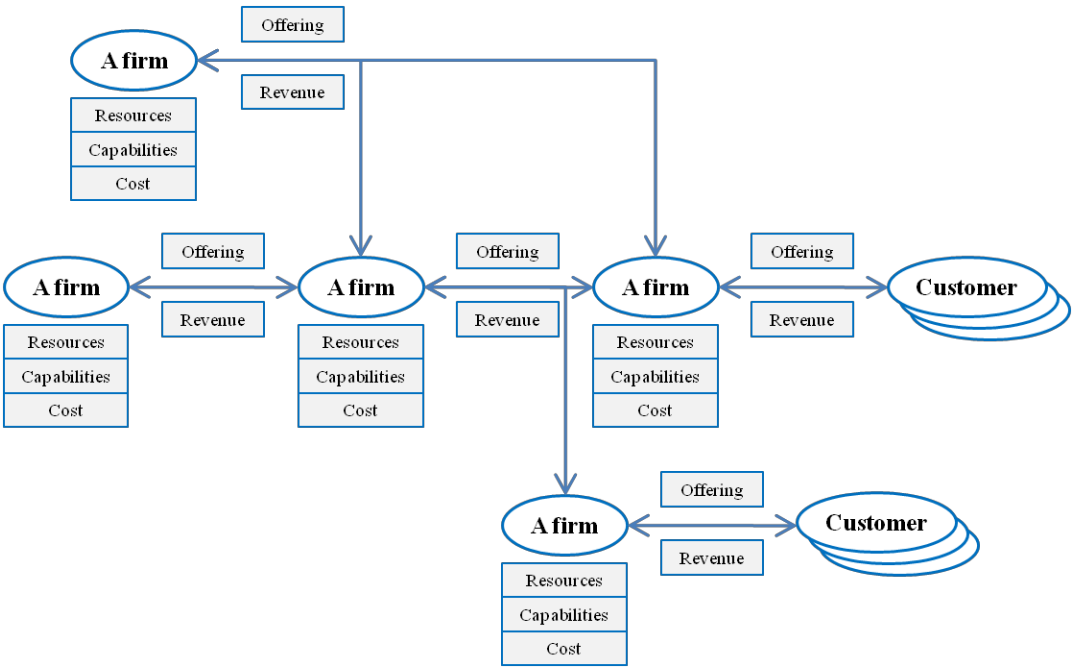

Figure 2: Theoretical view on business ecosystem based on actors' business models.

Ecosystem structure comes from vertically and horizontally interconnected members. In the case ecosystem, model is constructed from three key elements described in Table 2. These elements are *actors, offering* and *revenue*.

RESEARCH FRAME

Research context: Service business industry

Finnish service business industry grew 8,5 % at the last quarter of 2010 compared to fourth quarter of 2009. Year earlier the turnover decreased 7,7 %. (SVT 2010) Actors in service business can be divided in service requestors and service providers. These two categories are the fundamentals of a business system. Service requestors have a need for a specific service as service providers are intended to produce this particular service. However, requestors and providers mainly determine the relationship between two different actors and do not provide further information alone. Therefore different actors should be categorized further to describe their position and function in an ecosystem. In this case, actors are divided in to seven groups based on their role and offering in the system. Actors of this service business ecosystem are presented in Figure **3**.

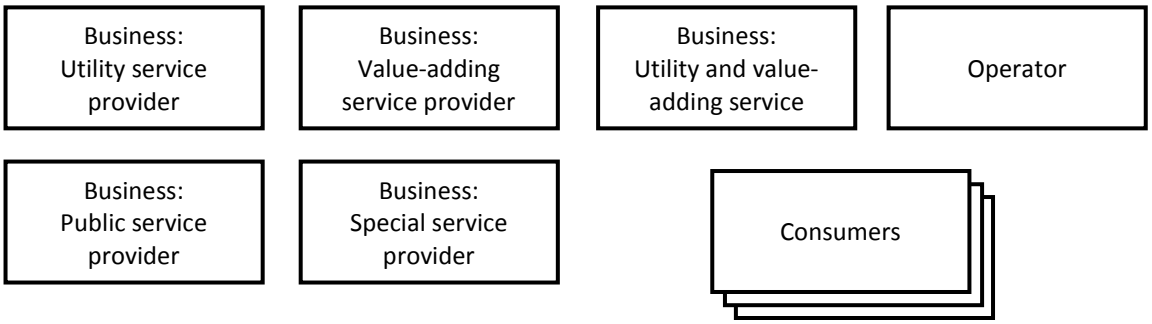

Figure 3: Main actor groups of service business ecosystem.

Consumers are the group which generates demand in the ecosystem. They are in the very end of a value chain while businesses are group which are generating supply to answer the demand. In contrast to groups mentioned above, operators are providing supply to consumers and businesses. In addition, operators can also channel demand and value between actors. Each actor in the case ecosystem is categorized to one of these groups introduced above. Furthermore, relationship between actors is modeled regarding two parts of their business models. This covers identifying their offerings and revenue streams to understand fundamentals of value capture and value creation functions. Case ecosystem is considered as a closed system. Thus actors outside this primary system are ignored although they would actually influence the ecosystem. Differences between actors are described in Table 3.

Table 3: Actors of service business ecosystem.

Actor	Description	Usage (frequency)	Customer relationship
Operator	Utility recource and service provider	Daily	Fixed
Utility service provider	Utility service procider with daily based transactions to customers. Offers services to both businesses and consumers	Daily	Fixed
Value-adding service provider	Value-adding service provider which offers monthly consumed services to customer	Monthly	Fixed
Public service provider	Provides monthly consumed public services to consumers	Monthly	Variable
Special service provider	Provides daily consumed services to a specific segment of consumers	Daily	Fixed
Utility and value-adding service provider	Provides both utility and value-adding services to consumers	Daily	Variable
Consumers	Group which generates demand in the ecosystem	N/A	N/A

To describe the case ecosystem, each actor were identified and categorized to one of the three categories mentioned above (business, operator and consumer). Actors in business category were further categorized according the classes described in Figure 3. Secondly, value creation, in terms of offering, is modeled qualitatively between actors. Then value

capture, in terms of revenue stream, was modeled. Finally, both value creation and capture were attached to combine a comprehensive model of the case ecosystem. The model was then analyzed qualitatively focusing on the number and nature of relationships between actors.

SERVICE BUSINESS ECOSYSTEM CASE DESCRIPTION

Service business ecosystem described in this paper consists of one operator, five types of businesses and one group of consumers which is assumed to be creating all the demand in the ecosystem. Business categories are categorized by industries. In addition, there are more than one businesses operating under categories *Value-adding service providers* and *Public service providers* while other business categories consists from only one actual business. Case business ecosystem is presented in Figure 4 below.

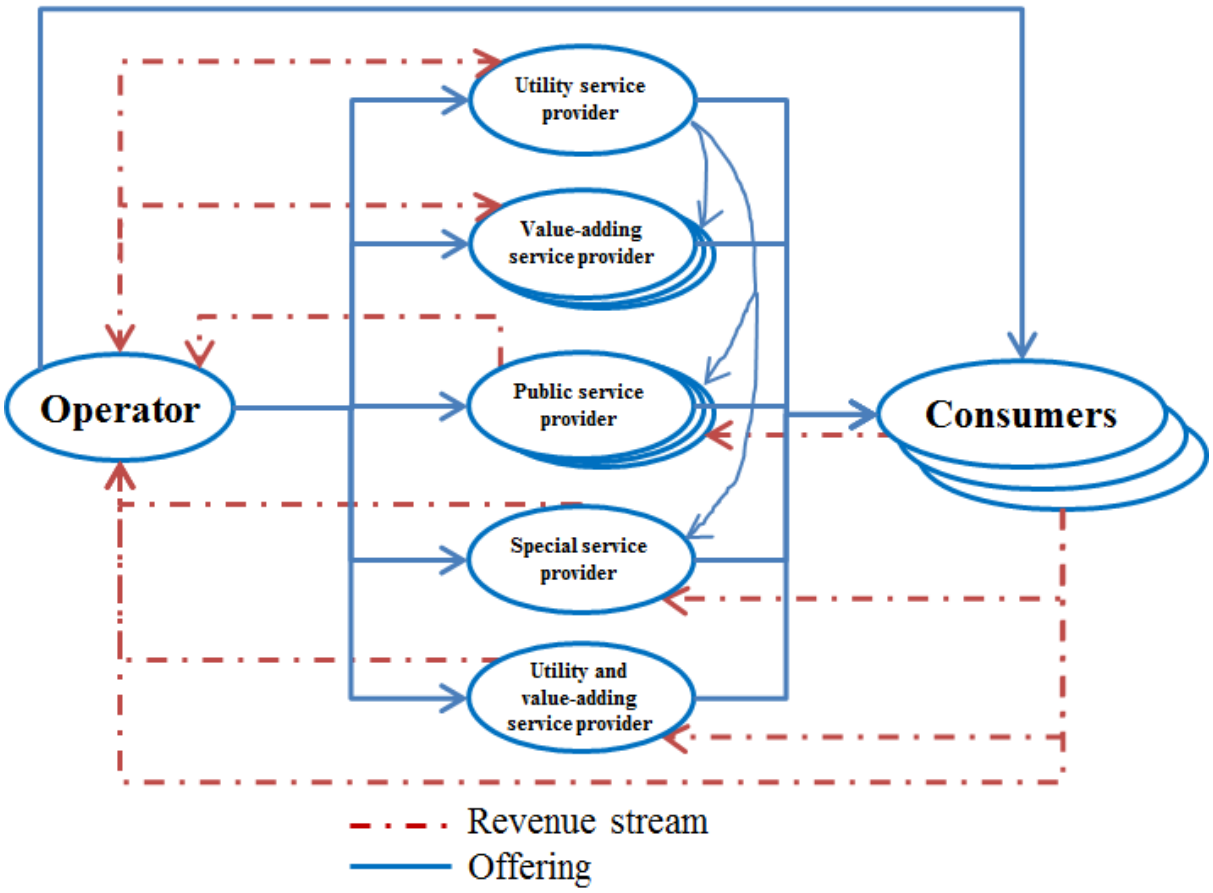

Figure 4: Service business case ecosystem.

As described in Figure 4, case business ecosystem consists of several actors, offerings and revenue streams. To raise the different roles of actors, relationships between each actor were tabulated in terms of offering and revenue stream. This data is presented in Tables 4 and 5. Moreover, offerings were categorized to resources and services. Resources indicate that receiver of created value are using the product of an offering in its own value creation process while other offerings are categorized to service category.

Table 4: Offerings between actors.

	Receiver of Created Value (Description)							
Actor	**Operator**	**Utility service provider**	**Value-adding service provider**	**Public service provider**	**Special service provider**	**Utility and value-adding service provide**	**Consumers**	**Connections in total**
Operator	N/A	(Resources)	(Resources)	(Resources)	(Resources)	(Resources)	(Services)	6
Utility service provider		N/A	(Services)	(Services)	(Services)		(Services)	4
Value-adding service provider			N/A				(Services)	1
Public service provider				N/A			(Services)	1
Special service provider					N/A		(Services)	1
Utility and value-adding service provider						N/A	(Services)	1
Consumers							N/A	0

In the case ecosystem, operator is offering resources to different businesses and this is explicit in a closed system as operator is the only supplier in this particular ecosystem. However, if the study would be extended, businesses would have other supply options. To maintain its special role, operator is offering resources below common market price, which generates a cost advantage to businesses of the case ecosystem. Operator has a cost advantage over direct competitors. Instead of just selling products with higher margin, operator is exploiting the cost advantage to gain extended control over value and revenue streams.

Table 5: Revenue streams between actors.

	Gains revenue from							
Actor	**Operator**	**Utility service provider**	**Value-adding service provider**	**Public service provider**	**Special service provider**	**Utility and value-adding service provide**	**Consumers**	**Connections in total**
Operator	N/A	1	1	1	1	1	1	6
Utility service provider	1	N/A						1
Value-adding service provider	1		N/A					1
Public service provider				N/A			1	1
Special service provider					N/A		1	1
Utility and value-adding service provider						N/A	1	1
Consumers							N/A	0

FINDINGS

To answer to the research question (*RQ: How can business models of actors be exploited in developing a new business ecosystem?*) research frame was developed and tested. Hence a case ecosystem was modeled. Even if the actual modeling didn't cover every single aspect of actors' business models, outcome provided an insightful map of an ecosystem. Therefore, business models of an ecosystem's actors can be exploited to model the value capture and value creation structures. Model can then be compared to competing ecosystems and an ecosystem under development can be elaborated to acquire competitive advantage over competing ecosystems.

In the case ecosystem, both *Operator* and *Utility service provider* are offering value to four to six different actors in the case ecosystem while other businesses are offering value to only one specific actor (Table 4). However, operator is the only actor which has more than one revenue stream (Table 5); operator gains revenue from every single member of the case ecosystem. Other actors besides the *Operator* and *Utility service provider* are focusing on a niche portion of the ecosystem. This phenomenon was also noticed by Corallo et al. (2007).

In addition, *Utility service provider* and *Value-adding service providers* are gaining revenue only from the operator even though they do not have direct offering towards operator. Therefore the actual cash flows are streaming from *Utility service provider's* and *Value-adding service providers'* customers to operator. Thus operator is completely controlling cash flows of *Utility service provider* and *Value-adding service provider*. For the operator to retain such a special role, it is crucial to have a competitive offering.

The case ecosystem modeled is not functioning as a closed system in practice. Each actor is competing with its competitors and the ecosystem is competing with other ecosystems. Key questions to ask when assessing the robustness of the case ecosystem are: 1) Why are the consumers staying in this ecosystem; 2) Why are businesses staying in this ecosystem; 3) How is the ecosystem worthwhile to the operator? What comes for the consumers, they prefer the ecosystem over competing systems because of cheaper services and value-added by operators administrative operations. Businesses, in the other hand, prefer the case ecosystem because they are gaining a cost advantage over direct competitors. And finally, operators extended control over the business ecosystem is just one technology of leveraging a cost advantage.

CONCLUSIONS

In the case ecosystem, operator is not operating in a monopoly in practice. Therefore, it's not obvious to operator to maintain control over cash flows and value creation processes. The key issues to retain its position, operator has to provide resources to businesses below market price. This is providing cost advantage to businesses of this specific ecosystem. Hypothetically, operator could dominate the ecosystem and suck all the profits from the system, but this is not feasible when competing with other ecosystem as the operator has to be able to provide more value to its co-actors than other ecosystems could.

Modeling technique developed is suitable for modeling and analyzing a business ecosystem. Mapping actors of the business ecosystem and describing their relationships will provide a model of an ecosystem. In addition to just modeling the value creation structure, approach taken in this paper covers the relationships between actors. This offers insights about roles of different actors. In particular, special roles, such as operator which controls every cash flow, should be elaborated. While developing a new business ecosystem, it's crucial to understand what is necessary for the ecosystem to succeed and compete against other systems.

This research mainly covered four relevant business model components which are actors, value creation structure, revenue and offering streams, but did not dig deeper on capabilities, resources and costs. In this study, operator was stated to be able to offer cost advantage to its customers via resources. This cost advantage, however, was not quantified. Therefore, this approach does not allow needed data to justify which ecosystem would be the most competent, if several ecosystems were modeled. To conclude, this approach developed and tested in this study provides a way to model business ecosystem by the business models of its actors, yet it does not provide data which could be used to analyze which business ecosystem would win over another.

Further research

Further research could be focused on analyzing other case ecosystems from service business industry to map different value creation structures. Furthermore, it could be interesting to study whether there is difference in success of ecosystems and what are the key issues which determine the success of an ecosystem. Do differently structured ecosystems perform differently in the market? Therefore, a hypothesis for further research could be set in the following way: *Competitiveness of an ecosystem is dependent from the structure of the ecosystem*. In addition, further research could focus on analyzing strategies of special players in an ecosystem. As in the case ecosystem, operator was in a special role, but is there other ways, than providing a cost advantage to customers via resources, to gain a special role in an ecosystem. Furthermore, is there other kind of special roles, than controlling the flows of value and cash?

ABSTRACT

Global warming is becoming a serious environmental concern, and current primary energy sources are also getting exhausted. Decentralized combined heat and power production using biofuels such as forest biomass could offer a qualified sustainable solution for many regions. The objective of this paper is to analyze what kind of heating plant manufacturers exist in the bioenergy field in Finland that also have future potential for supplying power generation units, and how they collaborate within their business networks. The primary sources of information for the industry evaluation were an analysis of major industry players based on financial and non-financial data and key expert interviews. The results reveal that the plant suppliers can be divided into three different clusters: network leaders, turnkey suppliers and distributors; and that they collaborate extensively within their business networks. The plant suppliers complement their own capabilities and competences by efficient networking that prepares the way for complete plant deliveries instead of component and parts supply only.

Keywords: Business networks; resources; capabilities; bioenergy technology; combined heat and power production

INTRODUCTION

The increased amount of greenhouse gases in the atmosphere has raised the Earth temperature, and Global warming is threatening to escalate to a serious environmental challenge. Increased use of renewable primary energy sources and improved overall energy efficiency play an important role in the future energy production and consumption. (Tekes, 2008) Decentralized (distributed) small scale combined heat and power production (CHP)

using biomasses, such as woodchips from logging residue, is also emerging as the technologies become more advanced and commercialized. At present, technologies for commercial heat and power production using various biomasses are mainly based on combustion technologies. (Kara et al., 2003) In particular, it is suitable for introducing novel production technologies utilizing forest biomasses in regions that have adequate natural resources enabling their sustainable exploitation. According to International Energy Agency (2011) biomass is a particularly lucrative primary energy source in countries where natural resources are abundant and conventional energy is expensive.

Firms operating in emerging industries, such as distributed bio-CHP generation, need various resources and competences, and they also need to collaborate with other players in order to develop the novel business environment. Firm resources, especially when they are valuable, rare, inimitable and non-substitutable, could provide sustainable competitive advantage, and thus enable the firm to find optimal product-market activities (e.g. Wernerfelt, 1984; Barney, 1991; Barney and Hesterly, 2006). However, many firms, including competitors, are sharing their resources and expertise to develop new products, achieve economies of scale, and gain access to new markets and technologies, because single firms often lack necessary resources. The go-it-alone strategy has changed into an alliance one. Strategic alliances can be either intra-industrial or inter-industrial and may include licensing, supplier relations, joint ventures, collaboration, R&D consortia, industry clusters, and innovation networks. (Trott, 2008; Doz and Hamel, 1998)

In spite of their growing importance, the Finnish manufacturers supplying distributed biofuel heating plants are still relatively unexplored. In order to fill this research gap, this paper strives to explore what kind of players and business networks operate within the group of plant manufacturers and suppliers that have future potential for also supplying power generation units. Thereby, the research question is: 'What kind of key players operate among biofuel heating plant manufacturers and suppliers in Finland, and how do they collaborate within their business networks?' Using financial data from national information provider's data sources and company literature from the firms' Internet home pages the paper analyses the key players within the business. The analysis is complemented by interviews of key industry informants in order to increase the understanding of the key players and their business networks. Finally, network analyses are conducted as a synthesis from the financial and non-financial data and the interviews.

The results reveal that the key players are small and medium size enterprises that deliver complete heating plants to end customers on turnkey basis including life cycle services, as well as parts and components of their own manufacture either to end customers or other manufacturers. The firms complement their own capabilities and competences by maintaining and developing diversified business networks that include suppliers, other manufacturers, competitors, universities, service providers and end customers. The firms can be divided into network leaders, turnkey suppliers and distributors. This paper contributes to providing evidence on firms complementing their competences by collaboration within their business networks. Knowledge about the key players, versatile network structures, and clusters in the industry have practical implications for the managers in the industry.

SMALL-SCALE COMBINED HEAT AND POWER GENERATION IN BIOENERGY

The principle of combined heat and power production (CHP), or cogeneration, has been known for quite a long time. Already in the beginning of the 20th century there were a number of units in operation. (Pehnt et al., 2006) According to WADE (2003) CHP is: 'The process of producing both electricity and usable thermal energy (heat and/or cooling) at high efficiency and near the point of use'. CHP thereby contains three focal elements: simultaneous heat and electricity production, high efficiency performance, and the proximity of energy production unit to customers. Today, several technologies capable of providing combined heat and power exist, especially in small scale, for example, reciprocating engines, gas turbines, Stirling engines, fuel cells, and thermophotovoltaics. Reciprocating engines already represent mature technology, whereas Stirling engines are just approaching commercialisation although the technological roots go back to the 19th century. The other technologies still have a few years until market introduction. (Pehnt et al., 2006) Further, Motiva (2010) adds that various technologies using different primary fuels are adequate for CHP production. Many technologies, however, still require significant R&D investments before they are feasible for viable commercialization.

At the moment, it is hard to predict which of the technologies will eventually attain new dominant design lock-in. According to Anderson and Tushman (1990) and Tushman (1997) technologies seem to undergo repeated cycles, and understanding the evolution of these cycles helps companies to predict the time of radical changes. Technological discontinuity generally leads to a single industry standard, a dominant design, which is then followed by a peak in sales and cease in innovation activity. (Anderson and Tushman, 1990; Tushman, 1997) The emergence of a dominant design is often the result of a combination of technological, economical and organizational factors, and thus it is not necessarily simply the most promising technological invention. However, when dominant design becomes the industry standard, it opens new possibilities to accelerate the adoption of a new design as dominant, for example: industry regulation and government intervention, strategic moves of firms, networking in the industry and possession of collateral assets. (Suarez and Utterback, 1995)

Compared to separate heat and power generation, decentralized CHP production provides several benefits, such as cost savings and lower emissions due to outstanding efficiency, as well as increased security, power quality and grid reinforcement due to on-site location. For example, fuel consumption could be about one third lower than in separate heat and power generation. (Combined Heat and Power Association, 2010; Ahtila et al., 2005) Small scale combined heat and power production could form a supplementary building block for a more sustainable future energy system in many countries. The economical and ecological performance of small scale CHP varies by technology and strongly depends on the implementation context. All in all, regulations and institutional frameworks play a crucial role in the development and diffusion of small scale bio CHP technologies. (Pehnt et al., 2006)

FIRM CAPABILITIES AND BUSINESS NETWORKS

Firm resources, especially when they are valuable, rare, inimitable and non-substitutable, i.e. when they fulfill the VRIN-conditions, tend to provide sustainable competitive advantage, and thus enable a firm to find optimal product-market activities (Wernerfelt, 1984; Barney, 1991; Barney and Hesterly, 2006; Bowman and Ambrosini, 2003; Johnson et al., 2006). Firms' competences are based on various resources that can be regarded as building blocks of enterprise capabilities and competencies. Core competences are a unique collection of competences that cross strategic business unit boundaries, are widespread in the firm, and are formed from the collective learning of the organization. Core competences provide access to a variety of potential markets, they contribute significantly to customer satisfaction and the company's end products, and they are difficult for others to recognize and imitate. Core competences are also rare, and typically even diversified corporations have only a few fundamental core competences. A company's long term competitiveness derives from systematically built core competences and company strategies and competences are also strongly interrelated. (Prahalad and Hamel, 1990; Javidan, 1998) It is vital for companies to integrate both company strategies and core competences. As a conclusion, companies should efficiently integrate their overall business strategy, core competences and key technologies. (Torkkeli and Tuominen, 2002)

The radical geopolitical and economical changes during the past decades have meant that company and industry boundaries have blurred and firms' legal boundaries differ considerably from their strategic boundaries. As a matter of fact, firms can achieve new innovations, growth and competitive advantage by cooperating with others in value networks (e.g. Parolini, 1999; Möller et al., 2004; Lipasti, 2007) Through collaboration and strategic alliances within a firm's external value network a firm can gain access to required capabilities by linking its own resources to partners' complementary ones, and thus achieve a sustainable competitive advantage (Barney and Hesterly, 2006; Johnson et al., 2006; Chen and Chen, 2003; Crain and Abraham, 2008). Today, a firm's supply chain (network) extends both upstream and downstream of the value chain integrating firm's suppliers, other manufacturers, service providers and customers. The ultimate objective of the value chain is to achieve a sustainable competitive advantage for the firms within the network, and furthermore, market competition takes places between supply chains rather than between single firms. (e.g. Xu, 2011; Jayaram et al., 2011; Liu and Zhang, 2011) In addition, a broad understanding exists about the significance of business networks for emerging firms and small and medium size firms (SME). Business networks are beneficial particularly for SMEs, since they are thus able to efficiently acquire resources they lack, and focus on their own core competences. (e.g. Hite and Hesterly, 2001; Fuller-Love and Thomas, 2004; O'Regan and Kling, 2011)

RESEARCH DESIGN AND DATA

The empirical study was executed as a case study. As a matter of fact, according to Eisenhardt (1989) a case study is not a methodology, but rather a research strategy that concentrates on increasing the understanding of present dynamics within a single setting. Case studies also typically combine diverse data collection methods, such as interviews,

questionnaires, observations and archives. Yin (2003) agrees with this and defines a case study a research strategy that investigates a contemporary phenomenon within its real world context. Creswell (2007) determines a case study as an exploration of a bounded system that can be defined in terms of time and place, and through detailed, in-depth data collection, involving multiple rich sources of information. The network analyses of the firms were based on financial data, literature review and interviews which were conducted in order to answer the research question: 'What kind of key players operate among the biofuel heating plant manufacturers and suppliers in Finland, and how do they collaborate within their business networks?'

The primary source for acquiring the list of companies was a trade magazine (BioEnergia, 2010), and the list was further augmented by experts' knowledge. There are, for the moment, fewer than 40 key players in the field in Finland, and 26 of them agreed to participate in the interview. These 26 firms were also included in the financial analysis. The firms' financial data was collected from a national information provider (Fonecta, 2010) whose data base includes financial data of approximately 100 000 national companies including publicly listed companies as well as privately owned small and medium size enterprises (SME). The financial data based on the financial statements of the firms included their revenue, net income, return on invested capital (ROIC), equity and quick ratio for the years 2005-2009. Based on Leppiniemi and Kykkänen (2007) while evaluating the firms' financial performance ROIC was regarded good if it was over 15 % and satisfactory if it was below 15 %. Negative ROIC was evaluated weak. Accordingly, over 40 % equity ratio was regarded good, 20 to 40 % satisfactory and below 20 % weak. Quick ratio over 1 was rated good, 0.5 to 1 satisfactory and below 0.5 weak.

The quantitative analysis was complemented with a literature review of the firms based on their Internet home pages, and with interviews with 26 key informants. The interview sessions were conducted in May and June 2010 by two researchers, the interviews were audio recorded and results were crosschecked by two other researchers. The interviewees were composed of top management and company experts including 15 CEOs and three other top executives. The key informants were interviewed using a semi-structured theme questionnaire concentrating on two main issue areas: (1) Firm related issues: background information such as market review, offered products and services, key technologies, CHP potential, human resources, competences, product modularity, exports; and (2) Network related issues: general network structure, network participants, network performance, customer orientation, network benefits to R&D. The network analyses are a synthesis from the firms' financial analysis, the literature review, and the interviews.

EMPIRICAL ANALYSES

The firms could be categorized into three clusters: (1) network leaders, (2) turnkey suppliers, and (3) distributors. Network leaders are larger firms in terms of revenue, balance sheet and number of personnel and thus their resources were estimated more significant than those of other firms. The majority of the network leaders also manufacture their core products in-house or own product-rights. Similarly, turnkey suppliers produce a part of their

products in their facilities or own the product-rights but their capabilities are lesser than those of the network leaders. Distributors mostly import their product range.

Financial analyses of the firms

The analysis included altogether 26 firms, for 19 of which financial data from the national data bank (Fonecta, 2010) was available. Financial statements of the firms were analysed from the years 2005-2009, and the firms that had financial data available for less than three years were ignored in the analysis. The results reveal that the average revenue of all the firms was 6.263 M€, the average revenue of the network leaders was 13.356 M€, the turnkey suppliers' 2.702 M€, and the distributors' 0.395 M€. The network leaders had the largest net income of 0.577 M€, (4.3 % of revenue), and the turnkey suppliers' net income of 0.173 M€ (6.4 %) was comparatively the best one. The distributors had a slightly negative net income. The return on invested capital (ROIC) was on good level in all the groups. The average equity ratio was on satisfactory level for all the company categories, whereas the average quick ratio was on good level. Generally, standard deviation (STDEV) in most of the studied factors and company groups was rather high revealing that the firms within the groups were relatively heterogeneous. All in all, the network leaders were medium size companies, the turnkey suppliers were small, and the distributors were micro companies. The good ROIC within all the groups could be a consequence of relatively good financial results and modest capital investments. The equity ratios of the firms give support to the modest capital investments. The good quick ratios of the firms reveal a generally healthy liquidity of the firms. Table 1 summarizes the comparisons of financial performance between the firms.

Interviews

The main portion of the heating suppliers' turnover consisted of domestic sales. The interviewed experts shared the view that increase in export activity is in reality the only possibility to increase company business in a sustainable fashion. The Scandinavian countries, Russia, the Baltic countries and Eastern Europe were regarded as the most promising export countries in the short term. Generally, the interviewees did not consider foreign competitors as a serious threat at the moment, since they estimated their own firm's competences higher than those of foreign competitors. The experts also estimated that customers would value e.g. warranties given by domestic firms and local maintenance services higher than those provided by foreign companies. The product assortment of the heating plant suppliers was very extensive; the plant capacity scale varied from 20 kW to 100 MW, although the typical nominal capacity of the plants was between one and two MW. Woodchips was the most common biofuel for all plants, and nine interviewees mentioned that their plant could use peat in addition to woodchips, and six plants were also able to use oil. Some plants could also use reed canary grass or grain as their biofuel.

The interviewees evaluated their firm's core competences quite differently; some mentioned just a single technology, while others specified a broader context as their competence. Ten firms named combustion technology as their core competence, three named boiler technology, and three modularity related issues. Four firms valued turnkey deliveries as their core competence, four value creating customer solutions, and two network relationships. According to the key informants, small scale CHP technology interest most of the firms. However, technological solutions are still in the emergent phase, and most of the firms would prefer to collaborate rather than to execute challenging R&D on their own. Political decisions and e.g. various investment subsidies and electricity feed-in tariffs play an important role in decision making processes.

Typically, most of the firms manufacture parts and components for the plants, such as boilers, conveyors, automation or firing (combustion) technology based on their capabilities and competences, or the product-rights belong to the firm and the parts may be outsourced. Heating plant building, construction, electrification and plumbing are typically acquired locally. However, end customers usually appreciate turnkey deliveries of the plants, and thus the plant suppliers have to collaborate with their sub-suppliers, service partners, universities, other manufacturers and even competitors in order to fulfill customer requirements.

The key informants shed light on the versatile business networks that the plant manufacturers have developed and maintain. To exemplify, a simplified business network among a part of the key players is illustrated in figure 1. For the sake of clarity, customer, sub-supplier, and service partner networks are omitted, and manufacturers' (M1; M2; etc) key technologies and focal own production activities are indicated in the figure by solid line ovals, whereas outsourced key activities and production are indicated by dashed line ovals. For example, Manufacturer number one's (M1) combustion technology is produced in-house, whereas automation is outsourced. In addition, M1 has intense relationships with manufacturers M2 and M13. In comparison, manufacturer M26 is independent from other

plant suppliers, and its in-house produced key technology is boiler technology, whereas plant implementation is outsourced. All in all, the plant manufacturers complement their own capabilities by efficiently exploiting their business networks including customers, subcontractors, other manufacturers, competitors, various service providers, and institutions such as universities. This kind of business strategy provides them for supplying turnkey deliveries to end customers instead of component supply only. A more in-depth network analysis is conducted in the following section.

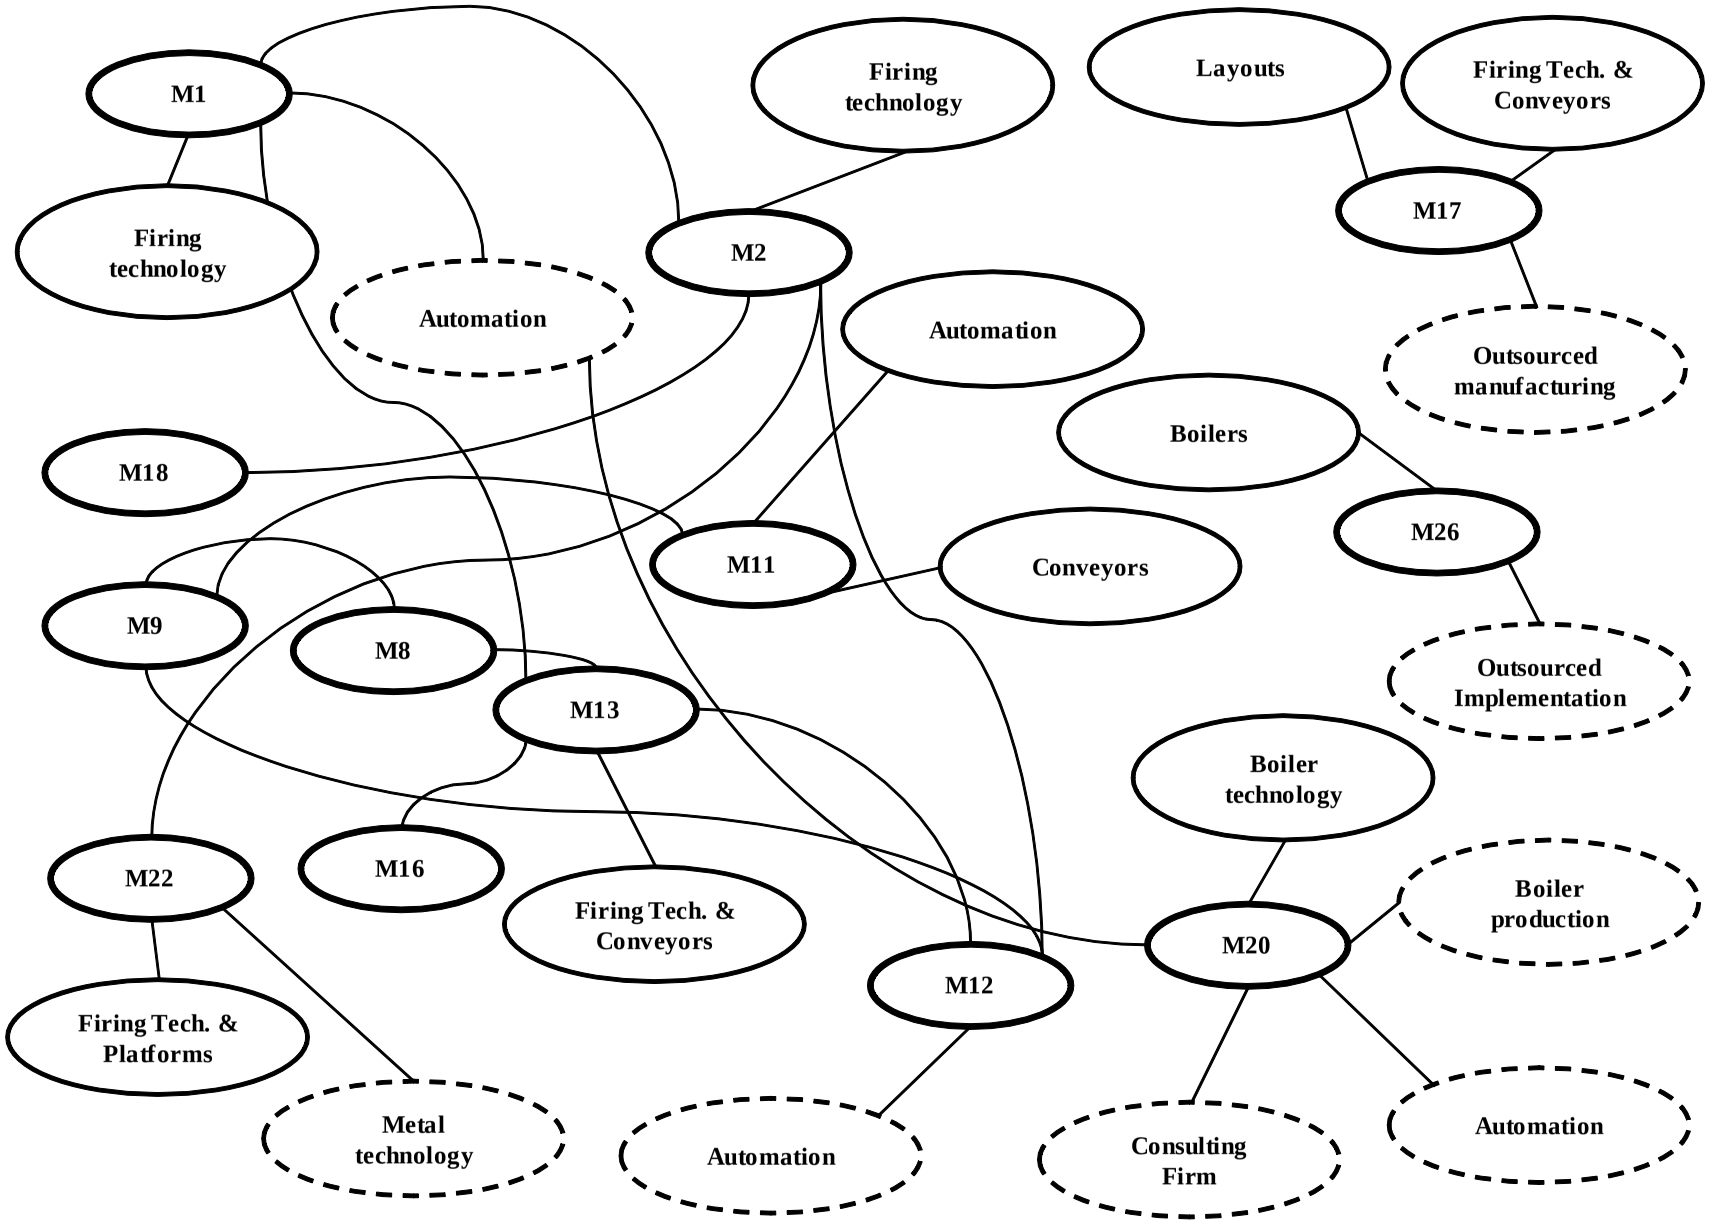

Figure 1 : Typical heating plant manufacturers' network structures.

Network analysis

Instead of making an attempt to investigate the often hidden company core competences, firms' overall capabilities were analysed by evaluating their human and physical resources, financial performance, export activities, as well as accumulated experience and know-how. Correspondingly, firms' network activities were analysed by evaluating their overall network performance, customer orientation, and network benefits to R&D. The evaluation of the different factors was based on the interviews supported by firms' data e.g. from their Internet home pages when applicable. The evaluation of financial performance was based on the financial statements of the companies, and the evaluation of the physical resources of the firms was based on actual observation of the researchers on site. Financial data was available for 19 firms, and researchers could observe 22 firms' physical resources on site. The individual factors were scored by numbers one to five so that the best value of the factor was five, the average value among the firms three and the worst value one. For example, if a firm had significant exports to several countries the value was five, and if it had very little or no exports at all the value was one. An average export activity within the firms justified the value three. Equally, if e.g. a firm's network exploitation and benefits to its R&D were significant the value was five, whereas if a firm's R&D was mostly performed in-house without any experienced network benefits the value was one. Other factors were evaluated similarly. The evaluation was executed individually by two researchers, and the results were crosschecked by two other researchers.

Finally, the firm's points for human resources, physical resources, and exports were weighted by a factor 2, whereas financial performance and experience / know-how were weighted by a factor 1. Equally, overall network performance and network benefits to R&D were weighted by a factor 2, whereas customer orientation was weighted by a factor 1. The motivation behind that reasoning was that firstly, financial data was available for only 19 firms, and the worldwide recession that hit industry and commerce in 2008-2009 may have significantly influenced these financial figures. Secondly, firms may have evaluated experience / know-how equally, but in case the capability depends merely on a few individuals, it may prove to be highly vulnerable. Thirdly, firm representatives typically tend to argue that their firm is customer oriented. Thereby, this kind of weighting in the evaluation gives higher importance to the most solid factors while at the same time balancing the influence of the factors that may carry some uncertainties. General directions for evaluation were as follows:

- Human resources (a): the number and education of employees in relation to firm's overall size
- Physical resources (b): firm's plant and machinery
- Financial performance (c): financial factors from firm's financial statements
- Exports (d): volume of exports and number of export countries
- Experience and know-how (e): background, history, and experience in heating plant supplies

- Overall firm capabilities: average outcome of (a+b+c+d+e)
- Overall network performance (f): number and nature of network partners, and network functionality
- Customer orientation (g): scope and functionality of customer relationships, partnerships
- Network benefits to R&D (h): exploitation and functionality of network for company R&D
- Network activity: average outcome of (f+g+h)

The network leaders' average score for overall firm capabilities is 6.54, the turnkey suppliers' average score is 4.21, whereas the distributors' score is 2.77. The network leaders have overwhelming capabilities compared to the other clusters, and the distributors evidently have the least capabilities. Table 2 summarizes the firms' overall capabilities.

Table 2 : Firms' overall capabilities.

	Human Resources a)	**Physical Resources b)**	**Financial Performance c)**	**Exports d)**	**Experience/ Know-how e)**	**Overall Firm Capabilities (Average a+b+c+d+e)**
Weighting	**2**	**2**	**1**	**2**	**1**	
Network Leaders, average score (STDEV)	**7.75 (1.98)**	**8.25 (1.67)**	**4 (1)**	**8.25 (2.49)**	**4.13 (0.64)**	**6.54 (1.24)**
Turnkey Suppliers, average score (STDEV)	**5.23 (1.01)**	**5.78 (2.11)**	**4.22 (1.09)**	**3.23 (2.09)**	**3.31 (0.86)**	**4.21 (1.02)**
Distributors, average score (STDEV)	**3.6 (1.67)**	**2.4 (0.89)**	**3 (1.73)**	**3.2 (2.68)**	**1.8 (0.45)**	**2.77 (0.73)**

Firms' network activities were estimated in a similar manner, and are summarized in table 3. The network leaders' average score for network activity is 4.88, the turnkey suppliers' average score is 4.69, and the distributors' is 3.4. Both the network leaders and turnkey suppliers exploit their business network to a similar extent. The distributors collaborate the least within their business network. The firms sell either turnkey plant deliveries to end customers, or components to other manufacturers, competitors and customers. This configuration has lead to a versatile network within various component suppliers, service providers, competitors and end customers. The network leaders and turnkey suppliers

operate actively in their business network, whereas the distributors link their local customers and foreign component suppliers.

Table 3 : Firms' network activities.

	Overall Network Performance f)	Customer Orientation g)	Network Benefits to R&D h)	Network Activity (average f+g+h)
Weighting	**2**	**1**	**2**	
Network Leaders,				
average score	**6.5**	**3.13**	**5**	**4.88**
(STDEV)	**(2.33)**	**(0.99)**	**(2.83)**	**(1.39)**
Turnkey Suppliers,				
average score	**6.31**	**3.46**	**4.31**	**4.69**
(STDEV)	**(1.97)**	**(1.20)**	**(2.56)**	**(1.66)**
Distributors,				
average score	**5.2**	**1.8**	**3.2**	**3.4**
(STDEV)	**(1.79)**	**(0.84)**	**(1.10)**	**(0.64)**

When the single firm's capabilities and network activities are located into a matrix (see figure 2), it is highly evident that the network leaders have the most extensive capabilities, the turnkey suppliers have lesser capabilities, and the distributors have the least capabilities. On average, the network leaders and the turnkey suppliers tend to utilize their business networks equally, whereas the distributors operate more independently. In spite of their overwhelming resources and capabilities, the network leaders actively exploit their networks. The reasoning is that their strategy is to focus on their core competences and core products and outsource other parts of the plant deliveries. The distributors act as a liaison between their end customers and the foreign component and plant suppliers that they represent. However, as the relatively high standard deviations reveal, single firms exploit their networks quite differently, which becomes especially evident while examining the turnkey suppliers' network activities. It can be concluded that single firms complement their inadequate resources and capabilities by exploiting their business network actively, whereas other firms are more independent, and tend to develop and manufacture more or less everything in-house based on their strategy and resources. The different clusters' capabilities and network activities are illustrated in figure 2.

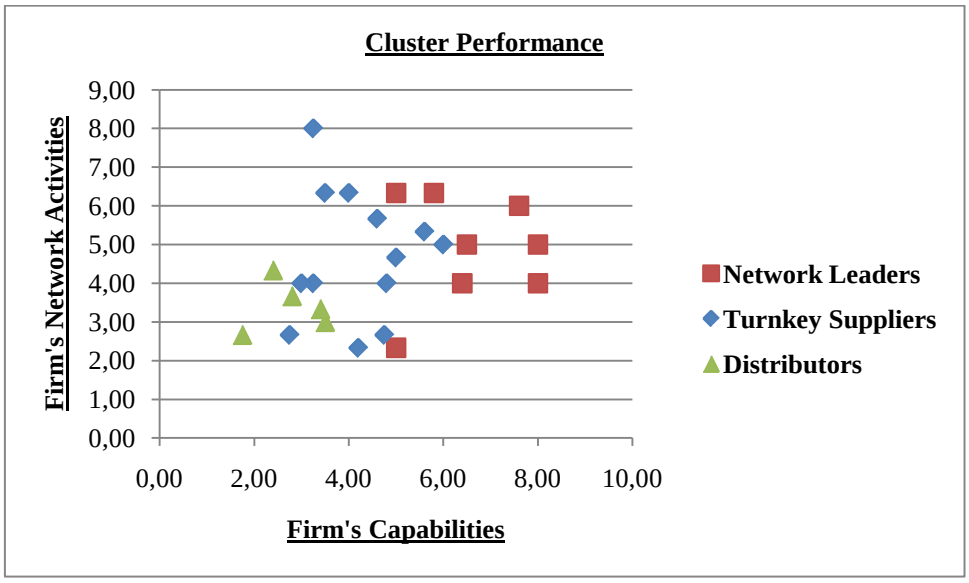

Figure 2 : Firm Capabilities vs. Network Activities of the Clusters.

CONCLUSIONS

Global warming is a rapidly growing environmental concern, and the current primary energy sources are also becoming exhausted. Increasing use of renewable energy sources has an ever growing importance for the future sustainable energy policy, and decentralized small scale CHP production using biofuels could provide a qualified solution for the environmental issue in many countries. The study increased understanding about the key heating plant manufacturers and suppliers in Finland that are also capable of providing power generation in their product portfolio in the future. The plant manufacturers produce their offering based on firm specific capabilities, competences and strategy, and they complement their competences by diversified business networks. Both the network leaders and the turnkey suppliers actively exploit their business networks. This enables them to satisfy end customer requirements, and to supply complete plant deliveries on turnkey basis instead of merely supplying components and parts. The distributors mostly operate as liaisons between their end customers and overseas plant and component manufacturers. The variation in network activity between single firms is relatively high in all the clusters revealing different strategies and capabilities of the firms.

This study contributes to providing evidence that firms complement their resources, capabilities and competences by collaborating within their business networks. The study also increased general understanding about the key players, networks, and clusters in the industry that can be considered as valuable knowledge for practical managers. The sample of the firms can be considered extensive, the interviewees were mostly top executives and company experts, and the results of the study were executed by two researchers and crosschecked by two others in order to ensure validity and reliability. The results of the study can also presumably be generalized to many other regions. The main limitations of the study are the to some extend limited financial data, and the potential influence of the global recession in 2008-2009 on the firms' financial figures. Bioenergy industry is rapidly

emerging, and it might be valuable to study in the future what kind of product modularity issues and business networks prevail in commercializing small scale CHP plants internationally.

ACKNOWLEDGMENTS

The authors are grateful to researchers Joni Vasama and Olli Viitikko for data collection and preliminary analysis.

ABSTRACT

Partner selection is a critical issue for the collaborative commerce (c-commerce) because it concerns the performance of a collaborative project. This study investigates the role of partner selection that may influence the collaborative performance via the collaborative relationship. After reviewing the related literature, a theoretical model was developed. This model includes the general partner selection factors of resource complementarity, organizational compatibility, trust and commitment and the c-commerce specific factor of information technology (IT) capability. For the collaborative relationship, this model takes into consideration of the two dimensions of the continuance and tightness within the partner relationship. The study conducted questionnaire survey to validate the proposed model and research hypotheses. The data collected from 103 Taiwanese enterprises that engage in c-commerce was analyzed and the research hypotheses are all supported. The study results show that the proposed five factors for c-commerce partner selection have influences on the collaborative performance through the collaborative relationship. This study contributes to revealing the mediating effect of collaborative relationship on the c-commerce partner selection and performance. The research findings may also serve as guidelines for collaborative partners to enhance relationship and performance in practice.

Keywords: collaborative commerce (c-commerce), partner selection, relationship, performance.

INTRODUCTION

An enterprise must constantly transform and upgrade to increase its competitiveness in the market and must extend its philosophy from single business entity to strategic alliance in order to survive the challenge of globalization. As a result, in addition to focusing on the development of core capability, collaboration becomes a critical strategy for modern enterprises. Collaborative commerce (c-commerce) is a win-win business model that integrates the needs of the suppliers, customers and partners through the Internet and mutually shares information and operation procedures with other entities [50]. Establishing a sound partnership through c-commerce allows an enterprise to rapidly respond to the needs of the market and enhance the competitive advantage of the entire value chain through information exchange, technical cooperation and resource integration with collaborative partners.

While c-commerce may bring a business synergy and interest, some companies often ignore the potential obstacles and risks associated with the partnership when implementing such an application. Change of organization structure, increased complexity, mutual trust and dependency and conflict management, for examples, can affect the development and maintenance of the partnership. Kanter [36] finds that some partnerships have existed more than 20 years and some others collapsed shortly after. A corporate strategic alliance has a chance of failure as high as 70% [26], and choosing the wrong partner accounts for 50% of it [21].

C-commerce is an electronic application of a corporate strategic alliance; partners must be chosen with discretion, compatibility must be considered, and reciprocal advantages must be taken into account. However, choosing the good partner does not necessarily guarantee good collaborative performance, and this study aims to fill the theory gap by investigating the role that partner selection plays in influencing the performance of c-commerce. In addition to an electronic application, c-commerce by nature is a partner relationship that may determine the result of resource integration among the partners. This study believes the collaborative relationship (or partnership of the c-commerce) has a mediating function in the process in which the partner selection influences the collaborative performance. The purpose of this study is to identify the role of collaborative relationship amidst the influence of partner selection on the collaborative performance. After reviewing the related literature, a research model will be proposed to explain how partner selection influences collaborative performance through collaborative relationship; and the model with its derived hypotheses will then be empirically validated using the data collected through a mail questionnaire survey.

LITERATURE REVIEW

Collaborative relationship

The popularity of the Internet allows collaboration to expand from within a corporation to inter-organizational relationship enabling effective communication and resource sharing for increased revenue, reduced cost, and competitive advantage. C-commerce is a model that allows the employee, business partners and customers to cooperate dynamically in a trade community or market [7]; with such model an enterprise may create greater business values by integrating its partners' resources via the Internet [19,42].

Business partners work together for the agreed objectives in c-commerce. The collaborative relationship brings benefits such as improved utilization of resources, shortened process time and reduced operation cost through information sharing, knowledge exchange and process integration [44,50]. For c-commerce to work more effectively an enterprise must pay attention to the forming and developing of partnership; a long term collaborative relationship may further promotes the success of the collaboration [43]. Successful partnership usually has high involvement in decision making and problem solving [38,44], and has features like high commitment, low conflict, effective conflict resolution, high cooperation and high trust [8,44,50].

Relationship refers to social connections based on mutual interests and benefits [31]. The partners in a collaborative relationship cooperate with one another for the common objectives, of which accomplishment requires sharing resources and risks. In such a mutually dependent relationship, business partners need to develop an effective collaboration pattern from the interaction with one another, which is a learning process that takes time to adapt to. Therefore an effective collaborative relationship must have a partnership continuance [5,27] and partnership tightness [15,22], and such a relationship will deliver a better collaborative performance [16,47]. Because the performance of c-commerce involves different prospects among the partners, it is difficult to measure objectively. The frequently used subjective indicators include project satisfaction and goal attainment [25,51].

Partner selection

Huang [29] believed that partner selection is the most important step in the forming of a strategic alliance. Choosing the right partner is critical to a sound and effective partnership. When choosing partners an enterprise must consider many factors. For a joint-venture, partner selection must consider the industry characteristics, firm capability, resource complementarity between the partner and the company, and organization compatibility [24]. For a collaboration partner, the factors have to be taken into consideration include the complementarity of advantages and capability, partner commitment, status similarity [10], social capital, goal compatibility, interdependency [13], task coordination, culture

compatibility [52], value and belief [54].

Though until recently there is not yet a consensus about the criteria for partner selection, the commonly used criteria found in the related literatures include resource complementarity, organization compatibility, commitment, trust, financial status, past experience and size difference [3,10,13,24,29,52,54]. Among these factors of partner selection, this study considers only four of them because c-commerce integrates mainly the technical and procedural resources of collaborative partners: resource complementarity, organization compatibility, commitment and trust. In addition, c-commerce adopts information technology (IT) to establish an electronic platform for the collaboration [7,19]; therefore this study also includes IT capability in the criteria for partner selection.

RESEARCH MODEL AND HYPOTHESES

This study concerns primarily about the influence of partner selection on the effectiveness of the collaborative relationship when an enterprise implements the c-commerce application. According to the above literature review, the criteria for selecting collaborative partners include resource complementarity, organization compatibility, commitment, trust, and IT capability. The collaborative relationship is divided into relationship continuance and relationship tightness, and such a collaborative relationship can affect the collaborative performance as shown in Figure 1. Relationship continuance means the partnership of the c-commerce should be long-term and the collaborative partners are willing to give up short-term interest in exchange for long-term cooperative advantages. Relationship tightness denotes that collaborative partners work together for the common objectives with sound interactions and value the interdependency between one another. Collaborative performance refers to the degree of satisfaction and goal attainment of a collaboration project.

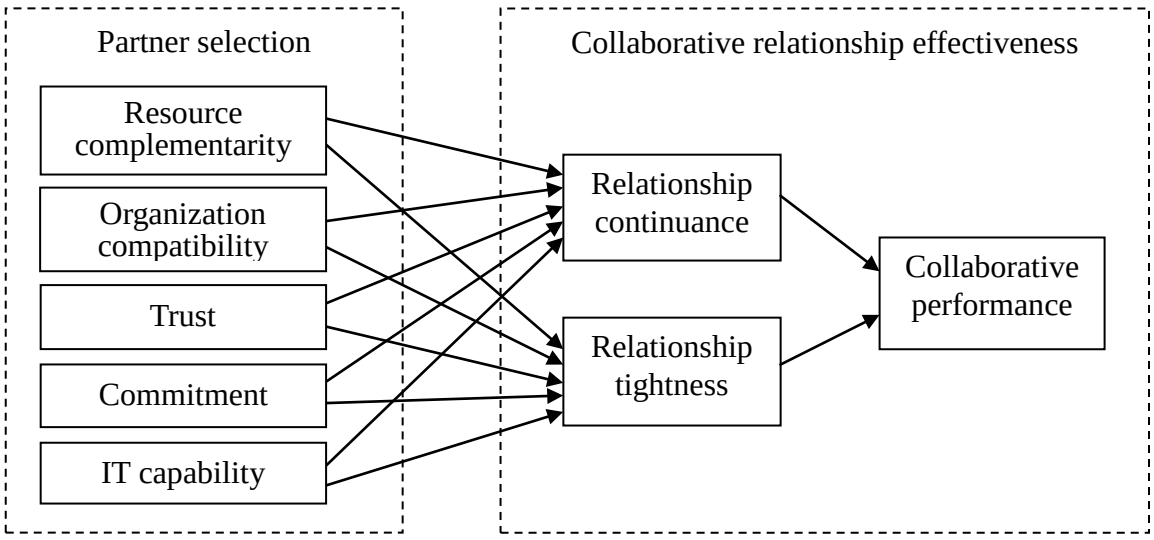

Figure 1: Research model.

Resource complementarity indicates a collaborative partner is able to provide valuable resources needed by the other and such resources are helpful to the accomplishment of the collaborative objectives [10,13,34]. Complementary resources can enhance the partner enterprises' business values and further promote the willingness of the engaged parties to strengthen the relationship [52]. Resource complementarity between partners implies the possibility of the potentially high development of the collaborative relationship; not only it may strengthen the attitudes of both partners toward the continuance of the long-term relationship, but also promotes the tight interaction between the partners [22,33]. Therefore, this study proposes the first set of hypothesis:

H1a: Resource complementarity between the collaborative partners is positively correlated to their relationship continuance
H1b: Resource complementarity between the collaborative partners is positively correlated to their relationship tightness

Organization compatibility is the similarities in terms of organization cultures, business models and strategic goals between the collaborative partners. Smaller difference in organization cultures makes it easier for the partners to communicate and may benefit the development of the collaborative relationship [28,48]. Similar business models and strategic goals between the partners may benefit the resource integration and tight cooperation between the partners [6,50]. Therefore this study proposes another set of hypothesis:

H2a: Organization compatibility between the collaborative partners is positively correlated to their relationship continuance
H2b: Organization compatibility between the collaborative partners is positively correlated to their relationship tightness

Trust means the collaborative partners have reliable professional knowledge and resource and will consider the best interest for one another [32]. Mutual trust between the partners enables resource sharing and the development of a tight collaborative relationship. Trust may reduce coordination cost, opportunistic behaviors and conflict and benefit the maintenance of a stable collaborative relationship [4]. Therefore this study proposes the third set of hypothesis:

H3a: Trust between the collaborative partners is positively correlated to their relationship continuance
H3b: Trust between the collaborative partners is positively correlated to their relationship tightness

Commitment means an enterprise believes its relationship with its partner is important and is willing to maintain such a valuable relationship with its best efforts [48]. Commitment

between the collaborative partners leads to the willingness on both sides to dedicate more investments, which implies a tighter and longer relationship [40]. Therefore this study proposes the next set of hypothesis:

H4a: Mutual commitment between the collaborative partners is positively correlated to their relationship continuance
H4b: Mutual commitment between the collaborative partners is positively correlated to their relationship tightness

Effective application of IT not only can reduce the transaction cost between the collaborative partners, but also promote the information sharing and process integration that contribute to a tighter relationship between the partners [11]. The implementation of a c-commerce application concerns with the IT capability, and the IT capability of a collaborative partner can affect the performance of the collaborative operation and the development of the partnership [37,42]. Therefore this study proposes the fifth set of hypothesis:

H5a: IT capability of the collaborative partners is positively correlated to their relationship continuance
H5b: IT capability of the collaborative partner is positively correlated to their relationship tightness

Once a continuing collaborative relationship is established, the cooperation between partners will be easier and the performance will be better. In a supply chain collaboration, for example, the buyer may know better about the supplier's capability and may acquire better product supply. On the other hand, the supplier may receive resource assistance from the buyer to reduce cost, improve quality and increase output [17,35]. C-commerce primarily concerns with the integration of related resources of the partners to accomplish the project together. A tight collaborative relationship makes the resource integration between the partners easier and the project execution more effective, and therefore the collaborative performance will be better [22,41,47]. Finally this study proposes two more hypotheses:

H6: Relationship continuance is positively correlated to the collaborative performance
H7: Relationship tightness is positively correlated to the collaborative performance

METHODOLOGY

This study investigates the role of collaborative relationship in the influence of partner selection on the collaborative performance. The proposed research model and hypotheses will be validated on the data collected through a mailed questionnaire survey. The survey was conducted to the companies with c-commerce experience in Taiwan. Visual PLS 1.04 and SPSS 17.0 are used for the data analysis, which includes descriptive statistic,

non-response bias analysis, measurement model and structural model analyses.

Measures

The items used in the survey instrument of this study were adapted from the scales developed in prior researches. The primary constructs include partner selection, collaborative relationship and collaborative performance. The factors for partner selection include resource complementarity, organization compatibility, commitment, trust and IT capability. Resource complementarity, which is the level to which a partner provides valuable and matching resource for the other partner, includes three items [2]. Organization compatibility, which measures the similarity among corporate cultures, business models and strategic goals of the partners, consists of three items [17,48]. Trust, which means the collaborative partners have reliable professional knowledge and resource and will consider the best interest for each other, comprises three items [16,23]. Commitment, which indicates that an enterprise believes its relationships with its partners are important and is willing to maintain such valuable relationships with its best efforts, contains three items [1,14]. IT capability, which measures the IT infrastructure and IT human resource, includes three items [53].

Collaborative relationship is divided into relationship continuance and relationship tightness. Relationship continuance, which means the partners believe the relationship with the other partner is important and expect to continue the current collaboration, comprises three items [14]. Relationship tightness, which measures the degrees of activity connection, resource integration and member interaction between the partners, includes three items [5, 9,18]. As for collaborative performance, which measures the degrees of satisfaction and goal attainment of a collaboration project, it consists of three items [25,51].

Each of the above-mentioned multi-items of constructs was measured using a five- point Likert scale with items ranging from strongly disagree to strongly agree. See Appendix A for details.

Data collection and sample profile

The subjects of the survey were 900 companies in Taiwan, which have actually implemented c-commerce. They were selected using the stratified sampling method from a list comprising 1,700 companies and provided by the Corporate Synergy Development Center, an official organization dedicated to promoting industrial collaboration in Taiwan. The questionnaires were mailed to the managers in charge of c-commerce in their respective companies. There were 113 returned questionnaires, which yield 103 valid responses (11.44%) for analysis after discarding invalid ones. This study adopts independent t-test to analyze non-response bias [39] by comparing the 70 earlier responses and the later 33 responses. With a significance level of 0.05, the two groups show no difference in their basic characteristics.

Therefore the non-response bias was acceptable in the study.

The sample characteristics are shown in Table 1. In years since establishment, the majority of the companies have more than 26 years of history; total 62 of them (60.19%). In partnership duration, most of the companies have more than 20 years of partnership duration; total 57 of them (55.34%). In company size, more than half of the companies have 50 or less employees; total 63 of them (61.17%). Most of them have capital under NT$ 50 million; total 45 of them (43.69%). Most companies, total 26 of them (25.24%), are in the electronic/information industry. Such a profile suggests that most of these companies are small-medium enterprises and are more dependent on the resources of their collaborative partners due to their company size. So it can be reasonably argued that these companies were quite experienced about collaborative relationship. In addition, the respondents were mostly executives; they should know very well about the c-commerce in their companies, and therefore are good representatives of survey subjects.

DATA ANALYSIS AND RESULTS

This study used partial least squares regression analysis (PLS) to analyze the data collected. PLS is frequently adopted in the study of information system in recent years; its robustness requires the smallest sample size when compared with the other structural equation modeling (SEM) methods and is appropriate for this study. This study adopted a two-stage analysis to first estimate the measurement model for scale validation and then estimate the structural model for hypotheses testing.

Table 1. Sample profile.

Company data		Frequency	%
Years since establishment	1-5	3	2.91
	6-10	7	6.80
	11-15	5	4.85
	16-20	8	7.77

	Textiles	3	2.91
	Household appliances	9	8.74
	Steel	16	15.53
	Food	2	1.94

Measurement model

First, the result of the reliability analysis is shown in Table 2. The internal consistency reliability (Cronbach's α) and composite reliability (CR) of all constructs are higher than the recommended value of 0.7, suggesting that the instrument has an acceptable reliability [12,19]. Second, in terms of the validity of the instrument, three types of validity were assessed: content validity, convergent validity and discriminant validity. The content validity was established by ensuring that the measurement items were consistent with the review of related literature, interviews with academic researchers and the practitioner experts.

Convergent validity was assessed by looking at factor loadings and the average variance extracted (AVE) from the measures, in addition to the CR values just mentioned for the reliability. As can be seen in Table 2, the factor loading values ranged from 0.775 to 0.955 which were higher than the recommended threshold of 0.5, with the t-test values of the items have all reached the significance level ($p<0.001$),; the AVE values of all constructs ranged from 0.698 to 0.895 which were also higher than the recommended threshold of 0.5 [12,19]. Moreover, the factor loading matrix suggested that the loadings of all items in all constructs were higher than their loadings in other constructs [12,19], which indicated a sound discriminant validity of the instrument.

Structural model

The proposed research model was analyzed using PLS [30]. The hypotheses were estimated by calculating the significance of the path coefficients. The result of PLS analysis, as shown in Table 3, reveals that the relationship continuance is positively influenced by resource complementarity ($p<0.001$), organization compatibility ($p<0.01$), trust ($p<0.01$), commitment ($p<0.05$) and IT capability ($p<0.001$), and supports hypotheses H1a, H2a, H3a, H4a and H5a. Relationship tightness is also positively influenced by resource complementarity ($p<0.05$), organization compatibility ($p<0.05$), trust ($p<0.01$) commitment ($pp<0.001$), and IT capability ($p<0.05$). Therefore, hypotheses H1b, H2b, H3b, H4b and H5b are also supported. Finally, collaborative performance is positively influenced by relationship continuance ($p<0.001$) and relationship tightness ($p<0.001$). So hypotheses H6 and H7 are supported as well.

The model also exhibits a good explanatory power. As can be seen in Figure 2, the five factors of partner selection explain 57.3 percent of the variances of relationship continuance and 43.3 percent of the relationship tightness, while the collaborative relationship, in terms of relationship continuance and relationship tightness, explain 76 percent of the variances of collaborative performance.

DISCUSSION

Influence of partner selection on collaborative relationship

In the fast-changing and globalization environment, an enterprise must acquire higher resource advantage to survive. Enterprises in all industries need tremendous amount of resources for the development of new products or technologies and entrance to new market; few can afford such resource along. Therefore, c-commerce is an important electronic application for corporate strategic alliance [50]. Partner selection is the first step for an enterprise to adopt c-commerce. This study finds that resource complementarity, organization compatibility, trust, commitment and IT capability can positively influence the continuance and tightness of relationships with the collaborative partners.

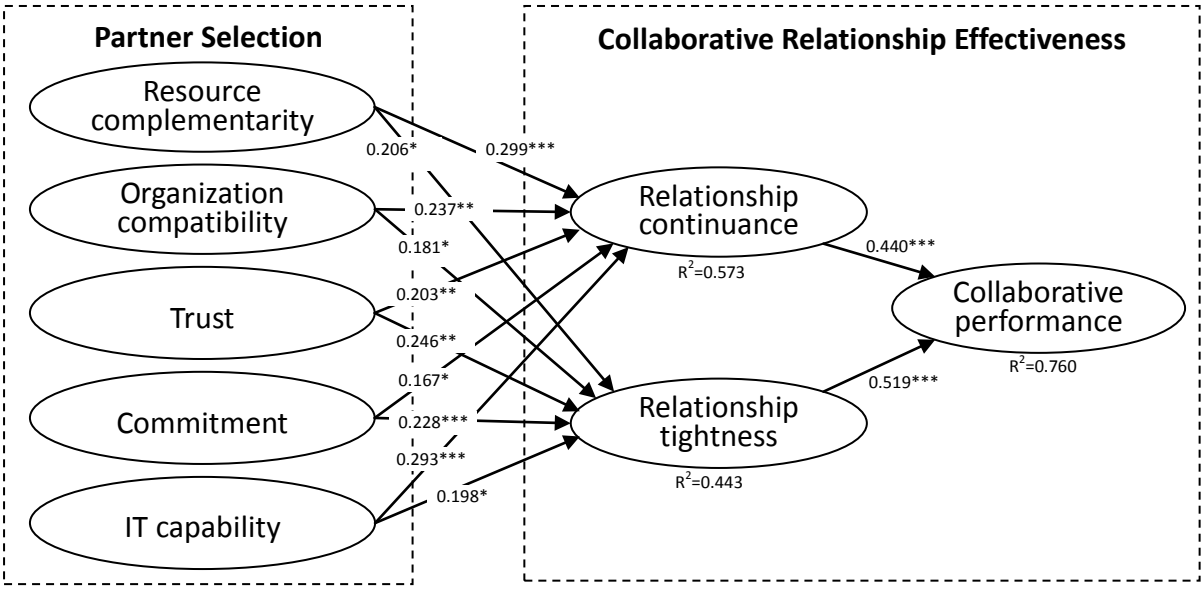

Figure 2: Results of the structure model analysis.

Complementary resource and capability of partners can influence the willingness to collaborate on both sides, promote close interaction, information exchange, knowledge

sharing, process integration, and therefore better collaborative relationship. When selecting a collaborative partner, the organization compatibility between both sides must be considered; the more similarities they share, the more tolerant they are to each other during collaboration, which is helpful to the continuance of the partnership. A higher cultural compatibility between the partners makes inter-organizational communication easier; it allows more open learning and exchange and promotes frequent relational connection [28]. Therefore, choosing a partner with organization compatibility can help with developing a longer and tighter collaborative relationship.

Trust is also an important factor for partner selection. An effective collaborative relationship is based on mutual trust. A higher trust developed during the early stage of collaboration may attribute to the development of a closer interaction and the willingness to dedicate assets. Therefore it can help with the development of a tighter relationship. Trust is also a critical factor for an enterprise to share information with its partners. A higher trust can reduce unnecessary costs of transaction and supervision, encourage more attention from both sides to the collaboration and sustain such a relationship. Therefore, trust is the key factor to the success of a long-term relationship that allows the partners to solve potential risks with more tolerance when dealing with conflict or temporary power imbalance [32].

Commitments from both sides to the collaborative project should be considered when selecting a partner. Commitment refers the recognitions and guarantees from both sides for their relationship, including the provision of resource and mutual support for the collaborative project. It is the willingness driven by emotion to maintain the binding of their relationship and can be regarded as an approval for the future collaboration. Mentzer et al. [44] argued that commitment is the core factor to the success of a long-term strategic partnership and represents the willingness of bearing risks and sacrificing short-term interest that indicates the intention for a deeper relationship in exchange for long-term interest.

Finally, IT capability is also an important factor for selecting a partner for collaborative commerce. IT is an effective tool often used to strengthen the binding between companies and promote interaction between the partners. Therefore IT capability has a positive influence on the development of collaborative relationship. Applying IT in the establishment of an inter-organizational collaborative system not only may form a close binding between the partners, but also obtain electronic competitive advantages [45].

Influence of collaborative relationship on collaborative performance

The study results show that collaborative relationship has positive influences on collaborative performance. As the environment changes and IT development progresses rapidly, enterprises have learned the importance of collective survival and collective prosperity through partnership. A good partnership is not only helpful to develop innovative products, shorten the new products' time to market, reduce operational costs, improve

productivity, but also may create competitive advantages to benefit the partner enterprises. Tight interaction between the collaborative partners encourages both sides to invest resource, share information promptly and adapt to the change of the external environment; therefore it may lead to better results [5]. The continuance of the collaborative relationship promotes mutual understanding, increases confidence in investing assets required for the collaboration, encourages expectations on long-term partnership, binds the interests of the partners, and therefore increases collaborative performance [22].

CONCLUSION

This study investigates the role of the collaborative relationship in the influences of the factors adopted in c-commerce partner selection on the collaborative performance. After reviewing the related literature, resource complementarity, organization compatibility, trust, commitment and IT capability were considered the major factors of partner selection in the study, and the collaborative relationship was divided into relationship continuance and relationship tightness. The results analyzed on the data collected from a questionnaire survey show that the five factors of partner selection have great influence on the two dimensions of collaborative relationship, and the collaborative relationship combining the relationship continuance and tightness has major impact on the collaborative performance.

Collaborative relationship plays a mediating role in partner selection and collaborative performance. This study contributes to showing the critical role of collaborative relationship in c-commerce. Despite the importance of selecting a partner for the c-commerce, it can only be applied to increase collaborative performance though a good collaborative relationship. This study divides the collaborative relationship into two constructs. The study findings show that although the five factors of partner selection have a higher explanatory power on relationship continuance (R^2=0.573) than on relationship tightness (R^2=0.443), the effect of relationship tightness on collaborative performance (path coefficient 0.519) is greater than that of relationship continuance (path coefficient 0.44). That suggests enterprise partners may improve the collaborative performance with process integration or system connection that encourages tight interaction.

This study provides several managerial implications. First, an enterprise must take into consideration on a wider scope when selecting a partner for c-commerce. In the globalized business environment, selecting a collaborative partner is a crucial strategic issue. According to the findings of this study, resource complementarity, organization compatibility, trust, commitment and IT capability will influence the collaborative relationship and in turn the collaborative performance. Therefore when an enterprise selects its collaborative partner, it must consider comprehensively instead of one particular factor. Next, when adopting c-commerce, attention should be paid on relationship continuance and relationship tightness to achieve collaborative performance. For this purpose, an enterprise should confirm the issues of resource complementarity and organization compatibility with its

partners, work hard to reduce the possibility and degree of conflict, and collaborate on establishing the initial trust and commitment in order to develop a continuing and tight relationship.

There exist several limitations in this study. First, though various standards for evaluating collaborative performance are possible from different perspectives, this study adopts the degrees of satisfaction and goal attainment of a collaboration project as the measures for collaborative performance that are subjectively determined. Second, the questionnaire survey is designed from the aspect that an enterprise selects its collaborative partner, and the information of their partners is not collected. Finally, the development of a relationship needs an extensive period of time. This study adopts a cross-sectional research and is unable to develop a more comprehensive understanding about the development process of a collaborative relationship. These issues also offer opportunities of further study.

APPENDIX A

The structure of the survey instrument

The instrument is measured using a five-point Likert scale (1 = strongly disagree, 5 = strongly agree).

Part 1: Consideration factors in selecting a collaborative partner

1. The resource owned by a collaborative partner is valuable to each other.
2. Both collaborative partners need the resource of each other to achieve their respective goals.
3. The resource provided by a collaborative partner is the resource the other partner lacks of.
4. The collaborative partner’s business management philosophy is compatible
5. The goal of the collaborative partner is compatible.
6. The code of conduct adopted by the collaborative partner is similar.
7. The collaborative partners have great faith in each other.
8. The collaborative partner is willing to comply with the commitment agreed by both sides.
9. The collaborative partner will consider the impact that its partner will have to sustain when making a critical decision.
10. The partner values the collaboration very much.
11. The partner is willing to provide human resources for this collaboration.
12. The partner will not easily terminate the collaboration.
13. The collaborative partner has high capacity in computer and information.
14. The collaborative partner is capable to establish and maintain the computer network connected to each other.
15. The collaborative partner has committed considerable investment on new information

technology software and hardware.

Part 2: Effectiveness of the collaborative relationship

1. If there is any other opportunity, your company is still willing to continue working with the current partner.
2. The collaborative partners have very high loyalty to each other.
3. The collaborative partners are willing to devote their best efforts for each other.
4. The collaborative partners are tightly connected in business process.
5. The negotiations on critical issues concerning the collaboration between the collaborative partners are conducted by personnel of higher ranks from both sides.
6. The partners are willing to invest on the proprietary equipment required for the collaboration.
7. The collaboration between the partners has attained the original goals.
8. Your company is satisfied with the result brought by the collaborative partnership.
9. Your company believes the collaborative partnership is worthwhile.

ABSTRACT

The paper concerns the problem of industrial workshops allocation regarding the logistics and economics point of view. The function goal is – the minimal transportation costs. Usually in the workshops allocation projecting we are doing different kind of calculations. Traditionally those calculations are iterative and follow step-by-step procedure. In this paper we are going to use a new method, based on the Theory of Connection (ToC) and we try to answer to the question: how to use the geometrical modeling to support the workshops deployment. Applying the new method to solve an industrial problem we are developing a new tool supporting the industrial engineers in production processes organization and management.

Keywords: Production, modeling, workshop, allocation, theory of connection

INTRODUCTION

In this paper, we are using the theory of connection (ToC) based approach for formulation of mathematical models of engineering and management processes, especially concerning the workshops placement processes. Theory of connection (ToC), previously known as manufacturing system theory, in the form it is presented here, is due to the work of the Scandinavian School of Systems Theory for the past 30 years (Bjorke, 1995). Additionally the tool general purpose Petri net simulator (GPenSIM, 2009) can be used for processes simulation.

The idea behind ToC is to bring geometry and algebra together; we use geometric modeling to model an physical phenomenon, make a set of algebraic equations out of this geometric model. In the next step, by using a computer these equations can be solved. The usefulness of ToC is that, different subsystems of different disciplines can be modeled and integrated by performing the same procedure; this is very important for fields like e-commerce as e-commerce involves diverse disciplines like manufacturing, business management, supplier selection, computer hardware and software, control systems etc (Davidrajuh, 2007; Davidrajuh and Melberg, 2008, Davidrajuh and Pastuszak, 2010). The modeling approach based on ToC is explained below.

As shown in figure 1, a system consists of three fundamental components, such as *elements*, *connections*, and *sources*.

The elements carry all the physical or economical *properties* of the system. Elements are the building blocks of the physical system, and can be based on *nominal scale* or *ordinal scale* form (Haavardtun, 1995). Nominal scale element means, the direction of flow through it depends on the type of the production. This means, nominal scale elements are bi-directional. For ordinal scale elements, like a production step, the direction of flow through it is given by the element itself, and does not change with applied source or potential across it.

When there is no connection between the elements, the set of isolated elements is called the *primitive system*. The connections reflect how the elements influence each other and it represents the structure of the system. The set of connected elements is called the *connected system*. Finally, the sources reflect the influence between the total system and the environment. Sources are the environment's influence on the system; in an electrical circuit, source s could be current or voltage sources; in production planning, demand of products, startup-setup times, costs involved are some of the sources.

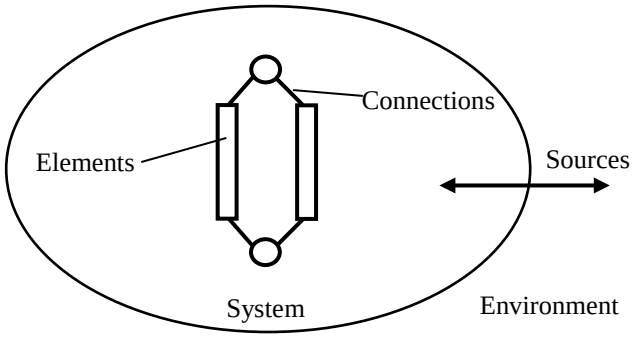

Figure 1: The System model

THE APPROACH

The research problem discussed in this paper is the existence of redundancy in workshop placement. The industrial processes join with a number of collaborating workshops (machines, people, etc.), to manufacture a class of product with the characteristics such as qualitative, agility, and leanness, to achieve minimal transportation cost. When market requirements are changed, a new class of products or an improved version of the product should be turned out to meet the new market requirements. In this case, we can observe the change of a number and a type of operations and as well as the workshops sequence in the manufacturing processes. The enterprise may seek for a new combination of collaborating workshops that are more suitable to manufacture the new class of products; thus the main aspect of our idea is dynamic logic of organization and reorganization of workshops placement and collaboration.

Let we use the following example. We are producing some 4 products (details). The production plant is consist of 6 machines describes at the Table 1. The production operations and quantity are described at the Table 2.

Table 1: Workshops information.

No.	Name of the machine	Symbol
1	Saw (cutting machine)	PM 120
2	Lathe (machine tool)	TUM 35 x 800
3	Drill	WKA 40
4	Milling machine	FYC 26
5	Grinder	SWA 25
6	Control position	KT

Table 2: Details and technology process information.

No.	The order of the operations on the machines	Production plan	Weight of the detail [kg]
1	1 – 2 – 3 – 4 – 5 – 6	100	1.5
2	2 – 3 – 6 – 5 – 4 – 1	150	2.0
3	1 – 3 – 5 – 4 – 6 – 2	200	1.2
4	1 – 2 – 3 – 6 – 4 – 5	180	1.0

Let we take the assumption that all of the details are produced within the same number of the operations. The production process criterion is to minimize of the transportation operations.

Following the CRAFT (*Computerized Relative Allocation of Facilities Technique*) method, we can establish the formula below:

$$Q = \sum_{i=1}^{n} \sum_{j=1}^{n} S_{ij} \cdot L_{m(ij)} \rightarrow \min$$

where:

Q – goal function (sum of load of the workshops that have to be allocated),
n – number of the workshops to allocation,
i, j – allocated workshops numbers,
$m_{(i)}$ – place of allocation of the i object (workshop),
$m_{(j)}$ – place of allocation of j object (workshop),
S_{ij} – ij-element of the matrix of workshops load,
$L_{m(ij)}$ – a distance between two of m-workshops, contains of i and j objects.

After Q function calculation we can get the begin allocation of the workshops by creation of the first workshops allocation vector which is the permutation:

$$P = \{p(1), p(2), p(3), \ldots, p(n)\},$$

is makes possible following changes:

$p(1) \leftrightarrow p(2),\ p(1) \leftrightarrow p(3), \ldots,\ p(1) \leftrightarrow p(n),$
$p(2) \leftrightarrow p(3),\ p(2) \leftrightarrow p(4), \ldots,\ p(2) \leftrightarrow p(n),$
$\ldots,$
$p(n-1) \leftrightarrow p(n).$

We change the position of the workshops deployed at the places: 1, 2; 1, 3; ..., 1, *n*; 2, 3; ..., 2, *n*; ... , *n* – 1, *n*. The environment of the solution is consist of $1 \cdot \frac{2 \cdot n}{n-1}$ points.

The goal function is going to be as follows:

$$Q^0 = \frac{1}{2} \cdot \sum_{i=1}^{n} \sum_{j=1}^{n} S_{p(i)p(j)} \cdot L_{ij},$$

where:

$S_{p(i,j)}$ – matrix of the connections of *p*-objects allocated at *i* and *j* workshops,
L_{ij} – a distance between *i* and *j* workshops.

After the change of objects allocated at the place *x* and y, we will observe the change of the goal function (*Q*) value:

$$Q_{p(x)p(y)} = \frac{1}{2} \cdot \sum_{i=1}^{n} \sum_{j=1}^{n} S_{p(i)p(j)} \cdot L_{ij} + \sum_{\substack{i=1 \\ i \neq x,y}}^{n} \left(S_{p(x)p(i)} \cdot L_{yi} + S_{p(y)p(i)} \cdot L_{xi} \right) + + S_{p(x)p(y)} \cdot L_{xy}.$$

Finally, the new value of goal function will be equal to:

$$\Delta Q_{p(x)p(y)} = Q^0 - Q_{p(x)p(y)}.$$

And, after change:

$$\Delta Q_{p(x)p(y)} = \sum_{\substack{i=1 \\ i \neq x,y}}^{n} \left[S_{p(i)p(x)} - S_{p(i)p(y)} \right] \cdot \left(L_{ix} - L_{iy} \right).$$

We have to change the workshops positions till the change of goal function value is decreasing.

So, backing to our example we can do the following calculations (see Table 3).

Table 3: The flow of products between workshops [kg].

	1	2	3	4	5	6
1	–	150 180	240			
2		–	150 300 180			
3			–	150	240	300 180
4	300			–	150 180	240
5				300 240	–	150
6		240		180	300	–

The direction of the flow is no important – so our calculations can be as showed at the Table 4.

Table 4: Symmetrical matrix of the workshops connections.

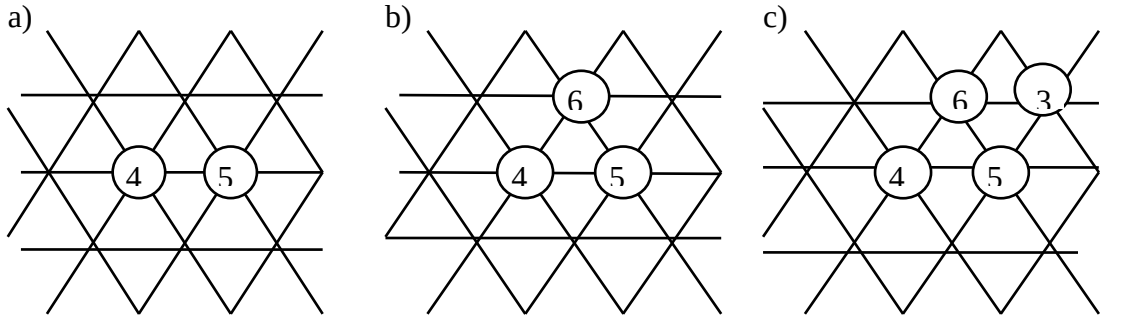
	1	2	3	4	5	6
1	–					
2	330	–				
3	240	630	–			
4	300	0	150	–		
5	0	0	240	870	–	
6	0	240	480	420	450	–

The highest value is the limitation for our production plant and it influences on the goal function value, so limited workshops have to be allocated both as first (Table 5).

Table 5: The order of workshops allocation.

Iteration	Order of workshops	1	2	3	4	5	6
	4	300	0	150	–	–	420
	5	0	0	240	–	–	450
1	Σ	300	0	390	–	–	870
	6	0	240	480	–	–	–
2	Σ	300	240	870	–	–	–
	3	240	630	–	–	–	–
3	Σ	540	870	–	–	–	–
	2	330	–	–	–	–	–
4	Σ	870	–	–	–	–	–
	1	–	–	–	–	–	–

After the calculation shown at the Table 5 we have to calculate next the goal function value (stating from No. 4 and No. 5 workshop) – it was shown at the Figure 2. The final value of Q function for our case is 5070 kg (Figure 2.e).



$Q_{4\text{-}5}$=870x1=870 Q_6=870+420x1+450x1=1740 Q_3=1740+150x2+240x1+480x1=2760

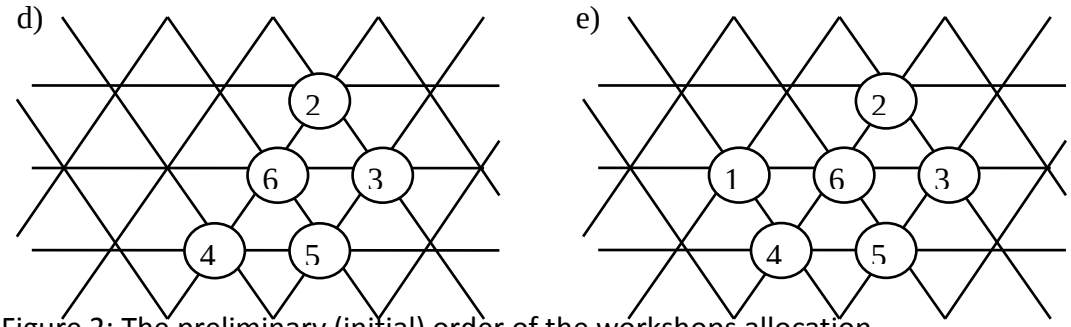


Figure 2: The preliminary (initial) order of the workshops allocation.

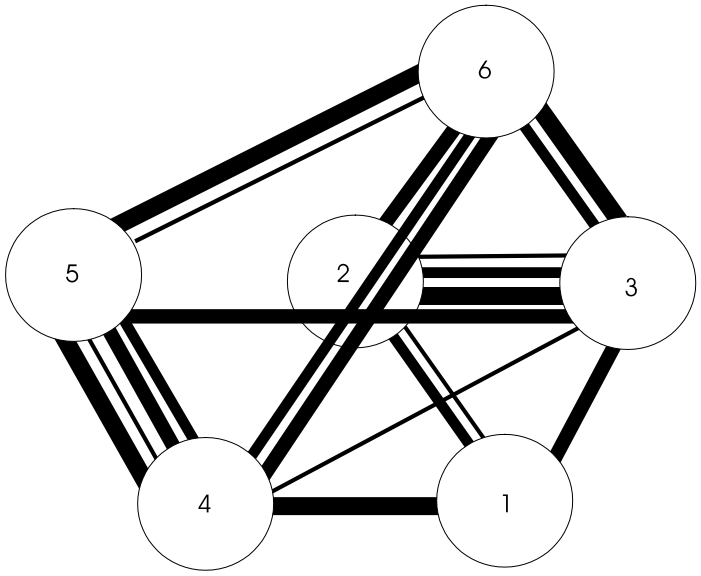
Q_2=2760+0x2+0x2+240x1+630x1=3630 Q_1=3630+300x1+0x2+0x1+240x2+330x2=5070

The flow of the details was shown at the Figure 3.



- 150 kg
- 180 kg
- 240 kg
- 300 kg

Figure 3: Flow of the details between workshops allocated [kg].

The model of the production hall – see Figure 4.

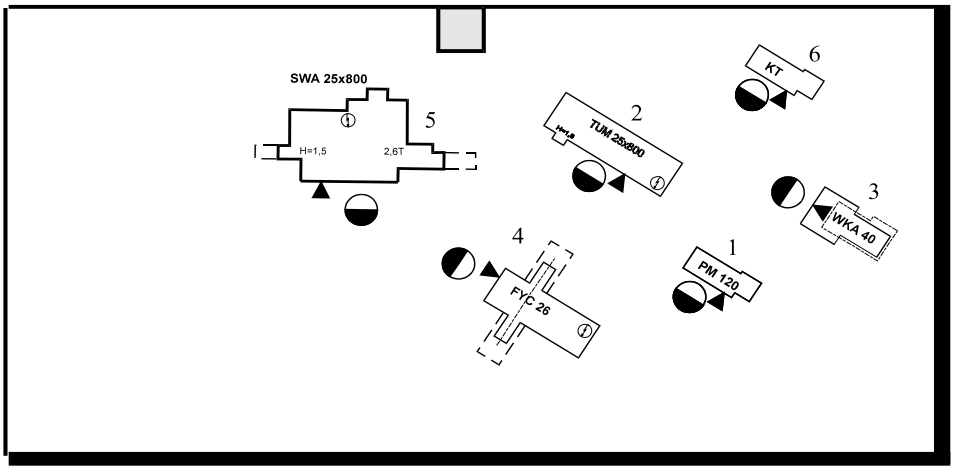


Figure 4: Production hall model (scale: 1:100).

CONCLUSION

This paper shows a new approach for detection and elimination of redundancy in workshops placement. The approach uses workflows. The working example proves that the approach can be put to use by using a Petri net based modeling and analysis tool. This paper also presents a Theory of Connection (ToC) based approach for modeling physical systems. The main benefit using ToC based approach is that the approach emphasizes the connection between the primitive elements that compose the system; in another words, geometry is used for system modeling.

IDENTIFYING BARRIERS AND ENABLERS FOR THE IMPLEMENTATION OF RISK MANAGEMENT IN A PROJECT NETWORK

Leena Pekkinen, Oulu University, Technical Faculty, Finland
leenak.pekkinen@pp.inet.fi

Kirsi Aaltonen, Aalto University, School of Science, Finland
kirsi.aaltonen@tkk.fi

ABSTRACT

Increasingly, projects are executed by networks of organizations. The networked form of organizing has many important implications for project risk management. Instead of focusing on risk management of single actors in order for risk management to be successful risk management activities should be integrated on a project network level. This study aims to examine the barriers and enablers for the implementation of risk management in a project network through an empirical analysis of the sales phase of one internally networked project of a globally operating project-based company. With regard to network level risk management, the paper identifies and describes the following five barriers: strict divisional approach, illusion of common approach, lack of formal structure of the common approach, lacking specification of the responsibilities and targets. In addition, three identified co-ordination mechanisms that support risk management on a project network level are described.

Keywords: risk management, project network, project sales phase, mechanisms of co-ordination

INTRODUCTION

Background

Project risk management has nowadays and acknowledged role as one of the key processes and research fields of project management (e.g. Chapman and Ward, 2003; Miller and Lessard, 2000). Recent project management studies have also emphasized the networked, inter-organizational nature of projects and argued that more attention should be paid to the study of projects as inter-organizational networks (Ahola; 2009; Cova et al. 2002; Engwall, 2003; Söderlund, 2004). Despite the central role of risk management and project networks in prior and current project management research only limited attention has been addressed to risk management in a networked project setting. The networked form of organizing has many fundamental implications for project risk management: The heterogeneous actors in project networks have contradictory and conflicting objectives which pose fundamental coordination and integration challenges (Flyvbjerg et al., 2003; Hellgren and Stjernberg, 1995; Morris and Hough, 1987). Therefore, a broader perspective concerned with managing the risks in networked projects and improving risk management -

related co-operation and integration over organizational boundaries within the project networks is needed. Instead of focusing on risk management of single actors in order for risk management to be successful risk management activities should be integrated on a project network level (Pekkinen, 2010).

The purpose of the present study is to examine the barriers and enablers for the implementation of risk management in a project network. The first research question of the paper is: What are the main barriers for implementing project risk management in a project network? In addition, we are interested in exploring the mechanisms that support the execution of risk management in project networks. Hence, the second research question of this paper is formulated as follows: What kinds of co-ordination mechanisms support the implementation of project risk management in a project network? In this paper the co-ordination mechanisms refer to activities that support the management of the interface processes related to risk management between the different organizations of the project network. To answer our research questions we examined risk management practices in the sales phase of a networked project in a globally operating project-based firm. In this paper our attention is on internal project network of the case company's delivery project. This internal network consists of sovereign business divisions. The analysis of the barriers and enablers for the implementation of risk management in a networked setting draws from literature on project risk management, project networks and coordination mechanisms in project-based firms.

The paper is structured as follows. Introduction describes the background and motivation for the study. In the literature review section research on project risk management, risk management in project networks and coordination mechanisms in project-based firms is reviewed. The next section introduces the research method and context. The empirical findings present the identified barriers for the implementation of risk management on a project network level. Furthermore, the coordination mechanisms that support the project network level risk management are presented. Finally, we discuss the findings in the light of the existing project risk management literature and summarize the contributions of the study.

LITERATURE REVIEW

Project risk management

Project risk management has nowadays an acknowledged role as one of the key processes of project management. Furthermore, project risk management is a widely researched area in project management research (e.g. Chapman and Ward, 2003; Floricel and Miller, 2001: Kähkönen and Artto, 1997; Miller and Lessard, 2000). Prior research on project risk management has primarily focused on the concept of project risk and on the identification of risk sources and effective managerial approaches and tools for reducing risks in projects (Chapman and Ward, 2003; Ward and Chapman, 2003).

There is a constant debate concerning the definition of risk in the context of project management and the term's relation to the concept of uncertainty in particular (Ward and Chapman, 2003, 2004; Miller and Lessard, 2001; Perminova et al., 2008). In the project management literature the term 'risk' is most often defined as the possibility that events, their resulting impacts and dynamic interactions, may turn out differently than anticipated (Ward and Chapman, 2003, 2004; Miller and Lessard, 2001). Similarly, according to Project Management Body of Knowledge that is an acknowledged project management standard, risk is an uncertain event or condition that, if it occurs, has a positive or negative effect on at least one project objective (PMI, 2008). In this definition both the threats and the opportunities are present. Traditionally, the emphasis of the risk assessment has been with threats rather than opportunities (Ward and Chapman, 2003). Various earlier studies have presented informed classifications on the sources of risks (Kähkönen and Artto, 2008; Ward and Chapman, 2003; Floricel and Miller, 2001). Whilst most of the studies have focused on the categorization of project risk sources in a single actor project context only few studies have addressed risk sources in networked multi-actor project (Artto et al., 2008; Hallikas et al., 2002; Kähkönen and Artto, 2008; Pekkinen, 2010; Ward, 1999).

The linear, rational and planning-oriented view towards projects and their management is also reflected in the existing project risk management applications and structured process guidelines: in an ideal process risks, their probabilities and impacts should be explicitly identified and estimated and decisions for appropriate responses and monitoring and control principles documented. Actually the whole planning oriented project management approach can be considered as a fundamental approach for reducing uncertainty in projects: through detailed planning and use of specific project management methods and tools, risks and uncertainties in projects are considered to be minimized and better managed (Morris and Hough, 1987). Accordingly, the well known formal risk management processes and standards (PMI, 2008; APM, 2006; Chapman and Ward, 2003) typically consist of a generic process description including three core project risk management processes: risk identification, risk evaluation and risk response planning (Kähkönen and Artto, 2008). Furthermore, within the current view of project management as a lifecycle process, project risk management is seen as an encompassing process, starting at project definition, continuing through planning, execution and control phases, up to completion and closure (Raz et al., 2002). All changes done in the project execution plan and changes of the ambient circumstances are sources of new risks and, therefore, continuous monitoring of the environment is needed.

Risk management in project networks

Increasingly, projects are executed by networks of organizations (Ahola, 2009; Artto et al., 2008; Söderlund, 2004; Hellgren and Stjernberg, 1995). Even though interrelationships are a new area of interest there has been very little discussion on the functioning and dynamics of project networks outside the field of project marketing (Cova and Salle, 2005). Hellgren and Stjernberg (1995) advocate that studies of collaborative arrangements and networks usually concern long-term inter-organizational arrangements, such as acquisitions and joint ventures. Project networks consist of relationships between actors or organizations to establish robust

capabilities to perform the tasks of the project to achieve the set targets of the project (Hellgren and Stjernberg, 1995). Consequently, project networks are intentionally developed networks – they are formed in order to create capital assets for the buyer over a certain period of time (Skaates and Tikkanen, 2003). Project networks can therefore be seen as an instrument of achieving specific, pre-defined targets. At a casual glance it may appear that this common target acts as the temporary underlying force which glues the project network actors together, and is the raison d´être of the project network (Hellgren and Stjernberg, 1995). Nevertheless, the individual actors involved in the temporary project network might have other rationales and motivations for their participation other than completing specific short-term tasks. Consequently, the heterogeneous actors in project networks have oftentimes contradictory and conflicting objectives which pose fundamental coordination and integration challenges in the project network (Morris and Hough, 1987; Flyvbjerg et al., 2003). In such networked projects, the role of effective risk management is emphasized as one of the critical success factor of the project.

The networked form of organizing has many important implications for project risk management. In particular, the literature on large projects lists various major challenges and suggestions in organizing and managing a project enterprise as a network of several participating organizations, especially related to analyzing risk, uncertainty and success issues (Flyvbjerg et al., 2003; Kharbanda and Stallworthy, 1983; Klemetti, 2006). Firstly, the network structure in itself poses new types of risks. The multiplicity of the project actors, as well as the interactions and relations between the actors are a source of uncertainty in the project network. Risk in the network context can be defined as an uncertain event or condition that results from the network form of work, having an impact that contradicts the expectations. An event is at least partially related to other actors in a network (Kähkönen and Artto, 2008). In other words, risks in project networks are due to relationships and interactions between project network parties (Artto et al., 2008). Prior literature has addressed to a limited extent the sources of risks in networked project settings (Artto et al., 2008; Kähkönen and Artto, 2008; Hallikas et al., 2002; Klemetti, 2006; Söderholm, 2008; Ward, 1999). Furthermore, the majority of the existing studies have focused on the nature of relationships of project network actors as a risk source. However, Ward (1999) states that the involvement of multiple actors in the project execution introduces uncertainty arising from the ambiguity related to the following six aspects: Specification of responsibilities, perceptions of roles and responsibilities, communication across interfaces, the capability of parties and contractual conditions and their effects.

Furthermore, the networked project setting highlights the importance of a broader perspective on risk management. Complex delivery projects are typically networked efforts where the traditional single company oriented risk management approach can be considered to result merely in too limited solutions (Artto et al., 2008). Instead of focusing on risk management of single actors in order for risk management to be successful, risk management activities should be integrated on a project network level (Artto et al., 2008; Pekkinen, 2010). Therefore, a broader perspective concerned with managing the risks in networked projects and also improving risk-related co-operation within the project networks is needed. Especially co-

operation and integration over organizational boundaries is required in project networks in order to ensure efficient and effective risk management approach. According to Kähkönen and Artto (2008) taking into account the dynamism of the project, interactions, interrelations as well as continuous risk register updating and scanning of an environment should be emphasized in the risk management approach in project networks. However, the current risk management literature does not fully appreciate the complexity and dynamism of the whole network of project actors.

Coordination mechanisms in a project-based firm

Recently, considerable interest has been addressed towards project-based firms as distinctive kinds of economic actors due to the increasing significance of project-based forms in organizing economic activities in many industries (Hobday, 2000; Wikström et al. 2009; Whitley, 2006). The term project-based firm refers to a company that organizes most of its internal and external activities around projects (Hobday 2000; Wikström et al. 2009). Both firms that use projects as their primary productive activity and firms that organize only a part of their activities around projects can be referred to as project-based firms (Artto et al. 2011).

Intra-organizational and inter-organizational integration in project-based firms aims to break the boundaries between functions and between companies. The project-based organization poses diverse challenges to its managers, one of which is to integrate the differentiated parts of the organization to work towards the goal of the whole organization. Intra-company integration in a globally operating project-based firm, in particular, aims to overcome the functional silos and divisional boundaries of the different sovereign divisions. It is typical that due to differentiation each department and division develops its own functional specialization, time horizon, operating practices, goals and jargon (Daft and Lengel, 1986). In the context of risk management the phenomenon of disintegration of risk management related to the separation of risk management activities e.g. between different business units and functions has been recently addressed by Ruuska et al. (2010).

Integration techniques or coordination mechanisms are decisions on how to manage and coordinate the interface processes. Through the adoption of integration techniques, firms may improve efficiency and effectiveness of intra- and inter-organizational interface processes. In the existing literature different types of classifications on inter-organizational coordination mechanisms exist (Daft and Lengel, 1986; Galbraith, 1974). Naturally, the versatile integration techniques and coordination mechanisms can be classified in diverse ways. In general, any administrative tool for achieving integration among different units within an organization can be counted as an integration mechanism (Martinez and Jarillo, 1989). Typically coordination mechanisms are divided into impersonal mechanisms based on authority (e.g. routines, rules and procedures, formalization, planning and programming, IT systems) and subtle integration mechanisms that are based on formal and informal communication (e.g. group problem solving, integration roles, sosialization) (Salli, 2011) . Existing project management research presents various examples of both subtle and

impersonal mechanisms applied in project-based firms (DeFillippi, 2002; Hobday, 2000; Prencipe and Tell, 2001).

In this study coordination mechanisms are divided into different categories (drawn from Galbraith, 1974; Daft and Lengel, 1986). An important coordination mechanism is information and process integration techniques: through accurate information sharing (e.g. e-mails, voicemails, decision support systems) functions have better possibilities to coordinate the functioning of the whole system. In turn, integration through standardized and formalized actions (Galbraith, 1974) involves use of written policies, rules and standard procedures. Communication and sharing of information are fundamental in facilitating and ensuring smooth co-operation between organizational units. Galbraith (1974) also presents the coordination by targets or goals as a means to lead the different parts of the organization towards the same ultimate target. Here, the critical issue is how to set right type of subgoals. Further, integrator roles such as cross-organizational teams, group meetings and interface roles are an important source of co-ordination as well as integrated management techniques such as contracts, agreement practices and joint mechanisms for problem solving (Daft and Lengel, 1986). These mechanisms are designed to facilitate communication between interdependent units or groups in an organization (Galbraith, 1974).

METHODOLOGY

To study the barriers and enablers for implementing project risk management in a project network a qualitative single case study was conducted (Yin, 2002). The scarcity of the risk management research in a project network context made us to select the case study research strategy. Qualitative research strategy was selected to empirically study the preconditions of efficient and effective risk management in the project network context of a globally operating project-based company. In this study the key persons working in the sales phase of the project network of the case company were interviewed.

The case company delivers world wide new production lines, departments of the production lines and modernizations of the departments for the pulp and paper industry as an EPC contractor. Approximately 100 projects are in active phase simultaneously. Formerly risk management in the case company was conducted on an individual project level. This was the case also in such projects where different divisions of the case company delivered their own projects to the same end customer, hence forming an internal project network. In this case study the practices and processes of risk management during the sales preparation phase were studied from the viewpoint of the internal project network. The studied case project is formed from different divisional projects forming therefore a large project network with large scope of supply. Thereby it is a representative project to study risk management in the project network. In this study the risk management activities of the case project’s network are studied particularly during the project sales phase.

The destination country of the case project is in South-America. The proposed production line consists of six separate departments. The delivery of these six departments will be executed by six parallel projects forming the studied internal project network. These six projects have some common areas in the field of civil construction and automation, instrumentation and electrification which will be executed as matrix projects. In the case study, new production line consisting of product concept of proven technology, monetary value of the turnkey project is > 300 USD and it will be built in challenging site conditions. The degree of coordination during the proposal preparation varies from weak coordination to a common approach in different disciplines in the project network. This is illustrated in the Figure 1.

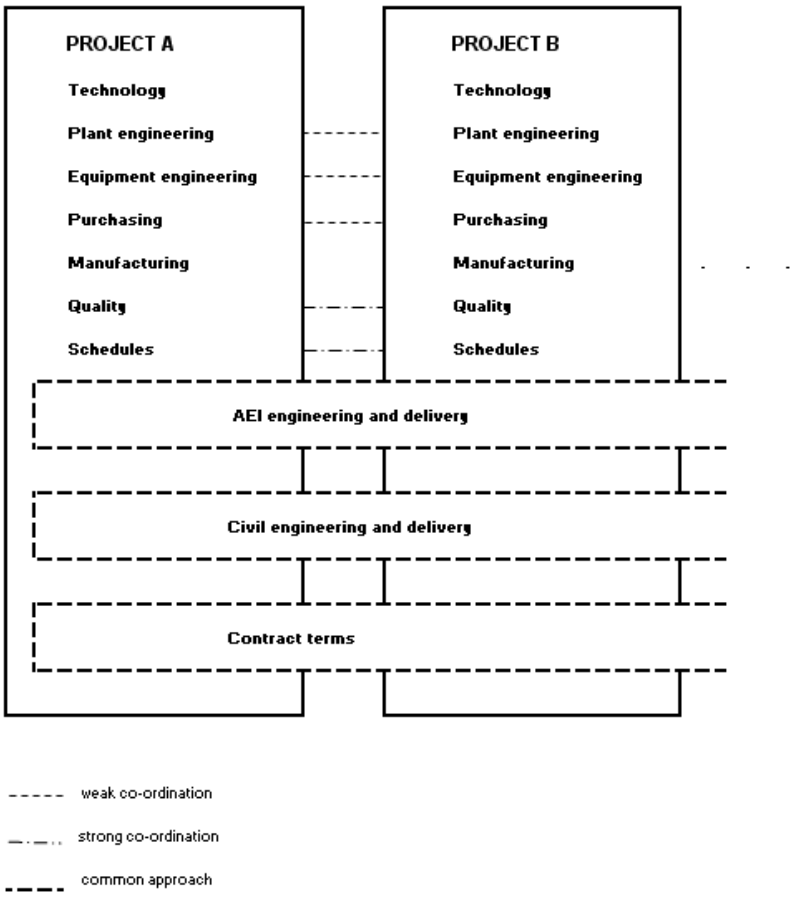

Figure 1. Different degrees of coordination in the sales phase

Persons working in the sales phase of the project to be executed with an internal project network structure were interviewed. The interviews were semi-structured lasting 45 - 90 minutes. The topics of the interviews were 1) comparison of the proposal to the other proposals of the own division with regard to technology, scope of supply, time schedule and complexity of the project, 2) proposal phase practises specified for this proposal, 3) risk

management practices and tools of the division as well as 4) risk management practices of the proposal of the project to be executed with an internal project network structure. Totally six interviews were conducted of which four with a wide perspective over the whole project network were transcribed. These four interviewed persons included one sales person, two persons with coordination responsibilities and one technology expert.

The interview data was content analyzed by two researchers. Analysis codes were generated based on the various reading rounds of the interview transcripts and literature on project risk management. Several barriers for risk management on a project network level were recognized. Furthermore, practices enabling and supporting risk management in the project network were identified. The following five different categories of barriers were observed: strict divisional approach, illusion of a common approach, no formal structure of the common approach, specification of the responsibilities and lack of common targets. Also many indicators of coordinating practices that supported risk management on a projects network level and were present in the sales work were found from the data. These practices were categorized into three categories as follows: common, competent and experienced resources in the sales work, group meetings and information sharing.

EMPIRICAL FINDINGS

In the interviews the risk management practices in the sales phase of the project to be executed with an internal project network structure were studied. Risk management practices of the individual project as well as practices of the project network were studied.
Based on the content analysis several barriers for implementing risk management in the project network level were identified. Mainly these barriers have their roots in the high degree of autonomy of the individual projects and in the own procedures and processes of the proposal preparation of separate divisions inside the globally operating project-based company. These barriers are related to the approach to the sales process, formulation of the work in the structured way with determination of the responsibilities and target setting of the proposal work. Based on the data analysis, it also appeared that there were several coordination mechanisms supporting the risk management of the internal project network in the sales phase. The nomination of competent and experienced persons in the role of integrator, group meetings and information sharing practices were notified as mechanisms enabling more efficient and effective risk management on a project network level.

Barriers

Barriers of the risk management in the project network prevent network level risk management in the sales phase. This fact results in only partly optimized common proposal with only partly harmonized common project execution plan.

Based on the data analysis, the following five barriers of the risk management in the project sales phase in the case project network were identified.

1. Strict divisional approach
2. Illusion of common approach
3. No formal structure of the common approach
4. No specification of the responsibilities
5. Lack of common targets

Strict divisional approach

The first category of divisional approach to risk management deals with the degree on which risk management is performed in the project network. In the case company most of the projects are executed as single, individual projects to the end customer without any relations to the other divisional projects of the company. Only in very few projects there are two or three divisions involved. The proposal of the whole production line is an infrequent case. Divisions prepare their proposals with regard to technology, the scope of supply and estimations quite independently resulting in very strong divisional approach during the sales phase of the case project network. We found evidence that the proposal work generally and risk management particularly are done independently by divisions as can be perceived from the following three quotations from the interviews of the schedule coordinator and technology expert.

> *" Divisions purely work for themselves."*
>
> *"In my opinion risks inside divisions are rather well managed."*
>
> *"Have we really thought how to do it in practice ? Or shall we start thinking what should be done at the moment when the whole project is got?"*

Illusion of the common approach

This category deals with prevailing imaginings of the common proposal work and common proposal. Six projects are put together to form a proposal of one entire production line. In some disciplines common for all projects the proposal preparation has been done according to common instructions and approach. Our evidence suggests that this gives a misbelieve of a totally common approach in the sales work as can be noted from the following citations.

> *"We have not striven to have common strategy, common schedules and common basic for estimation. This is a huge contradiction: we work in divisions and then we assume that we have suddenly somehow optimized concept. We have not been asked to think about the execution and management of the project network."*
>
> *"We have 5-6 separate proposals and then we think that we are quoting one entire project."*

In the divisions it is viewed that some parts of the proposals are prepared based on common principles and by common nominated sales persons. These common procedures make divisions to envisage the package of proposals being optimized and created based on a common strategy. The illusion of the common approach is present in all areas of sales preparation from conceptual design to the risk management.

No formal structure of the common approach

Formal structure of the common approach refers to the organizational form of proposal work. As divisional approach is prevailing in the proposal preparation work it is obvious that this is the result of the lack of structured common way to perform the proposal work. The person responsible for the coordination and in some extent the synchronization of the project main schedule out of the individual project schedules forming the project network has a perspective over the whole network. The following quotations of his interview emphasis the lack of project network organization structure and optimizing perspectives.

> "*We do not have any level in the top with resources and interests. If we had a division called " project network " we would have an organization with power and we would get benefits of the optimization of the project network. "*
>
> *" In the sense of project management we have not done this work [optimizing of the whole proposal] because it was not asked in the request of inquiry and our company has not seen it necessary to be done in reserve."*

The latter quote indicates the lack of formal structure in respect to project management approach. We found various indicators which show that this is not the case in some other disciplines where formal structure and common instructions exist. Generally the lack of the formal structure of the project network can be seen as a lack of power and authority to make strategic decisions of proposal making practices and principles including risk management procedures.

No specification of the responsibilities

This category deals with responsibilities of the project network actors. Structured way of perform the work is related to responsibilities as well as to power and authority. Without a clear structure of the project network there are not specifications of responsibilities with regards to decision making power. The coordinator of one discipline puts this to words as follows.

> *"We have to understand in the divisions that we have to give power and responsibility to the umbrella organization. And then it will do the job."*

”Particularly these interfaces [to schedule of discipline] should be defined. I could give more powerful instructions or state requirements concerning time frames. But I do not know these time frames, if nobody tells me.”

We found evidence that the project execution functions could be carried out more efficiently if responsibilities of the disciple representatives would be more accurately specified. This is valid also in respect to the risk management.

Lack of common targets

The category of common targets is related to target setting level in the proposal preparation work. When common target setting is missing it is very difficult to work for it. Harmonizing and synchronizing functions in the proposal preparation aim to well organised and formally similar proposals but when common target setting is missing the optimizing is done only in the single project level. Our data reveals that a missing target setting is considered as a missing vision of the proposal work outcome depicted in the following quote. Risk management process is one of the proposal preparation processes also suffering from the missing common targets.

“We do not have clear picture in either the perspective of organizing or thinking what it is to work for the common proposal and to what it could result in.”

Coordinating mechanisms in the organization

The data analysis revealed many indicators of supporting mechanisms that served as enablers for the network level risk management in the case project. The proposal work started individually in the divisions but soon the coordinating functions were included to the process of the proposal work. Some disciplines had nominated persons to prepare a proposal of the whole discipline separated from the proposal prepared by the divisions. The proposal work had the proposal coordinator who was involved in the previous project which had similar features with this project in respect to the country of the site, scope of supply and project network structure In addition, there was a separate proposal director who guided the proposal work. Proposal coordinator and proposal director conducted several group meetings sharing common guide lines of the proposal works as well as information inside the global proposal team. Based on our data analysis the coordinating mechanisms identified in the sales phase can be categorized into three following categories.

1. Competent and experienced persons in the role of integrators
2. Group meetings
3. Information sharing (common practices, mainly informal)

Competent and experienced persons in the role of integrators

This category emphasizes the personal competence and experience of the persons nominated to act in the coordinating and integrating positions in the proposal work. Although this network project proposal differs from the typical proposals prepared by the case company, case company has delivered one project with a same kind of approach to the same country of the site. In the sales team of the whole project network there were a couple of assigned integrators securing the interrelations between divisions during the proposal work. Our analysis proposes that the proposal director, proposal coordinator as well as a coordinator of the schedules worked as integrators also in relation to the risk management perspective. The experience in organization was utilized in this proposal work by nominating to the sales team persons, who had been involved in the previous project. Proposal coordinator who is personally experienced in the mentioned area of business was nominated to the sales work as the main coordinator. We observed that most of the interviewees named the project coordinator by name referring to his personal competence and experience. The coordinator of one discipline describes his own role of integrator as follows.

> *"In the previous project I coordinated the AEI discipline. In this case as in the previous project I put one AEI coordinator to the organization. "*

Group meetings

This category devotes focus on the practical tools of coordination in the format of meetings from the viewpoint of risk management. Proposal preparation is a team work by it´s nature. This aspect is emphasized in the sales phase of the project which consists of several proposals prepared simultaneously to one end customer having purpose to build an entire new production line. In the lifecycle of the sales phase there were many coordinating meetings and working meetings. During the preparation of the case proposal there were many group meetings conducted by the proposal director and the proposal coordinator. One discipline coordinator describes one group meeting as follows:

> *" On August we had a review meeting of the whole scope of the proposals. The meeting was conducted by proposal director and proposal coordinator. All responsible sales team leaders were present. And also I and my colleague were present as responsible persons of our own disciplines.. The meeting lasted two days and we finalized the whole package. After that we gave the price to the customer."*

Information sharing

Information sharing category of coordinating mechanisms of risk management covers formal and informal information sharing methods and practices carried out during the proposal work. Our analysis of the interviews indicates that during the proposal preparation there was much information sharing between the sales team members. Information sharing was partly formal having memos, lists, tables and servers as tools. Furthermore, information sharing had also informal features consisting of email-messages and

conversations beside the coffee machine and around the lunch table. Coordinator of one discipline told how he shared information in practice in his proposal work to enhance the project success.

> *" When I read the standards of my discipline and noticed some mechanical issues there I added those to our deviation lists. Then I told to the sales guys that – Hi, are you willing to struggle for these or not."*

In the area of standards the information sharing is vital to ensure good premises for the project execution. Quotation of the interview of the sales manager illustrates the importance of coordination related to the common customer standards in the sales phase.

> "*If one division accepts one of the requirements given in the standard and another does not mention this issue at all and the third one tries to get the deviation to the requirement it is obvious that in the end the customer preferred approach will prevail."*

DISCUSSION AND CONCLUSIONS

The results of this study contribute to research on risk management in project networks. In this paper barriers and enablers for the implementation of risk management in the sales phase of the project to be executed with an internal project network structure were empirically studied. Five categories of the barriers were identified. These five categories are strict divisional approach, illusion of common approach, no formal structure of the common approach, no specification of the responsibilities and lack of common targets. The studied project based company has long history and strong tradition of performing single projects to the end customer. The cases of such project networks where several divisions are involved are rare. We found strong evidence of the dominating divisional approach of the risk management in the case project network sales phase. Proposals are prepared in the divisions and the project network proposal is combined of the individual proposals. Risk management is performed according to the divisional practices and the project network risk management can be seen as a summary of the risk management of the divisional risk managements.

However, coordinators of the proposal work gave some guide lines of proposal preparation. The role of coordinators was observed as a coordinating mechanism but simultaneously it gave an illusion of an optimized proposal prepared according to common approach. Some disciplines of proposal preparation were carried out with the common structured approach. In these areas the project network proposal is seen as a proposal prepared according to common instructions and common approach. This kind of appearance of coordination also gives misbelieve of totally common approach in the proposal work. Although the proposal work was partly structured commonly the study revealed that the predominant approach is the divisional one. Hence, there were no precise specifications of the responsibilities

relating to the roles of the integrators. The deeper analysis uncovers also the lack of common targets of the entire project network with regards to the risk management.

Based on evidence found on the study there are many coordinating mechanisms in the project network sales phase. Perceived mechanisms in the case project network have their origin in the personal competence and experience, formal working methods and common practices. Rules, regulators, procedures, formal information system, hierarchy and coordination by targets and goals are presented in the literature as coordinative mechanisms. Actions and events reported by interviewees showed that some of these coordinating mechanisms were present in the sales phase of the case project network. On the other hand in the case study the shortcomings of some of the coordinating mechanisms turned out to be barriers of implementing risk management efficiently in the project network level. As a conclusion, it is apparent that internal project network benefits from the network level approach on the point of view of project risk management. According to the understanding gained during this study the coordinating mechanisms are not adequate enough to enhance efficient and effective risk management in the sales phase of the internal project network but a more structured goal oriented approach is needed

Only limited attention has been paid to risk management in project network context in prior literature (Artto et al., 2008; Pekkinen, 2010). The findings of this study increase our knowledge of challenges of risk management in project networks in particular. Furthermore, by applying existing research on co-ordination mechanisms (Daft and Lengel, 1986; Galbraith, 1974) to the context of a project-based firm, the results of this study reveal different mechanisms that support risk management on the level of the project network. The findings of this research have various managerial implications. The findings of the study suggest that managers should pay attention to the potentially existing barriers that may hinder an effective risk management approach when implementing risk management on a project network level. The formulation of common risk management processes and practices, detailed definition of responsibilities and coordination roles, as well as the creation of common goals and investments in efficient information sharing practices were found to be amongst the most important actions to support efficient and effective risk management on a project network level.

The current research of the risk management of the case project network will continue. The studied sales project turned into a delivery project via successful contract negotiations. The risk management practices of the case project network during the different project lifecycle phases will be the subjects in the further research. By adopting a lifecycle perspective on the studied project network i.e. by examining the risk management practices from the start of the project to the expiring of the warranty period, a more holistic and in-depth picture of the evolution and development of the risk management practices can be created. The appearance and effects of the perceived barriers and enablers for the implementation of risk management in a project network will play a key role in the further research.

ABSTRACT

Most corporate social responsibility standards have not paid enough attention to implementation in small and medium sized enterprises (SMEs). Given that 99% of Spanish companies are SMEs, this study aims to propose a selection of basic CSR material issues that because of their usefulness and significance should be adapted to Spanish SMEs and their stakeholders. This study contributes to the development of a common framework for CSR reporting that makes the task of comparing and verifying information from firms easier and more objective. Additionally, this tool can be used by firms in their internal assessment processes. The selected group of issues can also be used to increase the openness of corporate information to stakeholders.
We have constructed a CSR model for SMEs that includes the most important social, environmental, and corporate governance issues. This model is useful for integrating sustainability in the management of SMEs and enhancing the management of stakeholders.

Keywords: Corporate social responsibility (CSR), Small and medium sized enterprises (SMEs), reporting, materiality, stakeholders.

INTRODUCTION

Corporate social responsibility (CSR) reporting in companies has strongly increased within the framework of self-regulation in recent years. This framework has been developed using various tools such us the international standards GRI Guidelines (Global Reporting Initiative, 2002; 2006), ISO 26000, and SA 8000; as well as specific tools and protocols. However, the majority of these international standards have not paid enough attention to the implementation of these tools in SMEs. More than 99% of the Spanish productive fabric is based on SMEs and these firms suffer certain monetary and information limitations when implementing CSR. This study therefore proposes a selection of basic CSR issues that are useful, significant, and adapted to Spanish SMEs and their stakeholders. This study contributes to the development of a common framework for CSR reporting that will make

the comparison and verification of information provided by firms easier and more objective. Additionally, this tool can be used by firms in their internal assessment processes. The selection of issues will also make it possible to ensure that corporate information is more available to stakeholders.

The main aim of this study is to develop a proposal for helping Spanish SMEs report basic CSR issues. The developed materiality analysis is based on a literature review, expert knowledge, and a national SME survey.

As a result of the study, we propose a CSR model for SME reporting. This model includes the most important social, environmental, and corporate governance issues for SMEs. The model may be useful to integrate sustainability in the management of SMEs and improve stakeholder management and relationships. In addition, the results are important to advance CSR and sustainable development in SMEs.

The structure of this paper is as follows: the present introduction is followed by a description of the characteristic features in SME management, and the way these features influence CSR strategies. Section 3 defines the research design. The results of the study are analysed in Section 4. The final part of the paper presents the main conclusions of the study.

CSR MANAGEMENT AND REPORTING IN SMES

CSR can be defined as an aggregate of the voluntary policies and subsequent management processes arising from corporate decisions aimed at achieving actions in the field of economics, environment, social development, and corporate governance (Muñoz et al., 2009). Consequently, CSR may be considered as an organisational instrument for implementing the concept of business sustainability (European Commission, 2002).

Although there many academic articles related to the integration of CSR in companies, research on the implementation of CSR in SMEs is still in an early stage (Battaglia et al., 010; Rivera-Lirio and Munoz-Torres, 2010). As Morsing and Perrini (2009) indicated: '*although it is much more complex to identify, investigate, and communicate CSR in the small business, we believe this area deserves more attention due to its potential impact on the global economy*'.

In terms of CSR management, there seems to be considerable consensus that significant differences exist in the way SMEs and large companies approach and integrate CSR strategies (Jenkins, 2006). Table 1 shows the distinguishing elements of CSR in SMEs.

Some of the principal issues associated with the management of CSR refer to transparency and accountability. In recent years, the publication of sustainability reports has been established as the main mechanism for CSR reporting and is used by companies to communicate with their stakeholders and explain strategies and outcomes in terms of sustainability and CSR (Etxeberria, 2009).

Table 1. CSR in SMEs: some distinguishing elements.

Definition of CSR	**Obstacles/limits and issues to be developed**
- Difficulty understanding the concept of CSR - Concept seen as distant, possibly inoperative, or counter-productive - Activities performed seen as positive for the company and for a wide variety of interest groups - Company ethical values - Should be integrated in all elements of the business - Goes further than shareholder interests and creation of employment - Certificates used as a variable proxy for defining CSR - Participation in business organisations or openings to the public - Importance of character and values of company founders - Use of informal CSR policies	- Anxiety that activities undertaken will be seen as efforts to gain publicity and some SMEs prefer not to communicate their activities in these areas - Consider that there is information about CSR, but insufficient practical and financial aid - Consider that public authorities are not doing enough - In general, social practices are not communicated. Some internal diffusion and external diffusion in company's area of influence - Not enough time - Planning horizon is short-term - Fear of making errors during implementation of social and environmental policies - Lack of human, technical, and organisational resources

Source: (Battaglia et al., 2010; Jenkins, 2006; Murillo and Lozano, 2006; Muñoz et al., 2009; Roberts et al., 2006)

Given the distinct characteristics of these businesses, new tools for defining and communicating CSR strategies are being generated that are specifically aimed at small businesses. Various studies have emerged that aim to facilitate the production of sustainability reports by SMEs. Examples include GRI and EMS-key. GRI has developed a guide for SMEs termed 'Five Steps' and the principal aim is to help SMEs improve transparency in sustainability and CSR in the same way as has occurred with many large companies.

However, as Nielsen and Thomsen (2009) remarked CSR communication in SMEs is still at an early stage. Interestingly, authors such as Fassin (2008) consider that these published reports do not reflect 'real' CSR and that this kind of formalisation may even be counter-productive. CSR communication in SMEs is sometimes perceived as informal while personal relations are seen as being very important – yet this vision of CSR communication in SMEs ignores the importance for SMEs of corporate communication, reputation, and stakeholder relations (Nielsen and Thomsenn, 2009). This point is reinforced by the fact that SMEs are increasingly dealing with companies that operate worldwide in a competitive and complex business environment (Parsa and Kouhy, 2008).

Therefore, in light of the peculiarities of CSR in small companies, our aim has been to create a set of key CSR issues that are highly material and relevant for Spanish SMEs and their stakeholders. We have constructed a CSR model for SMEs that includes the most important social, environmental, and corporate governance issues. This model will be useful for integrating sustainability into SME management and reporting; as well as improving the management of stakeholders.

RESEARCH DESIGN

One of the aims of our research was to gain an understanding of which issues related to the management of CSR are of greatest relevance or materiality for Spanish SMEs. According to GRI (Global Reporting Initiative, 2006) materiality implies indicators and information regarding the significant social, environmental, and economic impacts of a company; or information that may have a substantial influence on the assessments and decisions of interest groups. In addition, GRI (Global Reporting Initiative, 2006) defines relevance as the degree of importance attached to each issue, indicator, or item of information – and the term refers to the threshold at which information becomes sufficiently important to be disclosed.

Our materiality analysis is based on a knowledge extraction process that is divided into the following steps: i) development of an initial draft of the main CSR material issues (based on a review of the literature) followed by an expert review; ii) a telephone survey of 500 Spanish SMEs aimed at establishing a consensus on the indicators that were not be agreed in the first step; and iii) an analysis of the results of the survey and the preparation of a proposal regarding basic CSR issues for Spanish SMEs.

The research method used in the first step combines scientific evidence with consensus. The goal was to make an initial selection of the basic CSR indicators in SMEs. Those indicators for which no consensus was agreed were then evaluated by the SMEs themselves in a survey. The RAND Appropriateness Method methodology -used in knowledge areas such as health sciences (Gonzalez et al., 2009)- has been specifically simplified and adapted for the study. As indicated by Campbell et al. (2002), the RAND method '*is a formal group judgement process which systematically and quantitatively combines expert opinion and scientific (systematic literature review) evidence by asking panellists to rate, discuss, and then re-rate indicators.*' It was considered that the RAND method was an appropriate methodology and adaptable to the study. This decision was made because, as in the case of the process of developing quality indicators in health care described by Campbell et al. (2002), a definition of material CSR issues for SMEs should take into account a number of points: i) the stakeholder perspectives of the issues; ii) the nature of the issue to be measured; and iii) the available evidence.

Under this premise, the study was divided into several sub-phases: i) an analysis of the literature on CSR tools and CSR studies in SMEs in order to create an initial set of social, environmental, and corporate governance issues; ii) a study and evaluation by a group of experts of an initial proposal for CSR material issues; and iii) discussion aimed at reaching a consensus with a group of experts on the results of the initial consultation.

After this first part of the investigation, an initial proposal regarding the material CSR issues for Spanish SMEs was obtained. Indicators that were agreed to be important by all of the experts were included in a questionnaire for a telephone survey of 500 Spanish SMEs. The development of this part of the research deepened our understanding of the perception that SME managers have regarding CSR management (Fassin, 2008).

The final stage of the investigation focused on an analysis of the results of a telephone survey and the creation of a model for CSR reporting by SMEs. In this model, the most important social, environmental, and corporate governance issues for SMEs were included. The model will be useful for integrating sustainability in the management of SMEs and improving the management of stakeholders and relationships.

ANALYSIS OF RESULTS

First part: scientific evidence and expert group consensus

As a first step, we made a thorough analysis of various tools used for CSR and sustainability management in SMEs. In parallel, we also used the results of previous research undertaken by the team that was related to the subject (Escrig et al., 2010; León et al., 2010; Muñoz et al., 2009; Rivera-Lirio and Munoz-Torres, 2010). As a result, we identified a number of potentially relevant stakeholders in the field of SME – employees, society, customers, corporate governance, environment, and suppliers – and a set of issues related to the socially responsible management of these stakeholders (Annex I).

As a next step, we relied on the support of a group of business experts whose experience would help ensure the suitability of the questionnaires before beginning the survey. To achieve this aim, we conducted a study of the materiality of the issues selected for inclusion in the survey that was based on the opinion of these experts.

The work with the expert group took place in late 2010 in two stages:

Stage 1. Compiling the expert opinions

During this stage, we contacted a group of qualified experts. The group members completed and returned the questionnaire we had developed. The questionnaire was intended to determine the materiality of a set of general issues regarding corporate social responsibility. The materiality of each issue was determined using five parameters (Lydenberg et al., 2010):

- **Financial performance and/or economic-financial risks:** Degree of importance or influence of the issues on economic performance and company risks.
- **Competitive position and strategic expectations:** Degree of strategic importance for the company and/or the perceived importance that the competition attaches to the issues.
- **Interest groups:** Degree of importance that the management of the issue may have on the decisions of interest groups.
- **Future regulations:** The likelihood of the issue being regulated in the future, and so offering the opportunity to obtain a strategic advantage by anticipating such regulation.
- **Opportunity for innovation:** Degree to which knowledge held by the company and/or its abilities may foster innovation as a result of managing this issue.

After collecting the questionnaires completed by the experts, we studied the materiality of the issues using statistical analysis – with averages used as a measure of importance and typical deviation as a measure of consensus. This subsequent analysis enabled us to establish a classification of the issues raised into two groups:

- **Issues that are clearly material:**
  - Development of products that are beneficial from a social environmental/perspective
  - Stable employment
  - Pollution, effluents, and waste
  - Training and education / professional development
  - Investment in environmental R & D + i / clean technology
  - Marketing
  - Client satisfaction
  - Product safety / health and safety of clients
  - Health and safety at work / working conditions

- **Issues of doubtful materiality:**
  - Product cycle management
  - Resource use
  - Transparency and communication
  - Evaluation and monitoring
  - Hiring practices / local hiring
  - Codes of conduct
  - Social action
  - Director salaries
  - Recycling
  - Environmental management systems
  - Compliance with regulations
  - Cooperation with local industries
  - Managing the interests of shareholders
  - Customer privacy
  - Sustainable behaviour among clients
  - Local community / local development
  - Reconciling work and family life
  - Discrimination / diversity and equal opportunities
  - Education and environmental awareness
  - Labelling of products and services
  - Freedom of association and collective bargaining
  - Transparency
  - Nature and biodiversity
  - Harassment
  - Unfair competition
  - Corruption and bribery
  - Rights for ethnic minorities
  - Forced labour and child exploitation

Stage 2. Work session with experts

We then met the expert panel to analyse and discuss the results of the previous stage and reach consensus on a classification of the issues.

During the discussions, special attention was paid to those issues whose materiality was not agreed by the various experts ('issues of doubtful materiality'). The experts argued the reasons for their classification, discussed the ratings assigned to each of the parameters of evaluation, and compared their values with those of other experts. During the process of reflection, the experts reconsidered their positions regarding the materiality of various issues considered as doubtful and so several issues were reclassified as being clearly material (see Table 2). The results of this discussion enabled us to design a questionnaire that was used in the telephone survey.

Table 2 reveals that corporate governance and supplier management are not important issues with respect to CSR management in SMEs. The reasons given in the case of corporate governance focused on the small size of the shareholdings in this type of business and the concentration of ownership and control – as well as the absence of formal mechanisms for structuring control systems.

The reasons for not including supplier management in the analysis of CSR were varied and reflected the bargaining power of small companies. Either the power of a small company to establish conditions is very limited, or small companies face oligarchic market structures in the supply of raw materials, and these factors prevent them from establishing mechanisms for selecting suppliers.

Table 2: Issues that the expert panel believe to be clearly material.

Stakeholder	**CSR Issue**
Customers	Development of products that are beneficial from a social/environmental/perspective
	Marketing
	Client satisfaction
	Product safety/health and safety of clients
Environment	Pollution, effluents, and waste
	Investment in environmental R & D + i / clean technology
	Resource use (energy, water, materials)
	Recycling
Society	Local community/local development
	Cooperation with local industries
	Transparency and communication
Employees	Stable employment
	Training and education/ professional development
	Health and safety at work/working conditions
	Reconciling work and family life
	Discrimination/diversity and equal opportunities

Part Two: Development and implementation of a telephone survey of 500 Spanish SMEs

From the meeting with the expert panel, it was concluded that it was necessary to translate the issues into practical questions that could be handled in the time available for the telephone survey and be easily understood by the respondents. A key aspect when developing a questionnaire is the wording of the questions: the objective being not discover to what extent the company has implemented CSR policy – but to discover the importance

that the company management attaches to the issue. The survey was therefore aimed at managers or directors of small companies.

The survey was conducted during the third quarter of 2010 and some 502 SMEs with between 10 and 200 employees were contacted. The firms operate in the following sectors: food and agriculture, industry, construction, and services – and all the Nielsen areas were taken into account. The survey included a total of 29 questions that were associated with the preparation of annual reports in the widest sense; as well as social and environmental information related to various stakeholders (suppliers, customers, shareholders, the environment, employees, and society).

Part Three: Analysis of survey results and proposed material CSR issues

Analysis of survey results

After conducting the survey and processing the results we drew some preliminary conclusions that are shown in Figure 1. The figure illustrates average and standard deviation of responses to survey questions. The labels correspond to the numbering system for the questionnaire. In Tables 3, 4, and 5, the first column refers to the stakeholder involved in the issue; and the second column shows the question used for each issue.

1. It is worth noting that none of the issues under evaluation is immaterial or irrelevant as the minimum average score was 3.49 (minimum 1, maximum 5).
2. There is considerable consensus on the issues most highly rated. However, in zones with lower scores, there is little consensus and there are major discrepancies between business managers regarding the importance of these issues. As a result, no issue can be out excluded a priori as immaterial.
3. We can define three zones of evaluation for the various issues raised in the survey. These zones are defined by the average deviation values found in the responses received. We have established the following zones of analysis in order of the most-to-least importance as given by the respondents: A, B, and C.
4. An analysis of the issues evaluated in Zone A (Table 3) reveals that there is little consensus and a generally low evaluation of the importance of issues linked to corporate governance and supplier relationships. It can also be seen that the issues in Zone A clearly correspond to CSR issues covered by the national legal framework and international standards.

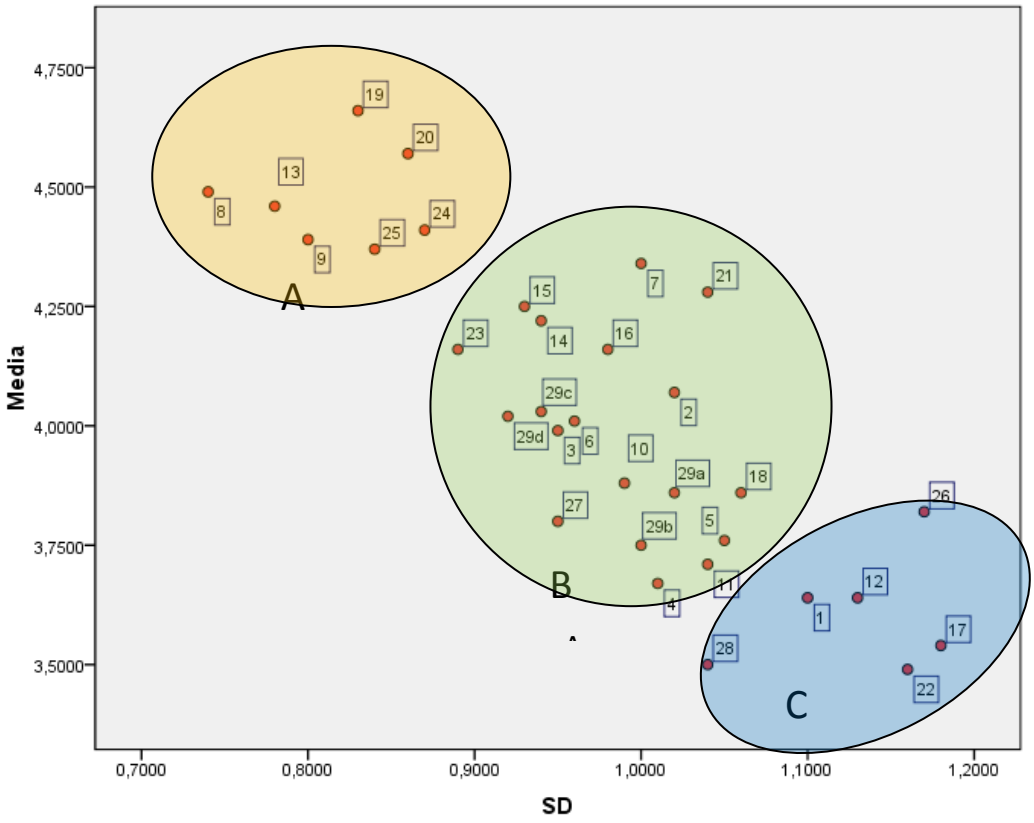

Figure 1: Average deviation analysis of the survey results

Table 3: Issues in Zone A.

Stakeholder	Code	CSR issue
Customers	8	Customer privacy
	9	Compliance with regulations
Environment	13	Nature and biodiversity
Society	25	Unfair competition
	24	Corruption and bribery
Employees	19	Forced labour and child exploitation
	20	Harassment

5. Within Zone B (Table 4) there are issues relating to all stakeholders with the exception of 'society'. The majority of these issues are directly related to managing the supply chain. It can be clearly seen that there is consistency in the responses to the questions that are closely related, such as those questions regarding a code of conduct for dealing with suppliers.

Table 4: Issues in Zone B.

Stakeholder	Code	CSR issues
Customers	10	Sustainable behaviour among clients
	7	Labelling of products and services
	23	Compliance with regulations
Corporate governance	11	Managing the interests of shareholders
Environment	15	Product cycle management
	14	Environmental management systems
	18	Education and environmental awareness
Suppliers	3	Evaluation and supervision
	2	Hiring practices
	4	Codes of conduct. Social and environmental commitments
	6	Codes of conduct. Stable relation with suppliers
	5	Hiring practices / local hiring. Sustainable behaviour with clients
Employees	21	Discrimination / diversity and equal opportunities
	16	Freedom of association and collective bargaining

6. Most of the issues in Zone C (Table 5) are related to the 'society' stakeholder. Question 1 regarding the importance of reporting on social and environmental issues in the annual accounting report, or other voluntary reports, has been rated with an average of 3.64 (minimum 1, maximum 5). This is a relatively low score and there is also considerable dissent. A possible explanations for this result may be that SME managers consider other uses of this information to be more important in relation with stakeholders – given that dissent is less and evaluations are higher when the information is focused on generating specific advantages for a company: such as improvements in economic performance; market position in comparison with the competition; strategic advantage relative to future regulation; and opportunity for innovation.

Table 5: Issues in Zone C.

Stakeholder	Code	CSR issue
Corporate Governance	12	Director salaries
Suppliers	28	Hiring practices / local hiring
Society	1	CSR information. Transparency and communication
	17	Social action. Corporate voluntary work
	22	Social action. Donations.
	26	Minority ethnic rights

Proposal regarding material CSR issues for SMEs

After an analysis of the results, Tables 6 and 7 contain the final proposal of issues considered as material for Spanish SMEs.

Table 6 lists the 23 issues considered as 'key' for a proper management and communication of sustainability in SMEs – as identified by their positioning in Zone A following the survey. This selection of major issues excludes managing the relationship with suppliers and organisational governance.

The management of these two stakeholders was considered immaterial by the expert group and this assessment was confirmed by the results of the survey.
Following the completion of the session with the group of experts and the subsequent survey, an analysis of the results enabled a pruning of the issues proposed in the first stage of the investigation.

Table 6: Core material issues.

Stakeholder	**CSR issue**
Customers	Development of product benefits that are beneficial from a social environmental/perspective
	Marketing
	Client satisfaction
	Product safety / health and safety of clients
	Client privacy
	Compliance with regulations
Environment	Pollution, effluents, and waste
	Investment in environmental R & D + i / clean technology
	Resource use (energy, water, and materials)
	Recycling
	Nature and biodiversity
Society	Local community / local development
	Cooperation with local industries
	Transparency and communication
	Unfair competition
	Corruption and bribery
Employees	Stable employment
	Training and education / professional development
	Health and safety at work / working conditions
	Reconciling work and family life
	Discrimination / diversity and equal opportunities
	Forced labour and child exploitation
	Harassment

The high average values scored for the other issues raised in the survey, and the lack of consensus among experts regarding their materiality, are a positive factor when proposing additional information structures to be considered by companies that, because of their specific characteristics, may need to disclose information covering all stakeholders.

Table 7: Complementary/additional material issues.

Stakeholder	CSR issue
Customers	Compliance with regulations
Employees	Discrimination / diversity and equal opportunities
	Freedom of association and collective bargaining
Customers	Sustainable behaviour among clients
	Labelling of products and services
Corporate Governance	Managing the interests of shareholders
	Director salaries
Environment	Product cycle management
	Environmental management systems
	Education and environmental awareness
Suppliers	Evaluation and supervision
	Codes of conduct
	Hiring practices / local hiring
Society	CSR information. Transparency and communication.
	Social action
	Minority rights

CONCLUSIONS

The amount of information that the expert panel and survey have generated has enabled us make an analysis of the perception of sustainability held Spanish SMEs – and its impact on management and the disclosure of information.

An analysis of materiality for Spanish SMEs provides information on the perception that these companies have of sustainability and the impact of sustainability on business management, as well as the disclosure of information regarding social, environmental, and corporate governance.

The study was conducted following a review of the CSR norms and standards that are most widely accepted by academic and professional experts; as well as a survey of 500 Spanish SMEs.

The results reveal that Spanish SMEs attach great importance to the correct management of 23 basic issues relating to customers and employees – as well as the environment and society in general. In addition, some 16 other additional issues of lesser materiality for smaller SMEs were also identified; and these issues were mostly related to corporate governance and supplier management.

ANNEX I. DESCRIPTION OF AREAS INITIALLY IDENTIFIED

	Issue	Description
Employees	***Stable employment***	Job security in the workplace through permanent employment contracts and activities to promote staff cohesion and a sense of belonging.
	Freedom of association and collective bargaining	Right of employees to join and form groups with legitimate aims, and to be represented by independent trade unions.
	Training and education / Professional development	Ongoing employee access to training to enable them to improve their job and/or social skills, as well as guarantees of personal and professional development in the company.
	Reconciling work and family life	Flexible schedule, telecommuting option, flexible leave of absence, flexibility for family care, aid for child care, school support, health insurance, life and/or accident insurance, risk prevention measures beyond the mandatory, etc.
	Health and safety at work/working conditions	Safe environment and working conditions appropriate to the tasks being performed. Risk prevention plans, as well as resources necessary for the proper management of work accidents.
	Forced labour and child exploitation	Policy against child labour and forced labour, as well as related procedures and programs. Report on monitoring systems and results.
	Harassment	Prevention of workplace bullying with policies and procedures to prevent employee harassment.
	Discrimination/diversity and equal opportunities	Fair pay and equal opportunities for advancement and improvement, regardless of sex, disability, or other criteria.
Society	***Rights for ethnic minorities***	Policies, guidelines, and procedures to manage the needs of ethnic minorities.
	Local community/local development	Measures to encourage the relationship with the community – such as attending meetings for community issues, training for people in the community, transfer of facilities for community use, purchasing of local products, etc.
	Corruption and bribery	Policies and management systems and compliance mechanisms related to corruption and bribery – aimed at the company and employees.
	Transparency and communication	Published information on policies and outcomes regarding sustainability.
	Cooperation with local industries	Cooperation with local companies to benefit the economic, social, and/or environmental community.
	Unfair competition	Prevention of conduct that is contrary to free competition by implementing policies, procedures, and suitable management systems.
	Social action: donations, philanthropy, voluntary work, sponsorship	Encouragement of volunteering among employees, support for stable economic sponsorship, and support for employment by groups that encounter problems finding jobs, etc.
Clients	***Product security/health and client safety (product impacts)***	Policies, practices, and procedures to evaluate and analyse the impacts of products on the health and safety of clients.
	Labelling of products and services	Suitable labelling that provides relevant information for the customer and assists their buying decisions.
	Marketing	Honest promotional activities and sponsorship appropriate to the company's strategic objectives – as well as activities promoting

		sustainability and management of social and environmental issues.
	Client privacy	Suitable treatment of personal data on clients.
	Compliance with regulations	Strict enforcement of the most restrictive legal framework that is applicable to the company according to its activities and location(s).
	Sustainable behaviour among clients	Establishment of policies and practices that encourage clients to behave in a socially responsible manner.
	Client satisfaction	Policies and practices to increase client satisfaction / wellbeing / quality of life.
	Development of product benefits that are beneficial from a social environmental/perspective	Product development and/or services that encourage sustainable development.
Governance	***Transparency***	Policies, practices, and procedures to ensure that information provided to governing bodies is useful and accurate.
	Managing the interests of shareholders	Policies and practices to defend the rights of shareholders – such as voting rights and information.
	Director salaries	Pay and reporting policy.
	Review panels	Review panels established in the governing bodies to ensure the proper functioning of various processes, business units (special emphasis on CSR panel), and other elements of the company.
Environment	***Resource use (energy, water, and materials)***	Control procedures and management of resources employed, savings plans, recycling, etc.
	Pollution, effluents, and waste	Control and management of pollution, and waste resulting from the business, traceability of origin and destination.
	Product cycle management	Management of main environmental impacts of products and services during life cycle.
	Recycling	Policies for recycling resources consumed.
	Investment in environmental R & D + i / clean technology – Eco-efficiency	New cleaner product design and implementation of clean technologies.
	Environmental management systems	Environmental management systems for the management of environmental impacts, as well as disaster prevention and appropriate response to accidents.
	Education and environmental awareness	Actions to raise employee awareness.
	Nature and biodiversity	Corporate action with respect to their impacts on living beings and the environment.
Suppliers	***Codes of conduct***	Codes of conduct with suppliers to specify criteria beyond the strictly economic and ensure long-term business relations.
	Evaluation / supervision	Awareness that suppliers must comply with tax laws and labour contracts and set minimum standards. Mechanism to detect and eliminate abusive practices against suppliers.
	Hiring practices / local hiring	Selection of suppliers based on commitment to corporate social responsibility; avoidance of dealings with companies that violate the rights of workers according to the ILO (for suppliers from outside the European Union).

THE PROCESS TO DETERMINE POSSIBILITIES AND NEEDS FOR MOBILE MAINTENANCE – APPROACH TO STRENGTHEN MAINTENANCE WITH MOBILE TECHNOLOGY

Jere Backman*, VTT Technical research Centre of Finland, Finland
jere.backman@vtt.fi, *corresponding author

Dr. Heli Helaakoski, Technical research Centre of Finland, Finland
heli.helaakoski@vtt.fi

ABSTRACT

The exploitation of mobile technologies keeps on expanding, but has not become popular in heavy industry and maintenance. One of the reasons is that companies do not see the possibilities of mobile solutions in professional use because current solutions have been developed for consumers. Maintenance companies are now looking for new ways to develop working methods and tools to be more efficient and real-time. Therefore the interest for mobile solutions in professional use has increased.

This paper presents the case study where the role of mobile technology was researched in strengthening the maintenance operations. One of the aims was to research the development process of professional mobile solutions for maintenance domain. The paper presents how case study applied the Solution Envisioning Approach with Capability Cases as a process in determining possibilities and needs for mobile maintenance.

Phases of the approach were gone through by applying its steps depending on situation. One reason for the customed appliance of the approach was the goals and purposes of the case study. Instead of designing or implementing, general scientific results and information about applying mobile technology in maintenance to boost up performance were required as a result. For example several Capability Cases were developed to support efficient maintenance by exploiting mobile technologies. The cases were developed as a result of workshops arranged in different enterprises. The participants in workshops represented different levels of maintenance organizations. Overall the approach was discovered as good guideline and the developed process can be now applied by enterprises themselves.

Keywords: Process, Mobile, Maintenance

INTRODUCTION

The exploitation of mobile technologies will keep on expanding. Mobile technologies and solutions have been used in consumer applications with good results, but still they have not become very popular in heavy industry and maintenance in Finnish context. One reason is that companies do not quite see the possibilities of mobile solutions in heavy industry and maintenance operations because current solutions have been developed for consumer sector. Due to recession maintenance companies are now looking for new ways to develop working methods and tools to be more efficient and real-time therefore the interest for

mobile solutions in professional use has been increased. Mobile solutions bring maintenance management closer to the daily practice in the field and lead to more efficient maintenance operations.

The general technology acceptance models focuses to user acceptance and adoption. These kinds of models are for example TRE (Ajzen and Fishbein, 1980), TAM (Fishbein and Ajzen, 1975), TPB (Ajzen, 1991), IDT (Rogers, 1995) and UTAUT (Vekatesh et al., 2003). Available are also mobile service and technology acceptance models, like Mobile Services Acceptance Model (Gao et al., 2008) and Conceptual model of mobile service adoption (Ervasti and Helaakoski, 2010), which are developed to test user's acceptance, attitude and intention to adopt new mobile services and mobile technologies. There are also case studies (Ervasti and Helaakoski, 2010) and researches (Kaasinen, 2005) about mobile service acceptance and consumer use. When considering use of professional mobile solutions in industry and especially in maintenance the available studies and researches focus mainly on e-maintenance (Crespo-Marquez and Iung, 2008; Mullera et al., 2008). In Finnish context there are also available research and studies about e-maintenance (Jantunen et al., 2009). Some e-maintenance specific case studies focus on mobile device architectures where the mobile device can for example help the maintenance engineer to perform maintenance tasks (Campos et al., 2009). Term e-maintenance is still quite large concept where the mobile solutions can be one part of it. When considering processes or models how to determine possibilities and needs for mobile solution in industry, and especially in maintenance, there is lack of available processes, models and researches. There are still some general methods for problem discovery and solution planning. The method called Solution Envisioning Approach with Capability Cases is a problem discovery, situation assessment and solution planning process that uses Capability Cases to achieve connections between Business and IT stakeholders (Polikoff et al., 2005).

In this paper the appliance of the Solution Envisioning Approach based process to determine possibilities and needs for mobile maintenance are presented. Also the results and experiences relating to appliance are presented and possibilities to use the process in enterprises by themselves are discussed. This paper presents the mobile maintenance case study which studied the role of mobile technology for supporting the maintenance operations to be more efficient and reliable. One of the aims was to research the development process of mobile solutions that are aimed for professional use in maintenance domain. This research applied Solution Envisioning Approach with Capability Cases for developing a concept for mobile solution development in maintenance. In the case study the approach was applied in addition to technology adoption perspective. The technology adoption perspective means that the factors affecting to acceptance and adoption of industrial mobile solutions have been taken in to account in addition to following to the approaches phases.

The work presented in this paper has been conducted in the Mobile Maintenance project (Moma). The case study was performed during 2009-2010. Four different enterprises were participating to this research. The participating enterprises were from era of energy, industry, maintenance and ICT.

This Paper is organized as follows. Chapter Solution Envisioning Approach with Capability Cases presents the background and basics of the approach applied. Chapter Mobile Maintenance Case Study introduces the case study of this research. The process applied in the case study is presented phase by phase in corresponding chapter. The results are presented in the corresponding chapter Results.

SOLUTION ENVISIONING APPROACH WITH CAPABILITY CASES

In this chapter the method called Solution Envisioning Approach with Capability Cases is presented. Solution Envisioning is a problem discovery, situation assessment and solution planning process that uses Capability Cases to achieve connections between Business and IT stakeholders. It was designed to improve chances of solution success by addressing the risks and challenges present in the early stage of the solution lifecycle. Solution Envisioning embraces a business-centric approach to designing and realizing technology enabled business capabilities. Its purpose is to 'bridge the gap' between business and IT by integrating and matching concepts and techniques from both best of breed business strategy methods and software development methods. Following figure 1 illustrates the process of Solution Envisioning Approach. (Polikoff et al., 2005)

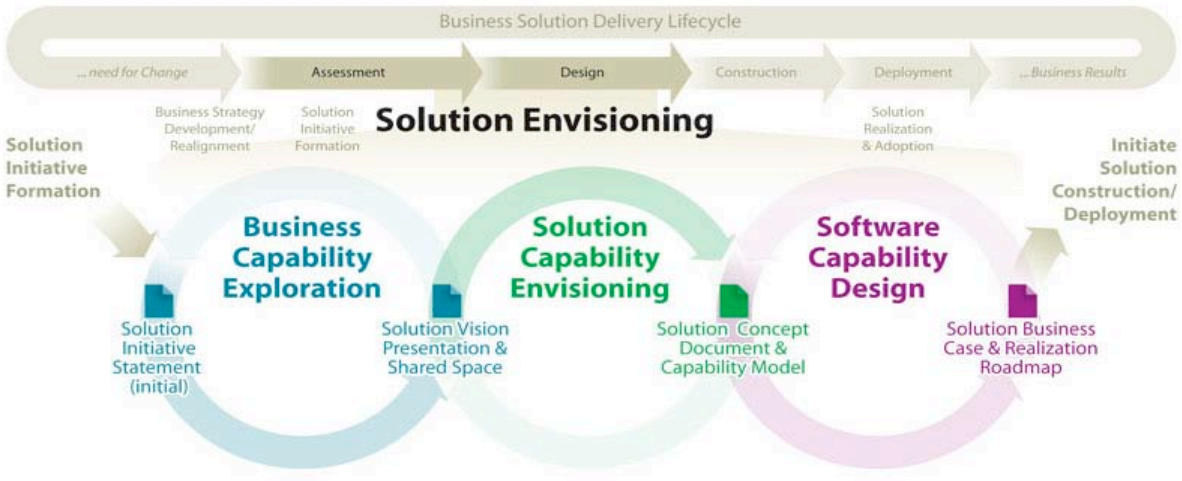

Figure 1: Solution Envisioning Approach (Polikoff et al., 2005).

Solution Envisioning with Capability Cases is designed for use at a front end of the software development lifecycle. The process can be partitioned into three major steps or phases, with the use of Capability Cases occurring throughout. The three phases of Solution Envisioning are (Polikoff et al., 2005):

1. Business Capability Exploration – BCE
   • Creating the Solution Vision and an initial Business Case

2. Solution Capability Envisioning – SCE
   • Creating the Solution Concept

3. Software Capability Design – SCD

- Elaborating and confirming the Business Case and delivering the Solution Implementation Roadmap

Business Capability Exploration – BCE

The nature of Business Capability Exploration is to do the necessary pre-work of laying the foundation for the solution. Its purpose is to establish the existing context of the business and to support a select, core-team of stakeholders who are initially driving the initiative as they produce a preliminary Solution Vision. Preliminary because it will be shared and shaped in successive phases. Following figure 1 illustrates the BCE phase. (Polikoff et al., 2005)

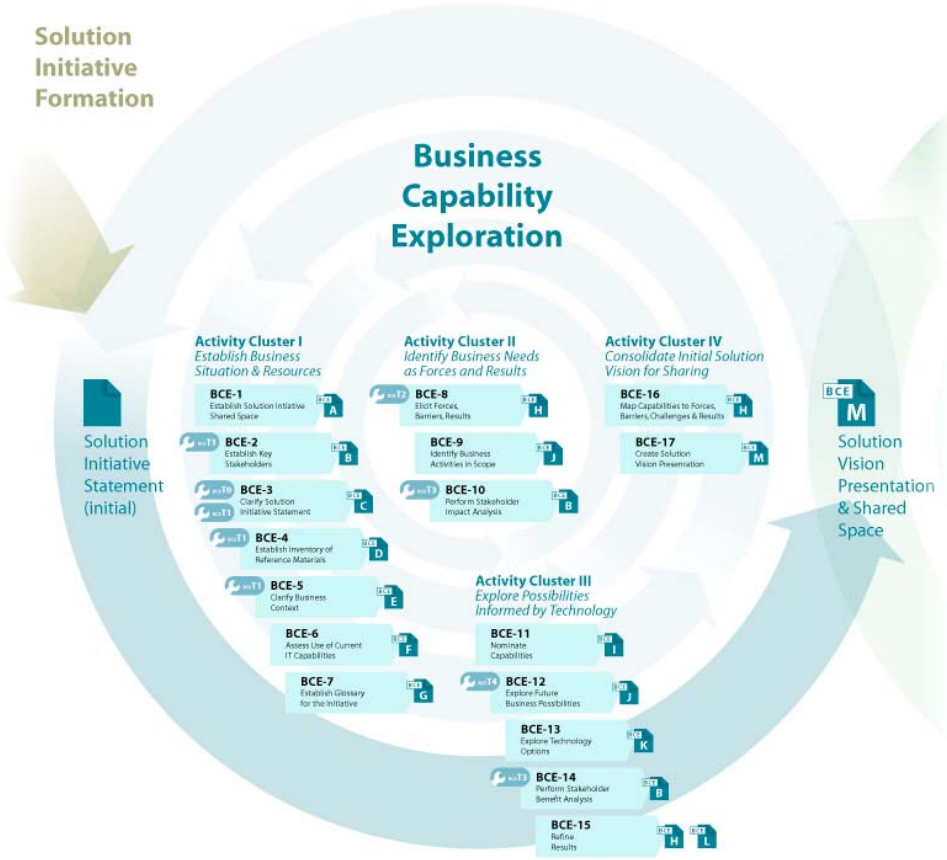

Figure 2: Phase I: Business Capability Exploration (BCE) (Polikoff et al., 2005).

To arrive somewhere new there is the need to understand where you are, what is causing the need to move and what results the move needs to achieve. Business Capability Exploration has a number of framing and focusing activities guided by these objectives (Polikoff et al., 2005):

- Assessment of business dynamics and predicaments
- Expression of root causes and their analysis – a relationship between cause and effect in the business environment

- Initial scan of potential solutions
- Agreement over business objectives

The phase is completed when an understanding is reached on the nature of business problems, the specific results the solution will need to bring about, and vision of how the solution might be realized. This understanding is documented as a Solution Vision Presentation and made available to a broader set of stakeholders within a suitable collaborative portal or workspace. (Polikoff et al., 2005)

Solution Capability Envisioning – SCE

The nature of Solution Capability Envisioning is to facilitate a series of collaborative interactions or envisioning workshops that enable a broad set of stakeholders to forge a shared understanding about the intent of the initiative and the details of the solution vision. Having understood and represented the problem in the activities of the previous phase, an exploration of solution alternatives proceeds with the confidence that there is now a framework for evaluation of proposed ideas and concepts. The purpose of this phase is to assemble solution building blocks by nominating, evaluating and prioritizing an integrated set of capabilities that will collectively meet the business goals. Following Figure 3 illustrates the SCE phase. (Polikoff et al., 2005)

Figure 3: Phase II: Solution Capability Envisioning (SCE) (Polikoff et al., 2005).

The phase is completed when the Solution Vision has been refined and confirmed by a broadly representative set of stakeholders. The result --an integrated and optimized set of capabilities sufficient to realize the business solution-- are captured and communicated in the form of a Solution Concept Document. Solutions need to be understood in terms of their effects on how people and systems will work. The Solution Concept is created through (Polikoff et al., 2005):

- Matching the problem at hand to known solution capabilities (via Capability Cases)
- Collaborative sessions to envision how solution capabilities will overcome challenges and bring about the desired results
- Story telling to establish shared understanding of the roles that the business side and technology side will play in the future world
- Arrangement of the capabilities into the various solution concept views of the conceptual architecture
- Agreement about business priorities for the implementation of capabilities

Software Capability Design – SCD

The nature of Software Capability Design work is the conversion of the results of envisioning – the Solution Concept – into an actionable set of high-level designs and plans for building the solution. Its purpose is to complete the development and documentation of a Solution Realization Roadmap. These deliverables must be sufficient to scope, fund and launch an efficient final phase for assembling, deploying and adopting the solution. Following Figure 4 illustrates the SCD phase. (Polikoff et al., 2005)

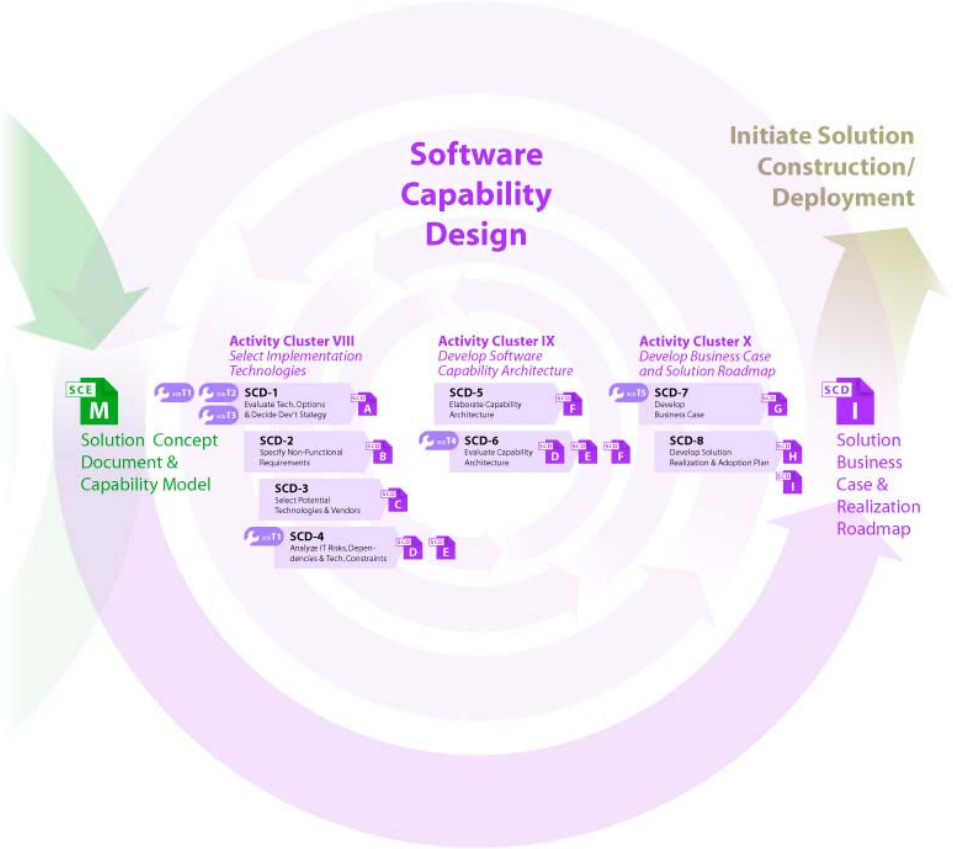

Figure 4: Phase III: Software Capability Design (SCD) (Polikoff et al., 2005).

When the capability view of the conceptual architecture has been developed, the technical components of the solution can be identified. It is at this stage that technology decisions will be made and a component or service-oriented architecture defined. The organizational impact of the solution will be understood and planned for. Priorities for implementation will guide the creation of a roadmap including a solution blueprint and plans for its realization.
In summary, the Capability Design work entails (Polikoff et al., 2005):

- Making commitments to technology decisions
- Elaborating the capability architecture of the solution
- Specifying evolvable solutions using component and service-oriented architectures
- Completing a business case sufficient to support the final development of the solution
- Creating communication and organizational change strategies
- Building a solution realization roadmap

The phase is completed when the work of Solution Envisioning has been packaged as an actionable shared memory in the organization. This means that the business goals, justification, high-level designs and plans have been clearly articulated and documented in a form directly usable in the construction phases. The construction can be accomplished in a number of ways. Whether the approach is to buy, build or both, the goal is to set the stage

for an efficient and successful realization and adoption. The Solution Envisioning deliverables are designed to provide a seamless connection to popular software engineering methods by providing the input they specify and require. (Polikoff et al., 2005)

MOBILE MAINTENANCE CASE STUDY

In this chapter mobile maintenance project, case study and process, are presented. The case study was performed in the project during 2009-2010. Four different enterprises were participating to this research performed by VTT. The participating enterprises were from era of energy, industry, maintenance and ICT. The case study researched the role of mobile technology in strengthening the maintenance operations.

The project had three major aims; firstly to identify the benefit of mobile technology in maintenance and to measure it, secondly to research the development process of mobile solutions aimed for professional use and thirdly to evaluate the potential of new technologies in developing more value added mobile solutions in industrial environment. The research was done in demanding industrial environment that will set hard requirements for mobile solutions. Therefore, the aim of this project was to develop solutions that will ease and fasten the maintenance operations in such environment. The project was researching new mobile technologies in order to provide user-friendly and convenient ways of using mobile solutions.
The project's case study experiences presented in this paper include mainly the process and appliance of it. Different stakeholders were involved in interviews and workshops to ensure different aspects and point of views to get noticed. Large stakeholder participation aimed also to better user acceptance and technology adoption since all parties were involved in the very beginning of the project. It is essential that also end users are participating to the work shops. User involvement is especially useful in the early stages of service development processes due to their high uncertainty and low formalization (Kaasinen et al., 2010).

Used process in the project was an appliance of the Solution Envisioning Approach (Polikoff et al., 2005). One of the aims was to research the development process of professional mobile solutions for maintenance domain. The paper presents how the case study applied the Solution Envisioning Approach with Capability Cases as a process in determining possibilities and needs for mobile maintenance. The applied process of the project is presented in the chapter The Process in the Case Study.

THE PROCESS IN THE CASE STUDY

In this chapter the used process applied in the case study is presented. The presentation includes mainly information about the work products and activities performed when different phases of the Solution Envisioning Approach (SE) were applied.

The process in the case study included following main activities: Specifying requirements, Technology study, Theoretical research about acceptance and adoption of industrial mobile solutions, Studying the present and future of mobile solutions in maintenance, Assessment of solution benefits, Assessment of possible solutions and creating initial solution concept, Focusing of the solution concept, Piloting the solution options and Documenting the process

of the case study. The following listing presents in more detail the main activities of the process used in the case study:

- Specifying requirements
  - Preliminary business investigation
  - Enterprise interviews
  - Specifying stakeholder requirements
  - Collecting reference materials
  - Defining business needs
  - Defining maintenance terminology used
  - Review by enterprises

- Technology study
  - Studying technologies and possibilities
  - Initial analysis about technologies for the solution
  - Review by enterprises

- Theoretical research about acceptance and adoption of industrial mobile solutions
  - Creating Industrial Mobile Solutions Adoption Model – IMSAM
  - Review by enterprises

- Studying the present and future of mobile solutions in maintenance
  - Studying the current situation and use of mobile solutions in the enterprises
  - Defining general maintenance processes used today
  - Creating initial capability cases portfolio as a result of internal workshop
  - Updating, focusing and enlarging capability cases portfolio in the enterprise workshops
  - Analyzing technology options needed for different capability cases
  - Verifying that capability cases are answering to the requirements of different stakeholder requirements
  - Visioning future maintenance processes supported with mobile solutions
  - Review by enterprises

- Assessment of solution benefits
  - Studying maintenance key figures and theories about benefits and measuring
  - Assessing the benefits of the mobile technology in maintenance domain
  - Defining how to measure benefits of mobile technology in maintenance domain
  - Review by enterprises

- Assessment of possible solutions and creating initial solution concept
  - Assessment of solution possibilities, processes and capability cases in internal workshop
  - Updating and focusing solution on the basis of assessment
  - Creating initial solution concept
  - Review by enterprises

- Focusing of the solution concept
    - State-of-art study
    - Theoretical research about solution concept including human factors
    - Collecting information about important issues needed to be noticed/handled by enterprises when implementing/taking solution in use
    - The focused solution concept and framework for mobile maintenance
    - Review by enterprises

- Piloting the solution options
    - Piloting different kind of solution options in enterprises
    - Three pilots: usability, map based resource management and possibilities of web-browser
    - Analysis of pilot experiences

- Documenting the process of the case study
    - Studying Solution Envisioning Approach and following and applying its steps according to situation
    - Documenting the appliance of approach as the process for the case study
    - Documenting the work products created as a result of the process
    - Review by enterprises

Some of the SE approach steps/phases were applied loosely or skipped depending on situation. In the case study for example it was not possible to make some specific decisions for participating enterprises. These decisions might be for example vendors, devices, roadmaps etc. In general it was possible to give information, advises, issues to be considered/noticed and research different possibilities, but not to give exact technical requirements, specifications, deadlines etc. for the product or solution.

In the following chapters the work products and activities performed are described step by step relating to different phases of the Solution Envisioning Approach (SE) applied. In addition to appliance of SE approach's steps and phases, some additional activities were considered necessary and useful. These activities were theoretical research about acceptance and adoption of industrial mobile solutions and theoretical research about human factors relating to mobile solutions and usage. In addition to this actual piloting were also performed outside the scope of applied approach.

The Activities and Work products of Phase I, Business Capability Exploration

The SE Approach BCE phase's steps 1-17 were applied as described in the following table 1:

Table 1: Activities and work products in the case study relating to BCE phase.

Step #	SE Activity Description	Applied activities	Created Work products
1	Establish Solution Initiative Shared Space	Creating shared space for information sharing and web site for marketing channel	Shared space and version control, Web site
2	Establish Key Stakeholders	Decided steering group members and named key persons	List of steering group members and key persons
3	Clarify Solution Initiative Statement	Confirmed solution initiative on the basis of enterprise interviews	Project plan and solution initiative
4	Establish Inventory of Reference Materials	Reference material gathered from enterprises and studied	Collection and inventory of Reference materials
5	Clarify Business Context	Created overall figure about descriptive value net and business environment	The model of the business environment
6	Assess Use of Current IT Capabilities	Assessment of current and piloted mobile solutions in enterprises relating to maintenance domain	Reported IT Givens relating to mobile solutions
7	Establish a Glossary for the Initiative	Common terminology between enterprises collected and listed	Terminology listing
8	Elicit Forces, Barriers, Results	On the basis of enterprise interviews defined three what's: Forces, Barriers and Results	Tables of Forces Barriers and Results
9	Identify Business Activities in Scope	Created general maintenance process diagrams about today's situation on the basis of reference materials from enterprises	General maintenance process diagrams today
10	Perform Stakeholder Impact Analysis	Created Business Capability Model on the basis of forces barriers and results	Business Capability Model
11	Nominate Capabilities	Created initial capability cases portfolio as a result of internal workshop	Initial capability cases portfolio
12	Explore Future Business Possibilities	Updated, focused and enlarged capability cases	Capability cases portfolio

		portfolio in the enterprise workshops	
13	Explore Technology Options	Performed technology mapping and defined needed mobile technologies and options	Technology study, mapping and tables about needed/possible technologies/ technological options
14	Perform Stakeholder Benefit Analysis	Analyzed how different stakeholders requirements/expectations are met by relevant capability cases	Tables about stakeholder different stakeholders' requirements and relevant capability cases
15	Refine Results	Defined measures for benefits/results	Tables about measures for the results
16	Map Capabilities to Forces, Barriers, Challenges, and Results	Assessment of benefits in the Business Capability Model	Diagrams about the benefits and tables about the capability cases supporting defined requirements and goals
17	Create Solution Vision Presentation	Conclusions and presentations made on the basis of previous steps	Conclusions documented and presentations

The Activities and Work products of Phase II, Solution Capability Envisioning

The SE Approach SCE phase's steps 1-17 were applied as described in the following table 2:

Table 2: Activities and work products in the case study relating to SCE phase.

Step #	SE Activity Description	Applied activities	Created Work products
1	Envisioning Workshop Planning	Planning workshop	Workshop plans
2	Elaborate Capability Cases Portfolio	Preparing capability case portfolio for the workshop	Prepared capability cases
3	Conduct Pre-Envisioning Workshop Walkthroughs	Searching evidence about Business Situation and Possibilities. Performing State-of-art study.	State-of-art presentation
4	Preparing for Capability Cases Gallery	Preparing capability cases for the work shop	Prepared capability cases
5	Launch Solution Envisioning Workshop	Envisioning workshop	
6	Review Solution Vision	Envisioning workshop	Reviewed solution vision
7	Envision Solution Possibilities	Envisioning workshop	Capability cases score cards
8	Conduct Solution Scenario Enactment	Envisioning workshop	Capability cases and future process diagrams
9	Prioritize Capabilities	Envisioning workshop	Prioritized capability cases
10	Assess Solution Realization Gap	Envisioning workshop	Capability cases realization gap. Needed technologies and technology options
11	Conduct Post-Workshop Analysis and Consolidation of Concepts	Envisioning workshop and conclusions	Initial Solution Concept and its framework

The Activities and Work products of Phase III, Software Capability Design

The SE Approach SCD phase's steps 1-8 were applied as described in the following table 3:

Table 3: Activities and work products in the case study relating to SCD phase.

Step #	SE Activity Description	Applied activities	Created Work products
1	Evaluate Technology Options and Decide Development Strategy	Evaluation of Technologies Software/product development principles	Documented listing of technologies needed for development strategy
2	Specify Non-functional Requirements	Presenting information about Non-functional Requirements	Basic information about non-functional Requirements
3	Select Potential Technologies and Vendors	Researching and collecting information about selecting and implementing: vendors, products, services, training, support, deployment, maintenance and continuous development	Documented information about selecting and implementing: vendors, products, services, training, support, deployment, maintenance and continuous development
4	Analyze IT Risks, Dependencies, and Technology Constraints	Analyzing SOA architectures and collecting general information about risks and risk management	General information about SOA architectures and risk management
5	Elaborate Capability Architecture	Considering SOA options	Information about the benefits and problems relating to different SOA options
6	Evaluate Capability Architecture	Designing and selecting SOA	Suggestion and guideline about SOA
7	Develop Business Case	Focusing and developing solution concept	The solution concept for mobile maintenance
8	Develop Solution Realization & Adoption Plan	Focusing and developing solution concept	The solution concept for mobile maintenance. Solution concept presentation

Human factors and user adoption

In addition to SE approach, some additional activities were considered necessary and useful in the process. These activities were research about acceptance and adoption of industrial mobile solutions and theoretical research about human factors relating to mobile solutions and usage. In addition to this solution piloting was also performed outside the scope of the applied approach.

The success of mobile services is not only depending on technological maturity of mobile technology and the capabilities of mobile devices. In the end, end users decide the success of the services. Herzberg's motivation and hygiene theories (Herzberg, 2003) can be exploited in the implementation and choosing of Computerized Maintenance Management Systems and Enterprise Asset Management (Bradshaw, 2000). The success or failure of CMMS depends on human factors like for example policies, rules, selection process, integration, training, support, resources, functionality, usability, usage, reviewing, work planners' motivation, work culture, skills, trust and commitment of management (Bradshaw, 2000).

User involvement can be seen as one human factor. User involvement is especially useful in the early stages of service development processes due to their high uncertainty and low formalization. Direct user-designer interaction helps in transferring user feedback and ideas to service innovations. User experience of the service is improved when users themselves can contribute to developing the service. (Kaasinen et al., 2010)

Usability can be seen as one of important factors relating to user acceptance and adoption of technology/solutions. If users perceive some solution difficult or even nearly impossible to use they will not like to use it. If users are forced to use the solution despite the usability problems they use it as little as possible and probably spend too much valuable time to get their activities accomplished.

There is large selection of different technology user acceptance models in general available. There are also some models developed to test user's acceptance, attitude and intention to adopt new mobile services and mobile technologies. Similarity in technology acceptance models' factors can be seen and in fact some of the models are based on other acceptance model in some level. The problem with using same models for industrial mobile solutions is that there are several different factors affecting on technology acceptance and adoption in industrial environment. Industrial mobile solutions must provide benefits to the business directly and/or indirectly and support employees work activities in easily usable manner.
According to the case study high level factors affecting to acceptance and adoption of industrial mobile solutions must be noticed in the process. According to the Industrial Mobile Solutions Adoption Model (IMSAM), developed in the case study, the factors affecting to acceptance and adoption of industrial mobile solutions are following:

- Mobile possibilities, needs, systems, information and integration
- Technology
    - Mobile competence and experience

- Enterprise
    - Market situation and customers
    - Regulations
    - Purposes, benefits and consequences
- Employees, users
    - Usability
    - Purposes, benefits and consequences

RESULTS

All three phases of the Solution Envisioning Approach were gone through in the case study by applying different phases' steps depending on needs and nature of the situation and project goals. Especially because of the fact that the project included several enterprises in the same domain and the Solution Envisioning Approach is designed for one at the time, some of the steps were applied loosely. One of the reasons for the customed appliance of the approach was the goals and purposes of the project. The purpose was not to design, specify or implement neither a software nor product exactly to a certain enterprise/organization as a product of the project. Instead general scientific results and information about applying mobile technology in maintenance to boost up performance were required as a result.

In the case study some phases of the approach were applied loosely or skipped depending on situation. For example it was not possible to make some specific decisions for participating enterprises. These decisions might be for example vendors, devices, roadmaps etc. In general it was possible to give information, advises, issues to be considered/noticed and research different possibilities, but not to give exact technical requirements, specifications, deadlines etc. for the product or solution.

In the case study it was discovered that the human factors are not the main focus of the Solution Envisioning Approach although the actual users are taken in to account and along for example in visioning workshops. The human and adoption factors were considered as important issue relating to success of the solutions and that's why the factors were also handled by the case study in addition to used approach. The human factors and user participation in the designing and developing process are essential when considering the success and actual exploitation of the solutions.

The approach as such is quite extensive and needs intensive acquaintance with the steps and phases. Without a practical case study it is challenging for enterprises themselves to apply the approach from scratch. By participating to the mobile maintenance case study the enterprises got valuable information and knowledge about applying the approach in practice as a process in determining possibilities and needs for different technologies and solutions in general.

The Solution Envisioning Approach was discovered as a good guideline and process in determining possibilities and needs for mobile maintenance. Now enterprises can use the approach precisely in a smaller scale to get most out of the approach. The enterprises

learned how to apply the approach in practice by themselves. The possibilities and needs for the mobile maintenance were successfully determined by following the applied process.

CONCLUSIONS

Solution Envisioning Approach was used in mobile maintenance case study as a project's process. Solution Envisioning is a problem discovery, situation assessment and solution planning process that uses Capability Cases to achieve connections between Business and IT stakeholders. Its purpose is to 'bridge the gap' between business and IT by integrating and matching concepts and techniques from both best of breed business strategy methods and software development methods. Solution Envisioning with Capability Cases is designed for use at a front end of the software development lifecycle.

In the case study Solution Envisioning Approach's all three phases were gone through by applying different phases' steps more or less exactly depending on needs and nature of the situation and project goals. Especially because of the fact that the project included several enterprises in the same domain and the Solution Envisioning Approach is designed for one at the time, some of the steps were applied loosely. Another reason for the customed appliance of the approach was the goals and purposes of the project. The purpose was not to design, specify or implement neither a software nor product exactly to a certain enterprise/organization as a product of the project. Instead general scientific results and information about applying mobile technology in maintenance to boost up performance were required as a result.

As stated before some of the approach were applied loosely or skipped depending on situation. In the case study for example it was not possible to make some specific decisions for participating enterprises. These decisions might be for example vendors, devices, roadmaps etc. In general it was possible to give information, advises, issues to be considered/noticed and research different possibilities, but not to give exact technical requirements, specifications, deadlines etc. for the product or solution.

The human factors are not the main focus of the Solution Envisioning Approach although the actual users are taken in to account and along for example in visioning workshops. The human and adoption factors were considered as important issue relating to success of the solutions and that's why the factors were also handled by the case study in addition to used approach.

Overall the Solution Envisioning Approach was discovered as a good guideline and process in determining possibilities and needs for mobile maintenance. The good thing is also that now enterprises by themselves can use the approach precisely in a smaller scale to get most out of the approach. The gap between the business and technology can be now narrowed.

ABSTRACT

Global business and rapidly changing environment requires companies to determine the most critical factors of their functions. With help of them crucial processes can be further developed and rearranged. The purpose of this study is to evaluate a new Scaled Critical Factor Index (SCFI) tool developed for analytically optimizing the operational competitiveness. Study is based on previous Critical Factor Index (CFI) tool, developed by Ranta and Takala, and questionnaire form by Takala and Liu. This study especially focuses on applying Sense and Respond (S&R) method to optimize operational competitiveness of the case companies. S&R method measures future expectations, previous experiences and the direction of development. As a result of this study, a more reliable way to evaluate CFI is proposed, but it should be further studied in order to gain the correlation with the real business environment.

Keywords: Flexibility, Operational Competitiveness, Sense and Respond

INTRODUCTION

The term sense and respond (S&R) as a business concept first appeared in 1992 Management Review article by Haeckel (1992). The S&R thinking is developed by Bradley and Nolan (1998) and Markides (2000) to analyze dynamic business strategies. S&R has contribution to respond the world where it is harder to effectively make decisions and implement them under uncertain business situations in the new economy (Cunningham et al, 2002). Mahadevan et al. (2009) propose that S&R level is the highest level in service business activities and decisions. Therefore, S&R approach is required in developing strategic plans when facing unpredictable and fast changing economic environment (Kapoor et al., 2005; Schatten and Schiefer, 2007).

The identification of critical factors for businesses is crucial in order to determine the areas that need attention in order to enhance the business and/or to avoid the downfalls caused be these critical factors. Competitiveness of future manufacturing operations relies on today's actions. The determination of these factors is not necessary easy in very complex business environments. Therefore there is a need for scientific methodology that provides useful results in determining these factors.

The purpose of this research is to evaluate a new Scaled Critical Factory Index (SCFI) tool developed for analytically optimizing the operational competitiveness. The result derived from new optimizing model are compared against the results given by the Sense and Respond questionnaire method developed by Rautiainen and Takala (2003) and further developed by Ranta and Takala (2007) in order to evaluate the results of SCFI tool. The questionnaire used within these methodologies has been developed by Forss and Toshev (2010). Only the results of the experiences and future expectations from the questionnaire were used in this research to test the SCFI tool.

For more reliable results the questionnaire was sent to four different companies. The usable results concluded three companies and total of 6, 3 and 3 answers that could be used. Other answers were not complete and for one case company there was received only one answer which is not enough for reliable results.

METHODOLOGY DEVELOPMENT

Sense-and-Respond methodology

Sense-and-respond method is based to the observation that the business is done in the more unexpected environment. It is difficult to answer the customers' demands. For this reason the know-how regarding people and processes are emphasized as well the modular customization. (Haeckel 1999: 12-13.) According to Haeckel (1999: 12-13) other important factors are the processes answering to the individual demands, the modular solutions reducing costs, teams and networking establishing in an important role, share of customer spending on a class of needs and the strategy being able to make flexible changes.

On the basis of the Sense-and-Respond methodology the further developed Sense and Respond questionnaire method was developed by Rautiainen and Takala (2003) and further developed by Ranta and Takala (2007) for monitoring and evaluating the company's inner customer's experiences and expectations of forthcoming events.

Critical factor index method

CFI is method which enables finding the critical factors of the process by utilizing the experts' views. CFI diagram consists of the average of the expectation, average of the experience, standard deviation of expectation, standard deviation of experience and direction of development. It is described in following calculations.

$$Gap\ Index = \frac{Avg.of\ experience. - Avg.of\ expectation}{10} - 1$$

The source scale 1-10 has been used so the denominator is in accordance with it.

$$Importance\ index = \frac{Avg.of\ Expectation}{10}$$

$$CFI = \frac{Standard\ deviation\ of\ expectation * Standard\ deviation\ of\ experience}{Gap\ index * Direction\ of\ development\ index * Importance\ index}$$

The smaller the value of CFI the more critical the factor is. On the other hand, more than the dispersion found regarding the factor, it is it difficult to say about its criticalness. All the CFI values can be multiplied for example by 10 or 100 to facilitate the comparison in which case, however, the relationship between the factors will be kept same. CFI is often calculated according to the group, an interviewee. In addition to it, CFI is calculated by connecting the answers of all the groups to the same table by telling the groups among themselves and by counting the averages also. This way the differences between the factors are obtained more distinctly in sight. (Rajala 2009; Ranta 2007; Takala 2009.)

The Critical Factory Index (CFI) tool introduced by Ranta and Takala (2007) measures the experience and future expectations in order to find out the critical factors that are the bases for the operational competence of the business. The factors that are interpreted as critical ones are the ones that would need the most attention in company to ensure the efficiency in competitiveness towards competitors.

Research questionnaire

The questionnaire used in the research is based on the Sense and Respond questionnaire method developed by Rajala and Takala (2007). The questionnaire measures the organization's opinions about the business performance of the firm. The respondents are asked to evaluate real life experiences and expectations. Expectations and experiences for each attribute are measured in a scale of 1-10. Direction of development is compared to the situation 1-2 years earlier and the firms' level of experiences is compared to the

competitors. The respondents are asked to evaluate the direction of development and the experiences against the competitors in three scale of *worse*, *same* or *better.* The questions in the questionnaire are divided into four categories; Knowledge & Technology Management, Processes & Work flows, Organizational systems, Information systems which are further divided into sub questions resulting 21 questions. The questions that are presented to respondents are presented in Table 1 below.

Table 1: Sense and respond questionnaire questions.

ID	ATTRIBUTES
Knowledge & Technology Management	
1	Training and development of the company's personnel
2	Innovativeness and performance of research and development
3	Communication between different departments and hierarchy levels
4	Adaptation to knowledge and technology
5	Knowledge and technology diffusion
6	Design and planning of the processes and products
Processes & Work flows	
7	Short and prompt lead-times in order-fulfilment process
8	Reduction of unprofitable time in processes
9	On-time deliveries to customer
10	Control and optimization of all types of inventories
11	Adaptiveness of changes in demands and in order backlog
Organizational systems	
12	Leadership and management systems of the company
13	Quality control of products, processes and operations
14	Well defined responsibilities and tasks for each operation
15	Utilizing different types of organizing systems (projects, teams, processes...)
16	Code of conduct and security of data and information
Information systems	
17	Information systems support the business processes
18	Visibility of information in information systems
19	Availability of information in information systems
20	Quality & reliability of information in information systems
21	Usability and functionality of information systems

RESEARCH METHOD

The former S&R model proposed by Ranta and Takala (2007) has been used in many case studies already. However, the S&R model has several flaws which do not reflect real situation when only using deviations after tested in case studies. The models established by Ranta and Takala (2007) does not consider the situation of $\mathrm{Std}\{experience\} = 0$, which means that they do not consider the situation that if the given answers for each index are the same, thus the implication of different values cannot be distinguished by the models, so

does $\mathrm{Std}\{expectation\}$. If that happens, the models make no sense to analyze the real value of CFI. Therefore, this paper improves the S&R model and proposes a new CFI model (NCFI) which is shown in equation (1).

$$NCFI = \frac{\sqrt{\frac{1}{n}\cdot\sum_{i=1}^{n}(experience(i)-1)^2}\cdot\sqrt{\frac{1}{n}\cdot\sum_{i=1}^{n}(expectation(i)-10)^2}}{Gap\ index\cdot Direction\ of\ development\cdot Importance\ index} \qquad (1)$$

For each respondent i in a case company (i=1...n, n>=1, which means minimum respondent number can be 1), their experience donated by epr(i) and their expectation donated by epc(i) are integers ranging from 1(min) to 10(max). The epr(i)-1 and epc(i)-10 measure the deviation between answer and lower/upper boundary to know how critical the attribute is, resulting the absolute value of the deviation is ranging from 0 to 9, and smaller number will drop NCFI value to indicate more critical (e.g. epr is approaching lower end 1 and epc is approaching higher end 10).

The NCFI value will not reach typically 0, since the root mean square is used. The sum of all answers of (epr(i)-1) and (epc(i)-10) will be highly unlikely to be 0 even if there are little number of answers, unless all the informants answer experience=1 or expectation=10.

However, the NCFI is allowed to be 0, when all the informants have answered experience=1 or expectation=10. That means this attribute is truly an extremely critical factor. However this situation will not happen so often, and there will not be many attributes are 0 at the same time either.

Each NCFI value is then linear scaled using NCFI/sum(NCFI) so that the sum of all scaled CFI (SCFI) values will be 100%, which make it possible to compare between different case companies. Since the sum(NCFI) of every case company is different, so we are not comparing the absolute value of each SCFI between companies, but only compared with the other SCFI of the same company. By setting independent threshold value for each company it shows most critical CFI of that company, and therefore it is still possible to compare between many case companies.

RESULTS

The following comparison between the old CFI model and the proposed SCFI model is based on responses received from three different companies. From company 1 there were 6 answers received and from companies 2 and 3 there were both 3 answers received. The company 4 was left out of the study since there was only 1 answer received which could not be kept as reliable enough in term of number of. Also one partial answer was left out since it was not analyzable. The following graphs show the deviation between these two different models.

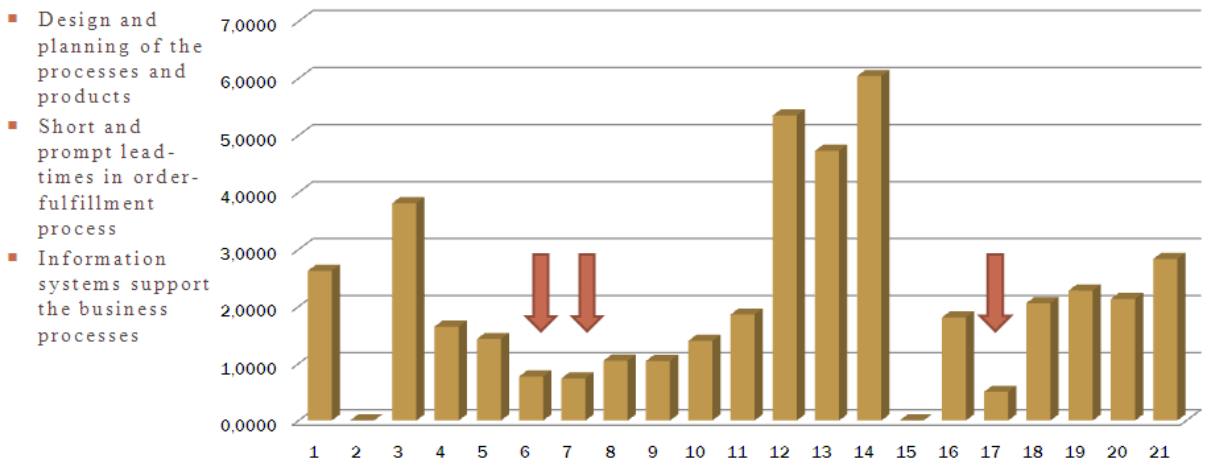

Figure 1: CFI results for company 1.

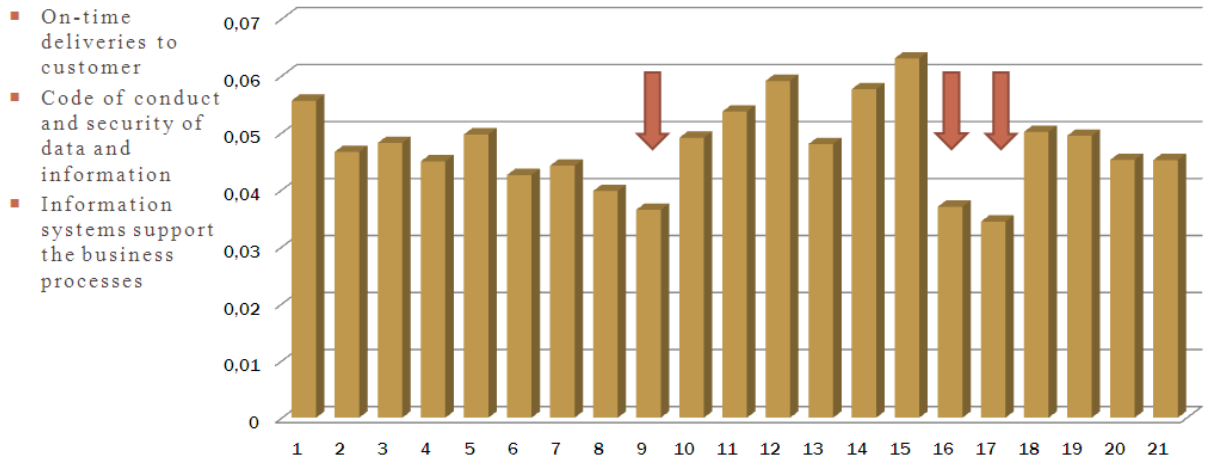

Figure 2: SCFI results for company 1.

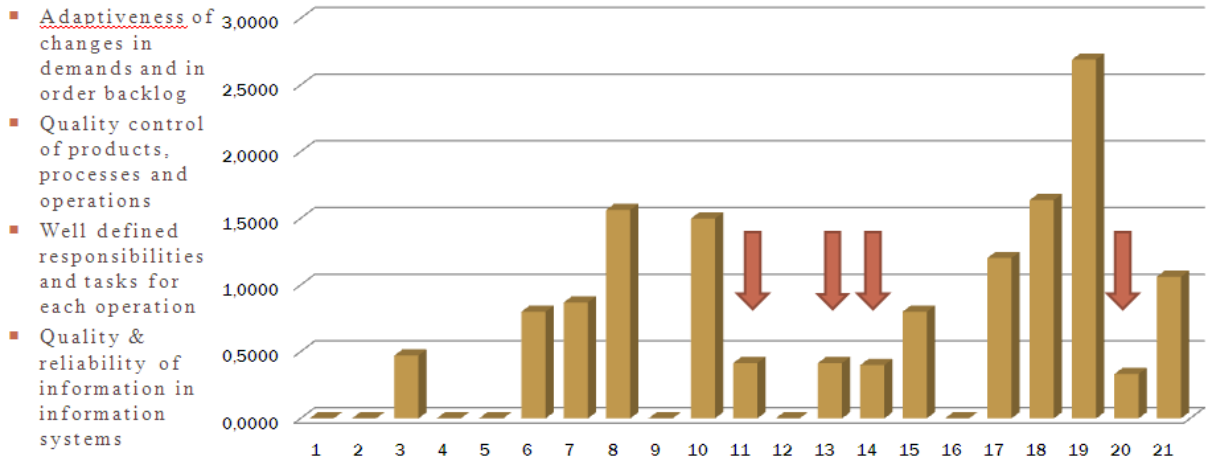

Figure 3: CFI results for company 2.

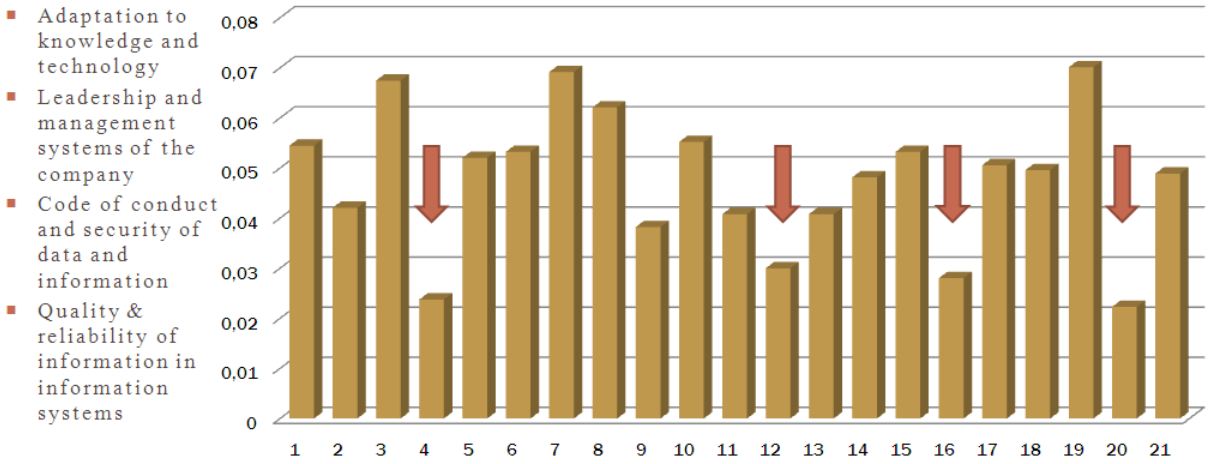

Figure 4: SCFI results for company 2.

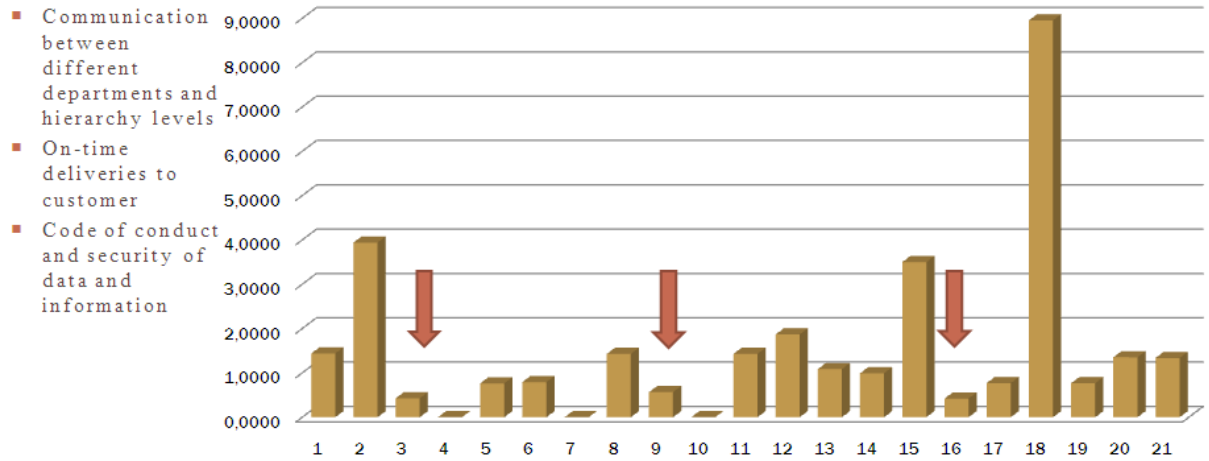

Figure 5: CFI results for company 3.

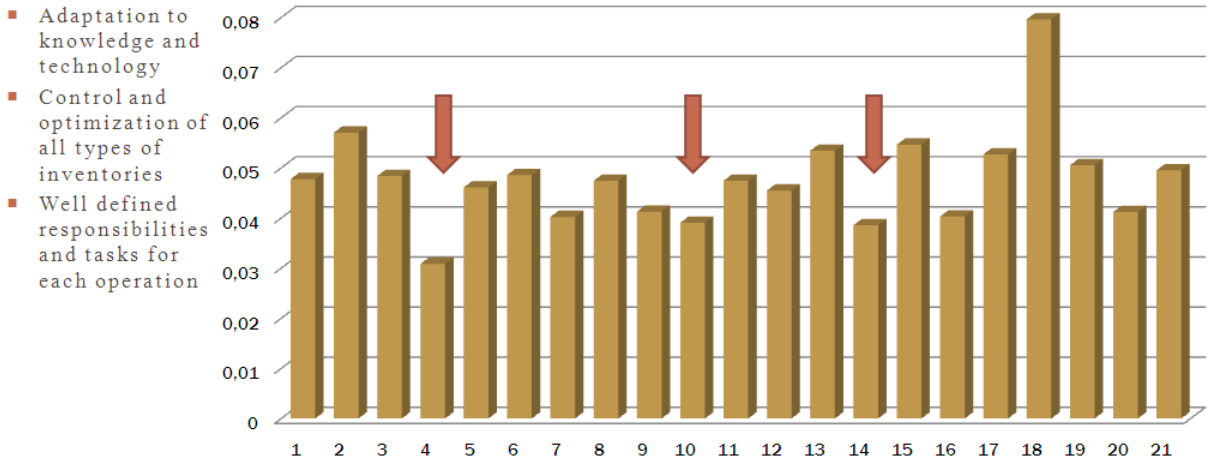

Figure 6: SCFI results for company 3.

By analyzing the results via CFI method the attributes 6, 7 and 17 in figure 1 can be identified as the most critical attributes of the company 1. On the other hand the SCFI model shows attributes 9, 16 and 17 in figure 2 to be the most critical ones. With more analysis it can be seen that the variation of the importance of the attributes varies also a lot

among the other attributes. The variation phenomenon is also clearly visible within the case companies 2 and 3. The analysis show that the most critical factors using CFI method are 11, 13, 14 and 20 in figure 3 for company 2 and 3, 9 and 16 in figure 5 for company 3, but using the SCFI method these critical factors change to 4, 12, 16 and 20 in figure 4 for company 2 and to 4, 10 and 14 in figure 6 for company 3.

Especially the problem that has been revealed with this research is that once the standard deviation of experiences or expectations go to the zero the result become less reliable. Within this study the main factor that results to this problem is the small sample size of responses that were received. Nadler and Takala (2010) were finding similar disadvantages of the CFI model on their study. Also the balanced critical factor index (BCFI) model they presented faces this same problem. This problem culminates with the company 2 as attributes 1, 2, 4, 5, 9, 12 and 16 are having a standard deviation of zero among either experiences or the expectations. With this amount of nil values it is impossible to say anything reliable about the results.

Even though there are only two attributes, 17 in company 1 and 20 in company 2, that appear to be critical in both cases it can be said that there are really critical factors to these companies. Otherwise the other factors that appear to be critical need more clarification and deeper analysis with the real business life and this research proves that no model is perfect in all circumstances as with the CFI model in this research and that the SCFI model that has been developed needs a lot more research before it can be said to be working. The feedback about the results of SCFI that was received from the company 1 was that the results are “very interesting and relevant”. So with this information the development of this SCFI model SCFI is promising and it is worthwhile to do research further to see if it is really producing relevant results in term of critical factors that can be identified to be crucial to the real business.

DISCUSSIONS

As presented above in the results the different critical factor index model result in totally different interpretations of the critical attributes. This result is uncertainty in the results which prevents us from making any supportive conclusions from the results to the analytically developed SCFI model. In the other hand SCFI model looks to be promising in terms of eliminating the standard deviation problem that is most likely to occur within small sample size researches. The standard deviation problem emerges when answers of either experiences or expectations are exactly the same among all the respondents. This means that the standard deviation becomes zero and once the CFI model is used the zero as multiplier and numerator; the critical factor index gets also a value of zero. The usage of SCFI model does not prevent the importance of single opinions in small sample size researches. This is very well know problem that the sample size should be rather bigger than smaller, but it may occur in times when there is not received enough answers from the respondents. Due to the facts these models should be evaluated in deep real business life situations in co-operation with respondents’ themselves to overcome the uncertainty of the correlation to the real life.

So hereby we propose that further researches with these models including the BCFI model introduced by Nadler and Takala (2010) should concentrate on finding the coherence between real life and the results that are derived from the questionnaires that are analyzed using these critical factor index models.

Since the other clear problem within this research is that too many attributes are getting a zero value due to the standard deviation problem the interpretation of the results becomes impossible. So in further studies this should be noted and the evaluation of this new model should be done with results that does not have the standard deviation problem to that the results itself can be compared if the critical factors are more similar that in this research. We suspect that this problem prevents us from getting even good results in terms of finding the critical factors with the CFI model. We think that the fact that was found by Nadler and Takala (2010) that the results are negatively influenced if any of the standard deviation of experiences or the expectations is below one; should be taken into the account in further research to really see the coherence between these critical factor index models.

Hereby we propose that future research should be done to really evaluate the differences between these different critical factor index models so see the differences without these influences from the standard deviation problem.

CONCLUSIONS

In order to survive within the global competition, companies must determine their critical factors. The task is challenging, since there are many variables involved. The study was based on results of three different companies, which were working in network model. There were only two attributes found to be critical, since they occurred in different calculation models. Any statements about the other attributes cannot be said, because any reliable way to calculate Critical Factor Index was not found.

All in all three different models of CFI were introduced in the paper. Weakness of the first model was standard deviation problem, which also occurred with SCFI. The main focus in further studies should be in standard deviation. Mathematic formula should be reliable in order to meet the need of the daily business. In addition sample size should be larger, in order to get reliable results that can be further analysed. Future research needs support from the companies and requires monitoring of the real critical factors. Critical Factor Index should be further studied concentrating on value- added perspective of the company. In addition function of network should be involved in the future study in order to explain why networking companies have different critical factors and how it is affected to their overall performance.

ABSTRACT

Time is one of the key resources in the production industry and it affects observed customer value. Nevertheless, in Finnish built environment, the lead times are very long in comparison to other industries, like car industry or mobile phone manufacturing. In a built environment research project KERVO (Value chains in sustainable community), the need for more accurate lead time and production analyses was identified. First a concept to evaluate the lead time was constructed based on value chain analysis. Secondly, a case research in Finnish built environment was conducted. Based on this research, long response time and pull production is mainly caused by problems in urban planning process and stock driven production. Also, the gaps of the production flow cause additional time reserves and incoherent production. To overcome these causes it is critical to re-engineer zoning process and especially the appeal process of the zoning. In addition, value chain management is needed to enhance the value chains as a whole, so that sub-optimization of production could be diminished.

Keywords: Built environment, value chain, lean, Just-in-Time Production

INTRODUCTION

The development of the productivity in the construction industry has been low compared to other industries. In the construction industry, there has not been systematic approach to develop the production systems or technologies in order to improve productivity. The lack of development is due that contracts are divided to small portions and contractors are selected based on the price. Hence, there are fragmented and unmanaged supply chains.

Other industries, like car manufacturing, have used lean methods to enhance the production systems in the whole value chain. One of the key finding of the Toyota Production system (Ohno 1988, Shingo 1988) considers time as a resource. Their aim was to shorten manufacturing/lead time of a product. Shortened lead time enabled to reduce an amount of the work in progress and reduce stock levels. Therefore, the needed capital for production could be minimised and the return of investment enhanced. One of the lean methods to reduce lead time is Just-In-time (JIT) production. JIT production offers several

significant opportunities to lower the stock levels, reduce unnecessary working and produce products as customers asked. However, to implement JIT methods, the lead time of product must be reduced. In manufacturing industry, e.g. car manufacturing, lead time is reduced by lot size reduction, layout configuration, supplier co-operation and set time reduction. (Liker 1990, Shingo 1988, Hines et al. 2004, Shingo 1988)

In addition, shortened lead time allows better capability to react to the changes of the customers need. The enhancements were made by reducing non-value adding activities rather than focusing on the efficiency of the single process. In this way, value creation stayed the same, but fewer resources, such as time, are consumed. Hence, shortened delivery time could offer added value for customers and possibility to differentiate in the market which also makes sense from business point of view. (Walker et al. 2000, Schmenner 1988, Womack 1990, Ohno 1988).

Also in construction industry lean methods are used to enhance the efficiency of production. (Ballard and Howell 1998, Green and May 2005, Jorgensen 2006). Koskela and Vrijhoef (2000) indicates the need for supply chain management in construction so that the supply chain could be enhanced as a whole. However, the adoption has not been completely successfully, because of project-based characteristics (Riley and Clare-Brown, 2001, Höök and Stehn, 2008). Nonetheless, it is essential to gear construction to JIT -production, if lean is wanted to implement in the built environment. By JIT -production it is possible to add the residents' value with fewer resources. Thus, JIT offer a possibility to enhance the productivity of the whole industry (Koskela 2000). In addition it could have significant impact on the profitability of the whole industry (Crowley 1998).

To enhance production and gear it towards lean, value stream mapping (VSM) is commonly used to analyse order-delivery process. By VSM, the production can be re-engineered so that lead time can be reduced in the whole value chain. Value stream mapping is a tool developed by Rother and Shook (1996), but its origins are as far as Ohno's Toyota production system (Ohno 1988). At that time, it was called a material and information flow mapping, which describes the main flows analysed. After that the VSM and its tools have been developed in several studies (eg. Hines and Rich 1997, Hines et al 2004, Lasa et al 2008, Womack and Jones 2009). Value stream mapping and its tools are geared to analyse the whole order-delivery process that non-value adding activities can be pointed out. These tools are not focused on value adding stages but they indicate where the waste is produced during the order fulfilment. Especially time is an important meter of the value stream mapping tool because it indicates how big portions the non-value adding activities take of the production lead-time. In several studies it has been pointed out that only small percentage of the lead-time is value adding, commonly below 10% (Chen and Meng 2010, Woll 2003, Womack and Jones 1996). There are some value chain analyses made in the construction industry (Segerstedt and Olofsson 2010, Gustavsson and Marzec 2007), however, in Finland these kinds of analyses have not taken place yet.

Based on the good results of the lead time reductions in the other industries, the hypothesis for this research is set as follows: *How to enhance the lead time of the built environment?* This question frames the basic of this research and the research questions are derived from this question.

RQ 1: How the value stream mapping tool has to be modified for the analysis of the built environment?
RQ 2: What are the problem areas identified in the Finnish built environment?
RQ 3: What is causing the problems of the supply?
RQ 4: How these causes could be eliminated based on lean philosophy?

The first aim of this research is to find an appropriate framework to evaluate the production of the built environment that further analyses could be executed. Although the VSM has been used several industries, it had to be modified for this research environment. Main reasons for modification were the long horizontal value chains and specific need to analyse the lead time of the value chains. Therefore, the selection process of the value stream mapping tools was executed and appropriate analysis model constructed. Secondly the analyses of selected built environment value chains were executed. Objective is to analyse the lead time and its generation in the built environment. An analysing framework is used to show the lead time generation in a case built environment. The third research question focuses on identifying causes for problems in the current process. Objective of the fourth research question is to find solutions to shorten lead time based on lean manufacturing. The progress of the paper is presented in figure 1.

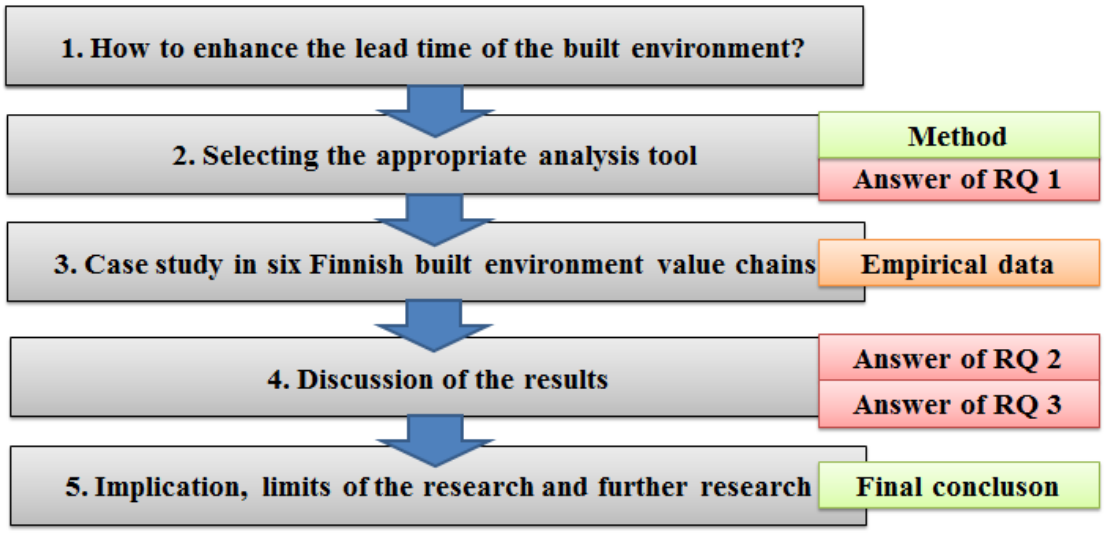

Figure 1: Progress of this paper.

By analysing the value chains of the Finnish built environment, it is possible to indicate the problems of the Finnish construction system and enhance it. VSM offer an opportunity to analyse the value chains as a whole so that the lead time of Finnish built environment production system could be reduced. VSM indicates three main flows of the value chains. Information flow indicates how the production is controlled, material flow indicates the production flow and time line indicates the flow of the value adding activities. Hence, VSM constitutes a comprehensive model of the production system.

RESEARCH METHOD

To analyse the lead time and production type of built environment, a review of production philosophies was conducted, so that appropriate model could be selected as a basis of the research. After review, the lean philosophy was selected because lean methods have been

indicated suitable for construction (Koskela 2000). Also the characteristics of Finnish built environment were researched from literature. As a result of the reviews, value stream mapping was selected as a tool for analysing the built environment. Value stream mapping was selected because it separates the value adding operations from waste (Womack and Jones 2009, Womack and Jones 1999, Womack and Jones 1996). By value stream mapping, it is possible to form a comprehensive understanding of the order-delivery system, because all activities (both value adding and non-value adding), information streams and time are mapped (Hines et al. 1998). The usefulness of the value stream mapping is presented in several researches (Kaplinsky 2000, Woll 2003, Taylor 2008). After the appropriate framework was created, a case study in one Finnish built environment was conducted. In the case study six different value chains were analysed. Information for case study was collected by interviewing 25 specialists from 15 organisations. Interviews were recorded and answers were typed into data sheets. In addition, value chain was modelled with the interviewees so that gathered data could be verified. Raw data was analysed by authors who also redraw merged value chains. Based on the material, the problem areas, root causes for problems and development targets were identified.

Short description of the case study

The case study included six different types of value streams. These are the main value chain types of the Finnish built environment and therefore give a representative sample. The analysed value chains were as follows:

- Infrastructure value chains
    1. Street networks (Municipality owned)
    2. Water networks (Municipality owned)
    3. Energy networks (Municipality owned)
- Real estate value chain
    1. Condominium housing (Privately owned)
    2. School buildings (Municipality owned)
    3. Commercial real estate (Privately owned)

The case study has a comprehensive horizontal scope of the value chains. All value chains are mapped from zoning stage to disposal of the structure. The analysed value chains were modelled by process activity mapping and included on average 80 activities each. Because of the large size of these maps, they were not included in this paper. However, in Figure 2 the main stages of the value chain are presented. The level of analysis was kept on the industry level rather than at the company level. Value chains were modelled by using the swim-line process chart, which is one of the applications of the flow charts (Krajewski et al. 2002). By using the swim line modelling, the role of the organisations in the value chain could be emphasised.

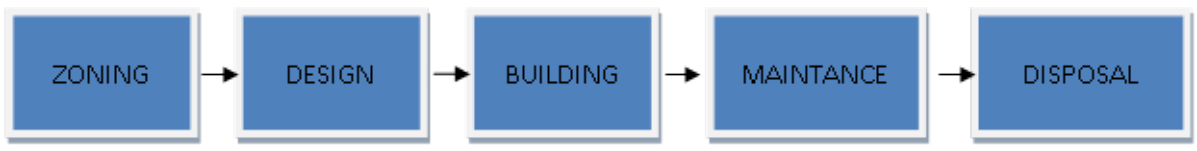

Figure 2: Main stages of researched value chains.

Analysing model

Based on the literature review of lean and VSM, an analysis framework was created. First, a collection of VSM's tools was gathered. Secondly, the appropriate tools were selected by assessing the benefits of the tools. The assessment was carried out by the researchers, who weighted the correlation between the research focus and tool benefits. After that the tools were selected for five target areas (Table 1).

Analysing framework target areas and tools.

Target area	Tool
Identification of value	Customer need
Value chain	Process activity mapping
Flow	Gap analysis
Pull production	Decision point analysis
Response time	Supply chain response matrix

First target area is the capability of value chain to identify customer value. This area is researched by analysing the customer need identification process. There are two main questions related to this area: How do the organisations identify their customers? How do the organisations find out their customers' need?

Value chain is mapped by process activity mapping. In this research, we wanted to separate organisations but still form the continuous picture of the activities. In this manner, we could analyse the roles of the organisations in the value chain. The flows of the whole value chain were analysed with GAP-analysis tool, which helps to analyse the problems of the flow.
The type of the value chain was analysed by decision point analysis. With this tool, we wanted to indicate which activities are demand/push driven and which are forecast/pull driven. The fifth area is the response time analysis, which indicates all the time needed from raw materials to shipment. This is not the same as an order lead time, but production lead time indicates the capabilities of the production system. Production lead time analysis indicated where the most time is spent during the product supply. Thus, it indicates the most attractive development areas.

RESULTS

After the data was gathered by interviewing the representatives of the value chains, data was analysed. Based on the analysis, three main finding can be presented. The first finding is the formation of the production lead time. Second observation considers the flow in the value chain. Third main result of this research is the indication of the production type. These three areas are presented next.

Production Lead Time

As a result of analysing six value chains, lead time of the case is presented in Figure 3. In the picture, the time spent in the production is on the horizontal axis and the time spent in the stock is in the vertical axis. This tool does not present actual amount of the lead time but indicates the relative difference between of the activities. This is due that there is a lot of variance between different projects but relative amounts are comparable. Anyhow, the

major development areas can be pointed out, because there is significant difference between activities.

As can be seen from the Figure 3, the zoning phase constitutes a very significant portion of the lead time in the Finnish built environment. The reason for long waiting times during zoning phases is slow decision-making and long appeal times. Every individual who is linked in the zoning area can make an appeal, which is wrought in the court. Although not all town plans are taken to the court, the appeals are usual and even unnecessary. Some people try to slow down the process and even extort by making the appeal. In addition, during the zoning process the zoning papers are approved several times in the municipal council. There are two main stages; general zoning and detailed zoning. Problem is that these two processes work quite separately so that there are matching problems between these processes.

By developing these key points, zoning could be more fluent and the lead time of the whole value chain enhanced significantly. It would also offer better value for the customers because they could access the final infrastructure faster.

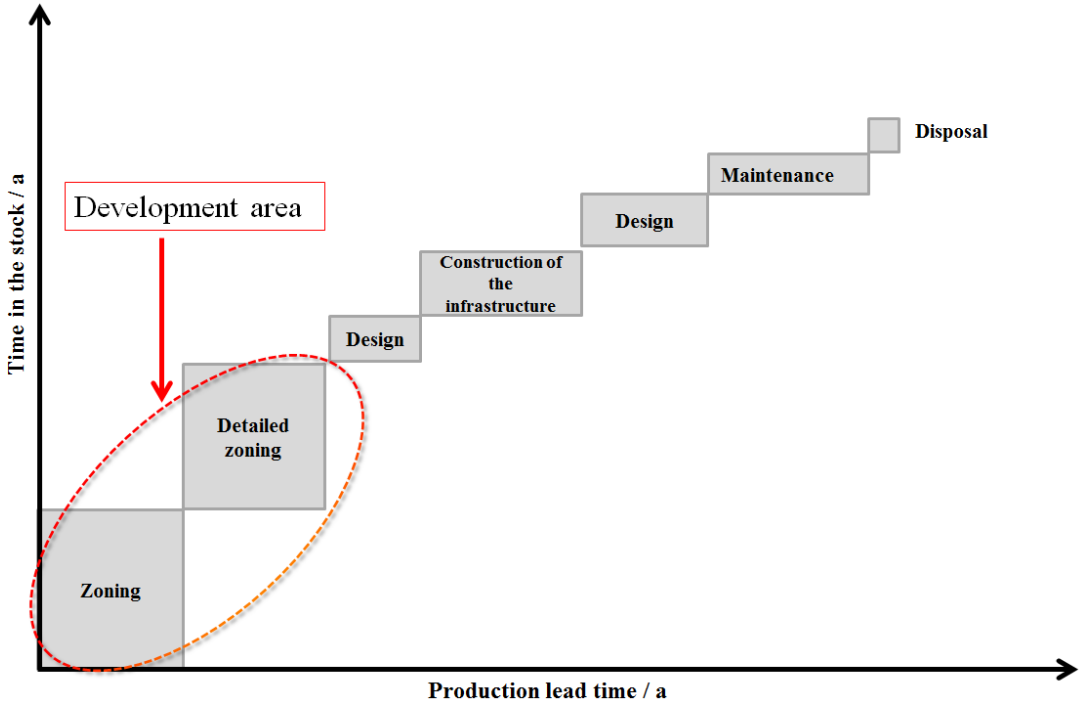

Figure 3: Production lead time.

Flow of value chain

Next step of analysis pointed out the gaps of the flow in the value chain so that reasons for long lead time could be analysed. We were especially interested in the information flows in the value chain. In Finnish built environment, the production is divided into small portions, because the actual operations are executed by small and specialised companies. Therefore, there are long and fragmented supply chains. Furthermore, the links between the contractors are weak although they are working in the same project.

A specialised tool, the GAP –analysis, was used to demonstrate these gaps in the flow. In this manner, the main reasons for the inconsistency of the value creation could be understood. Based on the analysis, five main gaps are found as illustrated in Figure 4. First gap is inside of the municipal zoning. The information flow between the general zoning and

detailed zoning is lacking which causes changes and inconsistency in the planning process. Consequently, there are different visions about the area development.

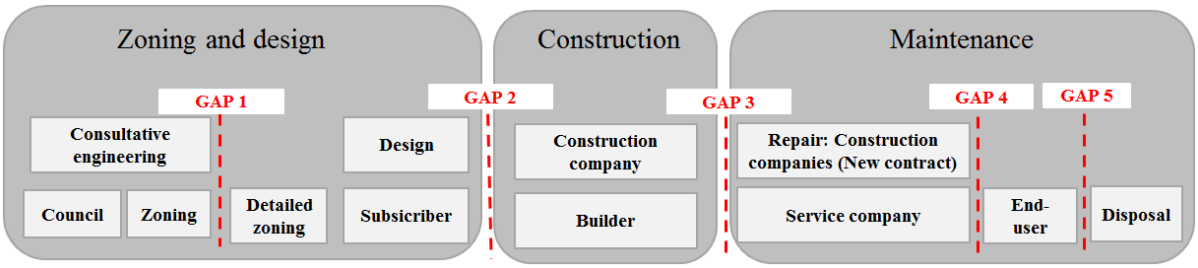

Figure 4: Gaps in the flow of the value chain.

Second gap is between the design and the construction phases. The problem is that there are very little or not any links between design and installation phases. Usually design companies and the construction companies are different and are competed separately. Design phases are focused on technical solutions and do not pay attention for assembly. Therefore the planning of the assembly is not really recognised at the design phase. Respectively, the problem is that the constructor order materials, which affect the design of the structure.

The third gap is between construction and maintenance phases. The life-cycle of the structure is not usually considered before the maintenance phase, because maintenance is considered as a separated part. This is due that the zoning, design and construction companies do not have the responsibility of the life-cycle of the structure. In addition, the revenue logic of the companies is not based on the quality of the product but on the amount of space. The lack of the responsibility of the structure life cycle may lead to bad quality of the built environment.

Fourth gap can be found between users and maintenance. The main reason for this gap is the lack of knowledge of maintenance. Thus, some of maintenance work is done too late that causes additional costs. Also, the knowledge of construction is missed, because the repairs are not linked in the maintenance or construction phases of the structure. If the maintenance is done properly and in time, it would offer additional value for end-users. Especially, it would be important to consistently pay attention to the life-cycle in the early phases of the value chain, like in the design and construction phases.

The fifth gap is between maintenance and disposal. This gap is presented because the disposal is unrecognised part of the value chain. No one in the value chain considers this part important, because it is so far in future. However, from an environmental point of view this is very important, because all materials have to be disposed somehow. In addition disposal phase forms also costs. Hence, it would make sense to find out re-use departments and consider the recycling of the materials.

Production type

On the final stage, the analysis of the production type of value chain was executed. This analysis indicates to what extent customers' needs lead the production. Production type

analysis is important, because it points how quickly the value chain can react to changes in variance of the customer's need. In addition, gearing value chain towards push production helps to reduce the stock levels.

In the Finnish built environment, a lot of the production is executed without the specific customer need as illustrated in Figure 5. Based on the research data, this is even more problematic in the real estate value chains than in the infrastructure value chains. In the real estate value chains, the old construction style where builder starts the project without customers, causes that houses are produced to stock. In the infrastructure value chains, the customer need rolls a little bit further, because these all are public administration organisations. However, there are still barriers between different actors.

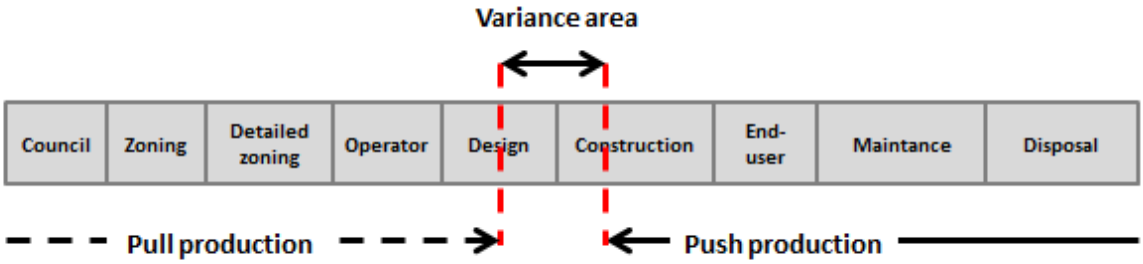

Figure 5: The production type of the value chain.

As Figure 5 shows, pull production dominate until construction. All the planning phases are done based on forecasts not direct customer need. This is a very significant problem, because in these phases the key factors of value creation are decided. In addition, it means that these phases cannot easily react to the changes of the customer need.

DISCUSSION

The main observation made in this study, is the long lead time of urban planning and the major stocks at the beginning of the value chain. These inventories consist of the work-in-process during urban planning and of unauthorised urban designs waiting for adoption (work done to stock). These stocks are owned by municipalities. Appeal time could be mostly eliminated if the quality of zoning processes is proved by quality criteria. Based on the quality criteria, it would be easy to point out that the process is executed as stated and the unnecessary appeals could be prevented. In addition, the self-explanatory processes in the zoning stage could reduce the appeals, because the citizens could notice that process is executed as required. In addition, the lead time could be reduced by enhancing the communication between organisations. This can be done by integrating the value chain organisations at the beginning of the project and by planning the assembly.

One more reason for long response time is lack of production control which causes a lot of variance in the production. Therefore, the organisations of the value chains have to take additional reservations when making a timetable. Based on project management studies (e.g. PMBOK 2004), allocated time is always used although the additional time would not be necessary. When every organisation takes these additional reservations, the lead time is

significantly longer than needed. The variance causes a lot of additional work, like rearrangements, because works are not finished in time. Variance could be managed by controlling the tasks and measuring used time. One good way to enhance the reliability is last planner system, where the organisations of the value chains are integrated to do the assembly timetable together. Therefore, the planning of the assembly could provide significant lead time reductions by eliminating the variance of the assembly. (Gabriel 1997)

The gaps in the flow cause incoherent value creation process, because value chains are geared towards local optimums rather than global optimum. The gaps are formed because the organisations of the value chain do not recognise each other's needs but organisations focuses on producing their own sub-products. This is due that no one have the responsibility and view of the whole value generation process. Hence, there should be clear responsibilities of the management in the value chain and all organisations revenue logic should be linked to overall value production. To implement the change, there is a need for new contract models, where organisations share common goal and responsibility of the project. In addition, information sharing between organisations is weak, because there are barriers between organisations. These barriers consist of the prejudices and old habits of doing things. Therefore, there are not discussion and common understanding how these organisations could enhance value generation and especially enhance their business. To improve the information sharing, organisations should build up clear channels and habits for information sharing.

Due to long response time, value chain is mostly geared towards push production. Only a few steps (mainly maintenance and service) are pull driven. Thus, almost the whole value chain production is forecast driven and customer needs are badly recognised. In addition, pull production causes unresponsive production and pull bullwhip effects in the value chains. These problems occur when there are changes in customer needs. These effects make the whole construction industry very unstable and riskier than it should be. These risks are added to the price of the construction. To gear the order-delivery system towards pull production, it is essential to shorten lead time, scale down production patch sizes and enhance the understanding about the customer demand. In addition, the basic meters like work in progress and size of the stocks could offer insightful information because currently these stocks are seen as a good reserve although they are waste.

Based on the analysis, a table of problem areas and theirs causes is formed (Table 1). In addition, based on literature and interviewee recommendations some ways to enhance the problem are presented. These recommendations are not the only ones but indicate that these problems and their causes could be solved.

The problem areas, causes for problem areas and methods to enhance

Problem	Cause	What to enhance?
The long response time in zoning process	The long appeal period.	Standardized process based on Quality Management. Sample testing. (Deming 1981)
	Large baths sizes	Using modularity system at early stage of the process. Planning as a basic level.(Lennartsson 2008)
	Communication problems. Especially considering production needs	Integrated project teams early in the project. Operations planning and control. (Isaac and Navon 2010)
	Unreliable project delivery, variance	Last planner, understanding time as a resource. Subcontractor control (Perera et al. 2010). Lean project management (Gabriel 1997, Rybkowski 2010)
Gaps of the flow	Incoherence of production	Organisations linked to the overall success of the project. => New contract models. (Ross 2009)
	Gaps between supply chain activites	Supply chain management (Koskela and Vrijhoerf 2000, Saad et al 2002)
	Problems of the information sharing.	Clear channels for information sharing. Adapting new ways to do construct, like project companies.(Salvatierra-Garrido 2010)
Push production	Long response time	Shorten response time (Look previous section)
	Focus on standards, not on customer need	Focusing on customer needs and identifying process. Understanding the possibility to differentiate on markets. (Walter et al 2001)
	Storages are not understood as a waste	Calculating the capital invested and return of capital.
	Large bath sizes	Focusing on steady production. (Womack and Jones 1996, Koskela 2000)
	Forecast driven production	Kanban methods for construction (Ohno 1988, Arbulu 2004)

Problems of the value chains are caused mainly by bad information sharing, large bath sizes, unreliable production and big stocks. Information sharing between organisations is not at the required level, because there are not clear channels to share information and only technical data is shared. Large bath sizes cause pulses in the value chain that causes bullwhip effect in the value chain. Unreliable production causes unnecessary time reservations and additional work. Big stock at the beginning of the value chain, at the zoning phases, causes the biggest portion of the lead time.

All presented causes for problems in the Finnish built environment are quite similar with the manufacturing industry. Therefore it was interesting to look for lean solutions for these causes. To shorten lead time it would be interesting to exploit the quality management tools, like sample testing. By this manner the approval process could be accelerated. Also, normal lean methods like standardisation, better information sharing, smaller bath sizes and lower stock rates could reduce the lead time and gear production towards JIT production. In addition, lean construction methods like the last planner system and integrated project teams, would offer significant benefits because these methods would merge organisations

of the value chain and enforce to do assembly planning. This all means closer relationships of the value chain organisations that enhancement could be continuous.

CONCLUSIONS

In this research the lead time and the production type of the Finnish built environment is analysed. Lead time analysis is interesting because time can be seen as a resource of the order-delivery process (Womack 1990, Ohno 1988). Therefore, by reducing the lead time of the supply, the efficiency of production can be enhanced as Toyota model has shown. In addition, by reducing the lead time, better value can be offered for customers by reacting faster and by producing more customised products. There is evidence of that in other researches (e.g. Walker et al. 2000)

Previously, order-delivery process analyses of this kind have been done in the manufacturing industry with good results. These analyses are done with the value stream mapping tool, which is geared towards lean philosophy. However, similar value chain analyses have not been done in the Finnish built environment. Hence, it seemed interesting to analyse the capability of the value creation process in the context of the Finnish built environment.
Based on the literature review of the value chain mapping researches, the appropriate tool set was selected for the analysis of Finnish built environment. Modification was needed, because the scope of the study was wide and included several organisations. As a result of the selection five tools were selected: Customer need, Process activity mapping, Gap analysis, Decision point analysis and Supply chain response matrix. These tools formed the analysis framework, which were then used to analyse the case value chains.

Six Finnish built environment value chains were analysed as a case study. In these value chains, the main factors causing long lead time were long response time in the zoning stage, gaps between the flow and the push production. In the zoning stage a lot of time is consumed waiting for approval and during the appeal process. The gaps cause incoherent production, which is not managed as one system. Hence, there are a lot of local optimums but no common goal, which causes a need for buffers like stocks.

The results of the study offer significant possibilities to enhance efficiency and the value generation of Finnish built environment. The efficiency is generated because fewer resources are needed during the project. For example, fewer resources are engaged in work in progress and stocks. Additional value is generated for the customers, because of the faster delivery. From a business point of view, suggested enhancement could offer fewer risks, because the variance of the project delivery could be reduced. In addition, there would be possibilities to generate new business models by linking value generation and revenue logic. Hence, there would be possibilities to differentiate on the markets and enhance the profitability of the industry.

There are several limitations in this study. First consideration links to the research scope and used tools. The analysis was done based only one tool, value stream mapping. In addition, the tool had to be modified for this study. Therefore, the analysis framework was totally new and it has never before tested. Hence, there is no previous evidence that VSM would

be an appropriate tool for this kind of analysis. Also, the researched value chains were wide so that organisation-based analysis could not be executed. Hence, the results are based on average approaches rather than real projects. The research method was case study and these results are limited for these six value chains of the studied built environment. Some of the results can be generalised for Finnish built environment, but for other nations these results can hardly be applied because of the difference in the standards and laws.
For further study, it would be interesting to do the same kind of research in other Finnish built environments so that the results of this study could be validated and generalised. Also, new studies would offer insightful information about how value chain mapping applies in these kinds of studies. In addition, the testing of the recommended lean methods, like last planner, in the real projects could offer evidence whatever these tools are appropriate tools for solving presented problems.

ABSTRACT

*The goal of Real Time Production Optimization (RTPO) models is to improve the efficiency and predictability of the optimization methodology itself, and to improve the flexibility in terms of the types of proxy models that can be used. Considering the present state of the art among the production optimization frameworks, the **Overall Equipment Efficiency (OEE)** methodology is the most popular one. However, this and other (RTPO) methodologies approach production optimization only from the technology point of view and ignore the economic perspective of optimization.*

*This is why we developed a new key performance indicator **Overall Cost Efficiency (OCE)** aimed at measuring the cost efficiency of a production process in real time. Its application is based on the Overall Equipment Efficiency (OEE) measurements and is convenient for application in industrial management praxis. We have used an ordinary mathematical modelling approach combined with descriptive microeconomic analysis techniques. The OCE algorithm is an original advanced improvement of a popular OEE framework.*

Keywords: Technical efficiency, Overall equipment efficiency (OEE), Cost efficiency, Overall cost efficiency (OCE), Industrial management.

INTRODUCTION

Production optimization is one of the important research fields that lies at the cross-section of a microeconomics, mathematics and informatics. One of the special research issues includes the so-called Real Time Production Optimization models (RTPO models). Their goal is to improve the efficiency and predictability of the optimization methodology itself, and to improve the flexibility in terms of the types of proxy models that can be used. The natural background for development of the production optimization models is provided by the mathematical optimization techniques (see for instance Strasek 2003 for their overview).

Considering the present state of the art among the production optimization frameworks, the Overall Equipment Efficiency (OEE) methodology is the most popular one. However, this and other (RTPO) methodologies approach production optimization only from the technology point of view and ignore the economic perspective of the optimization.

The present paper introduces a new key performance indicator (KPI) aimed at bridging this gap. Our KPI measures not only the technical efficiency of production, but also the belonging cost efficiency in real time. Especially from the industrial management and from

the productivity management point of view, it is crucial to know by what percentage the actual costs are higher due to the reduction of technical efficiency. For this purpose we suggest the use of our Overall Cost Efficiency (OCE) framework. Its theoretical deduction is the basic issue of the article.

The content of the article is organized as follows. In chapter two the Overall Equipment Efficiency (OEE) framework is reviewed. In chapter three the microeconomic relationships between productivity and production costs are described. Chapter four develops an Overall Cost Efficiency (OCE) framework. Chapter five develops an industrial management point of view on the OCE. Chapter six concludes with the pilot case study of OCE.

TECHNICAL EFFICIENCY AND OVERALL EQUIPMENT EFFICIENCY (OEE) FRAMEWORK

In manufacturing practice, especially in the case of automated production lines for mass production, the use of a key performance indicator (KPI) termed as Overall Equipment Efficiency (OEE) is very popular – see for instance Sharma et al. (2006, 261–264), Dal et al. (2000, 1488–1502). The OEE was introduced by Nakajima (1998), aimed at supporting the processes of total productivity maintenance (TPM). From the methodological point of view the OEE is a productivity metric that estimates the technical efficiency of a production process by controlling the availability, performance and quality of the production process – see for instance Huang et al. (2003, 513–527), De Ron and Rooda (2006, 4987–5003), Jonsson and Lesshammar (1999, 55–78) for scientific evaluation of the OEE and for the relevant analysis on the present state of the art.

There exist different varieties of the mathematical specification of an *OEE*, where the common framework is given as:

$$OEE = A \cdot P \cdot Q. \tag{1}$$

Symbols: OEE – overall equipment efficiency,
A – availability rate,
P – performance rate,
Q – quality rate.

The first parameter is the availability rate (*A*) which measures the share of effective operating time in total operating time. The total operating time (*TOT*) is a time-span within which the production process can proceed. However, due to different reasons, the production process does not take place within the whole available time-span. Therefore, a time-span within the production process in drive is measured as an effective operating time (*EOT*). Hence, the availability rate is a relative coefficient calculated as:

$$A = \frac{EOT}{TOT}. \tag{2}$$

Symbols: A – availability rate ($0 \le A \le 1$),
EOT – effective operating time,
TOT – total operating time.

If a production is a smooth process without any breakdowns and stops, then the effective operating time (*EOT*) has to be in line with the total operating time (*TOT*), and the coefficient of availability (A) reaches its potential level 1. If the effective operating time diminishes, the availability rate diminishes towards its minimum level 0.

The second parameter is the performance rate (*P*), which is a relative coefficient with an actual production speed (*APS*) in the numerator and a potential production speed (*PPS*) in the denominator. The production speed measures the amount of production in a certain time unit (for instance 1000 pieces per hour). According to this, the performance rate is calculated as:

$$P = \frac{APS}{PPS}. \tag{3}$$

Symbols: P – performance rate ($0 \le P \le 1$),
APS – actual production speed,
PPS – potential production speed.

In the case of full efficient production, there is no deviation between the actual and the potential production speed. However, due to various inefficiencies, there occurs the problem of speed reduction of the production process. Consequently, the actual production speed is reduced below its potential level, and the performance rate diminishes towards its minimum level 0.

Finally, there is the quality rate (*Q*). This parameter measures the share of good pieces of production in the total production realized within the effective operating time and at the given performance of the production line. According to this, the following definition equation is used when estimating the quality rate:

$$Q = \frac{TP}{TP_{\max}}. \tag{4}$$

Symbols: *Q* – quality rate ($0 \le Q \le 1$)
TP – actual total product (amount of good products),
$TP_{\max}$ – maximum total product (potential amount of products).

In the case of full quality production, there is no deviation between the amount of good products and the potential amount of products. However, due to various inefficiencies, the amount of good products is reduced below its potential level, and the quality rate diminishes towards its minimum level 0.

There exists an extensive amount of theoretical and empirical literature on the explanation and prediction power of *OEE* and its practicability for productivity management (see for instance Cebrain and Vinegla, 2002; Chou and Hsu, 2005; Leem and Kim. 2004; and Wang et al. 2004). However, so far one important point has not been recognized enough. Namely, everything that has an influence on production has also a systematic impact on production costs. In the following section this relationship is described.

RELATIONSHIPS: PRODUCTIVITY – AVERAGE COSTS AND TECHNICAL EFFICIENCY – COST EFFICIENCY

Production is a technical process with a relationship between the amount of used production factors (such as energy or raw materials, working hours etc.) and the total product. Analytically these relationships are presented by the so-called technical coefficients:

$$a_i = \frac{X_i}{TP}. \tag{5}$$

Symbols: a_i – i-th technical coefficient,
X_i – amount of i-th production factor used,
TP – total product.
Note: In this case we do not distinguish between actual and potential total product.

This technical coefficient measures the amount of i-th production factor used for producing a unit of final product.

The inverse value of the technical coefficient is the average productivity of the selected production factor:

$$AP_X = \frac{TP}{X_i}. \tag{6}$$

Symbols: AP_X – average productivity of production factor X,
X_i – amount of i-th production factor used,
TP – total product.
Note: In this case we do not distinguish between actual and potential total product.

The above specified average productivity measures the amount of total product per unit of i-th production factor X.

If we multiply the amount of the i-th production factor used by the belonging price of the production factor we obtain the costs of the i-th production factor. When adding up these partial costs, we obtain the total costs:

$$TC = \sum_{i=1}^{n} \left(X_i \cdot p_i \right). \tag{7}$$

Symbols: TC – total costs,
X_i – amount of i-th production factor used,
p_i – price of i-th production factor.

Finally, if we divide total costs by the amount of production, we obtain the so-called average costs that measure the amount of total costs per unit of product:

$$AC = \frac{TC}{TP}. \tag{8}$$

Symbols: AC – average costs,
TC – total costs,
TP – total product.
Note: In this case we do not distinguish between actual and potential total product.

If we relate average productivity (6) with average costs (8), keeping the price of production factor used constant, we can deduce the relationship between average productivity and average costs as follows: "*An increase of the AP_x demonstrates growth of TP by keeping the amount of production factor used unchanged. Consequently, the numerator in equation (8) is unchanged and the denominator is higher, thus causing a decrease of the AC, and vice versa.*" This demonstrates the inverse relationship between average productivity and average costs.

However, the focus of our analysis is not on average productivity and average costs, but on the relationship between technical efficiency and cost efficiency. For this purpose we have to introduce optimality criteria:

- In the case of average productivity, the optimality criterion is the highest possible amount of production per i-th production factor used.
- In the case of average costs this criterion is the lowest possible costs per unit of product.

Hence, we have to distinguish between potential and actual productivity and between potential and actual average costs. Graphically this issue is presented in the Figure 1.

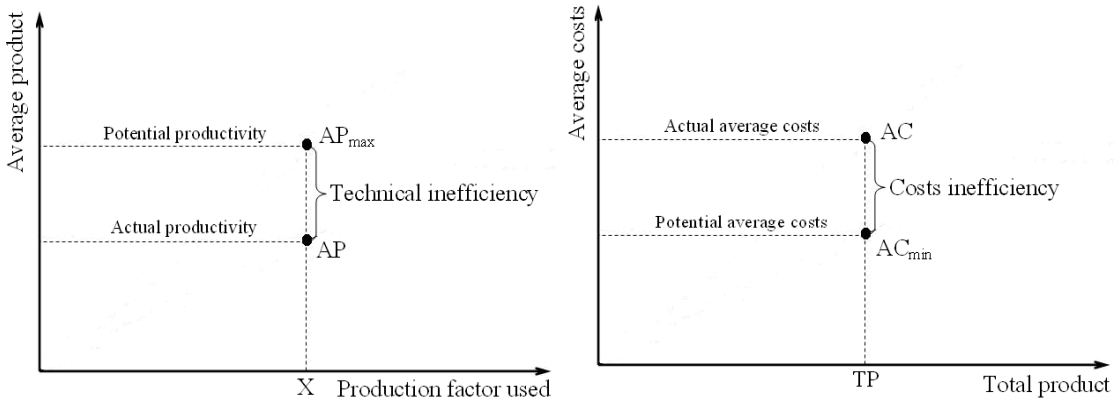

Figure 1: Technical and cost inefficiency.

On the left side of Figure 1 the graphical deduction of technical inefficiency is presented. The amount of production factor used equals X and is related with the average productivity at the *AP* level. However, the actual productivity level is below the potential productivity (AP_{max}). The potential productivity level is reached in specific cases when full availability $(A=1)$, maximal performance $(P=1)$ and full quality $(Q=1)$ are jointly reached. There are numerous inefficiency factors which reduce the availability and/or performance and/or quality, and cause the decrease of actual productivity below the potential productivity. The distance between actual and potential productivity is termed as technical inefficiency.

At this point it is important to highlight two different terms with equal meaning: technical inefficiency and technical efficiency, where both measure the difference between actual and potential productivity. In our case we recommend using the term technical efficiency rate, which does not measure the difference between actual and potential productivity, but rather the ratio between actual and potential productivity as follows:

$$TER = \frac{AP}{AP_{\max}}. \tag{9}$$

Symbols: *TER* – technical efficiency rate, 0 ≤ TER ≤ 1,
AP – actual average productivity,
AP_{max} – potential (maximum) average productivity.

If *AP* equals AP_{max} then *TER* equals 1, implying full technical efficiency – actual amount of production equals the potential amount of production.

On the right side of Figure 1 the graphical deduction of cost inefficiency is presented. The obtained cost inefficiency is the consequence of technical inefficiency. Namely, in the case of the production process analyzed in Figure 1 the amount of production factor used equals X. If this amount of production factor used is related to the potential productivity, then the lowest possible average costs are reached. When actual productivity is below the potential one, average costs are above the potential level. The distance between actual and potential average costs is termed as cost inefficiency.

In this case it is important to highlight two different terms with equal meaning: costs inefficiency and costs efficiency, where both measure the difference between actual and potential average costs. In our case we recommend using the term costs inefficiency rate, which does not measure the difference between actual and potential average costs, but rather the ratio between actual and potential average costs as follows:

$$CIR = \frac{AC}{AC_{\min}}. \tag{10}$$

Symbols: *CIR* – cost inefficiency rate, $1 \leq CIR \leq \infty$,
AC – actual average costs,
AC_{min} – potential (minimum) average costs.

If *AC* equals AC_{min}, then *CIR* equals 1, implying zero cost inefficiency (or full costs efficiency) that can be achieved only in the case of full technical efficiency. If technical efficiency diminishes towards zero, costs inefficiency rises towards ∞. Namely, technical efficiency at value zero implies TP = 0. As we know from (8), actual average costs are calculated as the ratio between total costs (in numerator) and total product (in denominator). When total product equals 0, the value of actual average costs expands towards∞. Hence, the value zero of technical efficiency (i.e. full technical inefficiency) is related with infinite cost inefficiency.

Now, since the definition equations for technical efficiency rate (*TER*) and cost inefficiency rate (*CIR*) have been established, their co-domains can be deduced.

- The co-domain of the technical efficiency rate (*TER*) is the interval [0, 1]. Rate 0 is reached if the actual amount of production equals 0, and level 1 is reached if the actual amount of production equals the potential amount of production (i.e. actual productivity equals potential productivity).
- The co-domain of the cost inefficiency rate (*CIR*) is the interval [1, ∞). Rate 1 is reached when actual average costs equal potential average costs. This can be reached in specific cases when actual productivity equals potential productivity. However, if technical efficiency diminishes away from its potential level, average costs rise above the potential ones. As described in the previous paragraph, zero technical efficiency causes infinite cost inefficiency. Therefore, the co-domain of cost inefficiency rate has no upper frontier.

According to the results discussed, two conclusions which demonstrate the inverse relationship between technical efficiency and cost inefficiency can be deduced:

- If technical efficiency rises towards 1, cost inefficiency decreases towards 1.
- If technical efficiency decreases towards 0, cost inefficiency grows towards ∞.

The description of the relationship between technical efficiency and cost inefficiency can be deduced from any basic or advanced literature on microeconomics production and cost functions. This literature also offers sufficient methodological frameworks on the measurement of technical efficiency and cost inefficiency. What is interesting, and has attracted our attention, is the existing dichotomy in measuring both parameters. Although the cost inefficiency is the consequence of the reached technical efficiency, the existing methodological frameworks do not estimate cost inefficiency directly from observed technical efficiency. We recognized this problem by conducting several applicative researches for companies that perform automated production processes and measure their technical efficiency in real time by using *OEE* methodology. It is in fact this extensive use of the *OEE* framework in industrial management that raises the question of how to obtain cost inefficiency measurements directly from *OEE* in real time. For this purpose we conduct extensive theoretical and applicative researches with the aim of developing new algorithm that provides the answer to the stated question – we have developed an algorithm that estimates cost inefficiency rates directly from the technical efficiency rates obtained. Its development is described in the following section.

OVERALL COST EFFICIENCY (OCE) - ALGORITHM AIMED AT TRANSFORMING TECHNICAL EFFICIENCY INTO COST INEFFICIENCY

The term Overall Cost Efficiency (*OCE*) was proposed by us. We proposed the name according to the fact that this parameter is deduced from the key performance indicator *OEE* that measures overall equipment efficiency (or the so-called technical efficiency).

In microeconomics analyses of the cost function we have to distinguish between fixed and variable costs. Fixed costs are independent of the production amount, while variable costs vary with the production amount. Typical fixed costs are for example costs of labour force. We have to pay the worker for his daily work, although the machine was operating only a half of his working time. This has an influence on fixed costs per unit of the product (average fixed costs), which are mathematically calculated as:

$$AFC = \frac{FC}{TP}. \tag{11}$$

Symbols: *AFC* – average fixed costs,
FC – fixed costs,
TP – actual total product.

Following the above specified definition equation of average fixed costs, we can establish that *AFC* continuously diminish towards 0 if TP increases towards ∞.

On the other hand, costs of material are typical variable costs, since the consumption of material depends on whether the machine is in operating position or not. Therefore the average variable costs are constant per unit of final product. Mathematically they are calculated as:

$$AVC = \frac{VC}{TP}. \tag{12}$$

Symbols: *AVC* – average variable costs,

VC – variable costs,
TP – actual total product.

If we sum up average fixed costs and average variable costs, we obtain average costs:

$$AC = \frac{TC}{TP} = \frac{FC + VC}{TP} = \frac{FC}{TP} + \frac{VC}{TP} = AFC + AVC. \tag{13}$$

Symbols: *AC* – average costs,
TC – total costs,
TP – total product,
FC – fixed costs,
VC – variable costs,
AFC – average fixed costs,
AVC – average variable costs.

Note: In this case we do not distinguish between actual and potential total product.

When deducing *OCE* from *OEE* we have to be aware that changes in availability (*A*), performance (*P*) or quality (*Q*), which determine the *OEE*, differently impact production costs. If we accept the above described system of average fixed and average variable costs, the following axioms about the impact of availability, performance and quality on average costs can be defined:

- Decreasing availability (*A*) raises average fixed costs, while average variable costs remain unchanged. As we know from (2), the decreasing availability is a consequence of decreasing effective operating time. The decreasing effective operating time-span has no impact on the consumption of variable production factors (such as raw materials, or energy). The only consequence is reduced actual total product – the actual amount of production is below the potential level. Since fixed costs remain unchanged, the diminishing total product causes growth of average fixed costs – see (11). Hence, the changes of availability cause changes of average costs only via changes of average fixed costs.
- Decreasing performance (*P*) raises average fixed costs, while average variable costs remain unchanged. Following the definition equation of performance rate (3), the decreasing performance is a consequence of the decreasing actual production speed. The decreasing actual production speed has no impact on the consumption of variable production factors. Hence, the only consequence is reduced total product – the same impact as this occurs in the case of reducing availability. Therefore, the changes of performance cause changes of average costs only via changes of average fixed costs.
- Decreasing quality (*Q*) raises average fixed costs as well as average variable costs. The decreasing quality rate implies growth of the amount of bad pieces of production in the total product. Therefore the actual amount of production is below the potential one, which causes, according to definition equation (11), growth of average fixed costs. However, production of bad pieces of production has also an influence on average variable costs. When calculating the actual average costs we have to multiply the costs of variable production factors inherent to good pieces also with costs of variable production factors inherent to bad pieces. Hence, changes of quality have additional effects on cost inefficiency. The first impact is via increasing average fixed costs (as in the case of availability and performance), and the second impact is via average variable costs.

So, generally, changes in availability rate and performance rate influence only average fixed costs, while quality rate has an impact on average fixed costs as well as on average variable costs. These facts are an integral part of the *OCE* algorithm proposed below. By evaluating the algorithm we have to be aware about definition of the following symbols:

TP – actual total product,
Q – quality rate,
A – availability rate,
P – performance rate,
TC – total costs,
VC – variable costs,
FC – fixed costs,
AC – average costs,
AFC – average fixed costs,
AVC – average variable costs.
min – minimum,
max – maximum.

We start the development of the *OCE* algorithm by using the definition equation of cost inefficiency rate (10), and introduce some rearrangements by using (11), (12) and (13):

$$CIR = \frac{AC}{AC_{\min}} = \frac{\left(\frac{FC}{TP}\right)+\left(\frac{VC}{TP}\right)}{\left(\frac{TC_{\min}}{TP_{\max}}\right)} = \frac{\left(\frac{FC}{TP}\right)+\left(\frac{VC}{TP}\right)}{\left(\frac{FC}{TP_{\max}}\right)+AVC_{\min}} \tag{14}$$

Note: The condition $AVC_{\min}$ implies full quality.

If we introduce *OEE* into (14), we transform *CIR* into the *OCE* algorithm that calculates costs inefficiency from technical efficiency (*OEE*):

$$OCE = \frac{\left(\frac{FC}{TP_{\max}OEE}\right)}{\left(\frac{TC_{\min}}{TP_{\max}}\right)} + \left(\frac{AVC}{AFC_{\min}+AVC_{\min}}\right). \tag{15}$$

Note: $TP_{\max}$ multiplied by availability rate (*A*), performance rate (*P*) and quality rate (*Q*), i.e. with OEE, gives actual total product (*TP*).

$$OCE = \frac{\left(\frac{AFC_{\min}}{OEE}\right)}{AC_{\min}} + \left(\frac{AVC}{AFC_{\min}+AVC_{\min}}\right) \tag{16}$$

$$= \frac{1}{OEE}\cdot\frac{AFC_{\min}}{AC_{\min}} + \frac{AVC}{AC_{\min}}.$$

The equation (16) is the first definition equation of our algorithm aimed at transforming technical efficiency measured on the basis of *OEE* into cost inefficiency measurement. The

term $\frac{1}{OEE}$ implies the known inverse relationship between technical efficiency and cost inefficiency.

However, *AVC* can be expressed also as:

$$AVC = \frac{VC}{TP} = \frac{AVC_{\min} \cdot TP_{\max} \cdot A \cdot P}{TP_{\max} \cdot A \cdot P \cdot Q} = \frac{AVC_{\min}}{Q}. \tag{17}$$

By introducing (17) into the (16) we can deduce the final *OCE* algorithm:

$$OCE = \frac{1}{OEE}\left[\frac{AFC_{\min}}{AC_{\min}}\right] + \left[\frac{\left(\frac{AVC_{\min}}{Q}\right)}{AC_{\min}}\right] \tag{18}$$

or

$$OCE = \frac{1}{OEE}\left[\frac{AFC_{\min}}{AC_{\min}}\right] + \frac{1}{Q}\left[\frac{AVC_{\min}}{AC_{\min}}\right]. \tag{19}$$

The equation (19) is the final solution to our research problem. As we can see, there is an inverse relationship between *OCE* and *OEE*, where quality rate has an additional impact via variable costs.

The specification (19) is a mathematically deduced estimator that transforms technical efficiency into cost inefficiency in real time. There are four factors that determine the impact of technical efficiency on cost inefficiency:

- The first impact is controlled by the inverse value of *OEE* ($0 \le OEE \le 1$). Therefore, if *OEE* diminishes towards 0 the inverse value of *OEE* rises towards infinity, and if *OEE* rises towards 1, its inverse value diminishes towards 1.
- The second impact is controlled via the share of fixed costs in total costs. The domain of this ratio is [0, 1] – it is zero if total costs are variable, and it is 1 if total costs are fixed costs. The greater the share of fixed costs in total costs, the higher the impact of technical efficiency on cost inefficiency.
- The third impact is controlled via the inverse value of quality rate. The domain of the inverse ratio is between $[1, \infty)$. It is 1 in the case of full quality, while decreasing quality rate causes its growth towards ∞.
- The fourth factor is controlled via the share of average variable costs in average costs. The domain of this share is between [0, 1] – it is zero if total costs are fixed costs, and it is 1 if total costs are variable costs.

According to the developed algorithm, the above described four separate factors are actually united into two impacts that jointly determine the value of *OCE*.

- The first one is the impact of *OEE* jointly with the share of fixed costs in total costs. This implies that *OEE* determines the cost inefficiency only via fixed costs.
- The second one is impact of quality rate jointly with the share of variable costs in total costs.

This implies that all of the parameters incorporated in *OEE* have a unique impact on costs inefficiency via the fixed costs, but the quality rate parameter has an additional impact on cost inefficiency via the variable costs.

The equation (19) is also suitable for application in industry practice. According to the proposed algorithm only data on the shares of fixed and variable costs in average costs are needed. Since those shares are known from the normative calculations of average costs, the equation (19) is suitable for application in industrial management.

OCE FROM INDUSTRIAL MANAGEMENT POINT OF VIEW

From the industrial management point of view, two groups of main conclusions can be established.

First, the proposed new key performance indicator (KPI), termed as *OCE*, is an efficient tool that enables production management to control for cost efficiency of the production process in real time. By using the proposed *OCE* algorithm we can evaluate each factor that causes technical inefficiency of the production process from the costs point of view. Once we have the *OEE* measures we can deduce OCE measures that inform us by what percentage production is more expensive than it can be in the case of full technical efficiency.

Second, although there is a systematic and inverse relationship between technical efficiency and cost inefficiency, this relationship is not unique, but heterogeneous. Two simple examples can demonstrate this issue.

Example 1	**Example 2**
$A=1,\ P=1,\ Q=0.8,$	$A=0.8,\ P=1,\ Q=1,$
consequently $OEE=0.8,$	consequently $OEE=0.8,$
and if $\frac{AVC_{\min}}{AC_{\min}}=\frac{AFC_{\min}}{AC_{\min}}=0.5,$	and if $\frac{AVC_{\min}}{AC_{\min}}=\frac{AFC_{\min}}{AC_{\min}}=0.5,$
$OCE=\frac{0.5}{0.8}+\frac{0.5}{0.8}=1.25.$	$OCE=\frac{0.5}{0.8}+\frac{0.5}{1}=1.125.$

In both cases *OEE* equals 0.8, implying that the actual amount of production reaches 80% of the potential amount of production. But, in the first case the *OCE* equals 1.25, which implies that actual average costs (i.e. costs per unit of total product) are 25% higher than they are in the case of full technical efficiency. And in the second case the *OCE* equals 1.125, implying that actual average costs are by 12.5% higher than they are in case of full technical efficiency.

So the same level of technical efficiency is related to different levels of cost inefficiency. And exactly this heterogeneous nature of the causal relationship between *OEE* and *OCE* is the basic argument in favour of introducing *OCE* in the industrial management praxis. This is inevitable, because efficiency improvements demand additional investments and, as we have demonstrated, it is quite possible that we may achieve large improvements in technical efficiency but will achieve only a small reduction in cost inefficiency. Therefore an efficient and successful industrial management needs to upgrade the *OEE* framework with the proposed *OCE* methodology.

PILOT CASE STUDY – PRODUCTION OF PÂTÉ

The pilot case study was made in a company which produces pâtés in Slovenia. The production line of pâtés is organized as an integrated system of four production processes.

- The first phase is the preparation (cooking) of meat.
- The second phase is the preparation of the meat mass (pâté). They add oil, spices and water to the prepared cooked meat from the first phase. This phase represents the beginning of the automated production process which continues into the filling in the containers.
- The third phase is filling in the containers with the pâté prepared in the second phase, and the transportation of those doses-containers to the sterilisator. First three phases represent the closed process from the technical point of view. If the production process in some of those phases stops, all other two phases stop, too.
- The fourth and the last phase is transportation of containers from the sterilisator and packaging of doses. If the transportation of containers from the sterilisator is stopped then also the packaging is stopped.

The whole production process is thus integrated and allows no by-passes which could prevent the transmition of interruptions from past onto next phases of production. The only such by-pass could be from filling in the containers to the packaging – there are namely four sterilisators which enable almost uninterrupted process of packaging.

From the viewpoint of technical efficiency all phases of the production process should be efficient, as the main aim is to ensure uninterrupted production. From the viewpoint of cost efficiency however the crucial phase is the last phase – the packaging of containers, as the 100 % of the technical efficiency of this phase can neutralise inefficiencies of former phases. This is why we concentrate only on the process of packaging of containers.
The observations and measurements of technical and cost efficiency on the packaging line were made between July 7 and November 30, 2008. First we have calculated the parameter OEE:

$$OEE = A \cdot P \cdot Q,$$

where individual parameters measure: A - Availability, P - Performance, Q - Quality.

Availability (A)

The availability rate measures the relationship between the effective and total operating time:

- The daily working time is 16 hours (2 shifts).
- The total operating time is the daily working time less planned interruptions. As planned interruptions amount to 2.4 hours per day, the total operating time is 16 – 2.4 = 13.6 hours per day (this is constant).
- The effective operating time is the total operating time less unplanned interruptions.

The availability rate (A) thus measures the percentage of the time in which the production line is actually available for production process (Figure 2).

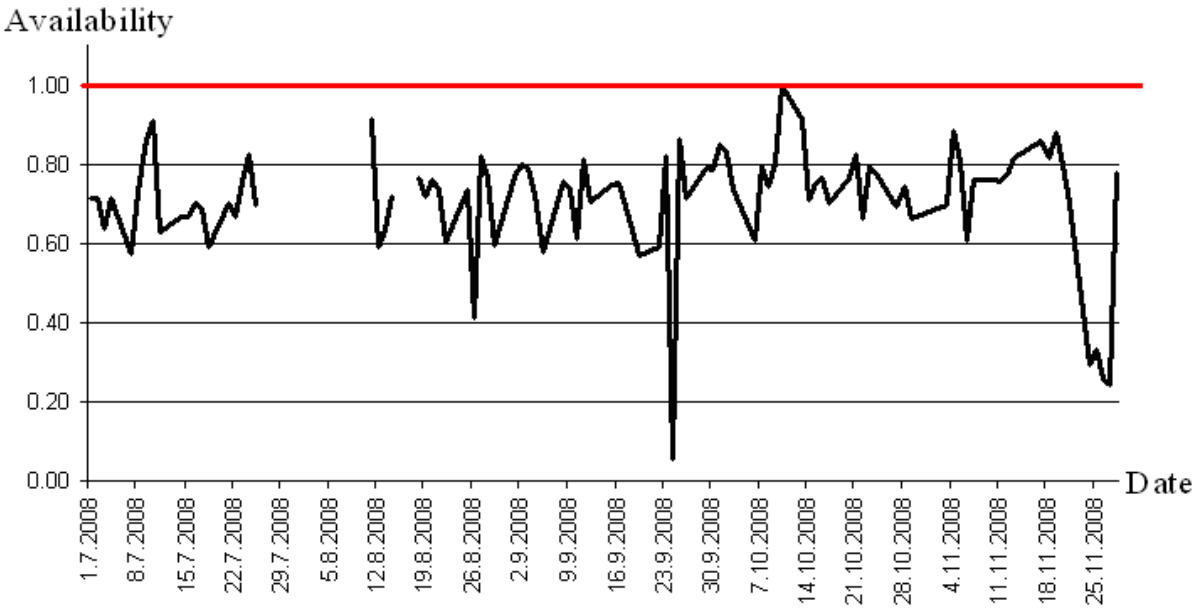

Figure 2: Availability rate of the packaging line (potential available time = 13.6 hours, number of observations: n = 95).

On the basis of 95 measurements we can conclude that the availability rate of the production line of packaging amounted on average to 71.23 %.

Performance

The performance rate (*P*) is a relative coefficient with an actual production speed (*APS*) in the numerator and a potential production speed (*PPS*) in the denominator. The performance is measured within the time frame of actual availability of the production line (Figure 3).

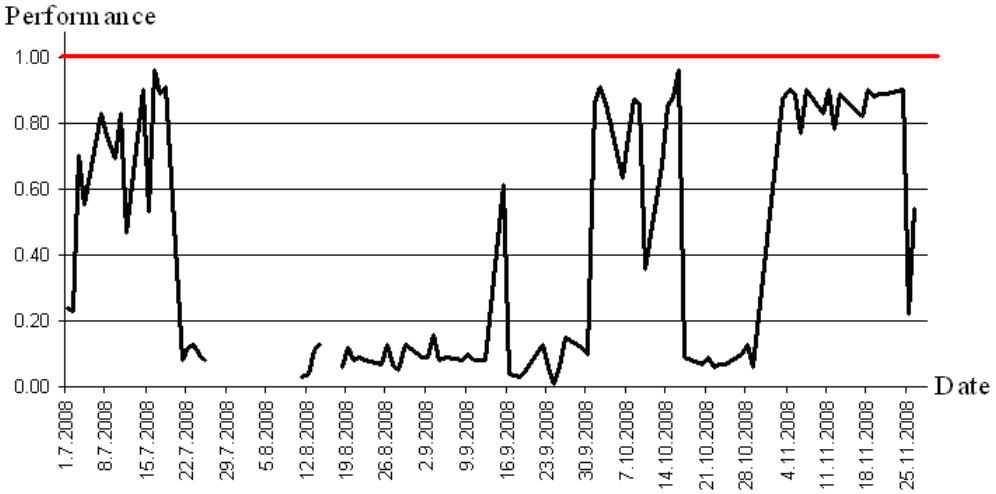

Figure 3: Performance rate of the packaging line (according to actual available time; number of observations: n = 94).

On the basis of 94 measurements we can conclude that the average value of the parameter P was 39.23 %. This means that on average the actual speed of the production line was by almost 60% lower than its potential speed within the actual available time of the production line.

Quality

This parameter measures the share of good pieces of production in the total production realized within the effective operating time and at the given performance of the production line.

As the analysed company was not measuring the quality rate in real time, we had to calculate it on the basis of previous production. We introduced the calculated rate of 98% as constant (Figure 4).

It must be stressed that the measurement of the parameter Q can not be limited only on the phase of packaging but must include the whole production process. This is because the parameter Q influences average fixed costs as well as average variable costs.

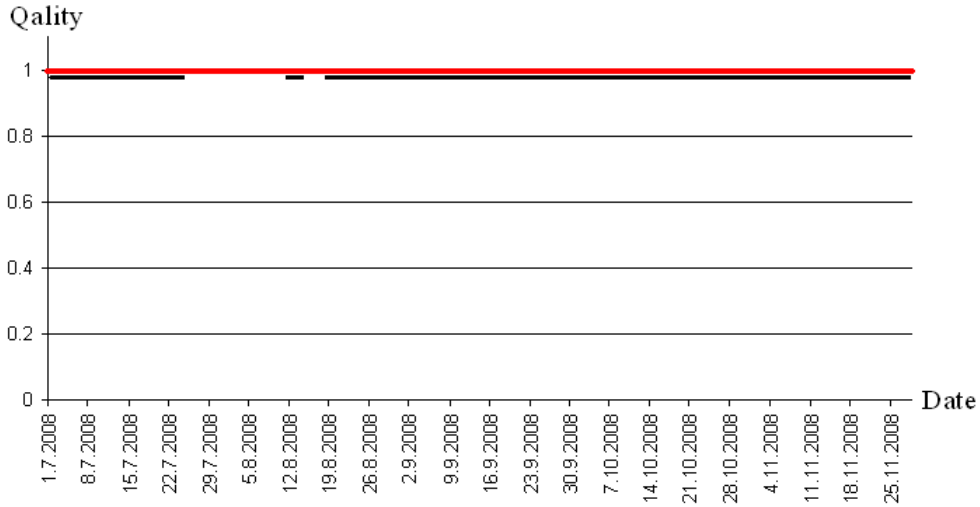

Figure 4: Supposed constant value of the parameter Quality for the whole production.

OEE

Parameter OEE measures the level of technical efficiency in the interval [0, 1]. Increasing value of OEE towards 1 means increasing (improving) of technical efficiency, and vice versa.

The average value of parameter OEE was 0.2915. It means that the actual quantity of production reached on average a little less than 30% of the potential amount of production in the observed period (Figure 5).

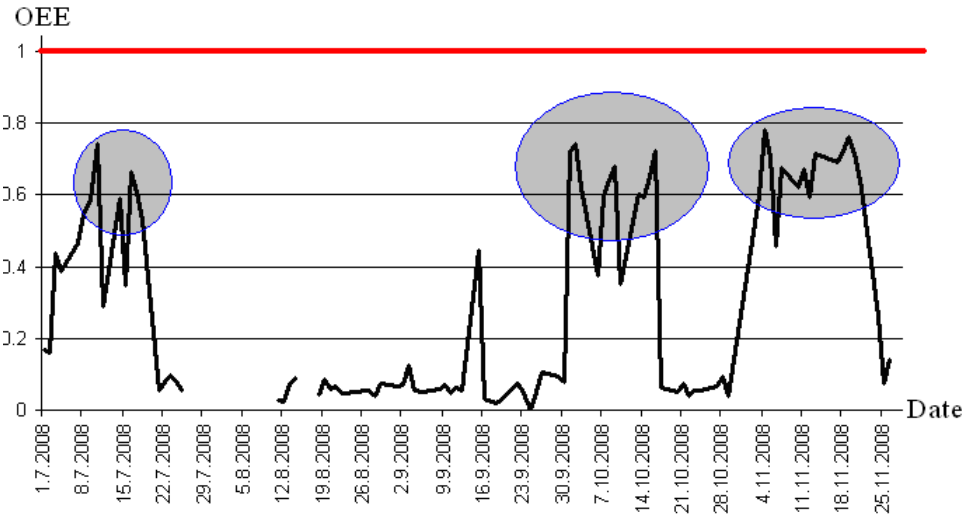

Figure 5: Values of parameter OEE for the packaging line of pâtés (number of observations: n = 94).

Very low average value of the parameter OEE is the consequence of low values of OEE in summer period of production. If we remove the values of OEE in the summer period and some extreme daily falls of the OEE and take into consideration only observations marked with gray, we get the average value of OEE = 0.6861. It means that the actual quantity of production reached a little less than 70% of the potential amount of production.

OCE

The relationship between the cost efficiency (OCE) and technical efficiency (OEE) is defined through equation:

$$OCE = \frac{1}{OEE}\left[\frac{AFC_{\min}}{AC_{\min}}\right] + \frac{1}{Q}\left[\frac{AVC_{\min}}{AC_{\min}}\right]. \tag{19}$$

OCE is the parameter which shows by how much percentage point the actual average costs exceed the potential minimal average costs. The potential minimal average costs would be achieved in the case of total technical efficiency (OEE = 1).

When estimating the cost efficiency the essential point is shares of fixed and variable costs in total costs. These shares are known from the normative calculations of average costs. Given the fact that the company produces some varieties of pâtés (chicken, tuna, salmon) these calculations are different for each product. But the average relation between costs is the following: 20% fixed costs and 80% variable costs. This ratio was supposed in our estimations of cost efficiency (Figure 6).

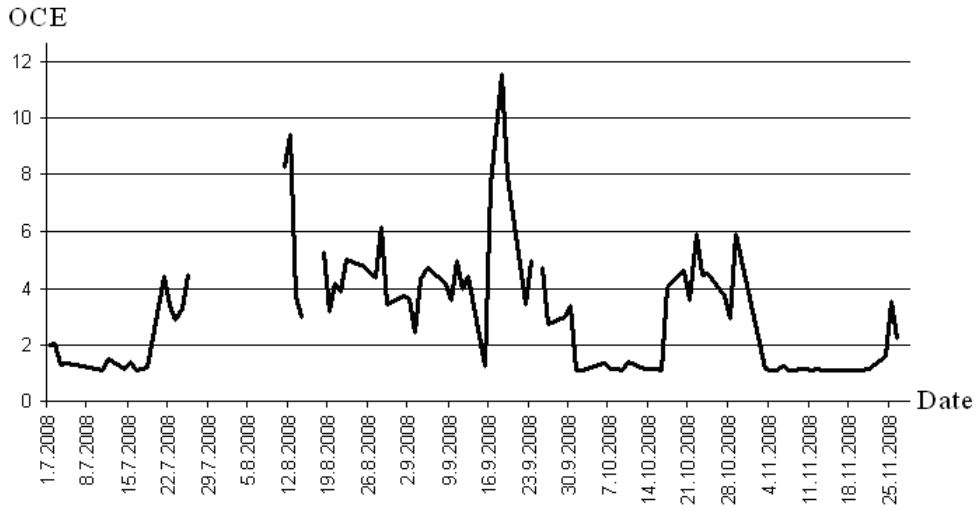

Figure 6: Estimations of cost efficiency (OCE) of packaging line of pâtés (number of observations: n = 93).

Supposing that all measurements of availability and performance of the packaging line are correct we must conclude that the average value of parameter OCE is 2.99. This means that the actual average costs exceed the potential minimum average costs by almost 3-times.

On the basis of our calculations of OEE and OCE we proposed some short term and long term measures to the management.

ABSTRACT

A lot of research has been done in the field of productivity because of its importance to the general well-being of the society. Productivity is often measured at a macro level which means the level where companies and industries operate. These research results are often considered controversial and the truth is that they often fail to fully explain the reasons behind the results. This paper explains the basic meaning of productivity and terms it is so often confused with. This paper also discusses the nature of productivity measurement and analyses the state of productivity in Finnish construction industry using data available in public. The implications of this research are that Finnish construction industry is doing all right when compared to its international counterparts, but is behind when compared to other industries in Finland. It is suggested that productivity should be approached at micro level where the physical change that is needed for productivity improvement takes place. Measurement should always pay attention to reliability and comparability of results, which means that the methods need to be standardized. As productivity is affected by many different factors and it is not useful as a measure in developing or in proactive management, the holistic set of different kind of performance measures should be used. This would ensure that the up-to-date information from the beginning of the cause-and-effect chain is taken into account when making management decisions.

Keywords: Productivity, Performance, Measurement, Management

INTRODUCTION

It is argued that productivity is perhaps one of the most important basic variables governing economic production activities (Singh et al., 2000; Tangen, 2005). Productivity development has a great importance on society for at least two reasons. Firstly, gains in productivity means that companies can increase wages without increasing prices, which in turn makes more money available for everyday spending (Fiume and Cunningham, 2003). Secondly, it is also one of the competitive advantages of companies who need to realize that gains in

productivity are one of their major weapons to achieve advantages on cost and quality over their competitors (Grossman, 1993; Tangen, 2005).

Because of its importance on well-being in a society, productivity has been widely discussed and researched since the beginning of the industrialization and even before. The performance of the construction industry has also been assessed with many studies from the productivity viewpoint (e.g. Allen, 1985; Rojas and Aramvareekul, 2003; Abdel-Wahab et al., 2008; Productivity Taskforce, 2009). The results from studies on different industries are often compared to each other, but that kind of macro level comparisons usually fail to explain the reasons behind the often so debatable results. Thus, some have even questioned the reliability and validity of the results and data used (i.e. Rojas and Aramvareekul, 2003; Sneck et al., 2007). Valid or not, people often seem to get on their back foot ahead of criticism directed on industries they work.

The term productivity is commonly used by both academics and practitioners, who however rarely give an adequate definition or explanation to it. Consequently, productivity is often mixed and used interchangeable with similar terms like performance or profitability (Sumanth, 1998; Tangen, 2005). In fact, misunderstandings may lead to measurement and improvement regimes built without a clear understanding what is going to be measured or improved. And ultimately opportunities to fully understand and optimize important factors relating to competitiveness and success can thus be missed. (Tangen, 2005).

In this study, the concepts of productivity, profitability and performance are clarified and the state of productivity in Finnish construction industry is analyzed. Analysis utilizes information available in public EU KLEMS database. And finally, the approach on productivity development is proposed. The paper aims to provide answers to the following research questions:

RQ1: What is the state of productivity in Finnish construction industry in relation to other industries in Finland and international counterparts?

RQ2: How the concept of productivity should be approached in construction industry?

PRODUCTIVITY – AN AMBIGUOUS CONCEPT

Productivity can be conceptualized as a system, which transforms inputs into outputs. In short, productivity is generally defined as a ratio between output factors and input factors of a system. Output is the outcome of the process – a product or service, and input factors consists of the resources used in a process of generating output factors. (Sumanth, 1998). According to The European Association of National Productivity Centres (2005) productivity expresses how efficiently and effectively products and services are being produced. Efficiency in this context means “doing things right” while effectiveness is often described simply as “doing the right things” (Grünberg, 2004). However, these kind of basic ratios are often regarded too “wide” to be useful in practice and there are numerous other definitions available.

Definitions for productivity are dependent on the reviewer point of view and the context within it is used. Generally verbal definitions aim to explain what the concept of productivity means while the mathematical definitions, on the other hand, can be used as the basis of performance measures, where the major aim is to improve (not to explain) productivity (Tangen, 2005). Some of the measures define productivity from different aspects depending on which input factors of production are taken into account. Approaches vary between the prevailing partial productivity that considers only one input factor (usually labor) at a time and total productivity, which tries to take all input factors into consideration (Sumanth, 1998).

Referring to Bernolak (1997) Tangen (2005) has highlighted two important characteristic of productivity. First, it is closely related to the use and availability of resources. This means that a company's productivity is reduced if its resources are not properly used or if it is short of them. Second, productivity is also strongly connected to the creation of value. Thus, high productivity is achieved when activities and resources used in process add value to the produced goods. Therefore one must eliminate waste in order to improve productivity: waste can be considered opposite of what productivity symbolizes.

Profitability

Productivity is often mixed with terms similar to it. One of them is profitability which is a crucial indicator for a company because it tells if the company is making money with its business or not. The difference between these concepts is that profitability has focus on money process, while productivity relates to physical phenomena in a real process. Still, productivity is often expressed and measured in monetary units per inputs as in many cases it seems to be only practical way (Stainer, 1997).

A significant issue is that profitability can change for reasons that have little to do with productivity. This is why productivity is considered a more suitable measure to monitor manufacturing excellence in the long run rather than profitability, since profits are influenced by many factors over the short term. (Miller, 1984; Tangen, 2005). Profit changes can be split into effects caused by changes in productivity, in sales activity and in price recovery (Van Loggerenberg and Cucchiaro, 1981). This is illustrated in Figure 1.

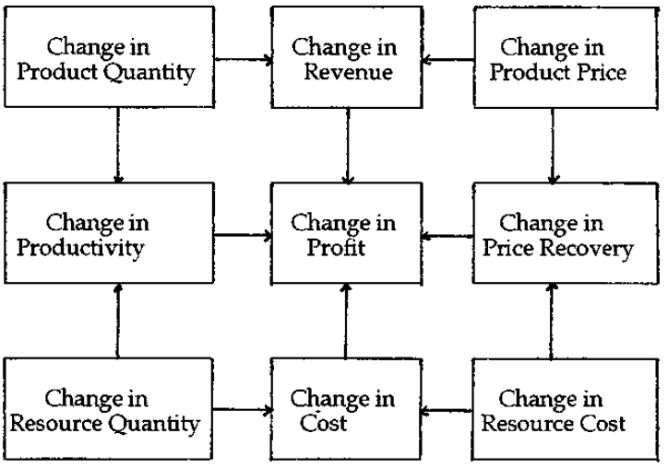

Figure 1: Productivity, profitability and price recovery (Van Loggerenberg and Cucchiaro, 1981).

Profitability does not have a direct impact when it comes to improvement purposes, since it is a result of, rather than a contributor to, the actions and processes in operations. A company can increase its profits and at the same time decrease profitability because monetary effects. But profitability is a useful addition to performance and productivity since it helps to identify the effects of monetary effects and distinguish them from "true" performance and productivity changes. (Grünberg, 2004).

Performance

Performance is the other concept that productivity is often confused with. Even though productivity is a multidimensional term, it is still a fairly specific concept related to physical phenomena in production. Performance, on the other hand is broader concept covering overall economic and operational aspects. It includes almost any objective of competition and manufacturing excellence whether it is related to cost, flexibility, speed, dependability or quality. "The triple P model" in the Figure 2 explains how the concepts of productivity, profitability and performance are related to each other. (Tangen, 2005).

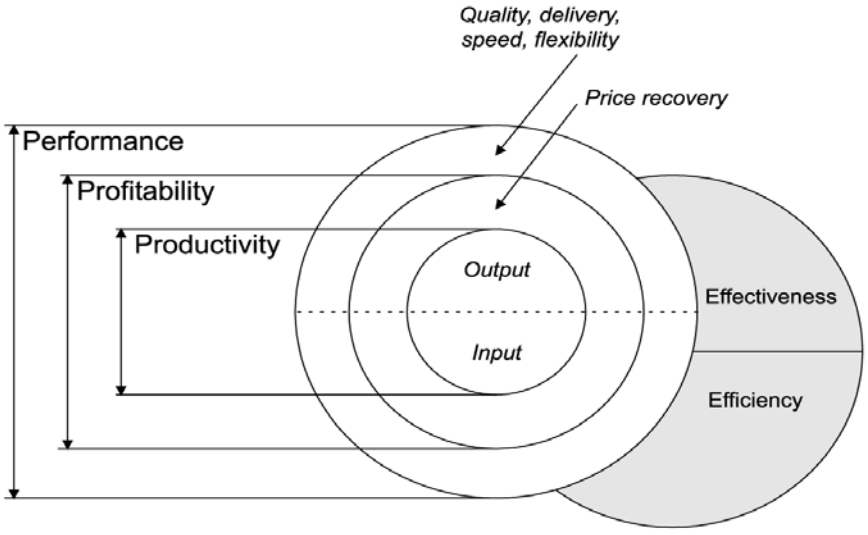

Figure 2: The triple P-model (Tangen, 2005).

Performance objectives often relate to a company's ability to compete and meet customer expectations. Some performance characteristics need to be sub-divided for easier measurement execution and they may turn out to resemble productivity measurements. It is suggested that a measure can be regarded as a performance measure if it is related to the five attributes mentioned in the previous paragraph. (Grünberg, 2004).

Measurement

Information from measurement is needed for two purposes: as a driver for internal improvement and for targeting and benchmarking projects and organizations (Koskela, 1992). A measurement system helps to reach long-term goals of an enterprise by connecting company objectives to improvements and setting targets for improvement activities (Grünberg, 2004). Indicators are defined in order to check the feasibility of the strategy and what kind of goals should be used on a daily basis (Haapasalo et al., 2006). Without knowing the impact of the decisions made it is difficult to improve productivity or any other important factor (Hannula, 2002). Yet, measurement should never become bureaucratic and inflexible or too supervisory from the employee perspective. It should provide practical information to the needs of management but with reasonable effort (Hannula, 2002). The ultimate goal of measurement should be to manage process, not results (Fiume and Cunningham, 2003).

Productivity can be measured at different levels: from broad economy and industry levels to very specific process or employee levels. At upper level financial indicators and physical measures are more common ways to describe the level and change of productivity. At lower levels there are numerous ways to keep track on productivity.

Problems considering broadness, allocation, comparability, value and measurement are characteristic to productivity measurement. The problem of broadness deals with the issue of which level of input and output should be taken into account when evaluating productivity. The problem of allocation instead occurs when deciding which input and output assets belong to the reviewing period. When comparing separate time periods with each other, the problem of comparability is faced. It is about eliminating price effect to make, for example, two sequential years comparable with each other. The problem of value is closely connected to the problem of comparability. It deals with the problem how the intangible assets and the value customer perceives are reported by quantitative means. The issue of selecting appropriate methods to achieve a high enough level of measurement accuracy occurs as the measuring problem. Broman (2004) refers to the commensurability problem, recognizing that each variable in the process is not measurable against the same standard or in the same units. Finding an appropriate way to solve the commensurability problem has resulted in various types of productivity measures and ways to aggregate inputs and outputs by use of weightings for example (Tangen, 2005).

In relatively many cases, especially at higher levels of analysis such as national and industry, productivity is being measured and indicated as labor productivity. This fact implies that industries characterized as labor intensive are not treated equally in relation to low-labor intensive industries. Comparing only labor productivity may not reveal productivity development in other factors.

To conclude, it can be said that productivity analysis at macro level (industry or economy) is a complex statistic process. This process includes lots of simplistic steps (e.g. deflation method) which aim at making data comparable over time and across enterprises and countries. To name a few, the following provides examples why such data is often incomparable (Mahony and Timmer, 2009):

- Data collection differences at national level.
- Labor input data does not cover all self-employed.
- Labor input data differs because of variations in contracts of employment.
- Multi factor productivity data differs depending on differences in vertical integration of firms.

When discussing about productivity analysis and growth accounting, Mahony and Timmer (2009) have put it in a simple form: *"…it should be emphasised that growth accounting is useful as a descriptive tool but that it is merely accounting and says nothing about causality."*

THE STATE OF PRODUCTIVITY IN FINNISH CONSTRUCTION INDUSTRY

Here, publicly available data from the EU KLEMS database was used for analyzing the state of Finnish construction industry from the productivity viewpoint. Analysis of the state of Finnish construction industry was made by comparing it to other main industries in Finland and its international counterparts. Industry classification is based on the EU KLEMS' classification of the main industry segments. Countries selected for international comparison were chosen to represent the considerable players in Europe (German and United Kingdom), Aasia (Japan) and United States. Denmark and Sweden on the other hand should ensure a good comparison with Finland, because of their location and size.

The EU KLEMS Growth and Productivity Accounts are financed by the European Commission to analyze productivity in the European Union at the industry level. The database has been largely constructed on the basis of data from national statistical institutes and is processed according to agreed procedures. It aims at moving beneath the aggregate economy level to examine productivity performance of individual industries and their contribution to aggregate growth. (Timmer et al., 2007).

Industry comparison in Finland

Figure 3 represents labor and total productivity development in the main industries in Finland over years 1970-2007. Both measures are based on gross value added per inputs. Input factor for labor productivity is hours worked while for total productivity capital, labor, energy, material and service inputs are taken into account.

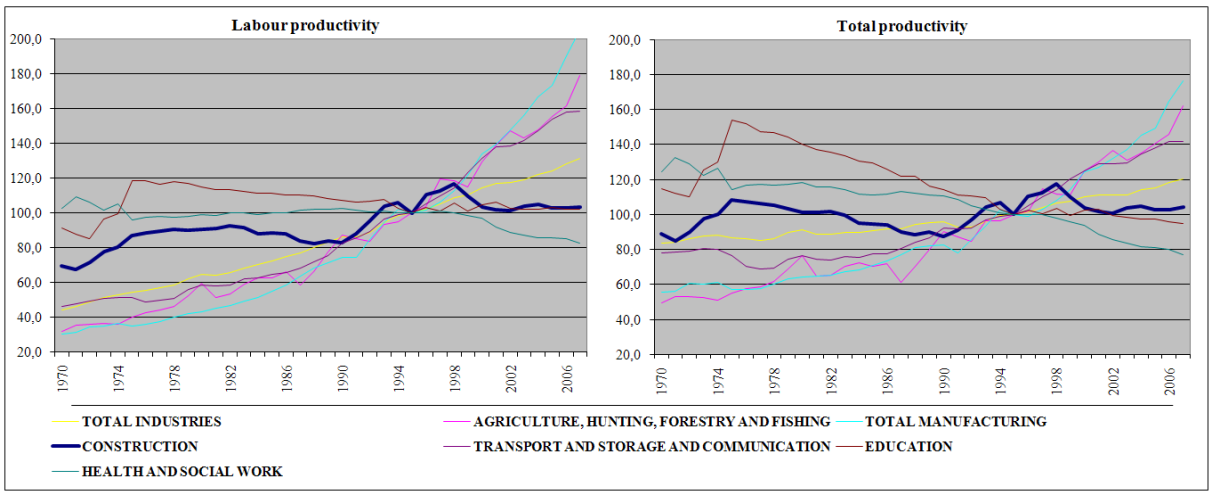

Figure 3: Labor and total productivity by industry in Finland, year 1995 = 100.

It appears that there are no big differences between labor and total productivity curves of a specific industry. And not surprisingly, most of the industries have positive trends. Still, there are industries that have stayed more or less the same over time and only education, and health and social work seem to have negative trend over longer time period. Surely productivity development efforts are done in every industry so how the negative trends are even possible? Because all graphs are based on indices (year 1995 = 100) it cannot be argued too deeply which industries are doing relatively better than others. Only the development rate between years can be learnt. Therefore, rather a few conclusions about the level of productivity of different industries can be made and even less can be said about causes behind the results. However, since the curves are rather smooth or having a smooth trend it seems that no individual innovation does play a remarkable role in productivity development. The trend of smooth development does imply that improvements are gained through continuous, step-by-step practices typical to lean thinking and described by i.e. Womack and Jones (2003) and Liker (2004).

The differences between industries are more likely to emphasize different business characteristics i.e. labor, capital or material intensiveness and maturity of the industry rather than inability or unwillingness to develop. Also the fact that monetary terms are mixed in productivity measurement should be considered. Remembering that the concept of productivity relates to physical phenomena it is even still variously expressed in monetary terms (Tangen, 2005). Surely every industry has better practices now than those used decades ago. It is also hard to believe that material, energy, capital or any physical efficiency would be so much worse now to explain declines over such a long time period. As Fiume and Cunningham (2003) have stated, changes in productivity requires physical change and thus cannot be made solely in the numbers from accounting or through financial engineering.

It can be concluded that construction industry has shown a steady positive curve compared to other industries, but it cannot match the development rate of the best ones and stays below the average of all industries. Construction industry can be considered a mature industry so it might be that there are fewer possibilities for improvement than in evolving manufacturing sector. Actually the newest of the industries, information technology, if separated from class of transport, storage and communications, would probably outpace

even the manufacturing sector itself. In other words, the different industries have a different development potential for small, continuous and natural development. IT sector benefits from constantly evolving products and it can take most out of the economies of scale. Also the value they provide to customers can outmuscle the cost of used resources hundredfold (e.g. in mobiles) which is not generally possible in construction. This in turn will come along to above figures if monetary terms are used to measure total output of industry.

International comparison of construction industry

Figure 4 provides international productivity development comparison in construction industry. Availability of data from each country differed slightly, thus curves can have different starting points. Input and output factors used are same as in industry comparison above. Both labor and total productivity were analyzed between the years of 1970 and 2007.

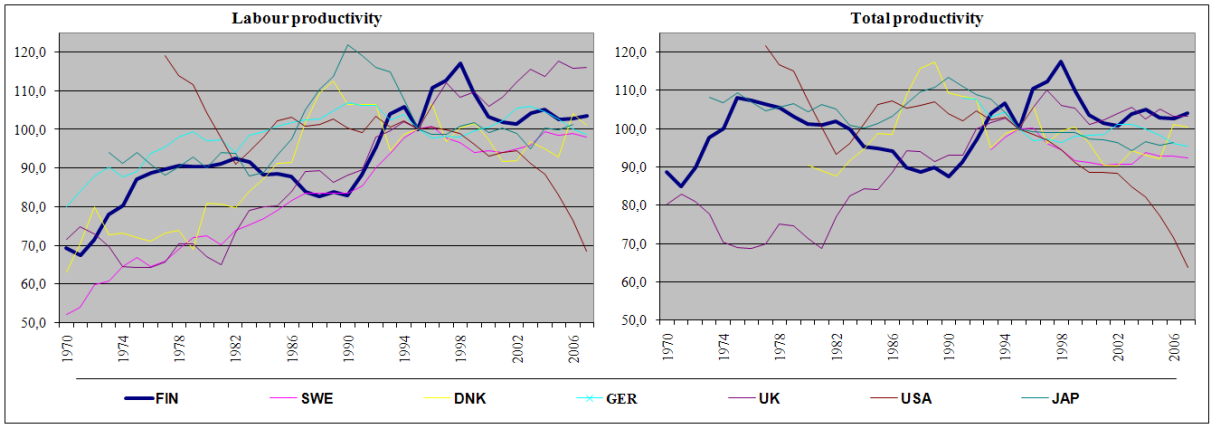

Figure 4: Labor and total productivity in construction industry, year 1995 = 100.

Figure 4 shows that the highest growth in labor productivity has been gained in Sweden, which has almost doubled its labor productivity during the period under review. United Kingdom and Denmark are slightly above Finland, but what is most striking is the long-term decline in the USA in both labor and total productivity. This seems a bit odd, concerning that other industries have remarkably better trends in both charts and raising doubts about validity of data used in this survey.

High up and down turns can be detected in this figure. Moreover, it seems that in general, growth in labor productivity has stopped or started to decline slightly between years 1989 - 1998. Alterations to the statistical procedures could be one explanation for such steep up and down turns, but they are unlikely to be the reason for long-term trends.

Productivity has increased more or less in some depth in all countries. The reversed case in the USA appears somewhat impossible. There must be differences in working methods and data collection at national level which can explain such movements. However, comparing countries within the same industry, providing same kind of products and services is more reasonable than conducting an economy-wide survey. Nevertheless, it is unclear whether or not the statistics are comparable with each other and which are the factors influencing

curves. Once again, it has to be noted that not many conclusions about relative productivity levels between the countries can be made based on these charts.

State of Finnish Construction Industry

Based on the above findings, it can be said that internationally, productivity development in Finnish construction industry has been slightly above the average level. It does not stand out as world class, but it is close to the industry's best performers. On the other hand development appears to have stopped from the year 2000 onwards, but the situation is same in the other countries too. In industry comparison the Finnish construction industry sets up slightly below average of the industry total, but its development curve appears to be steadily positive in long-term. Still the raise level is only about 1% in year during the last 30 years for labor productivity and less than half of that for total productivity. This may be the evidence of the maturity of the industry or the failing to embed the culture of continuous improvement and lack of tools to tackle other but value added activities on daily basis.

In general, construction industry has the same potential as anyone to eliminate its waste activities. It is true that the industry has its own peculiar characteristics like unique projects, site production and temporary multi organizations. (Koskela, 1992; Ballard and Howell, 1998). Also regulatory intervention of authorities can be considered one peculiarity (Koskela, 1992). But the emphasis on the construction industry is still too much on costs associated with materials and labor. In projects that are split in smaller and smaller pieces to be contracted this eventually leads to sub-optimization. To support this notion, Koskenvesa et al. (2010) state that the waste aspect is not paid enough attention to in the production planning and control processes in construction.

A lot have been said about the reasons of slow or declining productivity in construction industry. One interesting point was highlighted in the mid-1990s by Allen (1985) who explained the declining curves with a change that the industry has experienced. The outputs are changing a lot in the industry and emphasis is in different kinds of outputs now what it was decades ago. In general projects become more complex all the time. Teicholz (2001) states that productivity trends in different sectors of construction need to be better understood, because different sectors are most likely to be experiencing opposite kind of development in productivity. Also many firms who construct prefabricated units are classified as manufacturing firms, which in turn have experienced rapid development during the last decades.

Many more authors have given their contribution to identify the causes behind productivity development. Reduction of skilled labor, management capability, procurement, regulation and technology are only some of the reasons identified and discussed, but one which often comes up is the quality of construction work. It is mentioned that design problems constitutes almost half of the construction defects when measurement is done with the principle of "cost to correct". The other half splits almost equally between supervision and workmanship problems (Productivity Taskforce, 2009). Anyway, guidelines in construction set only the minimum level for quality (Saarenpää, 2010), which is opposite to the "zero defects principle" which forms the other basic pillar in lean thinking utilized in growing rate

in manufacturing firms all over the world. These kind of artificial acceptable quality levels are counterproductive and can only be striped with a cultural change towards quality.

IMPLICATIONS OF PRODUCTIVITY DEVELOPMENT IN CONSTRUCTION

In theoretical review on productivity it was stated that productivity is ambiguous concept which is usually used for macro level comparisons and to explain national growth. Analysis on Finnish construction industry showed that the development has been steady but slow and lack behind many other industries in Finland. Here are the main implications for productivity development learned in this study.

Focus to micro level measurement

When analyzing macro level productivity graphs one can only look backwards which is not of much help for improving productivity in future. The causes behind results stay hidden which leads to endless debate between the possible causes, and both validity and reliability of the results. Macro level approach to productivity is used to examine productivity performance of individual industries and their contribution to aggregate growth (Timmer et al., 2007) in relation to past performance of other nations or industries. Macro level measurement and measures based on monetary value are too rigid to be effective in developing productivity and too slow to help companies to make better decisions for the future.

Koskela (1992) have stated that measurement data is needed for two purposes: as a driver for internal improvement and for targeting and benchmarking projects and organizations. Measurement should always yield reasonable and comprehensible information in the first place as it is difficult to improve productivity or any other important factor without knowing the impact of decisions made (Hannula, 2002). Revealing root causes behind productivity and performance changes support this aim and since the physical change that is required for productivity increases takes place at micro level, it looks obvious to return closer to that level. Figure 5 shows examples of the levels productivity can be examined. Where macro level measurement is suitable in order to grasp a view of an overall situation, the bottom-up approach at a lower micro level is needed in order to seek and find real opportunities for productivity improvement.

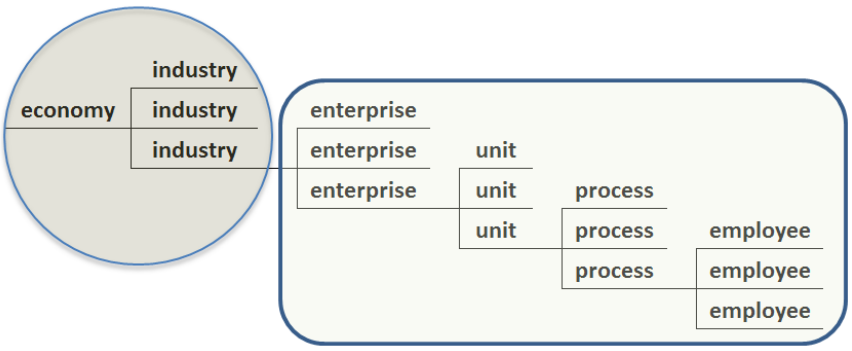

Figure 5: Levels for productivity examination.

Reliable and comparable results

In addition to reliability, measurement should provide also comparable results. Industry level productivity development programs could learn a lesson by following automotive industry's example. There an extensive benchmark study was conducted to develop the future of the industry in the late 1990s, which led to results describing how lean production system works in great detail. The comparability problem was taken seriously in that study and assembly was identified as a key activity in automotive manufacturing. Assembly was also a good choice because all plants over the world do almost exactly the same things, relying on very similar fabrication techniques. Within assembly a list of standard activities was further devised to be assessed and measured, making sure that they are comparing apples with apples. (Womack et al., 2007).

In construction there are similar possibilities to conduct wider studies to understand and then develop productivity. Even though there is no Toyota like example for the construction industry yet, it can be done to understand how the industry works as a whole. There are also similar characteristics of labor intensive work phases in design and assembly, and operations are also more or less based on similar fabrication techniques all over the world. On the other hand the practices vary between workers, companies and nations, which lead to the need of measurement method standardization, benchmarking and unifying the best practices within industry as part of the continuous improvement theme.

Only comparable information will give a real picture of any system at any level. In practice this means that definitions of what is being measured and improved must be done carefully and with great detail. The focus should be in factors that are important, but also measurable. This should be done without becoming too bureaucratic or inflexible, because measurement consumes resources as any other activity. Measuring should focus on critical factors affecting overall performance and it should be carried out with a reasonable amount of effort (Salminen, 2005).

Holistic measures drive productivity development

Productivity as a measure is complicated to use, because of so many base-level decisions what to include into outputs and inputs, and also how to carry out the measurement itself. The process is so complex that management decisions cannot be made according to results from productivity measurement. Instead, several performance factors do contribute to productivity and are also easier to define and measure. Using the formula of outputs-inputs can sometimes be deceiving in determining overall performance. Performance measurements that reflect the operational strategy of the company should be developed and used. (Singh et al., 2000). Therefore, performance development should be controlled and supported using a holistic set of performance indicators. Information about quality, costs, time, safety, leadership and motivation is usually available for this purpose, but still every company has to define its own indicators to match its long-term goals.

Stainer (1997) states that management must choose the productivity measure which would produce the most relevant information for their strategic decision making. Measurement should help companies to anticipate future, judge and fine-tune current performance and to

compare them to past performance. One way to approach this is balanced scorecard where financial performance shows the past, customer perspective and internal business processes the present and the measures for innovation and learning aim to anticipate the future (Kaplan and Norton, 1996). It is not that productivity itself would not be important, but the chain of cause-and-effect relationships (Figure 6) is suchlike that requires more flexible and up-to-date measures to enhance the productivity performance in the process.

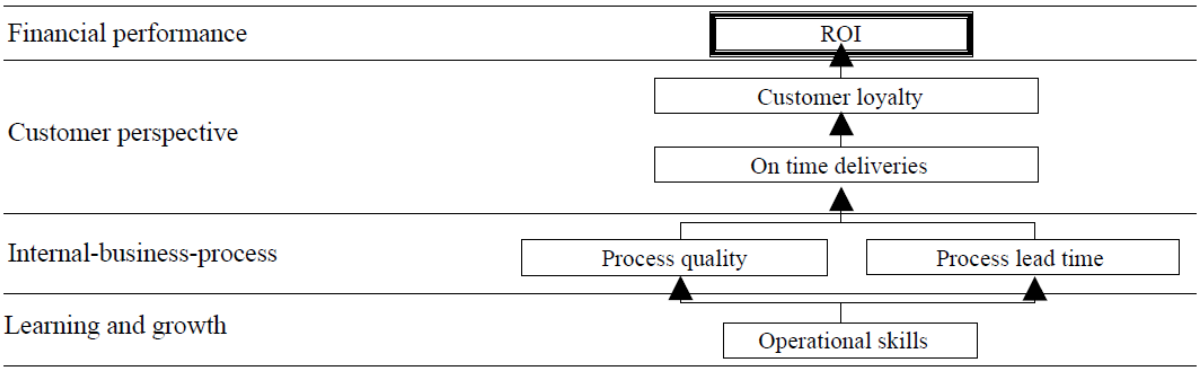

Figure 6: The chain of cause-and-effect relationships through the BSC perspectives (Kaplan and Norton, 1996).

CONCLUSIONS

In this paper the basic meaning of productivity and its similar terms were explained. The characteristics of productivity measurement were considered and further tested in the analysis of Finnish construction industry. A lot of effort has been used in the past to study productivity at macro level which has led to controversial results and endless debate of their validity. This study does not even try to represent its own version of truth, but it shows how hard it is to interpret and compare macro level analysis. According to the results of this study, the Finnish construction industry does basically all right when compared to its international counterparts. The comparison to other industries in Finland shows that the productivity development has been steady for long time, but not as rapid as it has been in some other industries. Implications from multi-dimensional characteristics that productivity has and from productivity development analysis in construction industry are, that the productivity should be approached at micro level and with more physical measures to reveal causes behind good and bad performance. Then the reliability and comparability of the results should be ensured by standardizing measurement methods within scope and measurement period. At last but not least, the use of holistic set of performance measures is recommended as productivity itself seems to be affected by many different factors, but as a measure it is too rigid and slow to be useful in developing and proactive management.

ABSTRACT

This study aims at better understanding the relationships among software engineering capabilities and profitability, as a representative business performance, of software vendors in the drastically changing IT industry in Japan. To do so, we designed a survey on software engineering excellence (SEE) and administered it in 2005, 2006 and 2007 with the Japanese Ministry of Economy, Trade and Industry. Then, we measured the SEE survey results with regard to seven factors: deliverables, project management, quality assurance, process improvement, research and development, human development, and customer contact. Based on the longitudinal modeling of the three-year SEE data and ten-year operating profit ratio of the 151 respondents to the SEE surveys, we significantly verified that IT firms who have excellent software engineering capabilities tend to improve their business performance in a medium- and long-term standpoint.

Keywords: software engineering capability, longitudinal modeling, social research

INTRODUCTION

Many companies that use enterprise software in Japan have not been fully satisfied with the quality, cost, speed and productivity of software that IT vendors deliver. At the same time, IT vendors in Japan are facing drastic changes in their business environment, such as technology innovations and new entrants from China, India and other countries. Also, the issues in the IT industry in Japan, such as the multilayer subcontractors and the business model depending on custom-made applications for domestic market orientation, have been pointed out over times (Cusumano, M., 2004; Kadono, Y., 2007).

The information service industry is a 10.5 trillion yen market in Japan, which includes 7.6 trillion yen in software development and programming. In 2009, orders for software totaled 6.4 trillion yen, accounting for 60.3% of the entire information service industry, while the software products market was 1.2 trillion yen (METI, 2010).

In order for the IT industry in Japan to meet these challenges, an important step is to understand how software engineering capability is significant as a core competence for achieving medium- and long-term success. Therefore, we designed the research on software engineering excellence and conducted it in 2005, 2006 and 2007 with Ministry of Economy, Trade and Industry, Japan.

As shown in Figure 1, the objectives of the research are to:

- assess the achievements of the Japanese software engineering discipline, as represented by IT vendors in Japan, and
- better understand the mechanism of how software engineering capabilities relate to IT vendors' business performance and business environment.

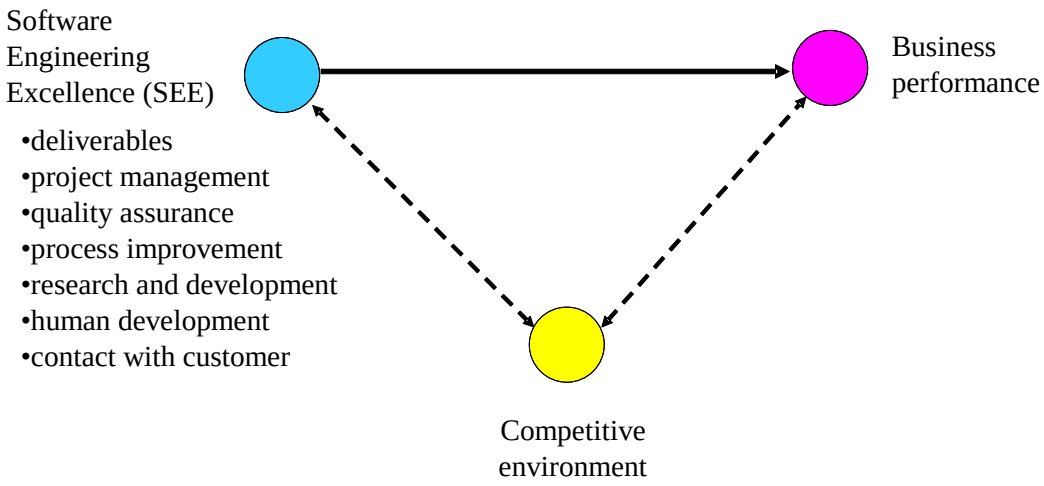

Figure 1: Conceptual model of overall SEE research.

To achieve these objectives, we developed a measurement tool called Software Engineering Excellence (SEE), which can evaluate the overall software engineering capabilities of IT vendors from the viewpoint of deliverables, project management, quality assurance, process improvement, research and development, human development, and contact with customers (Kadono et al. 2006). Also, we introduced other indicators: business performance and business environment. We assume that the business environment complements the relationship between SEE and the business performance of the software vendors.

In the SEE2005 survey, we analyzed the relationship among SEE, business performance and business environment based on the data collected from 55 major IT vendors in Japan. We conducted the path analysis, during which we found that SEE characteristics have a direct positive impact on business performance and that the competitive environment directly as well as indirectly (i.e., via SEE) affects business performance in the same year.

In the SEE2006 survey, we increased the number of surveyed Japanese IT vendors from 55 to 78 in order to more deeply investigate the impact of software engineering on business performance and the business environment. In particular, in this study we focus on the relationships among the SEE factors, the business environment, and business performance as measured by operating profit ratio in the same year (Kadono et al., 2007). By analyzing the data collected from 78 major IT vendors in Japan, we found that superior deliverables and business performance were correlated with the effort expended particularly on human resource development, quality assurance, research and development and process improvement at 5% significance.

In 2007, we analyzed the data collected from 100 major IT vendors in Japan. At that time, we reproducibly observed that the level of effort expended on human resource development, quality assurance and project management improved the performance of the IT vendors in Japan in customer contact, research and development and process improvement, the same tendency we found in 2006. However, we also observed that the causal relationships differ significantly depending on the vendors' origin, i.e., whether a business is a makers-turned vendor, a user-turned vendor or an independent vendor (Kadono, Tsubaki, Tsuruho, 2009).

In the previous paper (Kadono, Tsubaki, Tsuruho, 2010), we analyzed the relationships among the seven factors of software engineering capabilities and significantly verified the following results since human development and R&D should be statistically regarded as one concept, and the same aggregation can be suggested the relationship between project management and process improvement.

- Human development and R&D are significantly influential factors on the overall software engineering capabilities.
- Negative paths, e.g., from human development/R&D to deliverables, imply that effort invested in some factors did not pay off at least during the duration of this research. They might, however, be expected to have long-term effects. Otherwise, they might suggest the tradeoff between the factors, e.g., quality assurance and customer contact.
- The factors at the lower stream, e.g., deliverables, should be interpreted in relation to the other factors such as business environment and business performance.

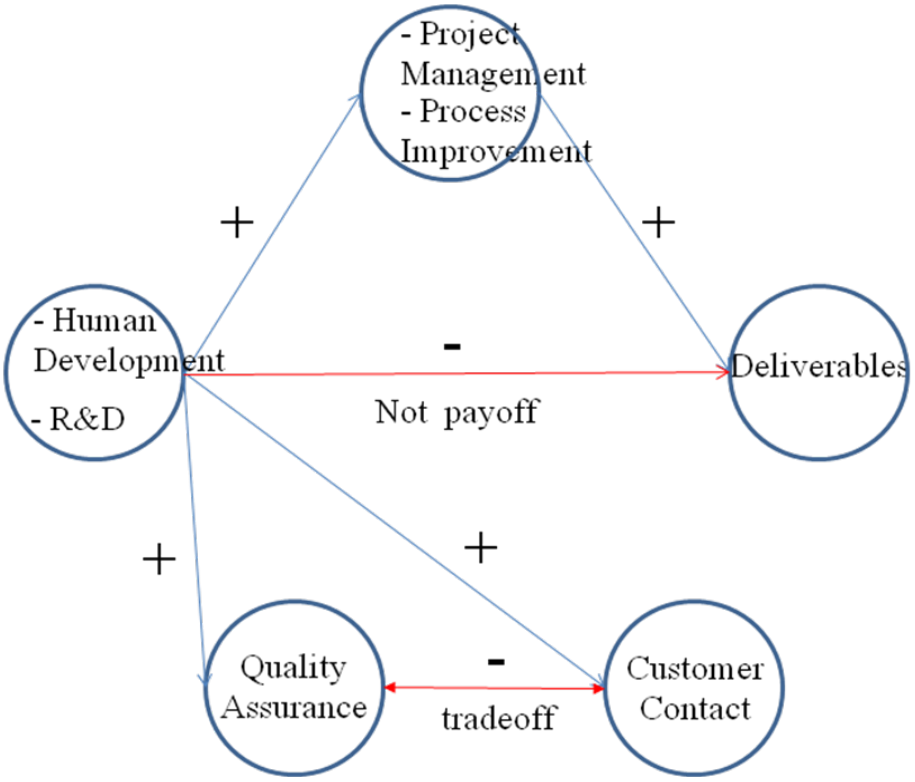

Figure 2: Implications of path analysis among SEE factors (Kadono et al., 2010).

Based on the above findings, the areas of software engineering should be managed in the future in the following way. First, human development and R&D should be considered to be fundamental capabilities to improve the quality of deliverables. Second, among the seven software engineering capabilities, improving project management and process improvement could be expected to be an immediate effect on deliverables. Third, on the contrary, quality assurance and customer contacts might need long-term efforts to be successful.
Therefore, based on the three-year SEE survey data, we verified that learning order effects among the seven software engineering capabilities contributes to software engineering improvement.

In addition to the analysis on the relationships among the seven SEE factors, in the present paper, we expand the research method to the analysis on the relationships between software engineering capabilities and business performance based on the longitudinal modeling. Here, we focus on the operating profit ratio as a representative business performance.

RESEARCH MODEL

We introduce the structural model and the measurement model of the research on software engineering excellence (SEE) in this section.

Structural model

Based on the interviews with successful IT vendors in Japan, we hypothesize that firms who have excellent software engineering capabilities tend to improve their business performance in a medium- and long-term standpoint. Therefore, we assume a path model as shown in Figure 3. Here, SEE consists of SEE2005, SEE2006 and SEE2007 and business performance is measured by a representative profitability factor, i.e., operating profit ratio, from 1999 through 2008 in this paper.

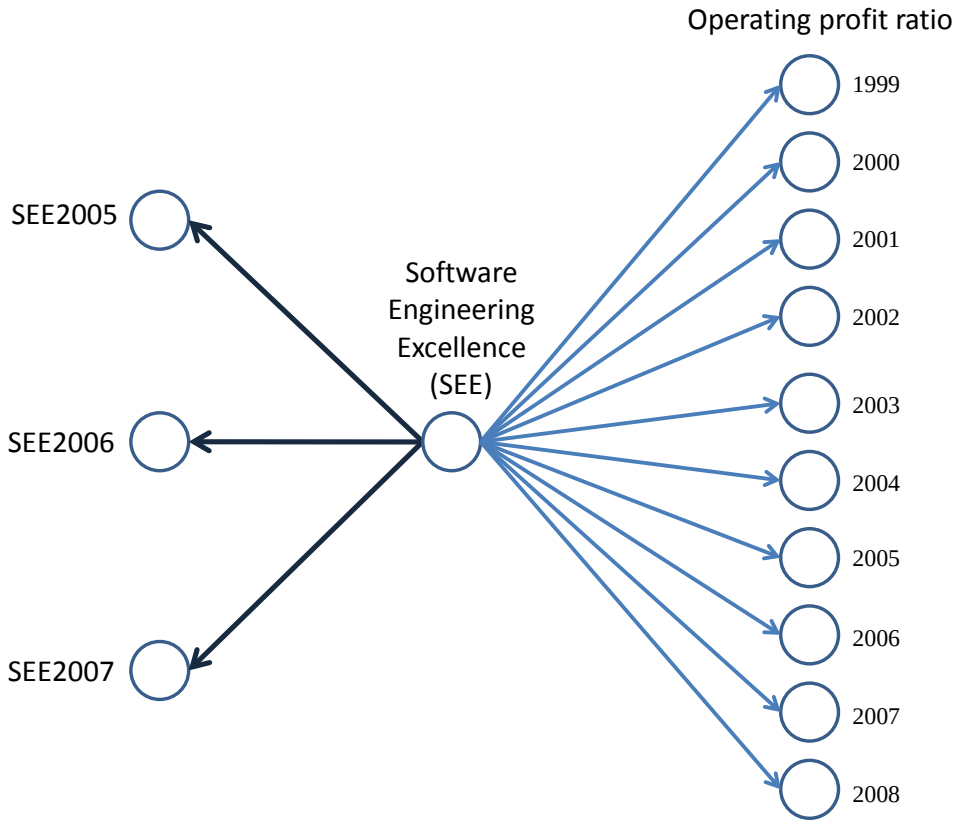

Figure 3: Structural model hypothesis.

Measurement model

Our measurement model of SEE was originally developed through interviews with over 30 industry experts in Japan and the U.S. as well as literature searches (Fujimoto, 2003; Matsumoto, 2005; Ministry of Economy, Trade and Industry, 2007). Since this research intends to encourage innovation, we surveyed state-of-the-art cases from the viewpoints of marketing, process, and product in order to develop our measurement model. Therefore, the scope of the survey includes intangible resources of vendors based on the resource-based view (Barney, 2007).

The SEE measurement model has a hierarchical structure with three layers: observed responses to question items, seven detailed concepts, and SEE as a primary indicator (Kadono et al. 2006). The measurement models for 2006 and 2007 were updated slightly based on the response rate of each question item, the statistical significance of each observed response to the 2005 and 2006 SEE surveys, and changes in technology and market trends.

SEE as we have defined it consists of the following seven concepts:

- deliverables: achievement ratio of quality, cost, speed, and productivity, grip on project information.
- project management: project monitoring, assistance to project managers, project planning capability, ratio of PMP(Project Management Professional).

- quality assurance: organization, method, review, testing, guideline, management of outsourcers .
- process improvement: data collection, improvement of estimation, assessment method, CMM/CMMI (Carnegie Mellon University's Capability Maturity Model Integration).
- research and development: strategy, organization, sharing technological skills, learning organization, development methodology, intellectual assets, commoditized software, readiness to state-of-the-art technology.
- human development: training hours, skill development systems, incentive schemes, measure of human development, moral support.
- contact with customers: ratio of prime contracts, scope of service offered, direct communication with customer's top management, deficit prevention, clarification of user specification.

Regarding the operating profit ratio as a representative business performance, we uniquely identified 151 IT firms responding to the three SEE surveys and calculated their operating profit ratios from 1999 to 2008 according to the corporate information of a Japanese credit research firm. Based on the time series data, we estimate the intercept and the slope of the operating profit ratios of the respondents for ten years.

SURVEY ON SOFTWARE ENGINEERING EXCELLENCE

Based on the measurement model, we conducted surveys on Software Engineering Excellence in 2005, 2006 and 2007 with Japan's Ministry of Economy, Trade and Industry. We designed a questionnaire on the practice of software engineering and the nature of the respondent's company. This questionnaire was sent to the CEOs of major Japanese IT vendors with over 300 employees as well as the member firms of the Japan Information Technology Services Industry Association (JISA), and was then distributed to the departments in charge of software engineering.

Responses were received from 117 companies with a total of 100 valid responses to the 2007 survey, a response rate of 10%. There were 55 valid responses, a response rate of 24%, for the 2005 survey and 78 (response rate of 15%) for 2006. For this paper, we integrated the 233 valid responses received over the three years into a new database including 151 unique companies consisting of 42 maker-turned vendors, 33 user-turned vendors and 76 independent vendors (Table 1).

Table 1: Software engineering excellence surveys.

Year	2005	2006	2007	2005/06/07
Questionnaires sent	230	537	1000	NA
Valid responses	55	78	100	151
Maker-turned User-turned Independent	17 15 23	27 15 36	27 20 53	42 33 76
Response rate (%)	24	15	10	NA

After collecting data from the vendors in 2005, 2006 and 2007, we calculated the factor loadings of seven factors: deliverables, project management, quality assurance, process improvement, research and development, human development and customer contact, based on the responses received to the questions relevant to the measurement model described in the previous section (Kadono, Tsubaki, Tsuruho, 2009).

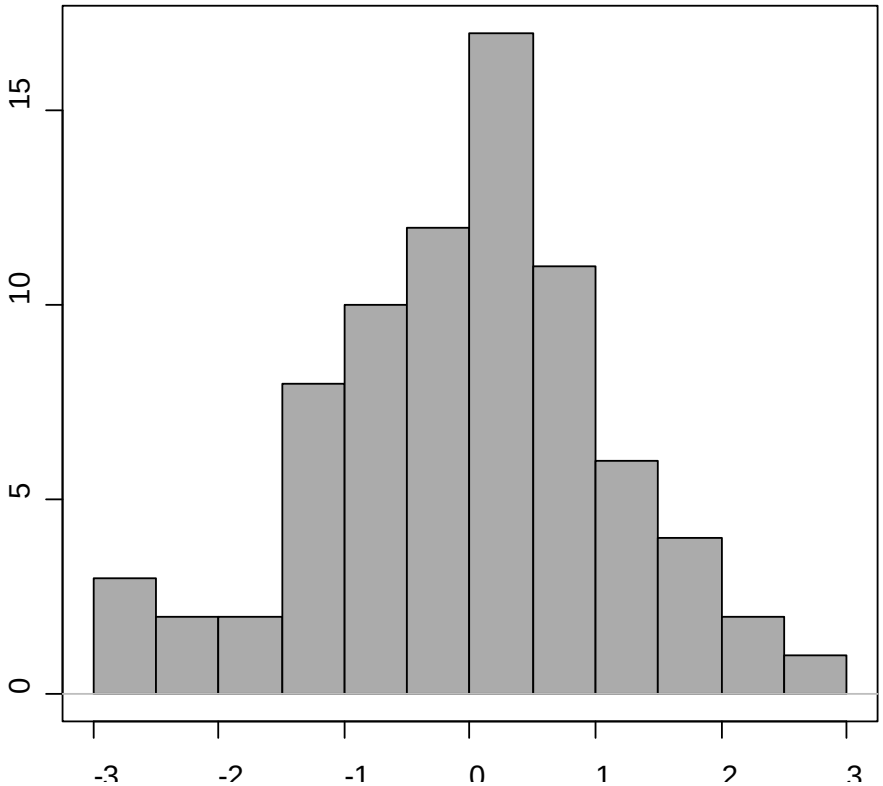

Figure 4: Histgram of deviation of SEE2006.

Then, the measurement model is fitted to the data by confirmatory factor analyses to estimate the score of SEE each year. For example, a histogram of deviation of the SEE2006 score is shown in Figure 4, and a scatter plot diagram matrix of the seven factors and SEE2006 is shown in Figure 5.

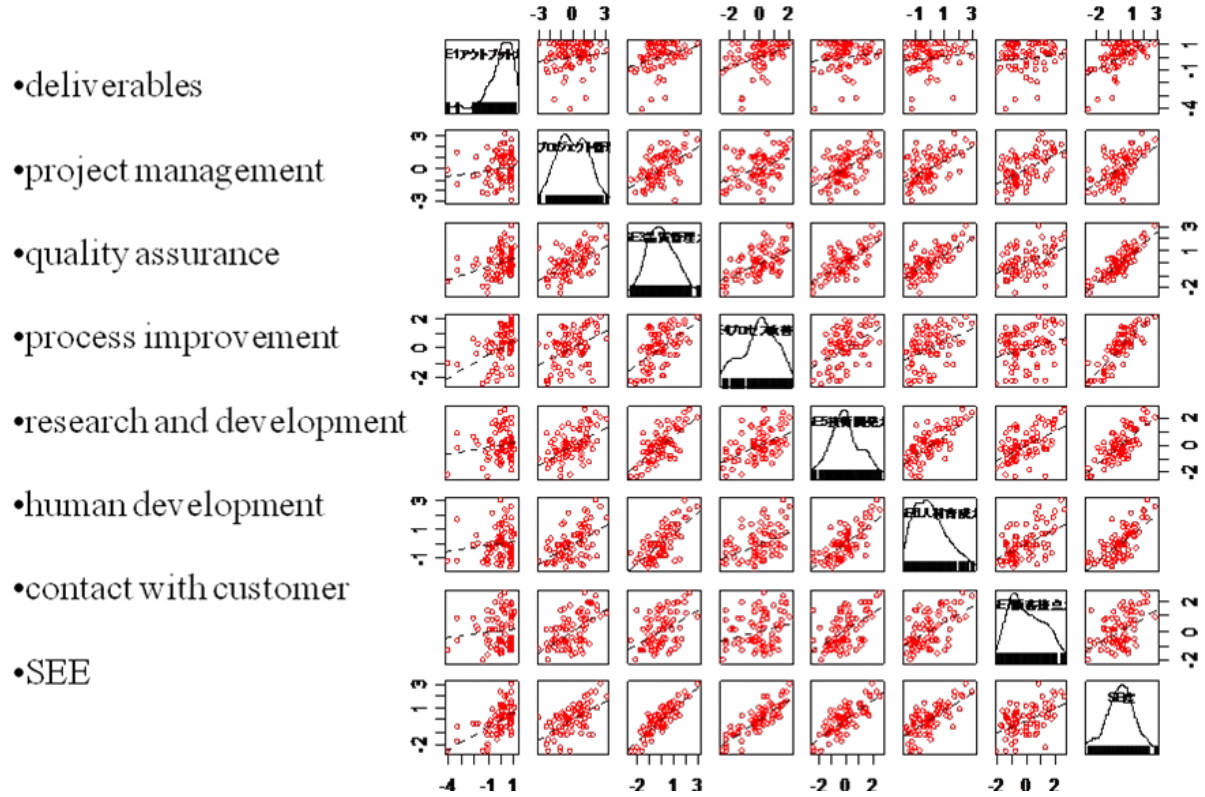

Figure 5: Scatter plot diagram matrix of the seven SEE factors and SEE2006.

In this paper we aggregate the three-year SEE scores, i.e., SEE2005, SEE2006 and SEE2007, to estimate overall SEE scores (Figure 3).

RESULTS

Based on the structural model hypotheses in Figure 3, we conducted path analysis of the data from the 233 valid responses we had received to the 2005, 2006, and 2007 surveys from 151 unique firms (Bollen, K. 1989). The result of the path analysis is shown in Figure 6. We found the following to be characteristics of the significant relationships among three-year SEE scores and ten-year operating profit ratios:

- Regarding SEE, overall SEE is relating to SEE2005, SEE2006 and SEE2007 at 0.1 % significance.
- Overall SEE has a positve impact on the intercept of operating profit ratio for ten years at 10 % significance.
- Also, overall SEE has a positve impact on the slope of operating profit ratio for ten years significantly at 5 % significance.
- The fittness of the model (CFI) is 0.415.

These results imply that the IT vendors with higher SEE, i.e., excellent software engineering capabilities, have improved their operating profit ratio in a medium- and long-term based on the ten-year financial data.

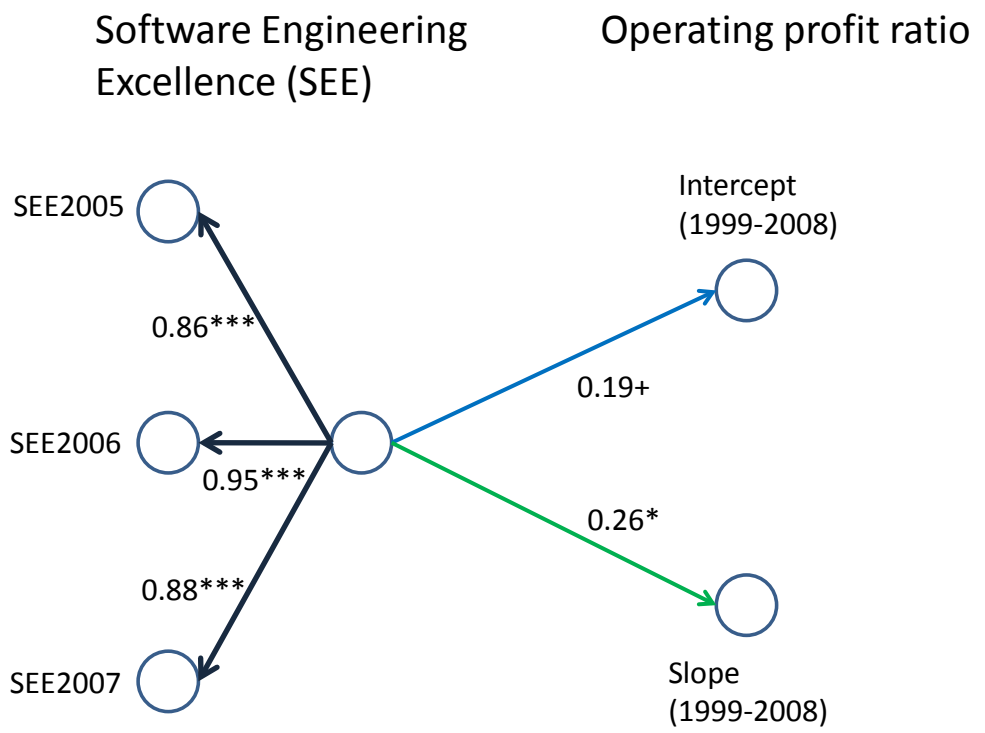

Figure 6: Path analysis results.

CONCLUSIONS

In the present paper, we significantly verified that firms who have excellent software engineering capabilities tend to improve their business performance in a medium- and long-term standpoint, based on the longitudinal modeling according to the data of three-year SEE surveys and ten-year financial data of IT vendors responding to the SEE surveys. In this paper, we focus on the relationships between overall SEE scores of the three surveys and the operating profit ratio as a representative business performance. For the future study, we would expand this longitudinal model so that we can analyze the relationships among the seven SEE factors, i.e., deliverables, project management, quality assurance, process improvement, research and development, human development, and customer contact, and other financial indicators such as the profitability and stability of management (Figure 7). The SEE part in the left-hand side of Figure 7 is the hypothetical model among the seven SEE factors adopted in the previous paper (Kadono, Tsubaki, Tsuruho, 2010).

Furthermore, the analysis of the relationships among SEE, business performance and business environment (Figure 1) e.g., number of software engineers, business model, and average age of employees, remains to be solved in the future.

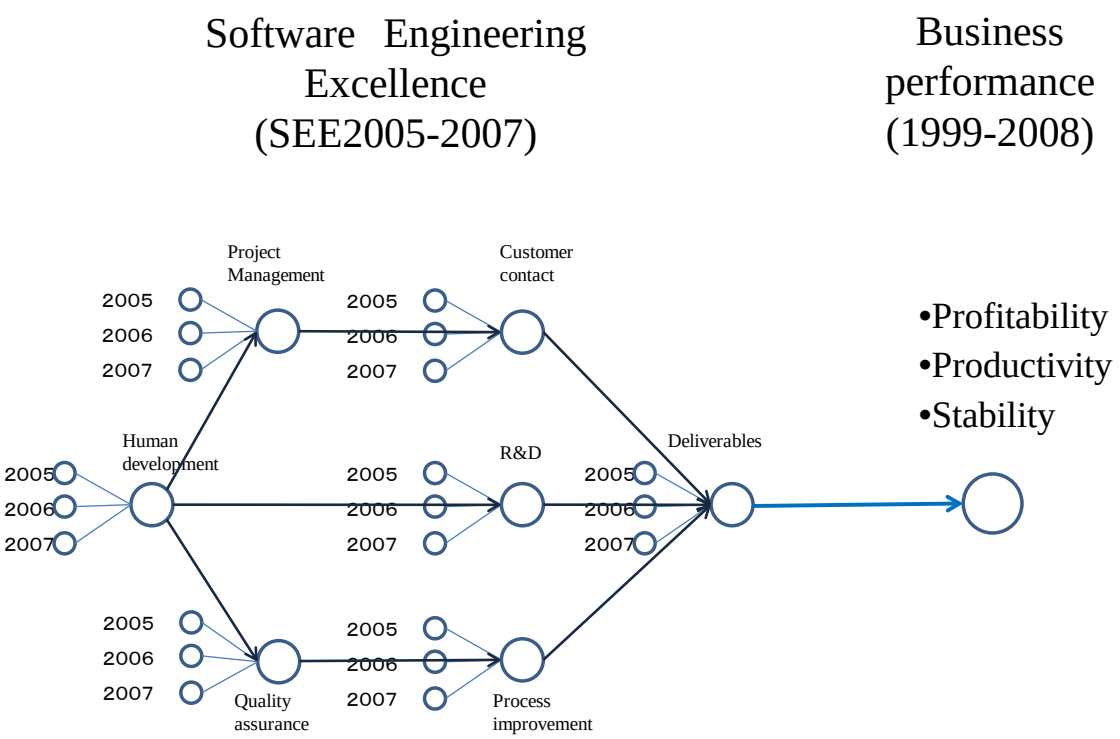

Figure 7: Hypothetical model of relationships between SEE and business performance.

ACKNOWLEDGEMENTS

ABSTRACT

This paper comparatively analyzes the technology strategy of innovation and its performance among three Chinese IC (Integrated Circuit) design firms. The intention was to clarify how technology strategy affects the outcome of technology innovation in the process of catching-up. The research question was studied from four aspects such as technology selection, technology opportunity, technology monopolization and resources required for technology innovation. The results show that the selection of technology strategy is of great importance for Chinese IC design firms to catch-up by technology innovation.

Keywords: Fabless Design Firm; Innovation; Technology Strategy

INTRODUCTION

It is necessary for Chinese firms to innovate by technology to catch-up their competitors in global competition. Many studies have analyzed late mover's advantage in technology innovation and its influence to the firm and industry in catching-up process (Shankar, Carpenter&Krishnamurthi, 1998; Lee, 2001; Huang, 2002). How to build the competitive advantage for the late mover through creative imitation, lower risk and lower cost of innovation compared to the first mover is always be focused. Our argument is that late mover's advantage is over stressed compare to the neglect of late mover's disadvantage in developing countries. As the latecomer in developing country, Chinese firms are confronted dual disadvantages. One is the common disadvantage confronted by followers in developed country, the other is the peculiar disadvantage faced by firms in developing country (Gao 2006). A key question for Chinese firms on innovation is how to choose a proper technology strategy to

utilize the advantage and to avoid disadvantage of latecomer.

This paper focuses on the impacts of technology strategy on the performance of innovation by comparatively analyzing the practices of three Chinese IC design firms. The research question is how technology strategy affects the outcome of technology innovation in developing country's firms to catch-up. It will be studied from four aspects, e.g. technology selection, technology opportunity, technology monopolization and necessary resources of technology innovation. The research results are expected to give some highlights on how Chinese firms acquire competitive advantage through technology innovation.

THEORETICAL BACKGROUND AND FRAMEWORK

A Review of the literature

The catching-up of developing countries has been paid more and more attention since 20'90s , From the perspective of national innovation system, Wong (1999) stated that the initial industrial condition has an important effect on the path choice of catching-up through analyzing the rapid caching-up process of semiconductor industry in Taiwan, Korea and Singapore. From the angle of technological regime, Breschi et al. (2000) presented that the technology regime will influence the technology catching-up of industries in developing countries, and measured the technology regime through many factors such as technology opportunity, rationality of innovation and the accumulation of technology. Through the case study of Korea, Lee and Lim (2001) concluded that the catching-up is easier to achieve in the regime that technology innovation occur frequently and is foreseeable. From the perspective of international innovation diffusion, Perez and Soete (1988) presented that sectors in developing countries that want to achieve technological catching-up through innovation, not only bear the fixed costs of innovation, but also pay the other costs to gain the resources required by catching-up, such as knowledge of science and technology relevant to innovation, experience on organizing, managing and marketing of innovation. They also presented that the opportunity for follower catching-up occurs in the period of technology paradigm transition. These literatures analyzed the catching-up from the industry level. A sector or an industry was looked as the research object and the black-box of firm's catching-up was not opened. Although many meaningful conclusions have been made, the theories can not explain the different technology innovation performance among firms in the same catching-up industry. To make up the shortage of studies mentioned above, some research is done from the micro-level. Lu and Mu （2003）had studied the indigenous innovation, capability development and competitive advantage in Chinese VCD industry, and presented that the innovation based on the characteristics of local demand is a necessary path for Chinese firms achieving technology catching-up. Gao (2005) pointed that emerging technologies supply an opportunity for developing countries to develop core technology with intellectual property right (IPR) and to catch-up. Gao presented the choice of technology area is very important to overcome the disadvantages of latecomer by analyzing the difficulties faced by Chinese firms in innovation independently. Wang and Yin (2007) apply the theory of emerging technology management to

analyze the innovation of Chinese firms. The study gave some suggestions to policy maker from the perspectives of industry environment and the evolution of technology strategy.

Theoretical Framework

Previous studies about catching-up on both levels have important light not only on the further research but also on the innovation practice of firms. But one question is how the industry-level factors such as technology regime affect the micro-level outcome such as technology innovation. Our arguments are that firm's technology strategy is an important mediating variable. It constructs the link between firms behavior and industry background. Based on this logic, this paper designs the theoretical framework as Figure1:

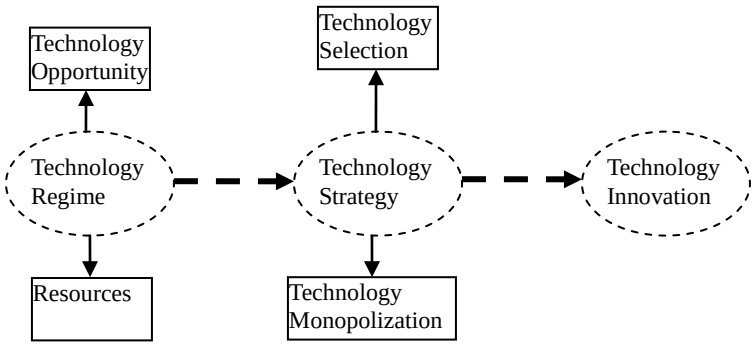

Figure 1: Theoretical Framework.

Extending the previous work (Breschi et al., 2001), technology regime includes two components, one is technology opportunity, refers to the possibility of realizing technology innovation (Lu & Yin 2006), the other is resources for the technology innovation. Perez and Soete (1988) presented that enterprises in developing countries intending to achieve technological catching-up through innovation, not only need the resources of hardware such as devices, but also need other resources including: 1) The resources to fill the gap between the internal knowledge and the knowledge required by the innovation; 2) To innovate successfully, the firm need to get the experiences and skills in organization, management and marketing; 3) It is necessary for firm to create an optimal external environment for successful innovation. The more advancement and newness of technology is and the more competition there is, the more resources are required. Additionally, the success of innovation is directly affected by the matching degree between the resources required by innovation and the operation capability of the firm. Technology strategy is measured by two constructs, one is technology selection, and the other is technology monopolization. Technology selection is one main component of technology strategy, and is the important premise to get the competition advantages of technology (Burgelman et al. 2004). The decision of technology selection will lead the different outcome of innovation and competition. Technology monopolization refers to the extent that the potential economic benefits of technology innovation monopolized by the firms developing the new technology (Day et al. 2000). When technology monopolization is in a high level, the firm will profit from the innovation. While technology monopolization is in a low level, the benefits of innovation will be minimized. The means to protect the technology monopolization include IPR, technology

confidentiality control, complementary assets management and lead time. (Day et al. 2000).

DATA AND METHOD

The reasons to choose IC design firms as sample are below. First, IC design is the most knowledge and intelligence intensive segment in IC industry. It also is the weakest one in Chinese IC industry. Due to the government initiatives and strong demand, Chinese IC design industry has had remarkable growth. From 243 companies in 2001, the industry grew to 450 companies in 2006 (Wang & Yin 2007).Despite the rapid growth, Chinese IC design firms face many problems comparing to oversea advanced firms. These problems include the low technological capability, small scale, lack of capital and IPR issue. Furthermore, Chinese IC design firms have to be confronted with the blockage to technology import. For instance, the sales of IC designed by Chinese firms only account for 8‰ of the world's total sales[1]. The core components still depend on import and the products mainly focus on the middle- and low-end market. These problems in IC design industry will restrict the further development of Chinese electronic and information industry. Therefore, it is significant for the development of Chinese electronic and information industry through studying on how IC design firms carry out technology innovation to acquire completive advantage.

This paper employs the case study method. There are four reasons to adopt the research method. Firstly, the developing history of Chinese IC design industry is short and turbulence. It is difficult to get the long-period and sequential data. Secondly, with highly creative and competitive in IC Design industry, the public data about technology innovation of the industry is very scarcity. Thirdly, because most of IC deign firms in China are start-ups and very small firms, the statistical data is very incomplete. Lastly, the case study is used for the explorative purpose. Based on the observation to the industry, the case study is suitable as the IC design firms in China can be classified into several types. Moreover, this paper comparatively studies three cases to enhance the reliability in order to overcome the unilateralism of single case.

The data in the research is mainly gathered by in-depth interview. The interviewees include the CEO, general management, the manager of R&D department and marketing department. The general information of firm and industry is collected by second-hand data such as industry database, electronic industrial journal and files of the firms. To guarantee the veracity of interview materials (Yin 2004), two interviewers were involved in the interviews. The interview material was processed by two interviewers respectively, and integrated later for further analysis.

THE CASE STUDY

IG Firm

[1] Resources from: A Global Sources, Special Issue for Electronic Engineering and China Semiconductor Industry Association, and is quoted by Sun C. X., www.esmchina.com/ART.8800068358_617671_c3df762e200605.HTM.

IG is a fabless design firm established in 2004. The founder of IG is a returnee from Singapore who owns the IPR of core technology of the firm. The firm is mainly engaged in the Intellectual Property (IP) core and Systems on a Chip (SOC） platform design and franchising. Its customers are mainly located in mainland China, Taiwan, Hong Kong and Korea. There are over 100 employees in this company. 90 employees are responsible for research and development (R&D) who working in the branch office located in Chengdu. 10 employees are responsible for marketing who are located in the branch office in Shenzhen. The first core technology is USB with the IPR by the founder. With the development of the firm, the entrepreneur realized that the rapid development of consumer electronic product would produce large scale demand for the audio coding and decoding technology. So the firm engaged into the product development of audio coder and decoder. With the rapid growth and development of the firm, the capabilities of technology innovation are improved continuously in the process of exploring new products. Up to 2008, the company could provide the design and development service for 13 types of the products. The market share accounts for 70% in domestic market segment. The products designed by IG began to be sold to Taiwan, Hong Kong, Europe and America. IG had mastered the core technology of USB2.0 PHY completely, and is the sole firm which has the ability to design the USB2.0 PHY IP in China. It is able to develop a series of USB IP with the world's leading technology in a short time. The sales revenue of the company was about CNY (Chinese currency) 100, 000 in 2004, but in 2007 its sales revenue exceeds CNY 20 million with an average annual growth rate as high as 300%. At present, the enterprise's investment of R&D account for 70-80% of the revenue, and the strong R&D supports the high-speed development of firm. In order to keep the technological advantage and lead the direction of technology innovation, IG has introduced some technical experts which have expertise required by the expanding of strategic business scope.

HW Firm

HW was established in 2005. It is a wholly owned subsidiary of a well-known Chinese home-appliance enterprises CH group. HW plays the role as IC design department of the group. The employees of HW are over 90 people, including over 10 management and administrative staff, 80 R&D staff. The establishment of HW was a strategic action for CH group to implement its strategic transition. Like most Chinese electronic makers, CH group is located in the end of the value chain, as it does not master the core technologies to manufacture a television. Especially in the fierce competition in the new business area of flat panel television, CH has to depend on imports to acquire the two core components - the core IC chips and PDP display. With the international competitive environment deteriorating, CH group decided to expand its business to the upstream of the value chain based on the long-term strategic plan. It focused on the independent innovation in the two technology field of IC chips and PDP display. This decision is support by the Ministry of Science and Technology of China, and two key projects were granted to support the independent innovation of CH. To achieve the strategic transition, CH adjusted its organization structure to set up two wholly owned subsidiary companies. One of them is HW to mainly focus on the video technology chip design and to develop the SOC design capability. The other is HS to mainly focus on the development of PDP display.

With relatively poor technical skills and talents, HW started SOC design from scratch. To fill the gap to the leading technology, the firm employed three engineers from USA. One of them works as the general manager of the firm. Furthermore, a large number of engineers were recruited to devote in the R&D. However, due to the mobility and a lack of experienced experts in IC design, the R&D works is in a slow process. As the strategic goal of HW is to supply the technological support to the transition of CH group, the R&D of HW had been focused on the basic technology with no clear target product since 2005. The R&D tasks were to accumulate technological capability and talents for CH group. In 2008, HW finished its first research mission. It started the first step of technology commercialization, although there is a long way to go for commercial purposes.

NSBIC Firm

NSBIC was established in June 2002 and mainly engaged in super large-scale integrated circuit (SLSI) design and sale service initially. Some entrepreneurs comprise the returnees from Silicon Valley who had rich chip design experience on data communication and the network security, and the others senior engineers came from famous Chinese IC corporations. NSBIC was an IC design fabless and a representative to the early pattern of Chinese IC design industry. Like other firms created by returnees, NSBIC has strong technological capability, and understand well the operation model abroad especially the model in Silicon Valley. However, it had to be subject to the localization in order to understand the domestic market and business environment in China. NSBIC selected the data communication (routers, switches) and information security as a strategic direction initially. It successfully developed a high performance exchange routing chip with own IPR. Although the technology was highly appreciated and supported by the state and local government on taxation, land preferential policies and technology projects, NSBIC encountered great difficulties in the process of technology commercialization because of tough competitor and the imperfect industrial environment. Later on, the firm won a domestic niche market by successfully developing a series of chips integrated data communication and information security with IPR. However, the revenue situation of the firm was worsening due to the strong challenges from the international competitor again. Facing the cut-throat competition, the top management team diverged from the strategic position. In 2007, great changes happened in the top management team. After the change, the firm adjusted its strategy to select the consumer electronic products as the further developing emphasis.

CASE COMAPARATIVE ANALYSIS

Technology selection

Based on its IP and technology advantage, IG firm comparatively analyzed the technology and market characteristics between high-end market such as Europe, USA and the low-end market in developing countries. Finally, IG firm selected the technological area which was ignored by foreign big companies but with high potential to grow up rapidly as the breakthrough. Avoiding competing with strong competitors in the early stage of development, IG reduced the uncertainty of technological innovation. In addition, as the degree of specialization and the

number of firms in IC design industry increased, IG firm gave up the design service in chips and systematic solution for customer. It fully concentrated on the development of own IP core. The operations not only distinguished itself from most of domestic IC design firm in business model, but also took the opportunity of the industrial specialization. IG firm became the largest IP core supplier in the similar products by franchising customers (IC design firms) to use its IP core in chip design.

Being the wholly owned subsidiary of CH group, the current technology strategy of HW firm is determined by the holistic technological strategy of the group. It severed the innovation strategy of CH. Flat panel television is going to be the strategic business of CH, but the key technologies are totally depend on the import. To fulfill the target of transition, CH needs to have the core technological capability on SOC design of audio and video in the future strategic business field. Hence, the mission of HW in the initial stage is to accumulate the SOC design capability and supply the technologies innovated by itself to support the strategic transition of CH.

NSBIC is the only firm in the cases selected the data communication and information security instead of consumer electronics as the initial breakthrough that required more advanced technological capability. The core technology in data communication and information security field was grasped by leading firms in USA and Europe. The core chips in this field needed by domestic integrated system manufactures were totally imported. The reasons why NSBIC selected this field were as follows: firstly, the key founder of NSBIC is of high expertise in this field; secondly, this field was inspired greatly by the government. The result of the selection is that NSBIC had to directly compete with the strong leading firms in high technological level. Although the chips designed by NSBIC achieved the world leading level, it suffered huge difficulties in the commercialization of technology.

Technology Opportunity

Although all the three case firms are IC design firms, they are involved in different technology field. Therefore, their technology opportunities are different. The following part will evaluate the technology opportunity of the case firms from two criteria. One is the technology superiority and scientificity. The other is the degree to meet the market demand (Lu & Yin 2006).

IG is mainly engaged in the IP core and SOC platform design and franchising. With the future development of IC industry, the rapid demand changing will require specialization in professional divisions. It is an inevitable tendency to use IP core in SOC platform design in order to improve the efficiency of design service. In the relatively mature area with high technological level such as PC and network communication, foreign firms have accumulated strong capability in IP core development to get competitive advantage. Whereas, in the emerging consumer electronic field, the design service of IP core and SOC just started in international and indigenous firms. Therefore, there are more possibilities that IG selected the business area to make innovation. With the increased number of IC design firms in consumer electronic industry,

the demand to the IP core and SOC platform will grow up rapidly. Thereby, the strategic position of IG gets a good chance to innovation from the perspective of market demand.

In the digital audio coding and decoding technology field, although the foreign firms have not the absolute technology advantage, the competition is still rather fierce because most of the IC design firms in Taiwan, Hong Kong and mainland China invest in this area. From the first criteria of technology superiority and scientificity, HW has not the leading technology capability in this field. The technology is gained by talents recruitment and R&D cooperation. There is big uncertainty in the technology superiority. However, CH is the direct big consumer, all of HW technology products have the priority to be applied to the product lines of CH. In this sense, HW has a better opportunity from the perspective of market demand.

From the criteria of technology superiority and scientificity, the product developed by NSBIC independently has excellent performance, and get a good opportunity to innovate successfully. However, from the criteria of market demand, the NSBIC's product did not consider the characteristics of downstream users' needs. It only supplied the core chips to users instead of the entire system solution. It failed to satisfy the requirement of integration so that it had difficulties in marketing. In this case, the technology opportunity of the company was reduced.

Table 1: Comparative Analysis on the Technology Opportunity in Three Firms.

Item / Firm	**Technology superiority and scientificity**	**Market demand**	**Technology opportunity**
IG	Middle	High	High
HW	Lower	High	Middle
NSBIC	High	Lowest	Lower

Technology Monopolization

In IC design industry, except the firms providing the reusable IP core use patens to protect their innovation, most of the firms in chips design control the confidentiality of the technology to protect their innovation. In the following part, the authors will analyze the characteristics of technology monopolization in the three case firms.
IG is the reusable IP core provider. It profits from the innovation by technology franchising and technology transfer. Thus, IPR is a proper means to protect the technology monopolization. In addition, the case study finds that IG increased the possibility to get the complementary assets through maintain a constructive and collaborative relationship with foundries (the IC chips manufacturers) in order to accelerate the commercialization of its innovation.

HW devoted into is an emerging industry with tough competition. HW does not have superior technology advantage on the core technological capability. In this case, its innovation is easily imitated. HW firm protected its innovation by technology confidentiality control. Due to the relationship with CH group, HW can easily get the complementary assets and technology from

its parent company. The speed to launch the new product is rapid, because its product can be verified more quickly than other homogeneous firms.

Comparing to IG and HW, the technology monopolization of NSBIC was decreased by the following reasons. First, NSBIC committed to a high-end technology field. The competitors were world leading firms in the business area such as Broadcom. Although NSBIC successfully developed and patented the leading product with high performance in a short time, it exposed the strategic intentions too early because of over publicity. The competitors quickly developed the similar product through bypassing the patent barriers. At the same time, the competitors set difficulties in marketing activities of NSBIC by adroit operational skills. Second, from the perspective of technical system, the core chips designed by NSBIC need a series of complementary technology and assets to fulfill its systematic solutions. As a start-up, the managers of NSBIC did not well understand the domestic industry environment. It led the difficulties to get the complementary technology and assets.

Table 2: Comparative Analysis on the Technology Monopolization in Three firms.

Item / Firm	IPR	Technology confidentiality	Complementary Assets	Lead Time	Technology Monopolization
IG	●		High	●	High
HW		●	High	●	Middle
NSBIC	●		Low		Low

Resources for Technological Innovation

In the consumer electronic business area, IG firm has no strong international competitor. The barriers of innovate was relatively low. It is a key factor for the success of IP supplier to keep cooperation with foundry. The direct customers of IG are firms which design consumer electronic chips and system solutions. It is very important to consider the requirement of downstream users in the design process. IG used different channels to acquire the resources required by innovation. First, with the development from single product to diversity products, IG had accumulated its technological capability, especially some important know-how. To expand its business, IG kept recruiting the senior technical personnel from some developed countries to guarantee the dynamic accumulation of technological capability. Second, IG set up a branch office in Shenzhen to ensure the fast response to the market through keeping a good relationship with key customers in a long term. Thirdly, by keeping a close relation with foundry which is difficult for other firms to imitate, IG improves the performance of product and shortens the testing time. Moreover, it can reach more client resources through the network of foundry. Finally, to enlarge the demand of IP core, IG cooperated with government and public media. It promoted domestic IC design firms to develop new chips more efficiently by using IP core.

Although the technology entry barrier of HW is low, the firm itself has weak technology capability. Comparing to domestic IC design firms developing similar products, of HW has the advantages to get necessary resources for innovation. First, HW was strongly supported by its

parent company on financial aspect. Moreover, its market position was very clear, so the competition pressure is relatively low. Second, HW was easier to access to the complementary resources for technical testing, because its product was applied to the product lines of CH group. Third, being the wholly owned subsidiary of CH group, HW can share the strong social capital with it parent company to get the external resources required by innovation. On the other hand, HW had to face some disadvantages because of its special situation. First, talents introduction is the main channel to accumulate technological capability, but because the CH is a state-owned enterprise, HW faced some mechanism obstacles to appeal talents. Second, the technology strategy of HW is determined by CH strategy. The firm can not adjust its technology to responses to the market needs. The situation leads to a result that the resources are not efficiently utilized. Although HW can improve the bargain ability of CH with foreign IC suppliers, it is not helpful for HW to strengthen the core competence because it lacks of the experience in management and marketing for further innovation.

NSBIC involved in the business area with high level of entry barrier, but the competitors are very strong with monopoly. In this sense, the innovation of NSBIC required more resources. Based on the views of Perez and Soete (1988), the failure of NSBIC can be explained by the lack of two resources. One is the resource shortage of the experiences on management and marketing. The firm copied the business model in Silicon-Valley initially. All the resources are invested in R&D activities. The resources for localization are very short. The other is the resource shortage on social capital. Although NSBIC got many encouragement and rewards from government, it is a lack of the social capital to realize technology commercialization. NSBIC had to provide the complementary technology and assets by consuming the scarce internal resources, because it could not get these resources from other firms. The risks of innovation are increased by the above reasons.

CONCLUSIONS AND POLICY SUGGESTIONS

Through comparative analysis of the three cases, the paper makes the below conclusions.

First, technological catching-up theory holds that the conversion of technology paradigms can provide an opportunity of technology catching-up for latecomers. However, through the case study we found that the opportunity window of latecomers firms can be opened not only in the conversion period of technology paradigms, but also in the conversion period of technology applications. The latter is more meaningful to independent innovation of Chinese enterprises. In reality, a number of key technology areas (such as IC) are not yet in the period of technology paradigm shift, but these areas have strategic impact on the upgrading of national industrial structure. The Chinese firms cannot wait for the arrival of technology paradigms conversion and then to innovate. In these technology areas, demand is increasingly becoming the main driving force of technological innovation. In other words, the firms have the advantage of innovation who can find firstly new applications of existing technology. The vast and diversification of market demand of China provide good opportunity of "trial and error" and the accumulation of technology capabilities for such innovation. It will act as an opportunity for technology catching-up.

Second, when Chinese enterprises select the technology areas of innovation, they should not only consider the technology capabilities and accumulation degree of the enterprises, but even more analyze the amount and their availability of necessary resources for successful innovation. To the large numbers of start-up enterprises with limited resources, it is reasonable to select the technology that close to the market needs and with short innovative cycle. An obvious example is the enterprises with comparatively good profitability all choose consumer electronics as their core technology areas in domestic IC design field. Although there are a number of leading IC design enterprises committed to the development of TD-SCDMA series product, the necessary resources of successful innovation cannot be afforded on their own. Although strong support is from government, it is still very difficult to reduce the tremendous uncertainty the firms facing.

Third, for Chinese enterprises (especially IC enterprises), once a reasonable technology area is chosen, the main difficulties affecting innovation is a lack of operational capacity rather than the lack of technology capacity. It leads to the lack of experience in marketing, management and channels access to complementary assets required by innovation.

Fourth, technology innovation of Chinese enterprises not only faces the common disadvantages of "late comer", but also faces the following disadvantages that are specific for innovation in under-developed countries. First, the enterprises of under-developed countries are always far away from the leading technology source, which limited the opportunity of achieving technology overtaking in the leading technology areas. Secondly, the enterprises of under-developed countries are always far away from the users of leading technology, which limited the commercialization experience of leading technology. Thirdly, it is a particular disadvantage that there is a lack of specialized technology, human resources, infrastructure and common technology in realizing technological overtaking. In our case study, many managers in IC design enterprises said that the lack of professional and technical personnel (especially in the high- and middle-level), professional design tools and software platforms are critical obstacles in the process of transferring to high-end products.
Finally, Chinese enterprises in the period of technology catching-up must make a tradeoff to design the strategy management tools, such as patent, confidentiality and complementary asset management, so that they can ensure obtaining the competitive advantage and financial benefits of technology innovation.

Based on the conclusions, this paper proposes the following policy recommendations, in order to more effectively promote technology innovation of Chinese IC design enterprises and achieve technology catching up.

Firms in IC design industry are mainly SMEs at present. Although the high flexibility of these enterprises is beneficial to achieving the technology catching up by disruptive strategy, the unfavorable position as latecomers may hamper the development and growth of the enterprises. Therefore, the government should learn the catching-up experiences of “Innovation Network of SMEs "in Taiwan. On the one hand, the government should accelerate the construction of

infrastructure and public technology platform, so as to provide specialized technology and equipment resources for SMEs and make up "latecomer disadvantage"; On the other hand, the government should actively guide and encourage enterprises to establish innovation networks in order to provide adequate external resources for innovation. At the same time, research institutions should be encouraged to conduct R&D on advanced technology with enterprises, so as to make up the shortage of enterprise technology source.

The professionals should be introduced and educated actively in IC design industry. The lack of high- and middle-level professional and market experience are two major bottlenecks to limit the innovation in domestic IC design enterprises. Currently, many high-level IC design talents in developed countries are Chinese, including personnel studying abroad. Government should design various systems and policies to attract overseas Chinese as entrepreneurs or employees in China. It will effectively solve the shortage of professionals in domestic IC design industry. In order to compensate for the lack of market experience, the Chinese firms cannot only transplant the foreign operation model. It is necessary to localize operation model based on understanding the advantages and disadvantages of local enterprises independent innovation. Government should establish platform to provide innovative experience exchange and training for SMES, thereby reducing the cost of "trial and error".

LIMITATION AND FURTHER RESEARCH

This study extends the previous research on the catching-up in developing country. The theories built on the industry-level are linked with the firms' strategic behavior in the micro-level through comparative analysis among three cases in Chinese IC design industry. This paper has some limitations as followes: 1) Due to the complexity of Cross-Level study, the research framework is not complete and perfect. For example, in our framework, technology regime affects the technology strategy by technology opportunity and innovation resources in one way. In fact, the technology strategy based on the capability of firm may has effect on the technology opportunity identification and on the acquisition of resources. To reduce the confusion and complexity, this paper only analyzed the main effect in one direction;2) Three cases are all from IC design industry, so the second research limitation is the replication logic. The case study can be questioned as a contingency instance. Can the case be duplicated in any other industry context? These are questions can be further studied in the technology innovation in the context of catching-up in developing countries.

ACKNOWLEDGEMENTS

The authors are grateful the fund supported by National Natural Science Foundation of China and Science Technology Department of Sichuan Province. We highly appreciate the interviewees of case companies to share their experience with us.

ABSTRACT

Training plays a crucial role in organizational employment. The enterprise must achieve sustainable competitive advantage by efficiently training its employees. Promoting the training satisfaction and consequently the training efficiency stands as a significant issue for the training unit. The service industries, among all the industries, reinforce the training satisfaction. Thus the industries cannot deny the importance of the trainer-trainee fit as the major contribution to training efficiency.

This research, making use of SPSS 12.0, analyzes the trainer-trainee fits as the influences on training satisfaction. The results, under the securitization of Regression Analysis and Independent Sample T Test, and One Way Analysis of Variance, show that supplementary fit has positive relation with training satisfaction. The trainer-trainee communication grows with their good interactions that would further promote the knowledge transferring. In the end, the trainee's satisfaction with the training will be increased and contribute to the expected efficiency. Furthermore, the supplementary fit for educational background has greater influence than complimentary fit on training satisfaction.

Keywords: Training Development, Trainer-Trainee Relationship, Trainer-Trainee Fit, Training Effectiveness

INTRODUCTION

Training is one of the most important strategies for organizations to help employees gain proper knowledge and skills needed to meet the environment challenges (Chuang, Liao and Tai, 2005; Goldstein and Gilliam, 1990; Rosow and Zager, 1988). Therefore, training plays a crucial role in organizational employment. The enterprise achieves sustainable competitive advantage by efficiently training its employees. While training changes workers by teaching them the working skills, the ultimate goal of training is to improve the employees' abilities in solving the organizational problems. Training is laden with issues regarding its contribution

to organizational value and employee effectiveness (Patrick and Owens, 2006). Therefore, the efficiency of training is more important than its process. In addition, the trainee's satisfaction with the training, which has been a significant scale index (Kirkpatrick, 1979) and becoming a major part of training efficiency (Carnevale and Schulz, 1990), includes the trainee's intimacy with and feeling about the trainer.

As a result, understanding the trainee's satisfaction as a way to achieve the training efficiency will be a great contribution to the competition of an enterprise. Past studies have examined training and its relationship with such factors as satisfaction, trust, and commitment (Korsgaard, Roberson, and Rymph, 1998; Skarlicki and Latham, 1997; Taylor, Masterson, Renard, and Tracy, 1998). However, improving training effectiveness by measuring training's effect on employee' training satisfaction has not often been context.

Chuang, Liao and Tai (2005) purpose that part of the training success hinges on trainee' learning, and meta-analysis reviews also confirmed that learning could influence trainees' transfer outcome (Alliger et al, 1997; Cheng and Ho, 2001). Moreover, training motivation can be described as a specific desire on the part of the trainee to learn the content of the training program (Noe and Schmitt, 1986), which is also likely to have a direct impact on training outcomes (Colquitt, LePine, and Noe, 2000; Martocchio and Webster, 1992; Mathieu, Tannenbaum, and Salas, 1992; Noe, 1986; Quińones, 1995). Motivation to learn among trainees can be enhanced and training outcomes will be increased (Liao and Tai, 2006; Colquitt et al., 2000; Korsgaard et al, 1998). Therefore, to improve the motivation to learn of the trainee and thus the training satisfaction and training efficiency becomes the important issue for training program.

Academic literature features that the trainer could greatly affect the training satisfaction and the consequent training efficiency (Bushnell, 1990; McDermott, 1987). Analoui (1994) also considers that the trainer, as the key transmitter of an amateur trainee to a mature employee, stands as the chief contributing cause for a successful training. The trainer serves the example for the trainees' behaviors within an organization and gives them positive attitude of working (Pettigrew, 1979). Furthermore, the trainer is also the conveyer of knowledge. The relationship between the trainer and the trainee influences the teaching of the former and the learning of the later. Such a situation indicates that the trainer is not only the central figure for the trainee's learning new abilities but also an important part of a successful training (Marx, 1986).

Many researchers point out that Teacher-Student relationship is positively relative to the effective studying (Freese, 1999; Zhuojun, 2000; Griffin, 2001; Klem and Connell, 2004).

Davis (2003) believes that a good teacher-student relationship makes a student active in studying. The students are confident of developing new abilities only when they feel being cared by the teacher. Therefore, good teacher-student relationship is helpful to the training efficiency (Murray and Greenberg, 2006). In addition, Hunt and Michael (1983) also state that the teacher-student relationship could inspire the working atmosphere, improve the intelligence of the workers, and decrease the staff turnover rate. Such a connection, therefore, as an important facility for the staff inside an organization, contributes a lot to the training and consequently the working efficiency.

The establishment of teacher-student relationship is partially founded on the similarities of the teacher and the student (Allen, Poteetm, and Burroughs, 1997). Jones (1989) believes that the student, feeling familiar with the one who educates him or her, might evaluate his or her teacher positively (have more satisfaction with his or her teacher). The student, according to Jones (1989), would consider such teach efficient. However, in the teacher-student relationship, the trainer-trainee relationship is also a significant concept. In the process of training, a trainee learns from the trainer the knowledge needed for the work. The learning relies heavily on the quality of the communication (Francis, 1995). In other words, if the trainer and the trainee may achieve in their fitness through their familiarity, which might contribute to the quality of communication and the student's satisfaction with the teacher, such a connection has great influence on an effective training.

"Fit" means the matching between people, emphasizing the similarity between two compared subjects. With such similarity, the two people may attract each other so as to achieve in good communication (Geddes and Konrad, 2003). Being similar, matching, and communicative, the two subjects would like, appreciate, and then have positive attitudes about each other (Jackson et al, 1991). Lankau and Riordan (2005) commented that the similarity and fitness within the teacher-student relationship might produce the inter-dependence. Such dependence would affect the two subjects' attractions to the other while the result in the improvement of the training connection. In addition, scholars also found that when the fitness between the employer and the employee works well in an organization, the employee is likely to identify him or herself with the actions of the employer and to work hard. The identification, therefore, is inclined to cause the satisfaction with the work (Tsui and O'Reilly, 1989).

Muchinsky and Monahan (1987) point out that there are two kinds of fit. The first one is "Supplementary Fit" emphasizing the sameness. People are inclined to attract one another with similarity; they would share values and socially interact with one another in positive ways (O'Reilly, Chatman, and Caldwell, 1991; Tsui and O'Reilly, 1989). The other one

emphasizes the compensation: the “Complementary Fit”. Such fit specifies that the differences among people, especially the ones on working techniques, might result in the positive relationship of two subjects within an organization (Dryer and Horowitz, 1997).

Some scholars point out that the “Supplementary Fit” (with the same backgrounds) is caused by the consensus and sympathy between two subjects within an organization. Those attitudes make the two people communicate and then cooperate with each other easily (Weldon and Weingart, 1993). There are also researchers with the points that “Complementary Fit” (with the different backgrounds) could inspire various ideas among the workers within an organization and consequently helps the working efficiency (Gladstein, 1984). Since the two kinds of fit positively assist the organization, which one of them might attain more importance to the organizational training by inspiring the trainee’s motivation to learn and his satisfaction with the training? This question has not been answered by the researchers of the past years and therefore stands as the theme of my research. The analysis within this research is to discover the connection between the trainer-trainee fit and the satisfaction with the training and to find the cause of this connection. The discoveries may be instrumental to the organizational managements for the trainings in academic units and enterprises in the future.

In addition, the training activities in human resource management contribute to the performances of small-and-medium businesses. The business, furthermore, evidently take training as the crucial means to improve skills, transform the attitudes, and update the ideas of management within the organization (Altinay, Altinay, and Gannon, 2008). The performances of organization serve as the determining factor of the economic development of a country (Soriano and Dobon, 2009). As a result, the analysis and discussion of the training in service industries deeply concerns the national economics. The findings of this research may be helpful for these analysis and discussion. The relationship between the trainer-trainee fit and the training satisfaction will provide an advantageous rationality for the businesses and academic researches. The purpose of this study is to provide the connection between the trainer-trainee fit and the satisfaction with the training and, moreover, to analyze trainer-trainee relationship as the influence on the satisfaction with the training.

THEORIES AND HYPOTHESES

The similarity-attraction theory suggests that the subjects within the same society are essentially similar to each other and are thus easier to establish intimacy. The intimate connection may provide for both sides the pleasure and positive attitudes to each other

(Byrne, 1971; Mark, Ellen, and Alana, 1988; Pfeffer, 1985; Jackson et al, 1991). Furthermore, if there is fit between the trainer and trainee, they could exchange the right information and result in the good communication and the increasing satisfaction with the training (Derosa et al, 2004). Therefore, this research holds the hypothesis that the trainer-trainee fit and the training efficiency are positively connected.

When there is the fit of values between two subjects, the communal attraction and closeness might increase (Byrne, Clore, and Worchel, 1966). The employer and employee establish similar perceptions because of the fit of values. The same usages of language, furthermore, will cause high-quality communication (Meglino, Ravlin, Adkins, 1989). The familiar behaviors and attitudes of dealing with works serve as the foundation of consensus. In addition, the fit of values will also make the subjects identify the others as the same kind of people as themselves, shortening the distance of both sides and producing trustiness and favor (Farh, Tsui, Xin, and Cheng, 1998).

According to the researches above stated, the fit of values between trainer and trainee cause the same logic in thinking about the works. In the training, the trainee may like the talking with the trainer because the former takes the later as the same kind of person and, not rejecting him or her, willingly receive the ideas of the later or the purpose of the training. The communal understanding on the basis of good interaction helps the social reliance, coming into the high satisfaction with the training. This study, therefore, presumes that the fit of the values between the trainer and the trainee can be positively connected with the satisfaction with the training:

Hypothesis 1: *The trainer-trainee fit will be positively related to training satisfaction.*

The research of Farh et al. (1998) consists of the discovery that the similar education of the employer and the employee is positively connected with the employer's evaluation of the employee's performance. Meanwhile, the members of an organization like to have the coworkers of the same characteristics. The inclination makes them choose their coworkers of such characteristics as graduating from the same university (Schneider, 1987). The subjects with the fits of education (or similar educational backgrounds), such as the same academic degree, the same university, or the same major, might have similar logics of thinking and therefore would not be frustrated in their communication. They are inclined to take each other as the insiders.

As a result, the people as "insiders" with similar educational backgrounds will provide each other the intimacy, confidence, comradeship, and eventually the fit. In the proceeding

training, when the trainer takes the trainee as the insider, the former will selflessly transmit the knowledge and techniques to the later, improving the efficiency of training. At the same time, when the trainee takes the trainer as the insider, the former will also willingly listen to the later, improving the satisfaction with the training.

However, according to the viewpoint of demand-supply, the fit of two subjects occurs when one's demand or personal desire are fulfilled by the other (Kristof, 1996). The supplementary fit in education might make the trainer and trainee share the different knowledge and techniques according to their different experiences, educations, or majors, because they, not understanding each other, would not come into competition and the conflicts of interests. Such a relationship of demand and supply might also be formed with the subjects' respect and admiration towards each other.

Therefore, if the trainer and trainee have supplementary fit in education, the trainer might supply the trainee with the knowledge or techniques the later lacks for working. When the training is satisfied with this supply, he or she is likely to be positively motivated. The respect and admiration that a trainee processes towards the trainer would also result in good communication and connection when the trainee is likely to humbly learn from the trainer. Furthermore, the discussion and sharing of different experience and knowledge would also produce the sense of achievement and the satisfaction with the learning. All those factors contribute to the satisfaction with the training.

The past researches and the discussions stated above reveal that both the supplementary and complementary fits in education for the trainer-trainee relationship will promote the satisfaction with the training. However, the past researches do not point out which kind of the fits works better. As discovered in this research, most trainings of the enterprises, as initial training or job training, are the short-term ones within 3 to 6 weeks, in which the trainers may not possible to develop good teacher-student relationship with the trainee. Furthermore, those trainers may come from the consulting company, academic or government units. The trainer and trainee do not know each other before the training and will just meet for a short time. There would be no close relationship, in other words. If, in this condition, the trainee identifies the trainer in the first impression, the relationship becomes better than the one in the demand-and-supply connection resulted from the sharing and discussion. The supplementary fit therefore works better than the complimentary one to improve the training satisfaction. This study thus holds the hypothesis that the supplementary fit in education has greater influence on the satisfaction with the training than the complimentary one.

Hypothesis 2: *In the trainer-trainee relationship, the influence of supplementary fit for educational background on training satisfaction will be greater than complimentary fit.*

METHODS

Sample and Data Collection Procedure

The questionnaires survey, with the advantages of low cost, carrying out easily, high reliability, and few frustrations in the operation, stands as the central method of this research. The samples of this research are the trainees in the trainings (like the ones for further education; for transferring the career; or for the commissions) held by *Department of Labor, Taipei City Government*. Focused on the list of the workers in service industries given by the official unit, the survey consists of the questionnaires of the random samples of trainees. In addition, there are also samples of the trainees in the training held by the enterprises, academic units and other administrations.

Before or right after the end of the trainings, the survey starts with the training assistants' distributions of questionnaires to the trainees in person or by mailing and then analyzes the trainees' reaction, learning, behavior, and results as the important standards for the training satisfaction. The assistants, or the employees who once participated in the trainings (before or on-service) recollected the questionnaires after the trainees complete filling. The period of questionnaires distribution starts on December 2, 2008 and ends on February 15, 2009. 826 questionnaires have been sent to the trainees and 535 copies have been recollected. The retrieve rate is 64.76%. After collation by ruling out the ones with incomplete or only-one answers, the invalid questionnaires are 138 copies and the valid ones are 397 copies. So the valid retrieve rate is 48.06%.

Variables Definition and Measures

Independent Variables

The "trainer-trainee fit" serves as the independent variable for this research. Taking Muchinsky and Monahan's points of "supplementary fit" and "complementary fit" (1987) as the overall range for the idea of fit, this research makes the chart for the "supplementary fit in values" with 19 articles. With Lakert's standards of "Strongly Disagree," "Disagree," "Neutral," "Agree," and "Strongly Agree," the points are given from 1 to 5. The higher the points are, the trainer-trainee fit should be.

In the parts of supplementary and complimentary fits in education, this research compares the education backgrounds of the trainers and the trainees. If one description of education for both sides reveals the same, it is given the point "1". In contrast, if it reveals the difference, it will be given the point "2" as the complimentary fit in education.

Dependent Variables

The training satisfaction is the dependent variable for this research. According the four levels issued by Kirkpatrick, the trainees' reactions, learning, behaviors, and results are designed into the evaluation chart. The chart has 27 entries, including the design of curses, the inspiration in class, the way the trainers carry out his or her teaching, the trainer-trainee interactions, the improvements of the trainees' professional knowledge, negotiation ability, and working attitudes, etc. With Lakert's standards of "Strongly Disagree," "Disagree," "Neutral," "Agree," and "Strongly Agree," the points are given from 1 to 5. The higher the points are, the training satisfaction should be.

Analysis Methods

The first step is to rule out the invalid questionnaires with incomplete answers. The second step is to code the data into computer files. And then SPSS 12.0 is used to analyze the codes into the statistics. The data analysis method includes: Reliability, validity analysis, description covariance analysis, Pearson's correlation, one way ANOVA, Regression Analysis, and Independent Sample T test.

RESULTS

Validity and Reliability

To hold Content Validity, the questions of the questionnaire in this research are mainly of professional predictive validity. They are composed of the opinions of the experts in the field and critically scrutinized in the procedure of composition, and are thus qualified to be the representatives for the studied issue. In addition to the researches in the past years, the scholars' professional advices are also necessary for the examination of the title and the questions as the expressive ideas to the questioned trainees. The final version of the questionnaire, therefore, with the professional helps, processes high predictive validity.

To construct Validity, this research makes use of Principle Component Analysis so as to find the Common Factor. The principle of selecting the characteristic root greater than 1, as

stated by Kaiser (1960), is accompanied with the corrected item-total loading to examine the relativities of each question. The factor loading is used to examine the proceeding questioning so as to decide whether one question should be ruled out or kept in the questionnaire. The variables are used to sieve the validity of the questionnaire. Finally, in this research I decide to rule out the relativity lower than 0.4 and the weight lesser than 0.6. The independent variables (supplementary fit of values) ruled out 2 of the 19 questions and the dependable variables ruled out one of the 27 questions.

As for the reliability, this research takes Cronbach's α coefficient to evaluate the degree of consistency under aspects. The chart with the coefficient over 0.90 processes high reliability. The complimentary fit in values in this research, with its 17 articles, gives the Cronbach's α result as 0.923. The training satisfaction, with its 19 articles, gives the Cronbach's α as 0.96. Both results are highly reliable.

Correlation Analyses

In this research, the variables of the supplementary fit and the dependent variables of the complimentary fit are both of continuous variables. Thus one of Pearson's Correlations, Pearson product-moment correlation, is here used to analyze the relation of the two variables as the indexes of continuous variables. These indexes are used to analyze coefficients of these two variables and p-value is used to examine the coefficients' significance. The correlation, between the independent variables (supplementary fit) and the dependent variables (training satisfaction) is 0.542, and the p-value is less then 0.01, indicating the positive relation.

The Relationship between Supplementary Fit and the Training Satisfaction

The simple regression is used to test the influence of the supplementary fit on the training satisfaction. Table 1 show that the regression analysis reveals that β is 0.576 (t=12,817, p=0.000), suggesting that the higher the supplementary fit in values between the trainer and trainee is, the better the training satisfaction is.

Table 1: Relationship between supplementary fit and the Training Satisfaction.

	Unstandardized Coefficients		Standardized Coefficients	t	Sig.
	β	Std. Error	β Distribution		
Constant	1.617	0.183		8.852	0.000(**)
Supplementary Fit in Values	0.576	0.045	0.542	12.817	0.000(**)

** indicates 0.01 level of significance

The Relationship between Supplementary and Complimentary Fits in Education and the Training Satisfaction

The independent sample T test is used to examine the influences of both fits in education. As revealed in Table 2, the result shows that the equality of variables through Levene test is 0.087<0.15 (t=0.015), indicating that the variances are significantly different from each other and that the supplementary and complimentary fits between trainers and trainees have significant influence on training satisfaction.

Table 2: Relationship between Supplementary and Complimentary Fits in Education and the Training Satisfaction.

	Levene's Test for Equality of Variances		t-test for Equality of Means	
	F	Sig.	T	Std. Error
Equal variances assumed	2.941	0.087*	2.339	0.020
Equal variances not assumed			2.456	0.015*

* indicates 0.05 level of significance

In addition, the average quantity is further used to test the degree of influence by the supplementary and complementary fits for education on training satisfaction. As shown in Table 3, the result shows that the mean of supplementary fit is 4.0271 greater than complementary fit which is equal to 3.8855, suggesting that the supplementary fit in education has greater influence on training satisfaction than the complimentary fit.

Table 3: Comparison of Average Quantities of Supplementary and Complementary Fits.

	N	Mean	Std. Deveiation	Std. Error Mean
Supplementary Fit in Education	146	4.0271	0.51284	0.04244
Complimentary Fit in Education	251	3.8855	0.61811	0.03902

The Relationship between Demographic Background and Training Satisfaction

For the further understanding of the difference the trainer and trainee within an organization as the influence on the training satisfaction, this research takes the single-reason variables for analysis. As shown in Table 4, the result shows that P=0.644>0.1, indicating that there is no obvious influence of the trainers' positions on the training satisfaction. In other words, wherever the trainer comes from, there will be no influence on the fit and thus no visible consequence on the training satisfaction.

Table 4: Relationship between the Trainer's Organizational Position and Training Satisfaction.

	Sum of Squares	Mean Square	F	Sig.
Between Group	71.967	1.124	0.922	0.644
Within Group	404.733	1.219		
Total	476.700			

Furthermore, this research tries to figure out the sex difference as the influence on the training satisfaction. Therefore, with the independent sample T test as the examination for the relationship between the sex difference and training satisfaction, the result (as in Table 5) shows that the of Levene test is 0.455>0.15 (t=0.935), indicating that the variables have no apparent difference. In other words, the sex distinction of the trainer and trainee does not stand as an influence on trainer-trainee fit and consequently on training satisfaction.

Table 5: Relationship between the Sex Difference within trainer-trainee relationship and Training Satisfaction.

	Levene's Test for Equality of Variances		t-test for Equality of Means	
	F	Sig.	T	Std. Error
Equal variances assumed	0.558	0.455	0.082	0.935
Equal variances not assumed			0.082	0.935

DISCUSSION

This study discovers that the higher the supplementary fit in values is, the better the training satisfaction is. The training will thus be supported. The sharing of values makes both the trainer and trainee thinks in the similar logic and then mutually communicative. The trainee, not rejecting such a person, will thus regard the trainer as the insider and willingly receive the order and purpose of the training. The good communication and positive social interaction within the training will therefore result in the high satisfaction.

One of the results in this research shows that, for educational background, the

supplementary fit has greater influence on the training satisfaction than complimentary fit. The supplementary fit makes both the trainer and trainee think of each other as insiders and therefore feel the intimacy in the training activities. The trainer will also take the trainee as the insider and selflessly deliver his or her knowledge to the trainee. The selflessness shortens the time of learning and increase the training efficiency. Meanwhile, when the trainee takes the trainer as the insider, the former will be more obedient and thus have more satisfaction with the training.

When the training unit is choosing the trainer, it will consider the various resources like the consultant company, the academic unit, the government unit, the original company (that holds the training), or other companies within the same industry. The result of this research shows that the trainer's organizational position does not affect the trainer-trainee fit and thus has little influence on the training satisfaction. The discovery suggests that the comradeship of being in the same company does not make the trainee feel more satisfied with the training. Similarly, the trainee will not take the trainer as a more professional lecturer even if the trainer comes from the academic unit or consulting company.

The stereotypical conception of sex difference consists of the idea that the people of different sexes might attract each other. However, it is still possible that the people with the same sex might get along with each other easily. As discovered in this research, the sex difference does not influence the trainer-trainee fit and has little effect on the training satisfaction. The discovery suggests that sex difference perhaps affects social relationships, but it does not stand as the key for the trainee's motive of learning. Confronting the trainer of the same or different sex, the trainee will not adjust his or her satisfaction with training.

CONTRIBUTION

Some scholars state that supplementary fit (the same backgrounds) makes the trainer and the trainee think and deal with things in the same way and thus makes them communicative (Weldon and Weigart, 1993). There are also scholars believe that the complimentary fit (different backgrounds) might inspire the members' different thoughts and thus achieve in the efficient working (Gladstein, 1984). However, the researches of the past years, focused on the positive influences of both supplementary and complimentary fits on the organizational training, do not include the comparison of the two kinds of fit so as to figure out which of them is the most important. Which kind of fit might work better to motivate the trainees' learning and increase the satisfaction with the training? This is the question this research tries to answer.

As the result shows, the higher the fit in values is, the better the satisfaction is. In addition, the supplementary fit has greater influence than the complementary fit, meaning that the background of sameness will make the trainer and trainee talk about the same topic either in training or in the private. The good communication brings good transmission of knowledge. The trainee's satisfaction with the trainee, therefore, will show the expected achievement. However, one of the reasons why the supplementary fits of education within trainer-trainee relationship are greater than complimentary fit is that this research is focused on the service industries in which the social relationship must be reinforced more than that in other industries. The employees, therefore, are inclined to think highly of the intimacy in the trainings. When the intimacy is good, so will be the interaction within the training and the training satisfaction. The different educations and the acquiring of new knowledge thus do not stand as the important factors for the training satisfaction.

Furthermore, this research also shows that the trainee with a under graduate degree present higher motive to be involved in the activities of the training. However, because of the problems of family and physical strength, the trainees after the middle age show lower motives in training. Meanwhile, the organization that holds the training has no inclination of selecting the trainer of some particular age or sex. However, the trainers of high education, like from graduate schools, serve as the good choice for the enterprises, because the sharing of knowledge as the essential activity in a training requires the professional learning of the trainers.

Confronting the impact of global depression of economy, the employees must struggle to keep their advantageous position in the fierce competition. Therefore, training (initial training or on-the-job training) stands as the necessary device for both the employee and the employer. In the training, although the employees may learn knowledge and techniques of working, they must take time and spirit to assimilate themselves to the new things. The process of assimilation inevitably produces the trainees' rejection and tiredness, which may have influence on the satisfaction with the training and the training efficiency.

The findings of this study suggest that organization should pay more attention to trainees' perceptions of training satisfaction when they are forced to attend remedial training programs. Since the enterprise has approved the budget for the training so as to improve the abilities of its employees, the training must has its positive performance. Therefore, this research suggests that the holder of a training should do some research on the backgrounds of the trainer and the trainee before the activity takes places. Consulting the analysis within this research, the trainer could thus start his or her training course with the topic that the trainees might be interested in. Such consideration makes the trainer more attractive to the

trainee and is possible to eliminate the trainee's rejection and tiredness. The elimination increases the trainee's motive to learn new things and produces the positive interaction between the trainer and the trainee, promoting the satisfaction with and the efficiency of training. Such positive results are helpful to the performance of the businesses.

Moreover, past studies have shown that job satisfaction is related to organizational performance (Ostroff, 1992; Hochwarter, Perrewé, Ferris, and Brymer, 1999), and training affects job satisfaction (Patrick and Owens, 2006). Thus, training satisfaction a positive effect on training effectiveness also connects itself with organizational performance. The study's results contribute to the current research literature. Evaluating training effectiveness as the result of training satisfaction, this study suggests that the higher trainer-trainee fit, the better the training satisfaction is.

ABSTRACT

There is a continuous flow of important business decisions made in companies; product development decisions, manufacturing location decisions, logistics decision, partnership decisions, pricing decisions, personnel decisions, marketing decisions, etc. Decision making circumstance is the collection of relevant factors impacting decision making. Author suggests decision making circumstance to include following factors: a) decision criteria, b) decision making time/urgency, c) contributors, d) decision making method, e) supporting tools and f) business uncertainty. This paper provides an empirical analysis with a focus on data communication consumer product business. The motivation of this study is to increase holistic awareness of business decision making as an opposite to scientific studies focusing only on one of the factors.

This study is based on the other hand on author's personal contribution to business management and on the other hand on author's earlier academic research around the subject. Three typical decision cases are discussed as well as a longer term trend. Intention is to recognize which of the decision circumstance factors, a) …f), are the most relevant ones and therefore attention should be paid on these in order to improve success of decision making.
Decision criteria (a), decision making method (d) and supporting tools (e) are found to be the most relevant factors. Business management should pay attention on these in order to improve decision making process. Contributors (c) and risk management/uncertainty (f) are rather self evident factors and do not require so much attention from management. Timing/urgency (b) is nearly always clearly known and set by business situation.

Keywords: decision making, business management, criteria, circumstance

INTRODUCTION

There is a continuous flow of important business decisions made in companies; product development decisions, manufacturing decisions, marketing decision, logistics decisions, partnership decisions, pricing decisions, personnel decisions, etc. This study is not about any of these particular decisions neither about the decision makers' behaviour but, instead, this study is about the circumstance where decisions are made. *Decision making circumstance* is a collection of relevant factors impacting decision making. Competent business management makes good decisions without recognizing the factors and methodologies. Management is mainly tacit skill rather than explicit skill. However, structuring the *decision making circumstance*, in other words making it explicit, helps in creating mutual understanding of the concept and provides a possibility for developing this important business process.

It is always most relevant for the operative management to adapt to today's *decision making circumstance*. The topical situation and circumstance influences companies in their attempt to achieve business success in short or long term. It would be a disaster if decisions were made either in the mode of historic circumstance or in the imagined future circumstance. History and future need to be taken into account but the decision is to be made today. In order to give perspective, this paper discusses of the trend from history until today and also lines out author's subjective vision of the future. This trend shows the changing nature of the *decision making circumstance*.

RESEARCH METHOD

The research method in this study is an analytical classification of author's experiences that are based on the other hand on author's personal contribution to business management and on the other hand on author's earlier academic research around the subject. Author has 30 years management experience from heavy metal, telecom, electronics and sports equipment business. This experience is the source of this research. As most of the actual documents are property of certain international companies those can not be publicized nor exactly referred. However, author has publicized some of the early research studies that are related to the subject, Verkasalo (1989….2000). This combined industrial and academic experience has made it possible to analyse this challenging subject, *decision making circumstance*, systematically even though author works currently in the industry, not in academy.
Due to the empirical nature of the study the results are lacking of scientific validation. Author invites researchers and practitioners to discuss and research the subject. This study has not been done in any specific company but refers to international business in general with a bias to data communications industry.

The main phases of the study:

- Review of experiences and early research material
- Creation of the proposed *decision making circumstance*
- Analysing and discussing the factors by using three realistic cases
- Discussion of the change from history→ today → future
- Concluding the research results

SCOPE AND OBJECTIVE

The scope of this research is to evaluate the relevance of the proposed factors of *decision making circumstance*. A factor is relevant if it need to be taken into account in decision process. It is a sign of relevance if a factor gets different values *) in different type of decisions. The case discussion simulates this. In such a case the decision taker need to pay actively attention on the possible value changes of the factors. An other sign of relevance is if a factor impacts differently today than in the past. Such a factor requires the decision taker to adapt to the development of business environment. A factor is not a relevant one if it does not react (value does not change) to the type of decision/case or to the time perspective. As author has himself proposed the factors and also carries out the evaluation himself it is rather natural the he can not find missing factors.

Intention of this paper is not to prove that the proposed factors could be widely used with good enough validity. Instead, the intention is on much lower level; to test the proposed definition in three cases and discuss of the relevance of the factors. Wider validity assessment of the results would require external researchers' contribution.

The main objective is to recognize possible areas of future research.

*) Terminology note: *value*. In this study "decision factor" is a synonym for "decision parameter". A parameter can get different values. In the same way factors in this study can get different values. Tables 1 and 2 give values for decision factors.

PROPOSED DECISION MAKING CIRCUMSTANCE

Author has studied decision making process and contributed to these processes widely. He has been modelling the factors that are relevant in business decision making. The research has been made in few phases. In the first phase, end of 80's and beginning of 90's, the focus was merely on decision criteria, Verkasalo et al (1989, 1991, 1992, 1994). That time it was thought that if decision takers can recognize the decision criteria and judge the decision alternatives with these criteria, the decision will obviously be optimal. In the next phase, mid 90's, author's research was focused on the availability of expert information, Verkasalo et al (1996a, 1996b, 1997a, 1997b, 1998). If a manager or team can collect quickly the knowledge and information required in the decision process the portion of intuition will be lower and decision will be a good one with low risk. Since that author's understanding of the decision circumstance has grown. Today, we could say in the third phase, author proposes *decision making circumstance* to include following six factors: a) decision criteria, b) decision making time/urgency, c) contributors, d) decision making method, e) supporting tools and f) business uncertainty.

BUSINESS CASE EXAMPLES

The three cases described in this chapter are in a way real ones even though they are not any particular cases but generalized from several such decisions. As an example author has participated to several production technology decision processes (case 1 below). The cases are not related to any company where author has worked. For the confidentiality reasons any individual business case can not be publicly reported.

Case 1: Production technology decision. Data communication devices include processors, memories, interface components, crystals, displays and many other components. It is of high importance which technology level will be selected. On the other hand technology needs to be mature enough to facilitate short enough time-to-market. On the other hand, too old technology may not keep product portfolio competitive long enough. In order to make industrially solid product the level of technology should be the same with all key components. For example if the selected processor will be of the technology just entering to the mass markets, it would be a mistake the select passive components that are of technology generation already in the "ramp-down" phase. Naturally the selection of technology impacts all key business aspects like: pricing, competitiveness of products, risks, development time, partnerships, etc.

Case 2: Management of documented knowledge. It is a business challenge today to manage documented information. Actually "documented" is not correct word since information is also increasingly in other electrical formats like video scripts, photos, emails and other ad-hoc notes and tool specific data formats. Information overflow may be a bigger problem than lack of information. Access to global data and information storages has made own documentation less important. Information management is today clearly an important area of business management. This generic case refers most concretely a decision where company management shall decide which kind of documentation management concept and related IS tools would best fit with the business requirements. Decision affects office work efficiency, motivation, legacy information management, customer satisfaction and many other important functions.

Case 3: Selection of manufacturing location and related logistics process. Any company trading world wide needs to organize manufacturing and distribution in the best possible way. As an example a company may sell 60% of products in USA, 20% in Europe, 15% in Japan and 5% in rest of Asia. The sold product requires typically localization in terms of user manual language and system configuration parameters. A company has several options to arrange manufacturing and logistics. Two examples: a) it can centralize manufacturing to a sub-contractor in China and use air fright to transport product boxes to each sales country, b) it can manufacture only the main product (like MP3 player) in China and localize the sales boxes (including charger, user manual, warranty cards, etc.) in logistics centres in each market area.

ANALYSIS OF THE CASES

The three cases have been analysed based on author's experience. Since the collection time of this knowledge has been quite long, several decades, the collected information is not perfectly structured but rather a collection of unstructured information. This limits the study to stay on low resolution level without details. Author has done the analysis based on the decision processes where he has been personally involved.

The result of the analysis is presented in table 1. Table 1 lists the values of each *decision circumstance factor* in the three different types of decision cases.

Decision factor	Case 1 Production technology selection	Case 2 Mgmt of documented knowledge	Case 3 Selection of Manufacturing location
a) Criteria	Profit during the entire life-cycle.	Required system functionality	"Door to Door" logistics costs
	Initial investments.	Initial investment.	Initial investment.
	Today's and future product	Life-time costs.	Environmental issues.
	Product quality.	Forecasted number of IS system users.	Flexibility.
	User experience.	Expected user behaviour and users' expectations.	Quality.
	Partner policy; to which "technology camp" company wants	Credibility of IT partner.	Ethical aspects. Fulfillment of social accountability requirements.
	Time to market with new products.	Integration with other IT systems	
	Own technical competence.	Office work efficiency	
	Availability of key HW		
b)Decision making time/urgency	Need to be done in about 2 months.	Need to be done in about 3 months.	Not necessarily very urgent. 3-4 months.
c) Contributors	R&D.	IT management.	CEO.
	Finance.	Finance.	Finance.
	Sales.	Behaviour analysts.	Logistics.
	SW and HW engineering specialists.	All functions.	Sales.
	Product management.	Quality mgmt.	
	After Sales.	Security mgmt	
	Partner management.		
	Production		
d) Decision making method	Rather analytic process. Perhaps 70% based on facts, 30% based on business intuition. Typically similar decision have been made but situation is always unique.	Disciplined method required. Decision can not be based on pure finance and other facts. Hardly no past experince of this type of decisions. Unique.	Very analytic. Mainly based on facts. No past experience of equivalent decision. Unique process.
e) Decision support tools	Facts and consultancy can be purchased for analyst companies or searched from Internet. ERP system used in sales forecasting and profict&loss calculation. An Excel based simulation application used to simulate different scenarios. A dedicated decision process project initiated in the company. Nominated project manager to coordinate and report of the progress in the decision process. Several structured	Rather good statistics from IT systems can be collected. Experimenting some potential IT tools. Structured decision making. Perhaps 3 to5 meetings to make the decision. Excel simulation used to analyze financial parameters.	External logistics consultants can provide lot of fact information of similar cases. Potential service providers can simulate quickly service level and cost of different options. Several articles and studies available from Internet.. ERP system used in transaction statistics collection. A dedicated decision process (project) initiated. Nominated project manger to coordinate and report of the progress in the decision process. Several structured meetings. .
f) Business uncertainty	It is very uncertain which of the technologies will be the winners in 2…3 years. Technology and customer behaviour changes	Rather high uncertainty since at the and the success and utilization rate of an IT system depends of the perceived satisfaction of employees.	Low uncertainty. Typically there are not quick and unexpected changes in the global logistics besides some temporary phenomena and currency fluctuations.

Table 1: Values of *decision making circumstance* factors in the three cases.

REVIEW OF LONGER TERM TREND

Today's *decision making circumstance* is consolidated by simply collecting the values of each factor (table 1) together. The consolidation is in column B of table 2. This represents the typical decision circumstance in 2010 in such business environment where this study has been made.

Then we will look back to discuss about the trend in the past decades. It is evident that the business environment changes all the time and unfortunately the trend is to a more demanding direction. All of the earlier requirements, disciplines and factors remain and new ones enter. Management will be under heavier pressure. On the other hand some factors, like easier collection of information, make decision making easier and quicker. In the column A of table 2 the decision circumstance in 90's is illustrated as author has recorded it.

Thirdly the future development is forecasted. Author did a small scale forecast of the development of decision environment already in 2000, Verkasalo (2000). That forecast has come true to its essential content. It would be glorious to know the factors that make business decisions successful in the future. Author does not have this wisdom. However, author has tried to interpret the developments that are in the initiation phase today but may be of business significance in the future. This is like an extrapolation of the continuous development. Author has illustrated his forecast into the column C of table 2.

Decision factor	A 1990	B 2010	C Future
a) Criteria	Cost efficiency/profit	Cost efficiency/profit	Cost efficiency/profit
	Return on Investment	Return on Investment	Return on Investment
	Quality	Quality	Quality
	Speed	Speed	Speed
	Flexibility	Flexibility	Flexibility
	Competence	Competence	Competence
		Customer Expecations	Customer Expecations
		Trading politics	Trading politics
		Partnerships	Partnerships
		Environmental issues	Environmental issues
		Expected future developement	Expected future developement
		Ethical aspects	Ethical aspects
		IT infrastructure	IT infrastructure
		Employee's behaviour	Employee's behaviour
			Health
			Wellbeing
			Comfort
			Safety
			Image
			Attractiveness
b) Decision making time/urgency	Typically from 1 month to 6 months	From few weeks to few months.	Shortens
c) Contributors	Company's top management including all functions	Company's top management including all functions	Company's top management including all functions
	Middle management	Middle management	Middle management
	Experts	Experts	Experts
		Partner management	Partner management
		User behaviour analysts	User behaviour analysts
			Key customers
d) Decision making method	Structured and analytic decision analysis.	Decisions are mainly analytic. Decision can not be based purely on facts but intuitive judging is also needed.	More contributive management model.
e) Decision support tools	Financial spread sheet calucations.	Transparent global information systems support significantly decision making. Plenty of valid information is available quickly from Internet and other data	Video meetings with own smart phones or tablet computers.
	Several stand-alone IT systems or other SW tools.	Video meetings.	Open information coordiantion system with visual and intuitive interface.
	Documents and presenattions.	Conventional Office tools like Excel facilitate quick and easy simulations and graphic visualisation.	Real time information during the decision process
	Extenal consultants	Plenty of possibilities to utilize domestic or international consultants.	Remote commenting and voting features.
	Structured and fixed decision process.	Very often structured decision process which adapts to changes during the	Contributors are "on line" at the time point of decision statement.
	Face-to-face meetings, lots of traveling.		Factual information about customer behaviour.
f) Business uncertainty	Short term (<1 year) busiess outlook rather stable.	Business uncertainty varies depending on the type of decision.	Global conflicts and catastrophes

Table 2: Change in factors' values over the time.

RELEVANCE OF FACTORS, CONCLUSIONS

The intention of this paper was to experiment the proposed *decision making circumstance* factors in three practical decision cases and to discuss their behaviour over the time. Tables 1 and table 2 are the key results. A factor is relevant if its value is different in the three cases (table 1) and/or the value changes over the time (table 2). The relevance of each factor, based on author's analysis, is following:

a) "Decision criteria" factor is very relevant as it gets significantly different values in the cases and also the value changes over the time.
b) "Decision making time/urgency" factor does not change very much and is rather self evident.
c) "Contributors" factor gets different values depending on the decision cases. Also new contributors are entering gradually over the time.
d) "Decision making method" factor is very relevant as it gets significantly different values in the cases and also the value changes over the time. Method is many times even unique.
e) "Supporting tools" factor is very relevant as it gets significantly different values in the cases and also the value changes over the time.
f) "Business uncertainty" factor gets different values depending on the decision cases.

All of the factors have at least some level of relevance. However, if business management wants to improve decision making they should recognize clearly decision criteria, decision making method and supporting tools. These are the factors are not self evident and require therefore special attention. Then contributors and risk management/uncertainty are the next relevant factors for successful business decision making. Timing/urgency is the most self evident and does not require so much special attention from management.

At least following areas are potential for further research:

1. The most relevant factors; decision criteria, decision making methodology and utilization of supporting decision tools are worth of further research.
2. It would be also interesting to study if the factors are orthogonal or do they have dependability on each other. Example: if there are many contributors shall the decision method be different compared to a decision process with only few contributors?
3. To survey if there are some additional factors shaping the *decision making circumstance*.
4. External testing and validation (so far author has done the study in a limited environment).
5. Literature study.

ABSTRACT

Today, research and development and related activities to access new technologies in the industrial world have been challenging activities. Although the research and industrial development companies in developed countries have been living for thirty years with increasing importance of R&D continuously, but developing countries recently have realized its importance. Undoubtedly R&D units were known as Technology pillars and are unique resources of innovation, creating R&D units and institutes or developing old ones to new effective ones for developing countries are inevitable issues.

There are various methods to access the Technologies and one of the most important ones, especially among developing countries is Reverse engineering which is Consciousness method taken from exist Technology.

This paper also reviews research background of (R & D) and reverse engineering, implements simulation software modeling to achieve the most effective parameters and their relationships and offer strategies for optimal per unit R & D and access to technologies of modern examined. This study contains R & D department of a chemical factory as selected population which is one of the important industrial factories in Iran.
In conclusion some key effective factors have been extracted through this simulation. The company can consider them to develop R&D unit and improve the product quality.

Keywords: Research and Development (R&D), Reverse engineering**,** Technology Transfer, System dynamic.

INTRODUCTION

Research, development and management are the pillars of creation, development and utilization of technology and they are the needs of economic and social development in every country, in the developing countries which are seeking industrial and economic self-reliance, policy and planning research programs and development and management of practices impact on these activities are considered as priorities for national, industrial and manufacturing activities. Expansion and enhance of R & D activities, particularly "industrial

research ", requires understanding the factors affecting research and development process and designing policies and effective activities of such mechanisms. In competitive conditions of the current industrial world, doing research and development activities is one of the most effective things that managers of economic enterprises can take on and in industrialized countries of the world, the costs allocated to these activities are being increased day by day, on the other hand referring to the research and development without creating the necessary infrastructure units such as: organizational structure, human resources characteristics and management of these organizations causes the failure of research and development process of economic institutions.[12]

Process of R & D includes: basic research, applied research and development. By using basic research, the scientific findings are presented in the form of hypothesis, theories and general rules and in the next stage, it would be the applied research which determines the possible applications for basic research findings. The stage of development, scientific knowledge obtained from basic research and applied research is applied in order to provide new and developed products or processes and innovation can occur. The main centers of the R & D process consists of industrial research institutes, academic research institutions and government R & D centers. Reverse engineering is extraction and development of technical information from available products. This method unlike the direct designing process meant to production according to customer requirements and the initial idea is based on the engineering analysis. [3]

Many activities in this area are done with different goals daily. Extraction of technical knowledge designed by R & D units in different industries, providing technical documentation of industrial equipment and probably copying the products are some examples in this field. Developing countries to access complicated technologies require a method that fills the technology gap between these countries and the developed countries at the right time and among different methods of having access to technology, reverse engineering is the most appropriate method.

This research was done in the context of systemic thought and to achieve research objectives and answer of research questions, System Dynamics modeling has been used. Modeling dynamic systems is an essential tool in systemic thought that in order to better understand the behavior of the system; imaging and strengthening the conceptive models and displaying the behavior of system are used. Since diversity of effective factors is very significant on issues, in order to obtain acceptable solutions, the least important factors are omitted by using modeling in the study. The general category type of research will also be an applied research.
This study utilizes a model (simulation), which includes relations with variables methods in reverse engineering in R & D units which will be done. This model can be considered as a new process in popular and applied industries. And the places where there is no new scientific and systematic approach in these projects, so this research and simulations can greatly help managers in making decisions and having reasonable controls.

Thus, at first there have been gathered interviews and questionnaires with key members collaboration and make a systematic relation between variables and suitable parameters base on model and achieved the desired data will be collected and model validation is done

and CLD related to basic parameters can be drawn. Then modeling using Vensim simulation software based on raw data and descriptive statistics are done and the parameter sensitivity analyses also take place.

Finally, based on the model output and parameters sensitivity analysis software, necessary suggestions and performed conclusions are provided.

THE ROLE OF INDUSTRIAL RESEARCH ACTIVITIES AND ENGINEERING SERVICES IN THE PROCESSES OF ACQUIRING TECHNOLOGY

The experiences of advanced countries suggests that technological progress in these countries owe R & D activities and technological infrastructure more than anything and without implementing such activities there is no way to achieve the desired technology for that, though by buying the product or purchase process, the required parts can be obtained, but even successful technology business by buying technology (research and development activities necessary for building or research strategies to produce copy that is necessary) also requires research activities and industrial engineering services. For example, before attempting to determine how to access to technology, knowledge and action for defining technology needed to meet demands and needs of development projects such countries need some activities which won't be fulfilled without collaboration of involved ones engineering services directly. [11], [4], [18]

SELECTING APPROPRIATE TECHNOLOGY AND RESEARCH AND DEVELOPMENT REQUIRED ACTIVITIES

The process of selecting technology and appropriate product includes all actions and activities which are contiguous with the objectives, conditions and specifications and technological needs to determine the most appropriate technology requirements and also the most appropriate strategy to achieve the goals is done by considering the circumstances and technical, economic and legal relations. This process typically includes steps such follows:
[6], [1], [2], [8]

1- Information on market needs consumer preferences and market traction for new products.

2 - Information about status of competition, situation of required innovation, research and development activities, products and environmental threats.

3- Having Information about the required global situation of technology and explanations of their pattern in some period of times by using technology forecasting techniques.

4 - Identification of technical and scientific facilities of country and possibility of access to materials, energy, and production processes.

5 - Analysis of investment company status among others in terms of scientific, technical, economic support and technical ability, communication and marketing.

6 - Strategic planning to determine and select the required technology, according to data collected.

7 - Designing strategies to achieve product and selecting the most appropriate strategy (according to the results of technical and economic feasibility studies later we will pay attention to this issue.)

Marketing efforts, policy and strategic planning and selecting the required technology to achieve the set of activities that make up except those involved with research and development activities and research and development, so reaching them is not possible except with effective management of information and technical experiences of engineers. The sensitivity of this action is so much in a way if investments policy and managements not to be done accurately and according to practical techniques and if a comprehensive analysis not to be done, the rest innovation activities will be overwhelmed and they eventually might lead to investment plan failure.

MAJOR RESEARCH AND DEVELOPMENT ACTIVITIES IN THE STAGES OF REVERSE ENGINEERING PROCESS

[9], [13], [14], [10]
1 - Controlling the possible technical and economic studies, making plans to copy a subset of product or product requirements inside the factory.
2 - Researching for understanding mechanisms of functioning components for realization of working mission for products and discovering the relationships between components during operation.
3 - Departing the components that we have decided to copy them and registering charts for the products and its details during operation.
4 - Providing maps and photos, or piece or pieces that they're going to be copied.
5 - Identifying, testing and determining the raw materials used to manufacture any component of product.
6 - Identifying, testing and diagnosis process for production of any component of product.
7 - Identifying, testing and diagnosis of complementary operation performed to achieve mechanical, physical, metallurgical, chemical properties… which are required.
8 - Detecting required machineries and tools for manufacturing and assembly.
9 - Compiling technical knowledge for production and assembly and its components.
10 - Preparing production drawings, maps, templates, models and tools needed for production and control stages.
11 - Monitoring the prototyping operation specifically or under direct supervision.
12 - Controlling samples made and matching them with the profile of desired standards.
13 - Assessing and analyzing test results and in case of necessary, revision of sizes and tolerances.
14 - Designing production and estimating required machinery and equipment.
15 - Planning of factory and designing factory production and assembly line.

METHODS

This paper aims to achieve a model to evaluate the capabilities and competencies of R & D of a chemical factory based on modeling system. This model is provided to managers and decision makers as a tool and it plays the role of easing in decision process and opting organizational strategies. So according to this view, this article is considered in the category

of applied research. On the other hand the type of approach used in the paper is in a way that by dynamic modeling, the effective components on planning present a new model and it solves the problems that current planning methods are facing with. In this study it is tried that modeling (simulation) and all factors and important variables and influencing patterns, trends empowerment of R & D unit for the chemical industry to be considered with an approach of reverse engineering in order to strengthen R & D unit. [8], [15], [19]
First stage: gathering effective factors on research and determining the primary assumptions
Second stage: determining the most important factors affecting research and inserting them in the initial model and draw CLD to determine relationships between factors and variables for the basic model.
Third stage: extending the primary model and finding datum and formulas for model and model validation
Fourth stage: testing Software Model (simulated) [17], [20]

Introducing the basic components in capability of Research and Development (R&D) of the chemical Factory

[7], [8], [19]
This section is based on offering presumptions that simply realize modeling process and it is attempted to present the model which can be implemented in Vensim software.
Assumptions made are extracted based on the information of a Chemical factory and interviews with senior managers and library studies and the most effective variables and essential factors are mentioned bellow:
1 - Professional and skilled personnel (manpower)
2 - Identification of risk factors
3 - Market and customers needs
4 - If necessary interaction with industries and marketing and production units
5 - System inputs include raw and new materials (new requirements)
6 - Technical Knowledge
7 - Sufficient capital (cash flow)
8 - Cost market
9 - Planning
10 - Economic blockade
11 - Project Manager
12 - Skillful and risky management of R & D

Model Validation Test

In order to demonstrate the model validity, we use real tests K Square test to explain credibility. Since based on calculations done on questionnaires and interviews, the most effective factors and variables in the model were determined, and information relevant to the years 2001 to 2011 are available.
So by putting this information in the model, the information of next year is predicted and they are measured with realities so the credit degree of model could be provided.

It should be mentioned that information and figures of influential factors, including system inputs (raw materials, equipment, technical knowledge), human resources, including (motivation, working group, spontaneous, education, good environment, planning and project control, management empowerment and the number of projects done in R & D through the questionnaire were determined. Also system inputs, planning and control of projects, skillful management of Research and Development and human resources were considered as independent variables and the numbers of projects R & D were considered as the dependent variables.

The aim is that according to the four-term factors: 1) system inputs, 2) Planning and Project control, 3) strong management, 4) Human Resources with a number of projects to reach an acceptable quality.

Model validation test by using of real data test & square of KAY :

Human Resources	Strong management of R&D unit	Planning & Project Control	System Input	Number of ended project in R&D unit	Year
6.45	5.6	7.75	6	2	2001
6.75	5.92	7	6.16	5	2002
6.8	6.08	7.75	6.4	7	2003
6.55	6	8	6.75	2	2004
6.45	5.92	7.5	6.66	1	2005
6.4	5.33	7.25	6.5	1	2006
6.2	5.41	7.25	6.33	3	2007
5.9	5.5	6.75	6.41	0	2008
5.6	5.33	6.75	6.08	0	2009
4.95	5.1	6.5	5.91	7	2010
7.6	7	8	7.6	5	2011
7.6	7	8	7.6	5	EI- Model (fit)
2.949	2.872	0.983	2.237	$X^2_{(n-1)}=x^2_{9,0/05}$	X^2

Table1: Model validation.

According to figures contained in the questionnaire, the average number of variables and factors extracted from 2001-2011, they have been mentioned in above table and then for

credibility and accuracy of model operation, the K Square test was measured by the following formula:

$$X^2_{(n-1)} = \sum \frac{Oi - Ei}{Ei}$$

And the figures of ^2X was extracted according to the above table; X^2 which was provided according to K Square test is $16.92 = X^2_{0/05,9}$ and since X^2 is four variables of model and is less than 16.92, so the modeling assumption is accurate and according to the figures and information listed above, the model is accepted with 0.95 confidence.

C.L.D Draw

After extracting the effective parameters on model, in the second step of modeling, the causal relations between the parameters must be considered, so for this purpose, we extract C.L.D. It is noteworthy that due to the volume of datum and the high number of parameters affecting the issue, single-step extraction of C.L.D is not feasible.

Therefore for the purpose of understanding it easier, we divided the casual model of the issue into five stages and in each stage a loop of causal model has been drawn; and then finally according to the defined relations, we link each stage to the other stages and each component to the other components to achieve the ultimate causal model of the problem. Finally, the effective parameters of the model simulation, sensitivity analysis and the related results are also presented.

CONCLUSIONS

As noted, the purpose of this paper is presenting a local model to consider capabilities and abilities of Research and Development unit by emphasizing on reverse engineering in a Chemical Factory. Based on the pattern provided, indicators and parameters to measure Features and capabilities of R & D unit are available.

In this model, some of the basic parameters which were measured, analyzed based on sensitivity analysis include:

Number of Projects done in R & D unit, system inputs such as raw materials and new requirements, professional and skilled manpower, skilled management of R & D, Project Planning and Control of research and development project in analyzing the sensitivity of above indices and parameters, some results were obtained. By eliminating restrictions of indices, it means in terms of optimism for the variables, we can mostly observe that growth is very rapid rate for parameters and variables and also features R & D unit and ultimately the growth of parameters lead to significant increase in the rate of the number of projects conducted by R & D unit. Also by considering the conditions of reverse condition it means, the sensitivity test of variables in terms of increase of barriers in the parameters, we can mostly witness decrease of parameters and number of projects done in R & D.

Finally by reviewing the outputs of model software graphs and sensitivity test of parameters and effective factors for model, in this article the capabilities and abilities of Research and development (R & D) of chemical factory have been determined.

We can use these indices and variables to achieve specific goals specific and by comparing them relatively with other industries of R & D and or by comparing them with research and development units of industrial plants located in other countries, the efficiency and effectiveness of R & D unit in the chemical factory to be measured.

Finally, this model can be used to identify desired features and capabilities of R & D and to use required managements to reach them and they be used to successfully control the programs. The model has the ability to generalize and use in most application areas for selection of strategies, policies and research and development projects and access to new technology and we can observe the basic parameters of the model by its effect on the capabilities and abilities of research and development unit.

By observing all tables and charts of the basic parameters we can conclude that in spite of reduced volatility variables and factors in the model during the years 2001-2010, the increase of projects number in R & D unit of chemical factory has had a good condition. This increase is relevant to the urgency and necessity of unfinished projects which are being done by the important factor of R & D Management.

According to the relations of all the basic parameters and doing regression and the corresponding formula model, we can conclude that the most effective factor on the number of projects is the factor of management, planning and control of projects and R & D

unit of the chemical factory has a good condition in terms of R & D management, and the reason of this issue in addition to observing relations of variables and formulas coefficients, in addition to the information and graphs is due to necessity and emergency point of unfinished projects and coordination of the main parameters by skillful of Research and development (R & D).

FINNISH SOCIAL HOUSING MODEL AS AN EFFICIENT POLICY MAKING TOOL IN TURBULENT ECONOMIC ENVIRONMENT

Rayko Toshev, University of Vaasa, Finland,
raytos@uwasa.fi

Teppo Forss, University of Vaasa, Finland,
teppo.forss@turku.fi

jot@uwasa.fi

ABSTRACT

This paper explores how effective a social housing policy can be in solving the challenging situation in North Africa and the Middle East. Economic pressure on food and energy prices combined with high unemployment among young people has triggered massive protests against long ruling regimes and dictators. It is obvious that the communication technology progress is uniting the voice of people from lower society levels and they start to feel much stronger in the act of searching freedom and equal social opportunities. Regimes in Tunis and Egypt were overthrown by rioting masses of demonstrators. Even long ruling dynasties from Middle East had to re-evaluate their policies and try to provide better conditions for prosperous future to their citizens. As one of the predominant factors that sparkles the crisis is the fact that these countries have high present of homeless young people, social housing can be seen as an effective tool to solve the needs of this people. Comparing these countries with the Finnish model gives the new people elected governors a lot of opportunities, while at the same time highlights major differences in the developing cycles of the real estate business.

Keywords: Decision support system, sense and respond, analytical hierarchical process

INTRODUCTION

This study discusses pragmatic business considerations in decision making. It considers the multi-focused strategy theory aspects of the decision-making process for TVT and relates the various decision-making models to that process. It is based on a vast collection of empirical interviews, secondary data and inside knowledge of city of Turku and examines the potential effects of critical factors recourse allocation design approach on the social housing, in context of national policy issues as well as local agendas.

Reallocating resources in housing market in times of global economic turbulence triggered from derivatives written over the same market segment is a responsible task. In ensuring affordability of owner-occupied and private rental housing and enhancing tenants living experience, management have to make decisions for the future of the company based on information dispatched from expectations for the capital flows and level of service needed.

The different business layers in real estate companies can generate versatile signals which create information gaps and retreat efficient decision making from day to day operations. To fill these breaches, we start from the company's systems and processes, which support customer deliverables. They are applicable sources for searching up much needed relevant information about whether or not the organization is satisfying the customer.

Front desk staff and maintenance process owners acquire first hand information about the demanded level of service and operational effectiveness. They gather experience about what customers expect from the company and provide estimate information for the operation management and company's network of service and product suppliers. When transmitted on to top management centre and executives, this information is filtered through the process; it does not contain too much relevant data for potential clients or competitor analysis. It would be inefficient to disregard free and easily accessible customer information accumulated inside the company. Utilizing effectively this knowledge requires flexible strategy orientation combined with proactive identification and assessment of service concepts. Considering the long time span of the business cycle in real estate market and the difficulties in forecasts in volatile economy, top management need to deal with heterogeneous hierarchy of variables, cost time quality and flexibility taking the main priority. Structured DSS prevent executives from setting up main business strategy goals, based on expectations about experience of customer's expectation, and establish high level of sensitivity enough to comply with turbulent business environment.

FINNISH HOUSING MARKET OVERVIEW

Finland is one of the first countries to provide public housing. In 1909 wooden houses designed by the architect A. Nyberg were built in Helsinki for the city's workers. The residents were mainly working-class families with several children. The apartments were constructed for communal living for five people per room, sometimes up to eight, equipped with basic utilities running water, a pantry and an attic cupboard. Electric lighting was installed in 1918. On other hand private real estate market in Finland is relatively young comparing to other European countries. The driving forces during the last 60 years have been migration from rural area to urban cities and it is dominated by the lack of capital. Nordic climate conditions and new demanding sustainability factors set the building price relatively high. There are complete set of regulations concerning the location, building processes, as well as the business operations to be followed. One third of all Finnish homes are rentals, situated in concentrated urban areas. Major market trend is the building of new houses, while renovation of old property is less than third. Government is using the housing market as a tool to implements political goals like social and economical equality, economic growth and stability, and environmental issues.

RESEARCH BACKGROUND

The roots of decision theory lay within models of conscious judgment and rational choice. Real estate companies are using models for optimal pricing and allocation of assets, based on assessment of performance and strategic goals. At the same time real estate economics does the research of real estate trends focus on the business and structural changes

impacting the industry. They both analyse the equilibrium between supply and demand, taking into consideration urban economics, spatial economics, extensive research, surveys on customer satisfaction and finance. In the increasingly complex world of real estate business, it is hard to balance multiple day to day operation decisions required with complex development projects and cardinal shareholders goals. Often, judgments are made relative to current expectations and current business constraints. While a decision-maker may believe in the required optimum resource allocation levels, as dictated by optimal pricing model, the final decision may/will be influenced by factors outside the parameters of that model. Yet, as Nick French points, much of decision theory does not lie entirely within any one discipline: it draws upon psychology, economics, mathematics, statistics, social sciences and many other areas of study.

Contemporary view of progression of economic values, spread out by Pine and Gilmore, puts experience and customer delight at the top of the competitive advantages and pricing level possibilities. It brings customers coming back for more, creates interest in new customers and distinguishes your company from the competition.

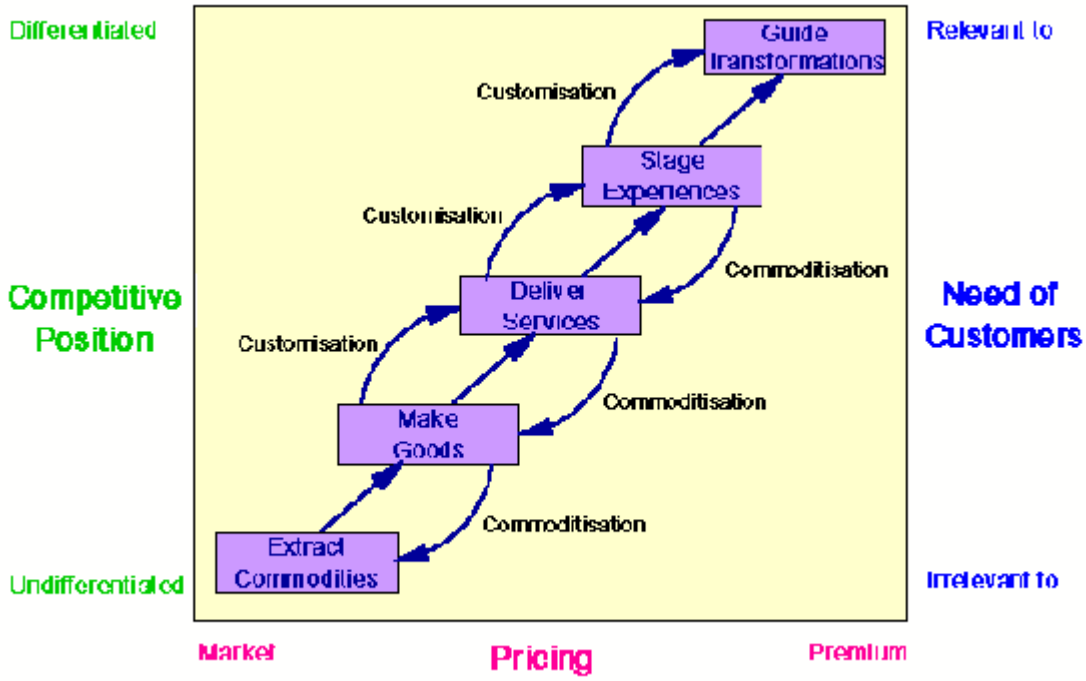

Figure 1 : Progression of economic values.

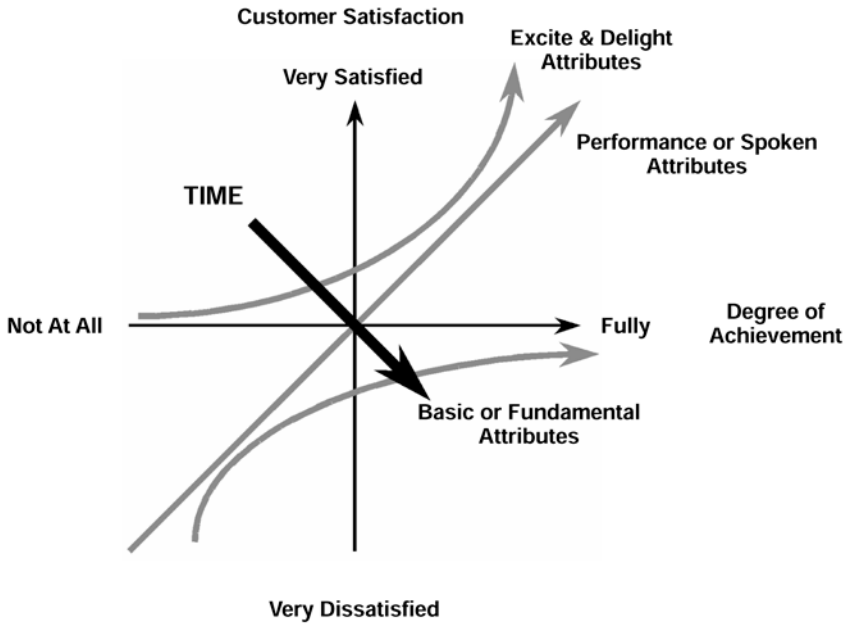
Real estate and service industries start to implement the power of a mass customization orientation. Front desk and call centres are leveraging agent-assisted technology to handle customers' inquiries and replenish data relevant for structural decision making. The process variation gets minimized with the expertise usage of that data as operators need to modify response only because of something the customer says or needs, as opposed to varying everything, every time. (Adsit, 2009).

At the same time to be able to get sustainable effect, one needs deep expertise in sensing customer behaviour as well as implementation of value added processes that are hard to

copy. Our case study in Finnish housing market targets the application of Customer Delight model in construction of DSS in making reasoned judgement in this selection and taking actual actions in re-allocation of resources.

CUSTOMER DELIGHT

The model of Dr. Noriaki Kano is aimed at capturing the voice of the customer for requirements for products and service. Originally conceived in the 1970s as a quality tool for obtaining a good match of customer need and product feature and function, project managers can apply this tool not only for grading requirements but also for evaluating budget allocations and priorities and for assessing qualitative risks. In this regard, Kano models are quite useful for project managers who must make dollar decisions about where discretionary funds can be best leveraged for business value.



Source: Kano *et al.* (1984)

Figure 2: Customer Delight Model.

Kano really only addresses two of the focus areas already described: customer perspective and product excellence. The Kano model pretty much ignores operational effectiveness, except as operational effectiveness is reflected in product or service quality that influences customer satisfaction. In addition the delight factor, proposed DSS implement AHP criteria weights for measuring the operational effectiveness. Only providing good customer service by itself is not enough cost effective. The goal is to enhance property values through active day-to-day management that focuses on maintaining high levels of occupancy and clients satisfaction, while lowering facility costs.

ANALYTICAL HIERARCHICAL PROCESS

AHP is a structured technique for handling complex decisions making. Rather than imposing a "best" solution, the AHP helps decision makers find one that structure of criteria priority suits best their goal and their understanding of the problem. It is a process of organizing decisions that people are already dealing with. AHP goal is to integrate different measures into single overall score for ranking decision alternatives. It uses pair wise comparison of chosen attributes. AHP allows executives to take into consideration both quantitative and qualitative measures and make trade-offs in between. The process initiates by structuring the decision problems in a hierarchy of criteria and then connecting the comparisons to get the weights of each criterion with respect to the goal. It is suitable when applying multi-focus strategy in large companies.

Value for a competitive index CI is calculate in different types of business groups such as prospectors, analyzers and defenders according to Miles and Snow organization types. The indexes have been calculated using normalized values of the main priorities Quality, Delivery, Cost and Flexibility respectively. The indexes are calculated as follows:

Prospectors:

$$\phi \sim 1-\{(1-Q\%^{\frac{1}{3}})(1-T\%)(1-C\%)\times F\%^{\frac{1}{3}}\}$$

Analysers:

$$\lambda \sim 1-\{(1-F\%)\times(ABS(\Delta Q*\Delta T*\Delta C))^{\frac{1}{3}}\}$$

Defender:

$$\varphi \sim 1-\{(1-C\%^{\frac{1}{3}})(1-T\%)(1-Q\%)\times F\%^{\frac{1}{3}}\}$$

DATA COLLECTION

Information about the company was collected from interviews, organized workshop for research method introduction and tutoring, approximately 25 questionnaires forms in the company to choose major critical factors, pair-wise comparison questionnaire conducted by the CEO, District manager and firm's financial statements to see how it reflects possible Business process orientation. After building up the empirical knowledge about corporate strategy the competitive priorities model was constructed using the AHP-Expert choice software. Main criteria were given weights considering two situations-before and after crisis to study the effect of the economic environment on the decision making process.

RESULTS

Results of questionnaires were analysed by AHP software "Expert choice". CI values and CFI were calculated according to the methodology formulas developed and presented in the

Industrial Management department of the University of Vaasa. They represent assessment of the multi-focused decision making process inside the company and the Sense and Response methodology evaluating critical factor values in particular.

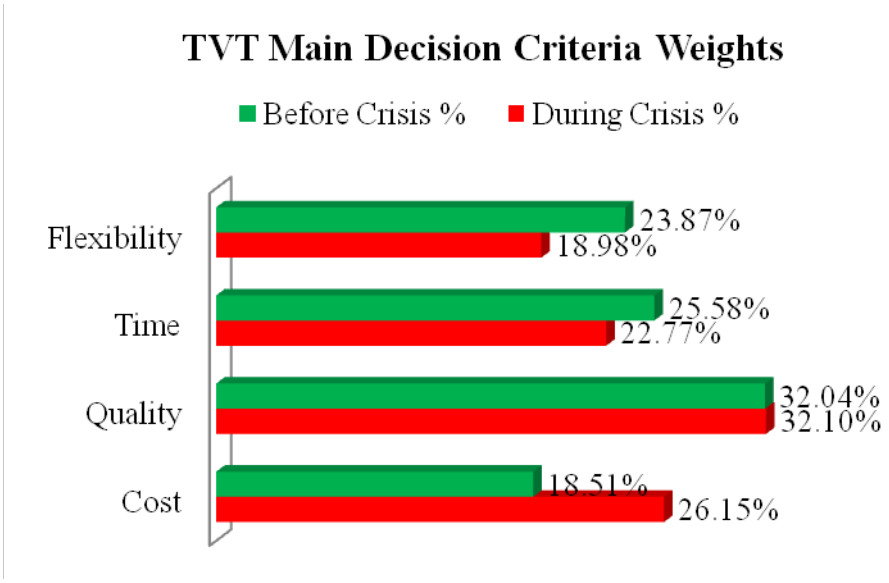


Figure 3: Main criteria weight results.

Main criteria values shows that the quality focus remains the most important criteria's for successful business, cost, timeliness and flexibility expanded their importance. The company more and more needs to achieve its quality goals in especially cost oriented manner. Flexibility priority takes the blow in the housing crisis situation and end up as the least important variable. Before crisis flexibility value turns out to be higher than expected. High level of flexibility is needed in companies looking for new markets or market share growth. Flexibility is a core competitive advantage in improvement of added value for customer and redesign of business cycle. The increase of market share is not a priority for TVT, neither in Turku or other areas. In this context from the high flexibility results TVT is unnecessary loosing resources, efforts and profit. As housing market is capital intensive business with long life cycle of products the company will not put itself at risk, as the business entrance barrier is high.

We calculate a numeric value for a competitive index in different types of business groups such as prospectors, analyzers and defenders according to Miles and Snow organization types.

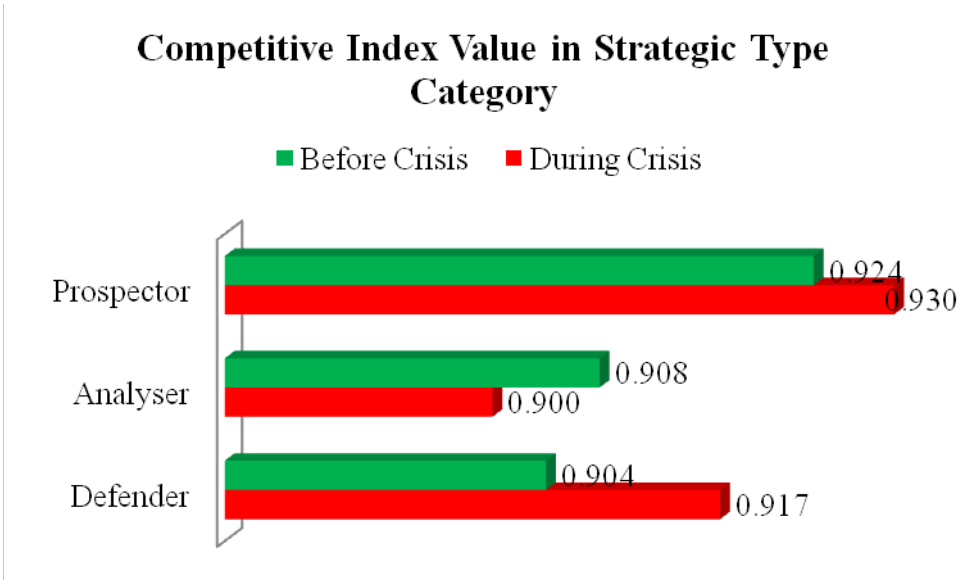

Figure 4: TVT Competitive index results.

From these results TVT performs as a prospector type of company in the segment of social housing market. Finnish Government offers direct subsidy supports for persons with economic issues, health problems, immigrants, unemployed, bad credit histories, which have low to no chance to be accepted as customers for the private home rentals. State authorities also give indirect credit guaranties to cap the interest rate to 3,4% on real estate properties offered to these individuals. This market niche is a 40% of the TVT clients. In this sense it is unique service function fitting.

Defender type of strategy is limited to cost competition. While TVT is keen on keeping its main customer group, price sensitive clients, it also possible to increase profit margin by adopting analyser features in segments like family and luxury, city centre wooden houses. By adding additional competition issues in the core competence portfolio, TVT services are moved up from continuous improvement to mass customization concept.

Customer Delight may be the difference between success and failure during turbulent times. It creates the additional clients attractiveness that one can't place a momentary value to. This exploratory study provides traffic light system for identifying critical factors that have to be taken care of immediately. After calculating series of indices, the results are generalized in the CFI index. It is also a basis for benchmarking of prioritization of factors in the business.

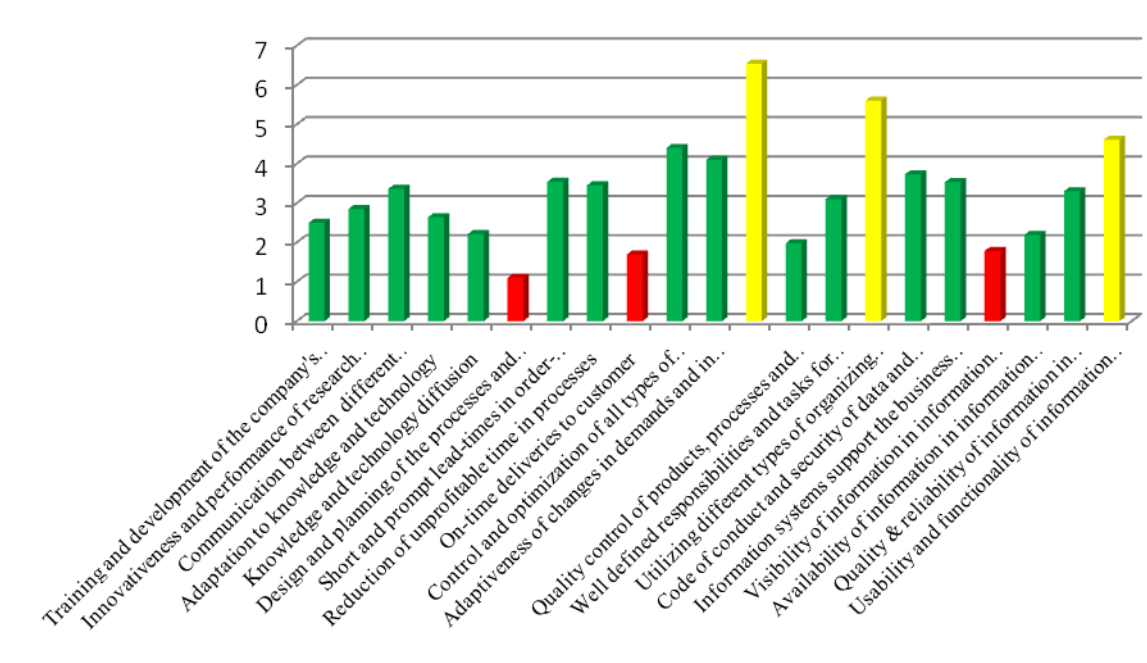

Figure 5: CFI index results.

CONCLUSIONS

Major competition issues in housing markets are price, location, size, condition and security. TVT performs as a defender type of company in the regular housing market, being price competitive to private housing organizations. Due to the government support system TVT can reallocate profit to keep low rental price level. Housing and real estate overall is capital intensive business, which translates to interest rate variation having high impact on rents. Government support system limits the effect of interest volatility to prices.

Time gap between tenants is one big loss generator. Streamlining this process with maintenance counterparts decreases vacancies rate. The housing management function is divided between company own unit and outsourced to outside companies. According to customer, the service provided by the own unit is valued higher by tenants. Cost analysis showed that the outside companies are more expensive than own work.

At the same time, advanced service segmentation between the different customer groups and optimal process design to reach the delight experience was pinpointed as the best option for profit increase.

TVT aim is to keep strong position in Prospector type of company in social housing market. It has a strong core competence operating in this market area without any competitors. This strategic advantage can be exploited in various ways. Pricing can be increased with the value of the administrative work done inside TVT, and by additional standardization of the whole service process.

The benefits of a fast and comprehensive method to gather important information in order to make resource allocation decisions at operational level are self-evident. Property fund

managers should be active - 'doing well by doing good' and as technology costs fall and energy costs rise, more and actions are economic driven. So improvement in the customer satisfaction can be seen as "low cost-high impact" action to combat lower rental growth, faster depreciation and higher risk premium, leading to higher yields and lower values over time. The benefits of our proposed DSS can be summarised as lower maintenance cost with efficient work order and preventative maintenance execution Reduce administrative costs by harmonizing lease execution and optimizing space utilization. Businesses that can effectively manage utilization and costs associated with real estate assets stand to reap substantial benefits. A complete, integrated strategy of all critical business functions is the foundation for effective real estate management.

However there is still the need of further development and therefore should be tested in future case studies. CFI can be utilized to test internal as well as external processes, based either on expectations and experiences of employees, customers or business partners.

FRAMEWORK FOR STRATEGIC TECHNOLOGY MANAGEMENT IN HIGH-TECHNOLOGY ENTERPRISE CONTEXT

Dr. Kari Sahlman*, Nokia Siemens Networks, Finland
kari.sahlman@nsn.com
***corresponding author**

Prof. Harri Haapasalo, University of Oulu, Finland
harri.haapasalo@oulu.fi

ABSTRACT

Strategic technology management is an important practice for enterprises in an increasingly complex economic and social environment. In technology-based global competition advancements of technology proliferate rapidly. Companies have to manage their technological capabilities for business model development, product innovations, and for maintaining their productivity and competitiveness.

Entire field of strategic technology management is ambiguous and literature on theoretical frameworks is diverse. Practitioners in companies are lacking a comprehensive frame of reference for strategic technology management. In this paper a framework is discovered to describe elements of strategic technology management in high-technology enterprise context.

The framework is developed based on literature findings and by obtaining qualitative information on enterprise practices. The empirical research was conducted in 2008 – 2009 in the context of 45 large and small to medium-sized high-technology product companies and involved some 70 informants. Mainly abductive reasoning is used to infer explanation for the framework. Integrated management theory is applied to consider technology management in strategic dimension, categorized as structures, objectives and impacts.

Strategic management, organizational management, and technology management concepts are united in the framework as the main theoretical contribution. The paper provisions an outline to assist practitioners in definition and development of the practices in enterprises. As managerial implication, it is suggested that companies should consider establishing strategic technology management as an own managerial function amongst other organizational management disciplines.

In summary, the framework provides for scholars and practitioners a logically structured framework for strategic technology management.

Keywords: Strategic management, technology management, framework, MoT, technology management framework, enterprise, enterprise development.

INTRODUCTION

In technology-based global competitive environment companies have to manage their technological capabilities to maintain their competitiveness. Strategic technology management is an important practice for enterprises in an increasingly complex economic and social environment. The field of strategic technology management is related to several management disciplines, and literature on theoretical frameworks is diverse (see e.g. Khalil, 2000; Tidd, 2001; Phaal et al., 2004; Pilkington & Teichert, 2006; Cetindamar et al., 2009). For practitioners in companies *the problem is that there is no comprehensive frame of reference for strategic technology management*. In this paper a framework for strategic technology management in high-technology enterprise context is synthesized from based on findings from four individual research phases. The research question is:

RQ What are the elements of strategic technology management in high-technology enterprise context?

The framework was developed during 2008-2009 based on literature findings and by obtaining qualitative information on enterprise practices. The empirical research was conducted in the context of 45 large and small to medium-sized high-technology product companies. In the interviews and workshops some 70 experiences informants who knew the topic well were involved for structures and impacts category study, and technology management decision making material from a large company was used to gather information for the objectives category. Mainly abductive reasoning was used to derive some 250 classes and sub-classes for the 18 main elements of the framework. Integrated management theory of Bleicher (2004) was applied to consider technology management in strategic dimension categorized as structures, objectives and impacts. For each of the category a complete research phase was conducted, the results were documented and an article was written. In each of the articles the research process is presented and discussed in detail. The overview of the research proceeding is presented in Figure 1. The 5th research phase is in the scope of this paper.

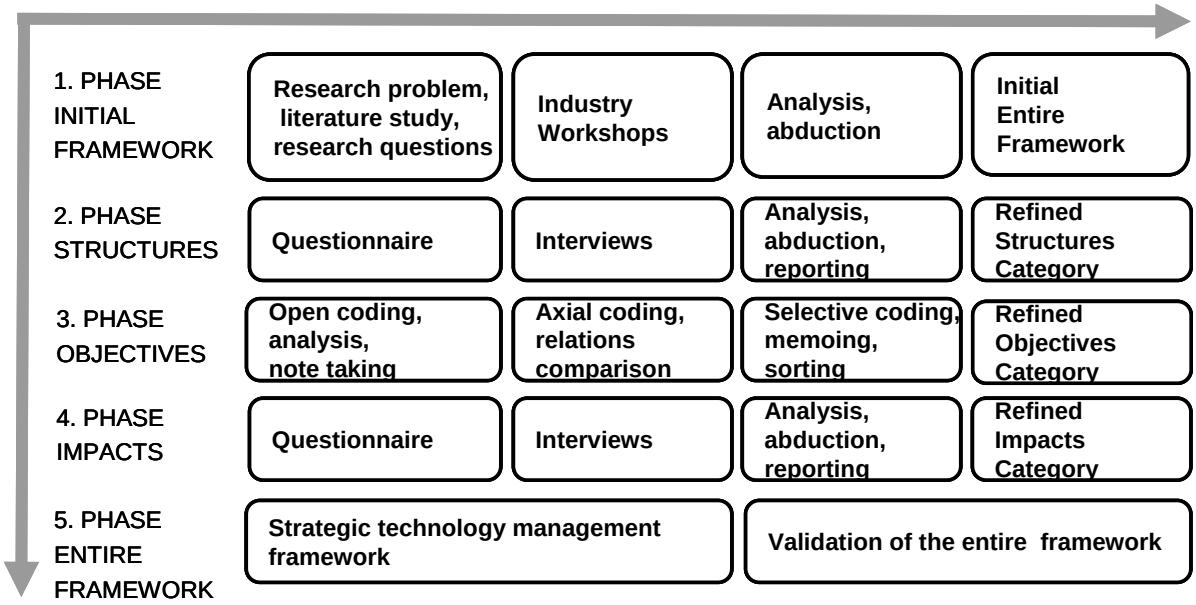

Figure 1: Proceeding of the research.

TYPES OF TECHNOLOGY MANAGEMENT FRAMEWORKS

Linking business to technology is a managerial challenge in enterprises. Strategic technology management is assumed to provide a solution to manage complexity caused by technology in dynamic environment (e.g. Burgelman et al., 2001; Dodgson et al., 2008). Technology management is often conducted as part of R&D management or innovation management (Drejer, 1997; Edler et al.; 2002, Tidd, 2001). Drejer (1997) have described four schools of technology management that emphasize R&D management, innovation management, technology planning or strategic technology management. According to Edler et al. (2002) so called 4th generation R&D management sees R&D and technology as strategic instruments for competitiveness and innovations, and emphasizes formulation of explicit technology strategy and integration of technology with business strategy. Current themes in R&D management are open innovation, networked R&D and knowledge management (Chesbrough, 2006; Lichtenthaler, 2008). In innovation management school the emphasis is on anticipation of technological changes and incubation of innovative products for commercialization, whereas in technology planning school the scope is to manage technology across the company using specific management methods like road mapping and portfolio management (e.g. Cooper et al., 1998; Tidd, 2001). Strategic technology management school combines technology and business aspects through management of technology activities (e.g. Drejer, 2004; Phaal et al., 2004; Lichtenthaler, 2008).

Positioning of strategic technology management is difficult due to the intertwined nature of technology in enterprise management. Multiple theoretical and practical frameworks for describing elements of technology management have evolved, but still the entire field is confusing and boundaries of concepts are blurred, and there are no commonly accepted frameworks (Phaal et al., 2004; Brent and Pretorius, 2008; Cetindamar et al., 2009). In table 1 is presented main types of technology management frameworks. Each of the framework types emphasize particular aspects of technology management i.e. processes, routines, methodology, need to integrate technology management with core business and strategic processes, or technology management as management of knowledge flows. Integrated management approach introduced by Tschirky (1991) sees technology management as a task of general management and divides the tasks into normative, strategic and operative dimensions.

Table 1: Main types of technology management frameworks.

Technology management framework type	**Example reference**
Generic process model	Gregory,1995; Cetindamar et al. 2009
Technology management functions	Kropsu-Vehkaperä et al. 2009
Technology management routines	Levin and Barnard 2008
Technology strategy approach	Burgelman et al. 2001
Innovation funnel	Wheelwright and Clark 1992
Knowledge management	Nonaka 1995
Methods and tools approach	See e.g. Phaal et al. 2006
Integration into core business processes	Metz 1996; Phaal et al. 2004
Integrated management concept	Tschirky 1991

FRAMEWORK FOR STRATEGIC TECHNOLOGY MANAGEMENT

For the framework development concepts from strategic management, technology management and organizational management theories are used. The essential concepts and key references are presented in dissertation of the author. From strategic management perspective the role of technology in value creation, business model definition and as a source of productivity is emphasized. Moreover, technological capabilities affect on company's success in formulation and execution of company's business strategy. In external socio-economic context technology has a major impact for sustained development and wealth creation. For the framework creation integrated management concept is used as the basis from organizational management theories. (Sahlman and Haapasalo, 2009a; Sahlman, 2010)

Elements of strategic technology management are described in strategic dimension in three categories: *structures, objectives and impacts*. The framework is a reference model that describes the categories, their main elements and contents to provide viewpoints on strategic technology management. The strategic technology management framework is presented in Figure 2.

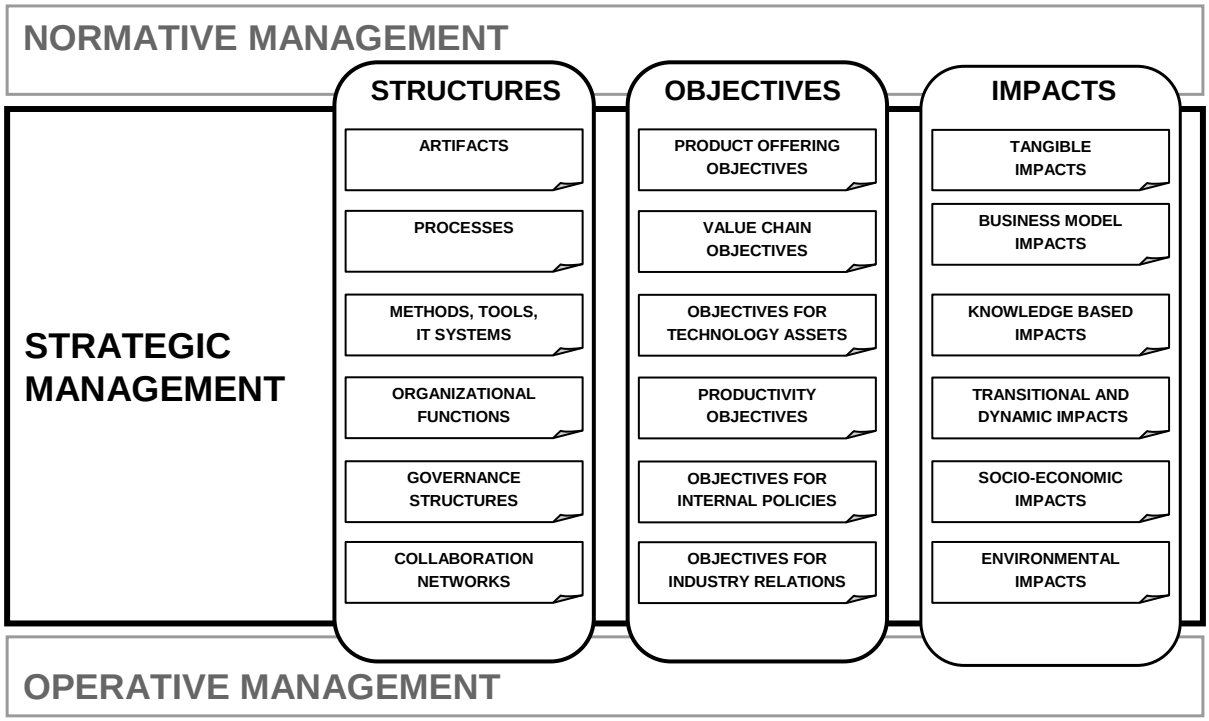

Figure 2: Strategic technology management framework (Sahlman, 2010; published by permission of ACTA Universitatis Ouluensis)

Structures category of the framework

The *structures* category contains the main classes of artifacts; processes; methods, tools and IT systems; governance; organizational functions and collaboration networks. The category contains a logical process view to a company considering methods, tools and IT systems that

are needed to produce artifacts by procedures and practices. The operative work is governed and performed by organizational functions that are making decisions and managing the activities. Furthermore collaborative networks represent stakeholders that are involved in the activities and form a part of the technology infrastructure for the company. The *structures* category of the framework is presented in Table 2.

Table 2: Structures category of strategic technology management framework (Sahlman and Haapasalo 2009b, published by permission of PICMET conference organization).

Main element	Definition
ARTIFACTS	Information, documents, reports, plans, prescriptions as the outcomes of the performed processes of technology management.
PROCESSES	Procedures and practices performed to transform inputs into artifacts of technology management.
METHODS, TOOLS, IT SYSTEMS	Techniques and tools to perform tasks of the procedures and practices of technology management. Information systems for processing and storing artifacts generated in the processes of technology management.
GOVERNANCE	Management structure, definition of authorization and policies for decision-making of technology management topics.
ORGANIZATIONAL FUNCTIONS	Managerial disciplines of an organization for planning, organizing, leading and monitoring technology management functions.
COLLABORATION NETWORKS	Stakeholder organizations involved in the company's processes of technology management.

Objectives category of the framework

The *objectives* category's main elements consist of product offering, value chain, technology assets, productivity, internal policies and industry relations. The *objectives* category of the framework is presented in Table 3.

Table 3: Objectives category of strategic technology management framework (Sahlman and Haapasalo, 2011b, published by permission of Inderscience).

Main element	Definition
PRODUCT OFFERING	Objectives for product offering enabled by technology e.g. cost, performance, capacity, quality, reliability, availability, maintainability, and commonality.
VALUE CHAIN	Value chain related objectives for technology supply e.g. business scope and scale of technology use, position in value chain, revenue logic, supplier lock-in, technology change cost.
TECHNOLOGY ASSETS	Objectives for technology assets e.g. scope, scale of deployment, lead time for products, life-cycle state, performance, and compliancy to internal and external standards.
PRODUCTIVITY	Objectives for productivity enabled by technology e.g. technology portfolio scope and scale, life-cycle position, operating expenses, capital expenses, scope and scale of competence and resources to develop and maintain the technology base.
