PREFACE

The 3rd International Technology Innovation and Industrial Management was organized in Oulu, Finland in 27.6. – 1.7.2011. The TIIM 2011 conference was jointly organized by the University of Oulu, the Oulu University of Applied Sciences and the Faculties of Engineering and Business Administration at Kasetsart University in Bangkok, Thailand.

The aim was that the TIIM 2011 brings together researchers, scholars, and practitioners from different countries from different parts of the world so that global viewpoints on technology, innovation and industrial management can be exchanged. The TIIM 2011 covered many topics. The scientific sessions were scheduled under titles: Organizational management perspectives, Decision-making and strategic management, Customer satisfaction, Knowledge management, Logistics, Productivity, Performance management, Sustainability, Well-being, Innovations in higher education, Product life-cycle management, Sourcing, Financial perspectives, Sustainability, Organizational learning and innovation, Business networks, Business process management and Trust in business relationships.

This proceeding is the collection of the 136 scientific papers accepted to be published and presented at the conference. They present many aspects of technology, innovation and industrial management. The papers are listed in the order of appearance in the conference itself. The editors wish that this publication was a useful tool for those participated in the TIIM 2011 conference and their co-authors to prepare new ideas for the TIIM 2012 in Lublin Poland. We also hope that some researchers outside the TIIM community find this edition useful with its very extensive scientific content.

We as the editors would like to express our sincere thanks to all authors and all those who made the TIIM 2011 a successful international academic event.

Editors

ABSTRACT

This study proposed an innovative and feasible Precise Marketing Model (PMM) which applies information sharing, collaborative marketing and data mining concepts to improve marketing efficiency and increase marketing performance. The purpose of this study is to develop the Precise Marketing Model prototype, which can assist small and medium sized enterprises (SMEs) locate new customers who match the 'significant few customer' profile according to the Pareto Principle and relocate 'the long tail' customers to other SMEs, in order to obtain the most favorable customers with greatest benefits.

This study adopted literature review, NGT and case study to develop the PMM operation mechanisms. There are six operating mechanisms of the PMM include collaborative regulations, user friendly operation system, co-marketing channel, information security, performance evaluation and attractive promotion activities.

This research will establish the PMM system prototype and validate the practical feasibility of the prototype by conducting three experimental studies and evaluating the performance of the prototype which are using. In the end, the study will discussed the implications for applying the CISM and suggested some directions for further study.

Keywords: precise marketing, collaboration commerce, database marketing, customer profiling

INTRODUCTION

Pareto Principle pointed out the concept of “trivial many and significant few”. 80% of the customers belong to “trivial many”. Without these customers, the company will be subjected to profit loss. But if the company lose a portion of the remaining 20% of the customers, the “significant few” group, the company will also be in trouble. How to keep the existing old customers and further develop the new customers belonging to “significant few” is becoming one of the most important strategies in business development.

Ulrich and Brockbank (2005) suggested customer literacy. Customer Literacy means that the business should clearly understand which customers are the significant few customers that bring in 80% of the company’s profit. The primary data, purchasing motives, purchasing habits and consumption behaviors of the customers are the customer literacy data that businesses should obtain and master. Information technology is quite a trend nowadays. Using it as a customer relationship management technique, not only can promote the interaction between the business and its customers, it can also help collect customer information from their interaction. By analyzing the marketing activities information like customer response, marketing and product supply relating statistical data, selling and purchasing data, customer data, customer online registration data, relating service data, product market data and internet selling data, businesses can clearly obtain the customer literacy of the significant few customers (Cachon and Lariviere, 2005). With clear customer literacy, the businesses can select different effective marketing strategies aimed for the significant few customers. In addition, businesses can undergo new customer development in target markets that conform to the customer literacy conditions and expect that the most efficient marketing strategy can help the company obtain the most profitable customers.

By leaning on marketing agent to obtain effective customer information is one of the fast methods for businesses to obtain effective customer information. In the recent years, due to the rapid development of information technology and internet, it is already very common to find both local and foreign companies through marketing agent to share their customer’s information. The credit card departments of many banks also use co-branded cards and inter-industry alliance to share each other’s customer database. For example, the credit card departments of banks and shopping malls use co-branded cards. Using the discounts and premiums to promote the consumption of the credit card users bring more business to shopping malls and the customers of shopping malls that apply for co-branded cards can obtain discounts and various services. The more important thing is that strategic alliance can combine both of their customer groups and the customers can also obtain more benefits and quality services. These examples of inter-industry alliance that shares customer information were already numerous (Weng et al., 2007).

Marketing agent need to establish customer relationship management system to all collaborative members in order to collect transaction information then use data mining to establish customer profile regulations. Then, add collaborative marketing to select and examine each other’s customer database. Lastly, through the marketing agent to integrated marketing platform to exchange the market information, marketing process and customer information.

LITERATURE REVIEW

There are important issues involved in the study: collaborative commerce, Transaction cost theory, and Social capital theory. The studies related to these issues will be reviewed in the section.

Corporate collaboration

Corporate collaboration allows organizations to improve the efficiency and quality of their business activities. It may occurs a workflow collaboration, a supply chain collaboration, or as collaborative commerce. Collaborative commerce uses information technology to achieve a closer integration and better management of business relationships between internal and external parties. There are many emerging issues in collaborative commerce and one of them is access control.

To implement collaborative commerce, interfaces between the system elements of the organizations that are involved in the collaboration are needed. However, access control policies are often inconsistent from interface to interface, and therefore conflict resolution should be considered to resolve multilevel access control policy problems. Many studies propose different rules for the resolution of the conflict between access control policies, but little attention has been given to the relationship between the groups or subject classes that represent the different types of corporate collaboration. In this paper, the format of corporate collaboration is considered, and the conflicts between the access control policies of interfaces are addressed. Some general guidelines, other than those that relate to minimum privilege on duty and maximum privilege on sharing, are proposed.

Transaction costs

Transaction costs arise because complete contracting is often impossible, and incomplete contracts give rise to subsequent renegotiations when the balance of power between the transacting parties shifts (Williamson, 1975). Five attributes of business exchange are positively associated with transaction costs:
(1) The necessity of investments in durable, specific assets;
(2) Infrequency of transacting;
(3) Task complexity and uncertainty;
(4) Difficulty in measuring task performance; and
(5) Interdependencies with other transactions.

The necessity of early investments in durable, transactions-specific assets (e.g. human and physical capital) shifts the balance of power between transaction participants, because in later renegotiations these costs are sunk costs of the party that incurs them. Infrequent transactions increase the likelihood of opportunistic behavior in later periods by reducing the threat of retribution. In situations where broader market reputations are at stake, infrequent transactions may be sustainable. However, even long-term contracts often do not provide sufficient adaptation mechanisms, and inflexibility may actually induce holdup. The five transaction attributes indicate settings in which opportunistic behavior is likely. If

transactions costs offset production cost advantages of the external supplier, the firm subsumes the activity an outcome termed vertical integration or in-sourcing.

Drawing on transaction cost economics theory, the sourcing decision is often seen as a rational decision made by firms that have considered transaction related factors such as asset specificity, environmental uncertainty, and other types of transaction costs. Whenever an activity is conducted under conditions of high uncertainty, or whenever an activity requires specific assets, transaction costs, the costs of writing, monitoring and enforcing contracts, are likely to be high. When transaction costs are high, outsourcing is deemed to be relatively inefficient compared with internal, hierarchical administration.

Social exchange theory

Social exchange theory was initially developed to examine interpersonal exchanges that are not purely economic. Several sociologists are responsible for the early development of this theory. These theorists view people's social behavior in terms of exchanges of resources. The need for social exchange is created by the scarcity of resources, prompting actors to engage one another to obtain valuable inputs. Social exchange can be defined as voluntary actions of individuals that are motivated by return they are expected to bring and typically in fact bring from others. Social exchange can be viewed as an ongoing reciprocal process in which actions are contingent on rewarding reactions from others (Das and Teng, 2002).

An exchange perspective places the study of international relations, such as global outsourcing, in a framework of negotiations. Central to this perspective are issues of equivalence (fairness) and contingency (responsiveness). The challenge for international actors is to define a precise medium for exchange. The more precise the medium, the less likely actors will misperceive one another's move. But, the more precise the medium the less likely will actors explore their relationships (Anderson, 2006). This is also a dilemma for IT outsourcing relationships. The more precise, the easier it is to follow-up service levels. And thus, value-added benefits will be difficult to achieve.

PRECISE MARKETING MODEL

Zha and Ding (2005) pointed out that information sharing is mostly used in the supply chain management of businesses. Most of the researches discussed the supply chain management of the information sharing among manufacturer, supplier and retailer. The shared information is mostly limited to the sales and inventory information to be used for the supply chain of the manufacturer and supplier. Besides, very few studies discussed the willingness of businesses to share information. In the analysis of Liu et al. (2006), the following were the main reasons: 1. The definition of information exchange model is unclear, 2. The distrust of the information exchange subjects, 3. There are some open questions in the information exchange contents, 4. How to evaluate the benefit of information exchange and 5. Internet privacy related responsibilities.

If the information exchange model can be applied to people exchange information in a virtual knowledge community, then, can this model also be applied to the inter-industry

alliance businesses that also share information? For example, gourmet restaurants and businesses under automobile industry can be of inter-industry alliance. The “trivial many” customers under the customer database of the gourmet restaurants might not be of much help for them but these customer information might be the valuable customers that conforms to the “significant few” customer conditions of the automobile company. Because the automobile company is familiar with the customer literacy of their own “significant few” customers, the customers that was originally to be abandoned by the gourmet restaurant might be the jewel that the automobile company are looking for. Once the automobile company has control over the new customer information provided by the gourmet restaurant and because these customers conform to the customer literacy of their significant few customers, they can immediately understand the needs and demands of their new customers and provide the best or most appropriate service for them. Similarly, the automobile company can also provide customer information that conforms to the significant few customers conditions of the gourmet restaurant. Not only have both of the businesses obtained the needed customer information, they also don’t need to use all the customer information in the customer database of the other party that cause ineffective and wasteful resources.

Although the case of the above-mentioned hypothesis seemed to be applicable, very few local or foreign studies focused on this topic. This study proposed the topic, “Why don’t we share?” for discussion. What are the reasons why inter-industry alliance businesses do not want to share their information? What are the factors considered by the inter-industry alliance companies when they undergo collaborative marketing? Which factors will influence the intention of the inter-industry alliance companies in exchange customer information? What are the barriers of marketing agent? What are the key success factors of marketing agent under collaborative marketing? This study hoped that the problems above can be answers after looking at the different angles in the discussion.

Developing new customers is always the one and only way of sustainability for businesses. How to accurately develop the “significant few” in Pareto Principle is the dream of every business top management. For large-scale businesses, with the use of customer relationship management and data mining, the customer profile of “significant few” customers can be obtained. Then use the strategic alliance model between the companies to collect or exchange customer data from the customer database of their alliance partner that conforms to the customer profile conditions. By using this model, the businesses can focus on a specific target market using customer segmentation method to satisfy every customer’s needs and accurately and efficiently develop new customers (Xu et al., 2002).

To be able to establish an innovative precise marketing model, the initial step of this study is to understand the framework, exchange method, exchange willingness and customer exchange critical factors of the present collaborative marketing information exchange. After collecting literatures on collaborative marketing, customer relationship management, data mining and exchange of customer information, design a conceptual framework of the precise marketing model under collaborative marketing. The framework and major components of the new model is illustrated. The framework can be illustrated as Figure 1.

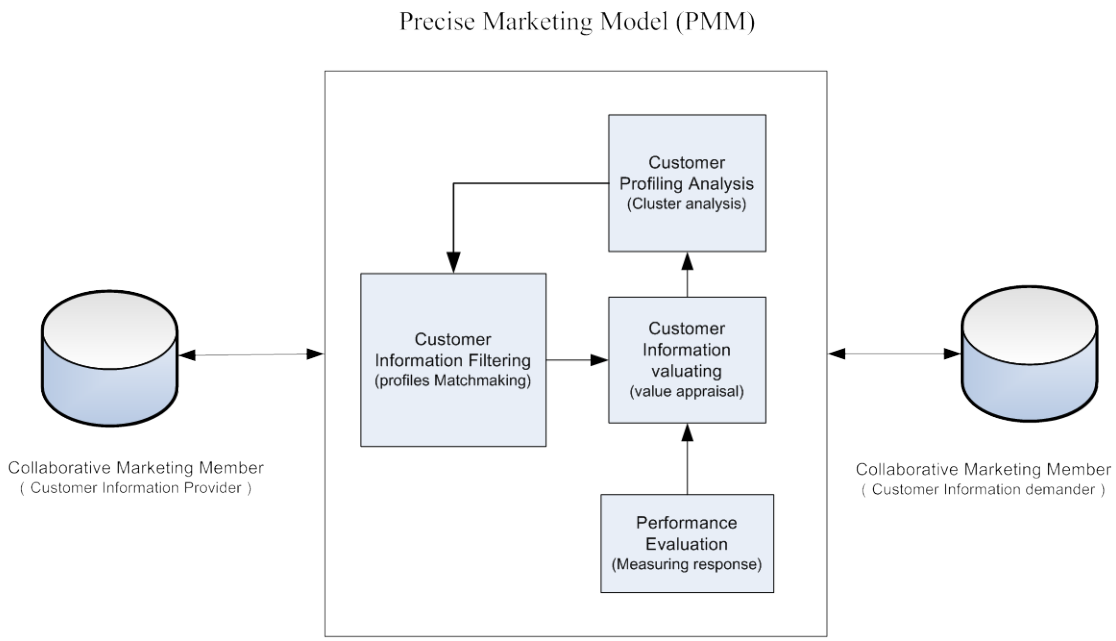

Figure 1: the Precise marketing model.

CONCLUSIONS

This study proposes a new precise marketing model to help enterprises developing new customers from each other. This model provides eight components for the collaborative marketing members: the integrated portal website with the personalized technology, the technical support for websites, the operations system, the integrated marketing and advertisement, the integrated management information system, the communication and control system, the education and training system, and the CRM system. Implementation strategies of the model are also proposed. These strategies are developed with respect to dimensions of operations, technology, and marketing, so that they can help the model be successfully implemented.

To implement the new model, several things should be noted. First, the proposed strategies should be appropriately executed. These strategies can help solve common problems of customer database sharing. Next, sufficient capabilities of the marketing agent and members are extremely important to implement the new model successfully. Third, to attract appropriate collaborative enterprises joining in the marketing agent is also quite crucial to the operation of the system. Providing sufficient assistance and support for these target enterprises according to their requirements will have a positive effect on the promotion of the marketing agent to potential members. Fourth, there may have some conflicts between the marketing agent and its members since the latter will lose a certain degree of autonomy due to regulations of the contract. Preparing some strategies of conflict management is therefore necessary to implement the new model smoothly.

This study builds up a new precise marketing model. The model is practically feasible and can be adapted to collaborative enterprises. In addition, the results of this study can also be used as the basis for the future study on database marketing or customer sharing models.

MODELING ELECTRONIC WORD OF MOUTH AND COMPLAINT BEHAVIOR FOR ELECTRONIC CRM SYSTEMS

Charles V. Trappey, National Chiao Tung University, Taiwan
trappey@faculty.nctu.edu.tw

Conna Yang, National Chiao Tung University, Taiwan
conna.yang@gmail.com

ABSTRACT

Word of mouth is one of the quickest and most efficient ways to increase a product's awareness among consumers. Nowadays, people access to the Internet as a ubiquitous channel for information and experience sharing. In addition to traditional word of mouth, electronic word of mouth is an extremely important issue due to the heavy use of the Internet in modern society. This research studies the use of electronic word of mouth due to willingness to communicate and individual trust. Furthermore, tie strength is used as a construct to measure the interaction with electronic word of mouth. The SPSS statistical analysis software was used to analyze the data retrieved. The research results supports the hypothesis of a significant relationship between trust and willingness to communicate (F(1,169) = 3.984, p = 0.048). In addition, willingness to communicate, electronic word of mouth activity, and positive electronic word of mouth also have significant relationships. The results support the proposition that willingness to communicate serves as a mediator between trust and electronic word of mouth. The implications of these results for CRM systems are presented as a strategic summary.

Keywords: Electronic Word of Mouth, Electronic CRM Systems, Trust, Willingness to Communicate

RESEARCH BACKGROUND

The Internet provides a means of communication that substitutes traditional ways of promoting products, brands, and services. Through Word of Mouth (WOM) communication, passing information and shared experience is well known as an efficient way of spreading commercial messages. Bone (1995) notes that there is a growing research interest in measuring and influencing WOM effects since, "pre-usage attitudes about a product can be influenced by WOM communications," WOM effects have grown in importance with the emergence of the Internet [3]. This research evaluates Internet based sources of WOM communications and proposes a study to measure and influence WOM commercial communications. Varying among different industries, the strength of WOM is hypothesized

to influence the purchase intentions of consumers. The Internet provides a platform for electronic word of mouth. In comparison to traditional word of mouth where the information is passed on from person to person, electronic word of mouth is spread among a larger network of people where the geological distance and time barriers are eliminated. This study analyzes the interaction between interpersonal trust, willingness to communicate, and the tie strength among individuals. The research examines whether or not willingness to communicate is the mediator between trust and electronic word of mouth. If this is shown to be true, than the implications for the construction and altering of CRM systems are indicated.

Word of mouth communications which exist across different cultures and countries enables information flow between people. Word of Mouth is still one of most familiar means by which people spread and gain information on certain issues and topics and is defined as "informal communication directed at other consumers about the characteristics, ownership, or their sellers [24]." WOM is thought to be an outcome of customer experiences with a product or services [5]. Both positive and negative Word of Mouth can influence consumer decision making. A disappointed customer's reactions can be categorized into three different actions. The consumer might break the relationship, complain to others, or make their dissatisfaction known to the suppliers or company [15]. Out of these three, complaining to others, which is known in the literature as "negative WOM," has the greatest impact on a company's reputation and sales. Consumer purchase intentions lead to the search of shared experience which influences the outcome of purchase and complaint behavior. According to earlier publications, individuals usually keep 10% of their emotional experiences, whether good or bad, to themselves; the majority of the experience will be shared through the sharing of conversation [9]. After acquiring word of mouth information, sometimes consumers may exclude their own opinions and private information and adopt attitudes and opinions given by others [10]. The word of mouth effect is stronger when consumers are faced with ambiguous information requiring immediate or delayed decisions [3]. The advice from friends, family, or other individuals with persuasive power serves as an important factor for consumer decision making. "Word of mouth communications (WOM) is an interpersonal communication in which none of the participants are marketing sources" [3]. Traditional word of mouth based on experience is passed on from opinion leaders on to others [13]. Word of mouth does not necessarily rely on opinion leaders to be transmitted since ordinary consumers can also generate word of mouth.

For this research, word of mouth uses three dimensions to model Internet based positive and negative word of mouth. These three constructs are seen as different aspects to a single and more generalized measurement of WOM that can be independently studied [12]. Word of mouth activity is the level of enthusiasm and detail of conversational content exchanged between consumers about products. The content and frequency of electronic word of mouth sharing influences whether individuals will choose according to their own preference, character, and other antecedents. Richins (1983) argued that people are more likely to

spread negative attitudes rather than positive attitudes. When dissatisfied or disappointed with a certain product, customers tend to reveal their experience to friends and advise them not to make the same purchase.

The traditional CRM has been taken into the next level known as e-CRM (electronic CRM) which integrates technologies of new channels such as the internet into the corporation's CRM strategy [21]. With the help of e-CRM, consumer complaints can be collected and responded to using retention orientation approach. An important motivational concept is to focus on a consumer's lifelong value and an important key is avoiding negative word of mouth circulating on the Internet [25]. Instead, these negative word of mouth should be viewed as a remedy to repairs the consumer's satisfaction and the consumer will not be lost. The behavior of electronic word of mouth and complaints should therefore be further examined to have a better understanding of how e-CRM systems should function.

New media platforms such as the Internet offer different ways to spread word of mouth. The Internet in particular is the main portal for electronic word of mouth and has greatly changed marketing communications. Similar to traditional word of mouth, electronic word of mouth has higher reliability for changing attitudes than other forms of marketing information and strategies on the web [2]. The Internet enables different choices for consumers to communicate including blogs, forums, and websites. The traditional spread of word of mouth is limited by barriers such as distance, time, and cost of disseminating information. The Internet enables consumers to share their opinions and experiences with a multitude of other consumers [14]. In addition, consumers form social communities and exchange opinions and share advice when the flow of content is free. Consumers gather shared experiences posted on websites to learn more about a product before making a purchase [7]. Electronic word of mouth not only benefits consumers, but is also a new tool for the advertising industry. Media providers freely interact with consumers and advertise through the Internet. Electronic word of mouth shortens the distance between consumers and corporations and enables companies to reach out to a larger target audience [16].

For traditional word of mouth, the source of information is more tangible and people communicate in person whereas for electronic word of mouth, there are more channels and formats for information communication. Weblogs, often called "blogs," are personal web pages that are frequently updated with new articles and include photos, music, and links to other Internet sites [20]. New forms of micro-blogging simplify functions and make it easier for users to share their status, post short messages, or upload pictures through mobile phones or the internet. The difference between traditional blogging and micro-blogging is that the later offers a faster way of sharing information by encouraging users to keep their posts short. In addition, instant messaging is a type of technology on the Web that allows users to send and receive short text based messages and check the status of their friends who are online and available [6].

Each person has different tendencies to speak, write, or communicate with other people. The willingness to communicate is a personality trait that underlies the communication process [17]. The tendency to avoid communication originated from Burgoon's 1976 research which was based on factors such as introversion, lack of communication competence, alienation, low self-esteem, and communication apprehension [4]. Mortenson, Arntson, and Lustig (1977) used this construct to further develop the construct "willingness to communicate" which measures predisposition towards verbal communication. McCroskey and Baer define this construct as "the intention to initiate communication when given the opportunity."

Trust defines whether one chooses to believe another person's words or advice. Therefore, trust can be used as a variable to model whether word of mouth is accepted by consumers or not. One of the classical definitions of trust is that it is "a generalized expectancy held by an individual that the word of another can be relied on [23]" When reliable information is consistently provided by others, our trust is strengthened. The willingness to share information and the expectancies underlying the communication are the foundation of trust. Schurr and Ozanne (1985) describe trust as "the belief that one party's word is reliable and that it will fulfill its obligation in an exchange." A feeling of fear for negative outcomes or loss may occur if there is no trust.

According to research done by Rempel, Holmes, and Zanna (1985), there are many definitions that define the features of trust. First, it is built upon past experience and a series of events that strengthen the feeling of trust. Second, dispositional characteristics are made towards the trustor, including attributes such as reliability, dependability, and predictability. The third conclusion is that one must be willing to be put at risk, whether it is the risk of being hurt, or loss of something either abstract or tangible. The last conclusion is that trust can be defined by the sense of security and confidence in the responses given and the intimacy and strength of the relationship.

This research focuses on a feature of trust called interpersonal trust, which is "the expectancy held by an individual or a party that the word, promise, verbal, promise, or written statement of another individual or party can be relied on" [22]. Interpersonal trust is chosen as one of the research constructs because different from the more general definition of trust and focuses on the interaction between two individuals.

The social relationship of individuals can be categorized according to the frequency of contact, and how well others are known and are defined as the "potency of a bond between members of a network [11]," or "tie strength." Strong tie sources are friends and family, whereas weak ties are acquaintances and strangers [8]. The influence of tie strength can affect consumer decision making, word of mouth, and intergroup interactions [19]. Word of mouth communication is a social behavior that includes the exchange of information between individuals. Past research shows that tie strength influences the flow of

information. According to past research, individuals who are strongly tied relationship have more opportunities to interact and share information. If the Internet is used for communication between people, then these individuals logically have weaker ties. On the contrary, a weakly tied relationship offers few chances for individuals to spread information. Thus, strong ties should lead to the positive spread of word of mouth information and vice versa.

METHODOLOGY

This research explores the interaction between electronic word of mouth, willingness, trust, and tie strength. Past research supports a relationship between these constructs. In Ben-Ner and Putterman's 2009 study on trust and communication, the results show that if one desires to establish a relationship, then individuals must take the communication process seriously. Thus, the depth of communication promotes trustworthy behaviors. Other researchers have shown the interaction between trust and communication in different fields of study. "Communication is critical to building a trusting relationship which will create stability [1]." However, few studies explore the relationship between the level of interpersonal trust, willingness to communicate, and the impact on CRM systems. Although the content of communication is not completely associated with personal privacy or other matters, it is reasonable to believe that the more one is willing to be exposed, the more willing they are to share information with others. Therefore this study proposes that interpersonal trust will have a positive effect on willingness to communicate.

Word of mouth is an initiative action where an individual chooses to express his opinions or share past experiences with others. Word of mouth is an action that depends on the individual's intention to communicate so an individual's willingness to communicate with another person should be positively related with it. Therefore "willingness to communicate" is used as the third construct in the research framework. The strength of social relationships between individuals, or "tie strength," relates to the way the Internet expands our social networks. Those that we communicate with on the Internet do not necessarily have strong ties with others. Granovetter's research in 1983 shows that individuals with strong ties would more often communicate with individuals that are similar to themselves. When exploring the interaction between tie strength and electronic word of mouth, Granovetter's research implies that there should be a negative relationship between tie strength and electronic word of mouth. We derive from this literature review ten hypotheses. Trust has a positive effect on willingness to communicate, electronic word of mouth has a positive effect on willingness to communicate and acts as the mediator between trust and eWOM. Finally, tie strength has a negative and significant effect on eWOM.

Hypothesis 1: Trust has a significant and positive relationship with an individual's willingness to communicate.

Hypothesis 2: Trust has a significant and positive relationship with an individual's electronic word of mouth.

Hypothesis 3: Willingness to communicate will mediate the relationship between trust and electronic word of mouth.

Hypothesis 4: An individual's willingness to communicate has a significant and positive relationship with an individual's electronic word of mouth.

Hypothesis 5: An individual's tie strength with another individual on the internet has a significant relationship with electronic word of mouth.

In this study, questionnaires were handed out in campus classrooms with the help of friends. All data was collected using paper-based questionnaires. Most items utilized a five-point Likert scale ranging from 1 to 5, with 1 being "strongly disagree" and 5 being "strongly agree." Willingness to communicate to others is a self-report scale which is scored by the participants themselves. All the original items were designed in English and then translated into Traditional Chinese by a native speaker who is fluent in both languages to ensure the content and meaning remained the same during the translation.

The official questionnaire is divided into 5 sections, electronic word of mouth, trust, willingness to communicate, tie strength, and demographic variables. Electronic word of mouth activities were measured using Churchill's word of mouth scale which was modified by Harrison-Walker in 2001. Positive electronic word of mouth was measured by 3 items from the loyalty scale and electronic negative word of mouth used the scale from Liu and McClure's research on cross-cultural customer complaint behavior study. To improve the efficiency and increase the unity of the questionnaire, scales were modified from 7 points to 5 points. Rotter's Interpersonal Trust scale, which was developed in 1967, was used in the study to measure trust. In 1985, McCroskey proposed a scale to measure willingness to communicate which is a personality-based trait like scale that is consistent across different receivers and different communication contexts. This scale has 20 items, with 8 items being filler items. The willingness to communicate scale includes four communication contexts and three different receivers. The study measured each individual's general willingness to communicate. Hansen's 1999 two item scale measured the closeness of a working relationship and frequency of contact and is used to the measure of tie strength.

RESEARCH RESULTS AND DATA ANALYSIS

A reliability analysis for the 4 different variables showed that each constructs' alpha was above 0.70. Electronic word of mouth activity reached a Cronbach α of 0.78, positive electronic word of mouth 0.78 and negative electronic word of mouth 0.81. The trust scale has a Cronbach α of 0.76, scoring much higher than the 2 pretests conducted. Furthermore,

the 12 items of willingness to communicate had an internal consistency of 0.81, while tie strength had the highest internal consistency with an alpha of 0.92.

Performing a Regression Analysis on the retrieved data, we conclude that the R-square for several models was quite low. Yet, the most crucial part of this study is established with the predictive power of trust on willingness to communicate passing the P-value standard of 0.05, ($F(1,169) = 3.984$, $p = 0.048$). The regression results for willingness to communicate on both electronic word of mouth activity and positive electronic word of mouth is highly significant with P-values of ($F(1,169)=10.643$, $p = 0.001$) and ($F(1,169) = 9.113$, $p = 0.003$). The predictive powers and relationships of tie strength on all three dimensions of Electronic Word of Mouth Activity are significant.

The results imply that the stronger the relationship between two individuals, the more likely they are to share their experiences of good product purchases. Also, the higher the degree of communication willingness, the more an individual will use positive word of mouth. Negative electronic word of mouth is the only dimension that does not have a significant relationship with willingness to communicate. Therefore, even if one is willing to communicate and trusts other individuals, this does not mean that they will share their negative experiences with others.

Tie strength has a positive and significant relationship with both positive and negative electronic word of mouth, yet the relationship is not supported by electronic word of mouth activity. Hypotheses 2 is rejected since there is no significant positive relationship between Trust and Electronic Word of Mouth. However, trust does have a significant relationship with willingness to communicate. This supports the argument that the higher the degree of interpersonal trust, then the more willing consumers are to communicate and talk with others.

STRATEGIC IMPLICATIONS FOR CRM SYSTEMS

This research provides several new insights on how corporations can use electronic word of mouth as part of their strategic CRM design to attract and hold consumers. One of the most important management steps in e-CRM is to be able to take the consumer's point of view instead of a marketer's [21]. If the corporation can take use of the consumer behavior and encourage consumers to give feedback on the products, the chances of stopping an unsatisfied consumer from switching brands will help increase the consumer's lifelong value to the company. The results point out that individuals in this study are more reluctant to share negative word of mouth online even when they have a high degree of interpersonal trust with the communicator. Corporations can learn how to increase the consumers trust towards the company so that consumers will be willing to interact.

Analyzing the common goals of CRM in Table 1, several conclusions related to this research

can be derived. Electronic word of mouth should not be generalized to a single target audience. Corporations should divide the consumers into groups by the consumer's level of tie strengths when managing CRM systems. Since some customers feel a lack of desire to share negative purchasing experiences, they should be encouraged by the corporation that any form of feedback on the product is welcome. Also, traditional word of mouth is important for marketing events and may be combined with these findings. Marketers can manipulate the level of trust between initial consumers so that they are more willing to discuss the company's products with other people.

Table 1: Common CRM Goals and Strategic Implications.

Common Goals	***Strategic Implications***
1. Adapt processes to satisfy specific customer preferences	**Enforce the level of consumer trust towards the company**
2. Preserve the value of customers, target profitable segments, and cultivate high-quality relationships to ensure customer loyalty	**Corporations should aim to encourage customer feedback through the boosting of willingness to communicate**
3. Customer segmentation is a core function of CRM and frequently uses geographical data, demographic data, and behavioral variables to group customers	**Not all unsatisfied customers choose to voice their complaints. These types of customers should be approached and encouraged to voice their opinions**
4. To analyze customer segments, customer preferences, and provide best case service models	**Consumers can be offered incentives for posting or blogging word of mouth via Internet. Potential consumers who have strong ties with these individuals will then be stimulated to learn more about the product**
5. To gain customer knowledge	**Through the building of trust and willingness to communicate, corporations can activate its consumers to share their purchase experiences and advice.**

A FUZZY HYPOTHESIS TEST BASED MODEL FOR CUSTOMER SATISFACTION MEASUREMENT
(CASE STUDY IN PARS KHODRO CO.)

ABSTRACT

The article proposes a model for customer satisfaction measuring, which is adapted to use in automobile industries. The proposed methodology evaluates the satisfaction level of a set of customers in different aspect of customer focus based on hypothesis values for utilizing the intuitive judgments and decision-making vagueness and diagnoses the satisfaction customers associated fields. This model also allows fully evaluates by analysis of all possible hypothesis cases. In the end, we implement our model in KHODRO CO. in IRAN and show the results. This research does asking the opinions of the experts through a number of questionnaires related to the L90 auto customers of PARS KHODRO CO. in 5 fields. Customers satisfaction of L90 auto in above fields attains among 81 hypothesis and conclude the following result:"product quality is good, financial problems is good, Total quality of services is good and Guarantee is medium then customer satisfaction is good'' This findings lead to get safeguarding strategy in product quality, financial problem, Total quality of services fields and improvement strategy in Guarantee approach. It permits to evaluate the validity of a service/manufacturing operation from the point of view of consumers. It leads to the real satisfaction level and specifies the foible, strength and improvement opportunity, which they are essential information in the strategic management and latest planning in a company The main advantages of this method are fully consider the qualitative form of customers' judgments through fuzzy theory and evaluate customers' satisfaction in different aspect of customer focus. Compare to the other researches, this approach presents more realistic results. Our study represents one of the first attempts at customer satisfaction measuring by fuzzy hypothesis testing. Finally, future research directions are provided.

Keywords: fuzzy hypothesis test; customer satisfaction analysis; subjective judgments

INTRODUCTION

Paper's introduction is in two parts as customer satisfaction models and fuzzy hypothesis testing. According to our knowledge and researches, there is not a method for customer satisfaction measuring based on fuzzy hypothesis testing approach.

Customer satisfaction models

Globalization and free trade carry on remodeling the business environment and expanding global competition. Customer satisfaction is a resume notion and show the actual state of satisfaction which can vary from person to person and product/service to product/service. Therefore, customer satisfaction should be determined and rendered into a number of quantifiable parameters [1]. Also Since, customer satisfaction index (CSI) have been widely developed in both theory and applications [2, 18, 4, 5], especially in the fields of marketing, education, medical treatment, guesthouse management ,therefore customer satisfaction has been one of the most frequently surveyed topics in literature. The work done by Berry et al. [6] between 1985 and 1988 delivered SERVQUAL (it is a service-quality scheme that has been incorporated into customer-satisfaction surveys [7]), supports the basis for the measurement of customer satisfaction with a service by using the gap between the customer's expectation of achievement and their perceived experience of achievement. In 1989, the first model of CSI was built by Swedish researchers [8]. The American customer satisfaction index (ASCI) was set up in 1994 [9]. Another well-known CSI was built by 11 countries of European Union in1999 [10, 11]. Some researchers introduce modified CSI for using in the different fields. Hsu (2008) proposes an index for online customer satisfaction, which was adapted from an American Customer Satisfaction Index (ACSI). It predicts customer loyalty and overall customer satisfaction via a way was similar to the average for the online retail industry in ACSI and The partial least square (PLS) method [12]. Customer satisfaction web-based don´t terminate in the above paper. Customer satisfaction measurement index system via mail service is designed by LIU et al. (2006) [13]. Some of researches also focused on the relationship between customer satisfaction and financial performance [14, 15, 16]. According to Grigoroudis et al. (2000), customer satisfaction information is analyzed based on a preference disaggregation model. Their tool (Software) is termed as TELOS that follows the principles of multicriteria analysis and uses subjective customers' judgments [17]. Therefore, they propose a model that called MUSA (Multicriteria Satisfaction Analysis). It is a preference disaggregation model following the principles of ordinal regression analysis. Same as their mentioned paper, MUSA model uses subjective customers' judgments, too [3]. The Research of Mihelis et al. (2001) are concerned with a model that is based on the principles of multicriteria analysis and preference disaggregation modeling and it is implemented in private bank sector. It determines critical service dimensions and the investigation to customer classes with distinctive preferences and expectations [19]. Jaime and Fonseca (2009) consider the latent

segment models (LSM) approach for evaluation of customer's service satisfaction that quantified through multiple indicators. They selected a three latent segment model that represents “The Very Satisfied”, “The Well Satisfied” and “Satisfaction Demanders” [20]. Since Zadeh introduces fuzzy set theory in 1965 [21], researchers intend to use it in their quests. For example, Xiaohonget et al. (2008) introduces new method for calculating the e-commerce customer satisfaction index (ECSI), using fuzzy techniques [22], so that ECSI obtains by fusion of comparison customers' cognition in e-commerce and their acclaims and complaints.

The purpose of our study is to utilize the fuzzy hypothesis testing for customer satisfaction measuring, such that, satisfaction level is caused by six fields as product quality ، financial problems ، total quality of services ، guarantee ، complaints and loyalty. The fuzzy hypothesis test is developed crisp hypothesis testing but it challenge the all possible hypotheses. In other hand, it utilizes ambiguity and vagueness of subjective judgments by fuzzy logic.

Fuzzy hypothesis testing

As discussed in previous section, main structure of our method is based on fuzzy hypothesis testing. In the real world, sometimes data cannot be recorded or collected precisely. Therefore, the fuzzy sets theory is naturally used as an appropriate tool in modeling the statistical models when the fuzzy data have been observed [23]. The concept of fuzzy sets used here was originally introduced in [21] and described in more detail e.g. in [24, 25]. It should be noted that in this paper only the hypotheses are allowed to be fuzzy and the data are assumed to remain crisp. Furthermore, the 'classical' way of statistical inference is generalized to fuzzy hypotheses. Note that there is a fundamental difference between a membership function of a linguistic term and a prior probability distribution. The membership function just gives a description of the linguistic term, whereas a prior probability distribution gives prior information about the truth of the hypotheses under consideration. Arnold [26, 27] proposed the fuzzification of usual statistical hypotheses and considered the hypotheses testing under fuzzy constraints on the type I and II errors. Casals and Gil [28] and Son et al. [29] considered the Neyman–Pearson type testing hypotheses. Saade [30, 31] considered the binary hypotheses testing and discussed the fuzzy likelihood functions in the decision making process by applying a fuzzified version of the Bayes criterion. Gil et al. [32] also discussed the likelihood ratio test for goodness of fit with fuzzy observations by means of the minimum inaccuracy principle of point estimation. Casals and Gil [33], Casals and Gil [34], and Gil et al. [35] considered the Bayesian sequential tests and χ^2 tests for goodness of fit with fuzzy observations by means of the notion of fuzzy information. Grzegorzewski [36], Watanabe and Imaizumi [37] proposed the fuzzy test for hypotheses testing with vague data, and the fuzzy test gave the acceptability of the null and alternative hypotheses. Niskanen [38] discussed the applications of soft statistical

hypotheses in the human sciences. The fuzzy hypothesis testing is developed of classic statistical hypothesis testing which zero and one are using for acceptance or rejection of any hypothesis. However, fuzzy hypothesis testing has two strength points versus classic statistical hypothesis testing. They are: (1) it considers all the possible hypotheses and (2) accepts them relatively by numbers in [0, 1].The fuzzy hypothesis testing – like the classic statistical hypothesis testing-has four steps: hypothesis formulation, sampling, hypothesis testing and decision-making. In hypothesis formulation step, all the possible hypotheses are formulated. Classical hypotheses define two type hypotheses as null hypothesis and alternative. However, fuzzy hypotheses formulated by a block consist of hard-core and associated auxiliary hypotheses. In the sampling step, a subset of all data is selected. The sample should has enough data to be a good indication of the all data. In hypothesis testing step, fuzzy conclusion for any hypothesis is done and then, results are aggregated by aggregation function. In final step, total result has to be analyzed and associated decisions are made.

The paper organization is according to the follows:
Section 2, describes information collection tools, its validity and reliability, and some information about case location. Section 3, is describes our methodology which is consist of fuzzy hypothesis concept, structure of our approach, model implementing and its finding. Finally the last section, conclude the models efficiency and results.

INFORMATION COLLECTIONS

Case Location and Sampling

Pars Khodro Company (P.K.C.) is an automobile manufacturer company that is established in 1956 and since then is operational. In P.K.C. the environment of the competitive markets changes intensely and it is necessary to improve the manufacturing quality continuously. Hence, we introduce a way to evaluate the P.K.C's manufacturing quality, which is based on the degree of user satisfaction. The statistical universe of this paper is considered from total customers of L90 (one of the Pars Khodro products started in 2009). In this paper, random systematic method for sampling is used [39] and due to list of total customers of L90 in 2009, Morgan table is utilized for numbers of samples [40] in which the best sample numbers corresponded to any universe cardinality. Accordingly, a sample of 380 from 20000 customers is considered as good representative of total data.

Tools

In this paper, main information collecting tool is questionnaires and interviews. Interview is used to analyze customers' viewpoints before questionnaire designing. Questionnaire also is

used to measure the satisfaction samples in framework of hypotheses. Initial questionnaire has six essential fields and each field has several sub-fields as follows:

1. Product quality
    1.1. Apparent form
    1.2. Safety
    1.3. Car body specifications
    1.4. Motor power and fuelling
    1.5. Good ventilation and power means
    1.6. Technical documents quality
2. Financial problems
    2.1. Cost of product
    2.2. Fair relation between cost and quality
    2.3. Purchase styles
    2.4. Financial operation rapidity
    2.5. Attention and clarity in financial affairs
3. Total quality of services
    3.1. Managers and experts communication manner
    3.2. Inform manner quality
    3.3. Delivery quality
    3.4. Guarantee conditions
4. Guarantee
    4.1. Provide the spare parts
    4.2. Parts ampleness and quality
    4.3. Guarantee access
    4.4. Repairs quality
    4.5. Guarantee cost and wage
5. Complaints
    5.1. Complaints receiving ways
    5.2. Complaints investigation quickness
    5.3. Complaints consideration
6. Loyalty
    6.1. Continuing cooperation
    6.2. Looking forward to the fresh products
    6.3. Suggest to other peoples

After the initial collection of 30 questionnaires and evaluation of feedbacks, we integrate them with experts' opinions. Accordingly, due to overlapping and concluded by another, loyalty eliminated from questionnaires and then, final questionnaire is formed. The Response of any question was set according to Likert scale [41], which scaled as: poor satisfaction, Medium poor satisfaction, Fair, medium good satisfaction and good satisfaction.

Validity and Reliability

The method of exploratory factor analysis has been used to analyze the questionnaire validity [39]. The KMO* value of questionnaire is 0.895 in 0.01 significant level which imply to sampling sufficiency for method of exploratory factor analysis. Varimax rotation was used for exploratory factor analysis, and result implies that: first factor (product quality) explains the 75% changes, second factor (financial problems) explains the 81% changes, third factor (Total quality of services) explains the 73% changes, Guarantee factor explains 74% changes and finally, complaints factor explains the 79% changes. Generally, the questionnaire forecast the 73% changes that indicate the validity. Of course, load factor of fields was greater than 0.5. The Cronbach's alpha method has been used to analyze the questionnaire reliability [42] which was calculated Cronbach's alpha for product quality , 75% ; financial problem , 79% ; Total quality of services , 72% ; Guarantee , 80% and complaints, 79%.This results indicates the reliability of customer satisfaction measurement scale. It is necessary to mention that the investigations have been done by MINITAB 15.0 software.

MATHEMATICAL FRAMEWORK OF FUZZY HYPOTHESIS TESTING

Fuzzy hypothesis test is extension of classical statistics hypothesis test. It leads to importance degree of each hypothesis compare with auxiliary rules. Let, X be universes of discourse ،$D = \{x_1 , x_2 , \dots , x_m\}$ be sample set and $H = \{H_1 , H_2 , \dots , H_n\}$ be if-then rule statements. In this view, we can demonstrate a fuzzy if-then rule as follows:
H_i: IF $\{Condition\ 1, Condition\ 2, \dots , Condition\ k\}$ to be considered true, THEN X is a member of F by membership degree(x).
Nevertheless, general structure of fuzzy hypothesis test is as Table 1:

Table 1: fuzzy hypothesis test matrix.

If-then statements	**Samples**				$\mathbf{M_L(D)}$
	x_1	x_2	$\cdots$	x_n	
$\mathbf{H_1}$					
$\mathbf{H_2}$					
$\vdots$					
$\mathbf{H_r}$					
					Summation=1

* Kaiser-Meyer-Olkin

It should be noted that, auxiliary rules are in $\{Condition\ 1, Condition\ 2, \ldots, Condition\ k\}$ and main hypothesis is included in F notation. The if-part of the rule is called the antecedent, while the then-part is called the consequent or conclusion. Each sample x_i satisfies $condition\ 1$, $condition\ 2$ through $conditionk$ within$\mu_1(x_i)$, $\mu_2(x_i)$ through$\mu_k(x_i)$, respectively. In other hand, x_i satisfies the consequent within $\mu(x)$ that is defined as:

$$\mu : (H, x) \rightarrow [0,1] \qquad (1)$$

Due to multiple parts related to the antecedent and consequent, apply fuzzy logic operators and resolve them to a single number between 0 and 1,therefore we apply multiplication operator (P.M. Larson relation) for combining the antecedent and consequent such as fuzzy logic operators. So, satisfaction degree of each hypothesis by x_i sample calculates by equation (2). Hence, attain associated array of jth row and ith column for Table (1).

$$Sat_{x_i}(H_j) = \mu_1(x_i) \times \mu_2(x_i) \times \ldots \times \mu_k(x_i) \times \mu(x_i) \qquad (2)$$

To determine the verification degree of each hypothesis (claim), so it is necessary to calculate all possible $Sat_{x_i}(H_j)$ $\forall i, j$ and then, find arithmetic mean as follows:

$$M_j(D) = \frac{\sum_{i=1}^{n} Sat_{x_i}(H_j)}{n} \quad j = 1,2, \ldots, r \qquad (3)$$

Fuzzy hypothesis testing in customer satisfaction measuring

In this section, we intend to introduce the set of hypotheses in our model. Claims $H = \{H_1, H_2, \ldots, H_n\}$have been introduced and are calculated verification degree of each ($\mu_k(x_i)$). As discussed in section 2.0, five fields are used in this model ; product quality, financial problems, Total quality of services, Guarantee are antecedents and then complaints is rule's consequent that implies to customer satisfaction level. We classify each of them in to the three scales as, good ، medium and bad. As an example, Total qualities of services investigate in the three classes; good Total quality، medium Total quality and bad Total quality. So, to analyze the total classifications of fields, we will have $3 \times 3 \times 3 \times 3 = 81$ hypothesis. All hypotheses have been analyzed in our paper. As an example, one of the hypothesis could be "product quality is good, financial problem is good, Total quality of services is bad, Guarantee is medium and then customer satisfaction level (complaints) is medium". The fuzzy classifications are as shown in Figure 1.

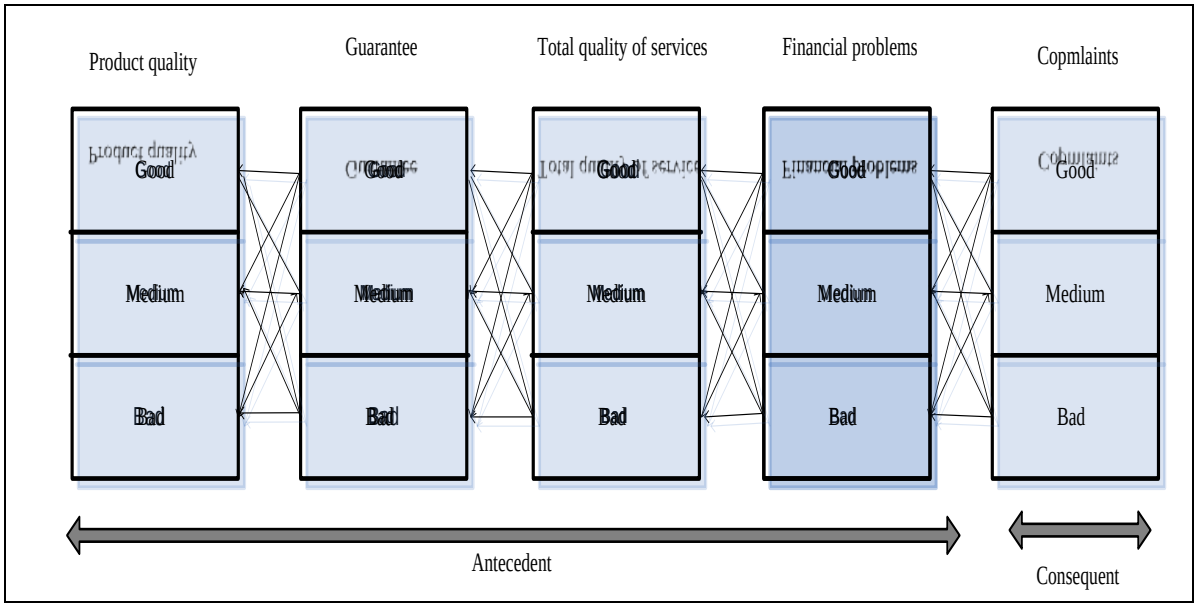

Figure 1: The fuzzy classification of case study variables.

As discussed in above, linguistic terms have been used in any classifications. Good ، medium and bad are our linguistic terms. So, accordingly we need to design theirs fuzzy distributions. Figure 2 demonstrate the linguistic values of any linguistic variable in which ranges have been got from interview with company experts. Note that, concept of "complaint" is negative, so, the more values imply to worse condition. Figure 3 demonstrate the linguistic terms that are based on the parameters which are different in each fields.

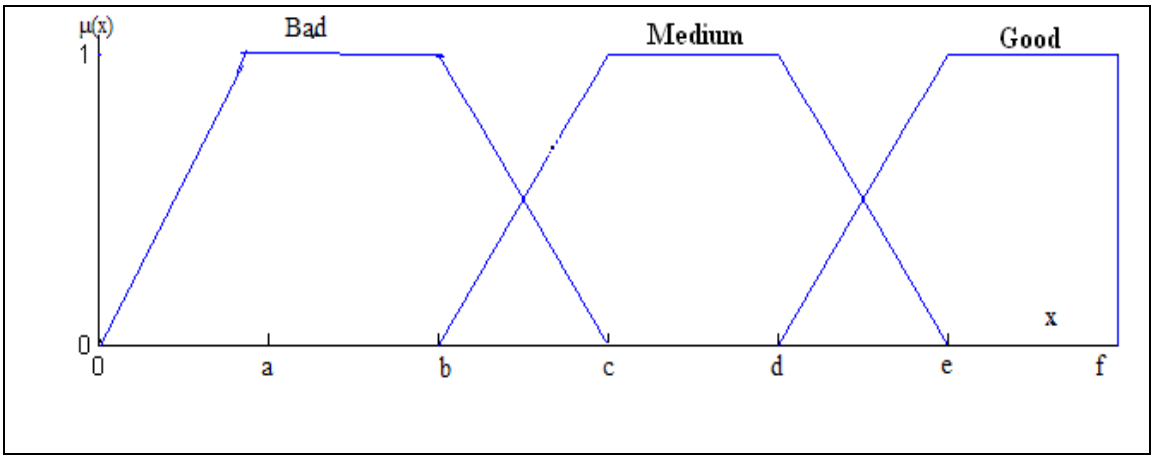

Figure 3: linguistic terms based on the parameters.

The parameters have been allotted as Figure 2.So, the membership functions of good, medium and bad linguistic terms are indicated as follows:

$$\mu_{good}(x) = \begin{cases} \frac{1}{e-d}(x-d) & x \in [d,e] \\ 1 & x \in [e,f] \end{cases} \qquad (4)$$

$$\mu_{\text{medium}}(x) = \begin{cases} \frac{1}{c-b}(x-b) & x \in [b,c] \\ 1 & x \in (c,d] \\ \frac{-1}{e-d}(x-d)+1 & x \in (d,e] \end{cases} \quad (5)$$

$$\mu_{\text{bad}}(x) = \begin{cases} \frac{1}{a}x & x \in [0,a] \\ 1 & x \in (a,b] \\ \frac{-1}{c-b}(x-c) & x \in (b,c] \end{cases} \quad (6)$$

	Bad = (0,12,20,25) Medium=(20,25,40,45) Good=(40,45,60,60)	Product Quality
	Bad = (0,7,11,14) Medium=(11,14,23,26) Good=(23,26,35,35)	Financial problems
	Bad = (0,14,23,29) Medium=(23,29,46,52) Good=(46,52,70,70)	Total quality of service
	Bad = (0,9,15,18) Medium=(15,18,30,33) Good=(30,33,45,45)	Guarantee
	Good = (0,1,2,3) Medium=(2,3,5,7) Bad =(5,7,inf,inf)	Complaints

Figure 2: Distribution of good, medium and bad linguistic values.

In this stage, the verification degree of each claim has been calculated according to the customers´ data. As an example, let "product quality is medium, financial problems is good, total quality of services is medium, Guarantee is medium and customer satisfaction level is medium" for one of the customer (Due to Table 2). So, the verification degree for this customer is$0.8 \times 0.25 \times 0.14 \times 0.87 \times 1 = 0.02$. In a similar way, via each customer, the verification degree for other hypotheses has been calculated. This procedure repeats for other customers and the verification degree of each 81 hypothesis are calculated as described in section 3.0. Note that, customer i play role of x_i that is explained in section3.0. Table 2 depicts satisfaction degree of each linguistic variable by one of the $customer$.

Table 2: satisfaction degree of each linguistic variable by one of the customer.

Ling. variables	**Product quality**				**Financial problems**				**Total quality of services**				**Guarantee**				**Customer satisfaction level (Complaints)**			
Ling. values	G[1]	M[2]	B[3]	Score	G	M	B	Score	G	M	B	Score	G	M	B	Score	G	M	B	Score
Sat. degree	0.2	0.8	-	42	0.25	0.75	-	36	0.86	0.14	-	32	0.13	0.87	-	35	-	1	-	4

1. G: Good 2. M: Medium 3. B: Bad

Findings

The results of hypotheses testing have been introduced as $M_{H_1}, M_{H_2}, \dots, M_{H_{81}}$ which are verification degrees of $H_1, H_2, \dots, H_{81}$ hypotheses. If verification degrees of H_i be greater than other hypotheses, then, we can conclude that H_i accurance possibility is greater than others. As shown in Table 3, the top five highest verification degrees are shown and the hypothesis "product quality is good, financial problem is good, Total quality of services is good and Guarantee is medium and as a result, customer satisfaction is good'' has the highest verification degree among the others. So, we can say, this claim has the more conformances in company case. This findings lead to get safeguarding strategy in product quality, financial problem, Total quality of services fields and improvement strategy in Guarantee approach.

Table 3: The top five highest verification degrees of hypotheses for L90.

Priority	Hypothesis
1	product quality is good , financial problems is good, Total quality of services is good , Guarantee is medium and as a result, customer satisfaction is good
2	product quality is good , financial problems is good, Total quality of services is good , Guarantee is good and as a result, customer satisfaction is good
3	product quality is medium, financial problems is good, Total quality of services is medium , Guarantee is medium and as a result, customer satisfaction is medium
4	product quality is good , financial problems is medium, Total quality of services is medium , Guarantee is medium and as a result, customer satisfaction is medium
5	product quality is medium, financial problems is medium, Total quality of services is medium , Guarantee is bad and as a result, customer satisfaction is medium

CONCLUSIONS

Due to increase global competition, customer satisfaction should be determined and rendered into a number of quantifiable parameters. Accordingly, different methods have been introduced to customer satisfaction measurement. Nevertheless, none of them did not use vagueness of customers' judgments and did not probe comprehensively the varied satisfaction fields. The proposed method used the fuzzy hypothesis testing for utilizing the intuitive judgments and decision-making vagueness and diagnoses the satisfaction customers associated fields. It leads to the real satisfaction level and specifies the foible, strength and improvement opportunity, which they are essential information in the strategic management and latest planning in a company. This paper was implemented in Pars Khodro Co. and study L90 satisfaction customers in 2009. Finally, the result of this research emphasize on “product quality is good, financial problem is good, Total quality of services is good and Guarantee is medium then customer satisfaction is good’’ hypothesis. Compare to the other researches, this approach presents more realistic results. Due to diversity of I.K.C's products, it is proposed this paper's method applied on other products and obtained results be aggregated as total customer satisfaction index. For the more attention, next researches must focus on most affecting the customer satisfaction parameters and gather them by reliable approach and then results compare with other company in automobile industries.

A PILOT SURVEY TO UNDERSTAND THE EFFECTS TECHNOLOGY READINESS, SATISFACTION AND ELECTRONIC WORD-OF-MOUTH ON BEHAVIORAL INTENTION IN ONLINE SHOPPING ENVIRONMENTS

Chia-I Pan, Tatung University, Taiwan
joypan123@hotmail.com

Huei-Huang Chen*, Tatung University, Taiwan
hhchen@ttu.edu.tw, *corresponding author

ABSTRACT

In this research, the effects of the electronic word-of-mouth in 3C products industry are investigated, and the suggestions to utilize the power of the electronic word-of-mouth more efficiently and effectively are also made. In order to target at all kinds of consumers, the technology readiness of consumers is also considered. Moreover, customer satisfaction and behavioral intention reflect the result of the electronic word-of-mouth. In order to understand the characteristics and the willingness to refer to the electronic word-of-mouth before consumers purchase 3C products, questionnaires are used to collect data for analysis.

The relationships between the four perceptions of technology readiness, the willingness to refer to the electronic word-of-mouth, customer satisfaction and behavioral intention are analyzed. According to the analysis results, five recommendations for 3C manufacturers are made. Firstly, 3C products manufacturers should cooperate with some online 3C products discussion forum. Secondly, 3C products manufacturers should always pay attention to customers' opinions and complaints on the Internet. Thirdly, 3C products manufacturers should make the instructions and information of their products easier to be understood. Fourthly, 3C products manufacturers should focus more on the opinion leaders on the Internet. Lastly, 3C products manufacturers should provide more advanced technical support to those pioneers of purchasing new products.

Keywords: electronic word-of-mouth, technology readiness, satisfaction, behavioral intention, online shopping

INTRODUCTION

Since the Internet technology was developed, the spread of information has been much faster than before. It is easier for people to search for information about all kinds of products on the Internet. Nowadays, more and more customers survey other consumers' experiences and opinions on products and services before purchasing something. Therefore, traditional advertisements, such as television advertisements, radio advertisements and newspaper advertisements, are not sufficient for companies to promote their products and services. Companies are forced to develop new strategies for Internet marketing.

However, due to the overload of advertisements every day, consumers do not have enough time to review each of them by themselves and are forced to ignore most of the advertisements. Instead, they usually prefer to gain opinions and experiences about products or services which they want to purchase from their friends, colleagues or families. This noncommercial information exchange is called word-of-mouth, and word-of-mouth plays a very important role in consumer behavior. It has an effect on consumers' decisions of long-term and short-term procurements (Bone, 1995). Furthermore, the Internet offers a fastest and most convenient channel for consumers to exchange information, so more and more people exchange their opinions and experiences about products and services on the Internet. Such exchanging behavior is regarded as the electronic word-of-mouth.

The rapid development of Internet technology has led the growth of computer relative industries which is called 3C (Computer, Communication and Consumer) industry. 3C industry has grown significantly for these twenty years, and most of the analysts agree that 3C industry will still occupy a significant position in the global market in the future. Nevertheless, 3C industry is highly competitive and has changed very fast. Manufacturers have to be highly sensitive to the market changes and the feedback from consumers.

Utilizing the electronic word-of-mouth is the most efficient approach to deliver information about new products to customers as well as gain the feedback from them. In order to promote new 3C products more effectively, 3C manufacturers have paid more and more attention to the electronic word-of-mouth. There are many professional online discussion forums which provide platforms for Internet users to share their experiences and opinions on 3C products, for example Mobile01 (www.mobile01.com) and My Mobile Life (www.mml.com.tw).

In spite of the fact that 3C manufacturers have noticed the importance of the electronic word-of-mouth, they still have much difficulty in utilizing the electronic word-or-mouth. For instance, the Internet users are anonymous and this makes it difficult for manufacturers to know if the information is delivered to their target customers. Thus, targeting at the right customers is important for manufacturers. Furthermore, although the development of Internet technology has fastened the spread of the electronic word-of-mouth, there are some customers who still do not have confidence to use new technologies.

In this research, the effects of the electronic word-of-mouth about 3C products are discussed. Customer satisfaction and behavioral intention represent that if consumers will purchase products again, recommend products to others and increase their loyalty of the 3C manufacturers. Therefore, consumers' satisfaction and behavioral intention directly affect 3C manufacturers' profit and market share. In view of this, one of the aims in this research is to find out if the electronic word-of-mouth does influence the customer satisfaction and behavioral intention when they purchase 3C products.

Furthermore, technology readiness index is used to measure customers' beliefs and feelings of adopting new technologies. Customers with different technology readiness may have different customer satisfaction and behavioral intention. Thus, another aim in this research is to make some suggestions for 3C manufacturers according to customers with different technology readiness.

Lastly, based on the analysis results, some recommendations of improving the effectiveness of the electronic word-of-mouth in 3C products industries are given.

LITERATURE REVIEW

Electronic word-of-mouth

Westbrook (1987) defines word-of-mouth as the opinion which consumers communicate to others in an unofficial way after they have used a product or taken a service. Bristor (1990) defines word-of-mouth as the approach to obtain others' experiences through the interaction of social network. Moreover, word-of-mouth is defined as all comments on a particular product or company within a certain time by Rosen (2001). This information communication is normally thought more neutral and more reliable, because it is mostly generated directly by consumers rather than by companies. Misner (2008) says that the word-of-mouth is "the world's best known marketing secret" and the most effective marketing strategy. Some people think that marketing is about advertisements and promotions. Engel, Blackwell and Miniard (2001) mentioned that the post-purchase behavior is reactions after consumers purchased a product. There are two types of reactions which are feeling satisfied and feeling dissatisfied.

The development of the Internet has promoted the growth of electronic word-of-mouth. Information and opinions are exchanged and spread by plenty different platforms such as emails, MSN messenger, BBS (Bulletin Board System), online discussion forums, message boards, newsgroup, industrial portal discussion area, chat room and so on. The traditional word-of-mouth is instantaneous and passed face to face, but the electronic word-of-mouth could be spread faster, in anytime, and in a way of one to many. Gelb and Johnson (1995) suggested that the information which is communicated via the Internet is a kind of word-of-mouth. Because the electronic word-of-mouth is not limited by time and distance, the electronic word-of-mouth is more effective, more convenient and broader. In physical world, if a customer feels dissatisfied, he/she may tell the other six people about his/her dissatisfaction. However, in the world of Internet, if a customer feels dissatisfied, his/her dissatisfaction can be delivered to more than six thousand people by Internet platforms. In some cases, this number may be underestimated (Wang, 2004). Therefore, even though the electronic word-of-mouth could not replace the traditional word-of-mouth, the electronic word-of-mouth has been thought as the most powerful potential marketing approach.

Litvin, Goldsmith and Pan (2008) mention challenges and opportunities of the electronic word-of-mouth, and Wang (2004) compares the difference between the electronic and the traditional word-of-mouth. The above discussions are summarized as below.

1. The electronic word-of-mouth is less restricted. The traditional word-of-mouth normally happens when two or a group of people meet in the same place at the same time. They talk face to face and discuss the same topic. However, when the information is exchanged on the Internet, it is not restricted by time, places and environments. The electronic word-of-mouth could even also be passed to people who don't know each other. This advantage accelerates the spread of electronic word-of-mouth.

2. The electronic word-of-mouth may sometimes be ignored. The traditional word-of-mouth is an interaction between the information transmitter and receiver. Because both parties are interested in the topic which they are discussing, the direct communication between each other helps to clarify questions and reduce the perceived risk more effectively. However, the electronic word-of-mouth is based on the Internet platforms, and sometimes it can't be interacted immediately. Therefore, the information transmitter could not be sure whether the receiver is interested in that issue, or the issue raised by the transmitter is clear enough or not. Consequently, the electronic word-of-mouth may be ignored as advertisements sometimes.

3. The electronic word-of-mouth contains multimedia information. The traditional word-of-mouth is mainly based on oral conversation and sometimes assisted by body languages. The electronic word-of-mouth can be communicated by multimedia such as words, photographs, images, sounds, 3D (three dimension) images, videos and so on. The various multimedia attracts more attention, and helps information receivers to understand the information more easily and more completely. Therefore, the electronic word-of-mouth provides richer and more diverse contents than the traditional one.

4. The electronic word-of-mouth could be spread out broader. Wang (2004) claims that the traditional word-of-mouth communicates as cell division which is one to one delivery. For example, the spread is started by one person, and every transmitter tells another person face to face at every stage. There will be 2^n persons receiving this message at the n^{th} stage. However, the spread of electronic word-of-mouth is broader, which is like nuclear reaction. For example, the information is posted on the Internet by one person, and every transmitter forwards this web link to m persons at every stage. There will be $\left(m^n - 1\right) / \left(m - 1\right)$ persons receiving this message at the n^{th} stage. By using the technology of the Internet, the electronic word-of-mouth could be spread more extensively and faster than the traditional one.

5. The electronic word-of-mouth is more cost effective. Nowadays, communications and information exchanges take place frequently in our workplace and daily life. However, comparing with the other communication approaches, face to face communication takes higher opportunity and time costs. Therefore, the occurring frequency of the traditional word-of-mouth is reduced. The Internet is used by most people everyday, and the cost is relatively low. Thus, the electronic word-of-mouth is more cost effective by using the Internet.

6. The electronic word-of-mouth may not be trusted. The traditional word-of-mouth is a kind of physical contact between people, and the face to face communication and interaction help people to build up trust and to reduce risks, which are the main purpose of searching for word-of-mouth. However, there are many fakes, lies, unreal advertisements on the Internet, and anonymity which is one of the properties of the Internet makes it hard for consumers to identify the reliability of the source of information (Fang and Chang, 2006). Thus, the electronic word-of-mouth is thought not as reliable as the traditional one, and may not be trusted sometimes.

7. The electronic word-of-mouth may generate new topics and ideas. Since the electronic word-of-mouth can be spread broader, there are more various Internet users participating in discussions. Because of the variety of Internet users and the extensive spread, they usually bring new ideas and information into discussions.

Nowadays, manufacturers and retailers promote and advertise their products and services by many different media such as newspapers, television programs, radios, Web sites and so on. However, how customers select a new product or service mainly depends on word-of-mouth. Rosen (2001) addresses three reasons explaining the significance of word-of-mouth. These three reasons are illustrated in the following.

1. "Customers are hardly hear you" (Rosen, 2001). The amount of information has grown sharply everyday. Since new technologies of media have been implemented, such as Internet and digital broadcasting, people receive various information everyday. For example, "a weekday edition of the New York Times contains more information than what an average person was likely to come cross in his/her lifetime in seventeenth-century England" (Richard Saul Wurman, cited in Rosen 2001). Some of the information is useful for receivers, but some is not. Therefore, information overload causes noises to customers. People are forced to ignore most of the information from these noises, and customers feel more comfortable to seek information from those people who they know.

2. "Customers are skeptical" (Rosen, 2001). According to the survey which is made by Porter Novelli co., there are only 37% people who think that information from software or computer companies are believable. If the information is from pharmacy companies, only 28% of the people consider the information believable. If the information is from vehicle manufacturers, only 18% of the people think the information believable. Moreover, if the information is from insurance companies, only 16% of the people think that it is believable (Rosen, 2001). It is difficult for customers to determine which information is real from those huge amounts of information. Besides, a lot of information is not real, and it results in unhappy purchase experience. Thus, customers are skeptical, and they would rather believe in word-of-mouth than advertisements.

3. "Customers are connected" (Rosen, 2001). Humans are a kind of animals who live in groups. Communication is human nature. Since the Internet has been well developed, communication has become easier for people to exchange information even with strangers or people who are in a different continent. Therefore, the opinions and information about a product are spread worldwide in a very short time, and it is very easy for consumers to get this word-of-mouth.

Technology readiness index

While adopting new technologies is easy for some people, it might be difficult for others. Parasuraman (2000) defines technology readiness index as "people's propensity to embrace and use new technologies for accomplishing goals in home life and work". Technology readiness can be seen as a psychological status. There are two kinds of forces in psychology affecting the willingness to use new technologies, which are enablers and inhibitors.

Parasuraman and Colby (2001) cooperated with Rockbridge Associates Inc. and interviewed customers of Rockbridge Associates Inc. with focus groups. After interviews, they summarized the positive and negative feelings about facing new technologies. According to this research, Parasuraman and Colby (2001) propose four dimensions of measuring technology readiness index, which are the optimism, innovativeness, discomfort and insecurity. These four dimensions are explained in the following.

1. The optimism represents positive views on new technologies, and it means that people feel more controllable, flexible and efficient when using new technologies. People who are optimistic about technology think that they have the ability to make good use of new technologies, and believe that new technologies can help them improve their life and work.
2. The innovativeness represents the intention to become a pioneer of technology and thought leader. People with the perception of the innovativeness feel like trying new technologies all the time.

3. The discomfort means the feelings of lack of control over new technologies. People with the perception of discomfort are not confident in using new technologies and are overwhelmed by using them.

4. The insecurity means the distrust of new technologies. People with the perception of insecurity doubt whether technology could work properly or not.

By using technology readiness index, it is clearer to understand customers' beliefs and feelings about adopting new technologies.

Customer satisfaction

Cardozo (1965) is the first person who discusses customer satisfaction in marketing area. He addresses that because the market has become so competitive, more and more companies have paid more attentions to customer satisfaction. Customer satisfaction has become a big issue in business governance. Customer satisfaction can affect consumers' intention to purchase the same products again or purchase other products.

Customer satisfaction can be discussed from two different angles: psychologically and economically. From customers' psychological point of view, if the purchase result is better than what a customer expects, the customer will feel satisfied. On the other hand, if the purchase result is worse than a customer's expectation, the customer will feel dissatisfied (Hampel, cited in Tsai 2005). From customers' economical viewpoint, if the benefit of the product or service is worthier than the time and money a consumer has invested, the consumer will feel satisfied. Otherwise, the consumer will be dissatisfied (Howard and Sheth, 1969). Oliver (1981) defines customer satisfaction as an emotional reaction which results from a purchase experience. Anderson, Fornell and Lehmann (1994) think that customer satisfaction is an overall accumulative evaluation of a company after consumers have experienced their products or services.

Kotler (2000) says that the cost on attracting a new customer is five times more than the cost on retaining an existing customer. Reichheld (1996) mentions that improving customer satisfaction helps enterprises to reduce their costs and increase their profits. What is more, it helps enterprises build and spread the positive word-of-mouth. According to Jones and Sasser (1995), those companies earning higher customer satisfaction perform better in profits and growth. Because of the higher customer satisfaction, customer loyalty and sales are also increased. Consequently, Lee (2006) addresses that customer satisfaction directly affects the reputation and the financial performance of a company.

To sum up the literatures mentioned above, customer satisfaction is an emotional reaction after consumers purchase and experience a product or service. These accumulative reactions have become the customer satisfaction with a company. The positive customer satisfaction results in the higher customer loyalty and the higher willingness to repurchase. Since customer relationship is a virtual asset of enterprise, higher customer satisfaction brings higher profits and higher market share for companies. Therefore, aiming high customer satisfaction is one of important goals for the majority of enterprises. Thus, in this research, we discuss how technology readiness index and the electronic word-of-mouth affect customer satisfaction.

Behavioral intention

Nowadays, the life cycle of products is shorter than before. A successful business relies on not only having good sales of products or services but also having a long term relationship with customers. Therefore, how to make consumers repurchase the products and build loyalties are more important than the promotion of single product or service. In order to understand if customers would buy products or services of the same company again, behavioral intention is used to forecast consumers' behavior.

Zeithaml, Berry and Parasuraman (1996) think that behavioral intention can be classified into two types which are the favorable and unfavorable intention. If consumers have the favorable intention towards a company, they would spread the positive word-of-mouth for the company, increase the loyalty to the company and increase the purchase amount of products or services of the company. On the other hand, if consumers have the unfavorable intention towards a company, they would reduce the purchase amount, spread the negative word-of-mouth and purchase other alternative products or services from other companies.

Zeithaml, Berry and Parasuraman (1996) measure behavioral intention in five dimensions. There are two dimensions related to the favorable intention, which are the loyalty and paying more. Chen (2002) mentions that behavioral intention is an important indicator which is used to understand if customers are going to remain in a company or defect from the company. Consequently, in this research, we discuss how technology readiness index, the electronic word-of-mouth and customer satisfaction influence behavioral intention.

RESEARCH METHODOLOGY

Research framework

In order to understand the relationships between technology readiness, the electronic word-of-mouth, customer satisfaction and behavioral intention, the research model is designed as Figure 1. According to Parasuraman and Colby (2001), technology readiness index can be measured in four dimensions which are the optimism, innovativeness, discomfort and insecurity. Relationships between these four dimensions and the electronic word-of-mouth, customer satisfaction and behavioral intention are also discussed respectively in this model.

Research method

There are two major research methods used in this research which are the qualitative and quantitative research method. The qualitative research method is used for the non-standardized data, the data which are expressed by words and conceptualized data. The quantitative research method is used for standardized data, the data which are represented by numbers or the statistic data (Saunders, Lewis and Thornhill, 2000). In this research, the statistic analysis is used to find out the relationships between variables, so the quantitative research method is used. Furthermore, the results of all measurement items are numerical.

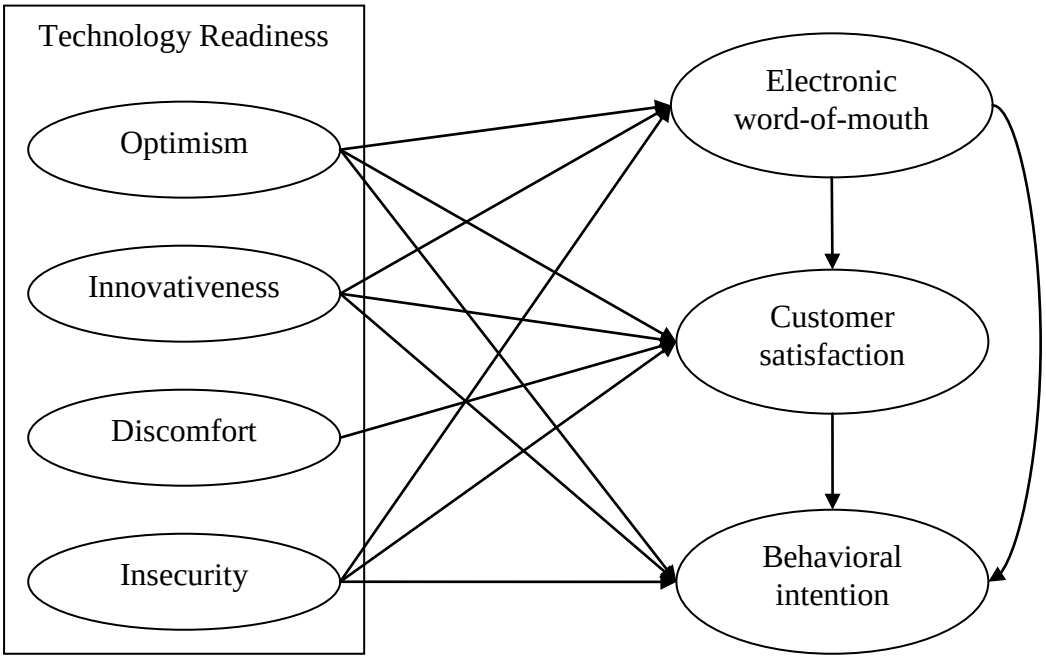

Figure 1: Research model.

The formal questionnaire contains 9 parts. The first part of the questionnaire asks respondents about their experiences of purchasing 3C products. The second part of the questionnaire asks respondents about their willingness to refer to the electronic word-of-mouth before purchasing 3C products. The third part of the questionnaire is used to understand if respondents are satisfied with the 3C products they have bought. The fourth

part of the questionnaire is used to understand respondents' behavioral intention. The fifth part of the questionnaire is used to measure respondents' perception of optimism. The sixth part of the questionnaire is used to measure respondents' perception of innovativeness. The seventh part of the questionnaire is used to measure respondents' perception of discomfort. The eighth part of the questionnaire is used to measure respondents' perception of insecurity. The last part of the questionnaire is used to understand the background of the respondents, such as their sex, age, marriage status and level of education. There are 38 questions in total.

The questions in the remaining parts of the questionnaire are measured by the seven point Likert scale, ranging from 7 (strongly agree) to 1 (strongly disagree).

Research subjects in this research were focused on consumers who have the experience of purchasing 3C products. The on-line questionnaire was used to collect data, and the on-line questionnaire was posted on http://www.my3q.com/ which is a professional questionnaires posting website and is free for academic purpose in conditions. Furthermore, the web link of the on-line questionnaire was also sent to research subjects by email and was posted on Facebook. The collection period was from the 16th of August to the 30th of August, 2010. A total of 184 questionnaires were collected. However, there were 24 invalid questionnaires, for example, the questionnaires with all the questions being answered in the same scale. Consequently, the number of the final valid questionnaires was 160.

ANALYSIS AND RESULT

In order to analyze the data which are collected from the questionnaires, statistic software such as Microsoft Excel, SPSS 12.0 and AMOS 6.0 are used. Mean and standard deviation of each measurement item are calculated and showed in Table 1.

Table 1: Mean and standard deviation of each measurement item.

Code	Serial Number	Mean	Standard deviation
WOM	Q3	6.16	0.99
	Q4	5.58	1.23
	Q5	5.91	1.07

	Q33	4.81	1.38
	Q34	5.28	1.23
	Q35	4.68	1.38

Reliability and validity test

In order to test the reliability and validity of the data gathered from the questionnaires, Cronbach's α value and the average variance extracted are calculated and showed in Table 2. According to Pallant (2007), Cronbach's α value is used to test the reliability, and 0.7 is the minimum level for Cronbach's α value. In Table 2, the Cronbach's α values of all variables are greater than 0.7, and it means the internal consistency is acceptable and the results of the questionnaires are highly stable and accurate. The average variance extracted is used to test the convergent validity. Fornell and Larcker (1981) suggest that 0.5 is the minimum level for the value of the average variance extracted. In Table 2, the average variance extracted values

of all variables are greater than or equal to 0.5, and it means that the convergent validity is acceptable. Since the reliability and validity test of the questionnaire are all acceptable, the result of the analysis can be seen as believable.

Table 2: The result of reliability and validity test.

Code	Serial Number	Cronbach's α	Average variance extracted
WOM	Q3 ~ Q5	0.76	0.51
SAT	Q6 ~ Q10	0.90	0.65
BI	Q11 ~ Q13	0.88	0.70
OPT	Q14 ~ Q20	0.91	0.60
INNO	Q21 ~ Q27	0.93	0.70
DIS	Q28 ~ Q31	0.79	0.50
INS	Q32 ~ Q35	0.89	0.68

Overall model fit

The overall model fit is used to test the fitness for the research model and the data collected from the questionnaires. The fit indexes are computed and showed in Table 3. The recommended minimum value of GFI (Goodness of Fit Index) is 0.9, and the recommended minimum value of AGFI (Adjusted Goodness of Fit Index) is 0.9 (Hu and Bentler, cited in Hsiu 2007). Moreover, the recommended minimum value of RFI (Relative Fit Index) and NFI (Normed Fit Index) are both 0.9 (Hsiu, 2007), and the recommended minimum value of PGFI (Parsimony Goodness of Fit Index) is 0.5. According to Table 3, all the fits indexes in this research reach the recommended values which mean that the overall model fit in this research is acceptable.

Table 3: Overall fitness of models.

Fit index	Recommended Value	Measurement model	Structural model
GFI	>= 0.90	0.97	0.97
AGFI	>= 0.80	0.97	0.96
PGFI	>= 0.50	0.82	0.82
NFI	>= 0.90	0.96	0.96
RFI	>= 0.90	0.96	0.96

Hypotheses tests

In order to test those hypotheses which are made in this research, AMOS software is used to compute the path coefficient values between the variables in the research model. If the path coefficient value between two variables is greater than 0.1, it means that there is a positive relationship between these two variables. If the path coefficient value between two variables is smaller than -0.1, it means that there is a negative relationship between these two variables. Otherwise, it is said that there is no strong relationship between these two variables. According to the results computed by AMOS, the path coefficient values in this research model are showed in Figure 2.

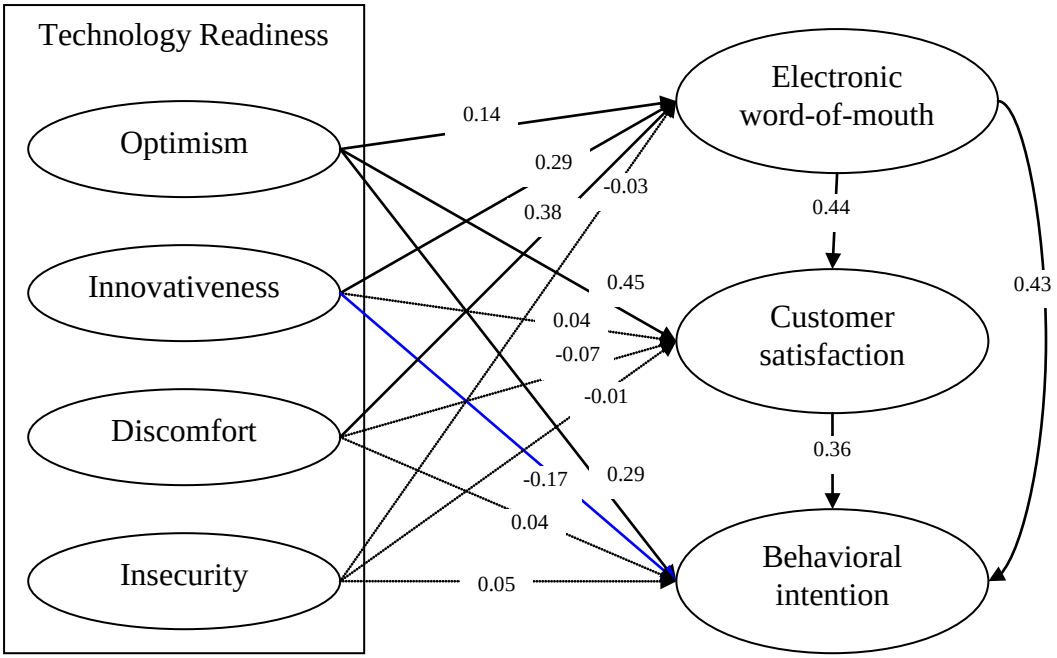

Figure 2: Path coefficient values of research model.

According to Figure 2, the path coefficient value between optimism and electronic word-of-mouth is 0.14 which is greater than 0.1, and thus hypothesis H_{1a} is supported by the analysis result. It means that the optimism about technology positively influences the willingness to refer to the electronic word-of-mouth. The path coefficient value between optimism and customer satisfaction is 0.45 which is greater than 0.1, and thus hypothesis H_{1b} is supported by the analysis result, meaning that the optimism about technology has a positive influence on customer satisfaction. The path coefficient value between optimism and behavioral intention is 0.29 which is greater than 0.1, and thus hypothesis H_{1c} is supported by the analysis result, which means that the optimism about technology positively influences behavioral intention.

The path coefficient value between innovativeness and electronic word-of-mouth is 0.29 which is greater than 0.1, and thus hypothesis H_{2a} is supported by the analysis result, which means that the innovativeness about technology positively influences the willingness to refer to the electronic word-of-mouth. The path coefficient value between innovativeness and customer satisfaction is 0.04 which is smaller than 0.1 and greater than -0.1, and therefore hypothesis H_{2b} is not supported by the analysis result, which means that there is no strong relationship between the innovativeness about technology and customer satisfaction. The path coefficient value between innovativeness and behavioral intention is -0.17 which is smaller than 0.1, and therefore hypothesis H_{2c} is not supported by the analysis result. However, the path coefficient value is smaller than -0.1, indicating that the innovativeness about technology have a negative influence on behavioral intention.

The path coefficient value between discomfort and electronic word-of-mouth is 0.38 which is not smaller than -0.1, and therefore hypothesis H_{3a} is not supported by the analysis result. Nevertheless, the path coefficient value is greater than 0.1, demonstrating that the discomfort about technology positively influences the willingness to refer to the electronic

word-of-mouth. The path coefficient value between discomfort and customer satisfaction is -0.07 which is smaller than 0.1 and greater than -0.1, and therefore hypothesis H_{3b} is not supported by the analysis result, showing that there is no strong relationship between the discomfort about technology and customer satisfaction. The path coefficient value between discomfort and behavioral intention is 0.04 which is smaller than 0.1 and greater than -0.1, and thus hypothesis H_{3c} is not supported by the analysis result, revealing that there is no strong relationship between the discomfort about technology and behavioral intention.

The path coefficient value between insecurity and electronic word-of-mouth is -0.03 which is smaller than 0.1 and greater than -0.1, and thus hypothesis H_{4a} is not supported by the analysis result, which indicates that the insecurity about technology and the willingness to refer to the electronic word-of-mouth is not strongly related. The path coefficient value between insecurity and customer satisfaction is -0.01 which is smaller than 0.1 and greater than -0.1, and therefore hypothesis H_{4b} is not supported by the analysis result, which shows that the insecurity about technology does not have a significant relation with customer satisfaction. The path coefficient value between insecurity and behavioral intention is 0.05 which is smaller than 0.1 and greater than -0.1, and thus hypothesis H_{4c} is not supported by the analysis result, which demonstrates that there is no strong relationship between the insecurity about technology and behavioral intention.

The path coefficient value between the willingness to refer to the electronic word-of-mouth and customer satisfaction is 0.44 which is greater than 0.1, and thus hypothesis H_5 is supported by the analysis result, meaning that the willingness to refer to the electronic word-of-mouth positively influences customer satisfaction.

The path coefficient value between customer satisfaction and behavioral intention is 0.36 which is greater than 0.1, and thus hypothesis H_6 is supported by the analysis results, indicating that customer satisfaction positively influences behavioral intention.

The path coefficient value between the willingness to refer to the electronic word-of-mouth and behavioral intention is 0.43 which is greater than 0.1, and therefore hypothesis H_7 is supported by the analysis result, showing that the willingness to refer to the electronic word-of-mouth positively influences behavioral intention.

The testing results of the hypotheses are summarized in Table 4. According the hypotheses testing results, it is obvious to see that people who are optimistic about technology are more willing to refer to the electronic word-of-mouth before purchasing 3C products. Moreover, after purchasing these products, they are more satisfied with the products they have bought, and they would like to repurchase the products and recommend others to buy the same products. Their customer satisfaction is relatively high because they usually make more preparations before purchasing the products. Besides, because they are more satisfied with the products, they are more willing to recommend the products to others.

People with the perception of the innovativeness about technology are also willing to refer to the electronic word-of-mouth before buying 3C products. However, according to the research results, there is no strong relationship between the innovativeness about technology and their customer satisfaction. It might be because people with the perception

of the innovativeness about technology usually want to be the pioneers of trying new 3C products and there may not be enough information about those products and support from manufacturers at that time. As a result, they may not always be satisfied with the products they have bought. Nevertheless, according to the research results, their behavior intention is relatively low. It is opposite to the hypothesis in this research. The reason might be that they are always interested in new products, so the willingness to buy the same 3C products is relatively low. In addition, their intention to recommend the products to others is influenced by their customer satisfaction, so their behavioral intention is not as strong as what is hypothesized.

Table 4: Summary of the hypotheses testing result.

	Hypothesis	**Results**
H_{1a}	**The optimism positively influences the willingness to refer to the electronic word-of-mouth.**	**Supported**
H_{1b}	**The optimism positively influences customer satisfaction.**	**Supported**
H_{1c}	**The optimism positively influences behavioral intention.**	**Supported**
H_{2a}	**The innovativeness positively influences the willingness to refer to the electronic word-of-mouth.**	**Supported**
H_{2b}	**The innovativeness positively influences customer satisfaction.**	**Not supported**
H_{2c}	**The innovativeness positively influences behavioral intention.**	**Not supported**
H_{3a}	**The discomfort negatively influences the willingness to refer to the electronic word-of-mouth.**	**Not supported**
H_{3b}	**The discomfort negatively influences customer satisfaction.**	**Not supported**
H_{3c}	**The discomfort negatively influences behavioral intention.**	**Not supported**
H_{4a}	**The insecurity negatively influences the willingness to refer to the electronic word-of-mouth.**	**Not supported**
H_{4b}	**The insecurity negatively influences customer satisfaction.**	**Not supported**
H_{4c}	**The insecurity negatively influences behavioral intention.**	**Not supported**
H_{5}	**The willingness to refer to the electronic word-of-mouth positively influences customer satisfaction.**	**Supported**
H_{6}	**Customer satisfaction positively influences behavioral intention.**	**Supported**
H_{7}	**The willingness to refer to the electronic word-of-mouth positively influences behavioral intention.**	**Supported**

According to Figure 2, there is no strong relationship between the discomfort about technology and customer satisfaction, and there is no strong relationship between the discomfort about technology and behavioral intention either. However, according to the research results, it is found that people with the perception of discomfort about technology are more willing to refer to the electronic word-of-mouth before buying 3C products, and this finding is opposite to the hypothesis H_{3a}. The possible reason is that they are not confident of selecting the right 3C products, so they would like to refer to the electronic word-of-mouth in order to understand other consumers' opinions and experiences.

According to the research results, it is found that the relationships between the perception of insecurity about technology and the willingness to refer to the electronic word-of-mouth, customer satisfaction and behavioral intention are not as strong as what are hypothesized in the beginning of this research.

From Figure 2, it shows that people who are more willing to refer to the electronic word-of-mouth before purchasing 3C products are more satisfied with the products they have bought. It is because referring to the electronic word-of-mouth helps customers to reduce the risk of buying unsuitable products and to gain more information. Consequently, their expectation of the 3C products should be easier to be reached. What is more, the analysis results also show that people who are more willing to refer to the electronic word-of-mouth before purchasing 3C products have a greater tendency to repurchase and recommend the products to others. The possible reason is that they are satisfied with the products which they have bought, and they would like to share their positive experience with their friends and families.

Lastly, it is found that people who are more satisfied with the 3C products they have bought are more inclined to repurchase and recommend the products to others. It is because their experience of purchasing these products is delightful. As a consequence, their behavioral intention is relatively higher.

DISCUSSION AND CONCLUSION

The purposes of this research are to understand if the electronic word-of-mouth has an influence on the customer satisfaction and behavioral intention when they purchase 3C products and to give recommendations for improving the effectiveness of the electronic word-of-mouth in 3C products industries.

In section one, the motives and the goals in this research work are introduced. 3C products industry changes very fast and is highly competitive. The Internet plays an important role in exchanging the information and all kinds of experiences of purchasing 3C products. In order to promote new products effectively and increase customer satisfaction, utilizing the power of the electronic word-of-mouth is essential for manufacturers. In addition, in order to deliver the electronic word-of-mouth efficiently, targeting the opinion leaders on the Internet accurately is necessary.

In section two, some literatures about this research work are reviewed. Firstly, literatures about word-of-mouth, the electronic word-of-mouth and opinion leaders are discussed. Secondly, literatures about technology readiness as well as the four dimensions of measuring technology readiness index are talked about. Thirdly, literatures about customer satisfaction and its importance are discussed. Fourthly, literatures about behavioral intention are mentioned.

In section three, the methodology which is used in this research is introduced. Firstly, the research model in this research work is made. Secondly, according to the research model, 15 hypotheses are made in order to find out the relationships between 7 variables. Thirdly, the reasons for surveying by means of questionnaires are explained. Fourthly, the pilot test and the questions in the formal questionnaires are introduced. Lastly, the sampling method which is used to collect data is introduced.

The data which are collected from questionnaires are analyzed in section four. Simple statistic data about the background of 160 respondents are introduced first. The reliability and validity test are conducted, and then the overall model fit is measured as well. After the tests of 15 hypotheses, the hypotheses test results and findings are introduced in the last part.

The conclusions, suggestions and limitations of this research are given in the following.

Conclusions and suggestions

According to the analysis results, it is obvious that the electronic word-of-mouth plays an important role in 3C products industry. Customers' willingness to refer to the electronic word-of-mouth before purchasing 3C products positively influences customer satisfaction and behavioral intention. It means that the information and opinions from other consumers on the Internet strongly affect customers' decisions to purchase certain products. Furthermore, it is found that customers who are satisfied with the 3C products they have bought are more willing to repurchase and to recommend these products to their friends and families. Therefore, the positive word-of-mouth is spread. In view of these, following suggestions are made for 3C products manufacturers in order to promote their products more effectively and increase customer satisfaction and consumers' behavioral intention.

1. 3C products manufacturers should cooperate with professional online discussion forums. Nowadays, there are too many advertisements in the public media, and customers are forced to ignore most of them. Therefore, the electronic word-of-mouth has become one of the most efficient approaches for consumers to gain the information about new 3C products. There are many professional online discussion forums which provide platforms for Internet users to express their experiences and opinions about 3C products. 3C manufacturers should cooperate with these online discussion forums and deliver the information about their products there.

2. 3C products manufacturers should always pay attentions to customers' opinions on the Internet. Sometimes the dissatisfying customers express their complaints on professional online discussion forums instead of responding to the customer service department of manufacturers. Since the effect of negative word-of-mouth is stronger than the positive one, manufacturers have to understand the complaints from customers on the Internet and to solve their problems in order to stop the spread of the negative word-of-mouth and increase customer satisfaction. Thus, 3C products manufacturers have to pay attention to professional online discussion forums and give resolutions to consumers' problems. In this way, customer satisfaction can be improved and the positive electronic word-of-mouth can be increased as well.

3. 3C products manufacturers should make the instructions and the information of their products easier to be understood. According to the analysis results, people with the perception of discomfort about technology are willing to refer to the electronic word-of-mouth before purchasing 3C products. However, these people are not confident of using new technologies and feel a lack of control over new technologies. In order to increase their customer satisfaction, manufacturers should help them to understand new 3C

products more effortlessly. In addition to providing more detailed instructions and information of products, manufacturers could answer their questions about products on the professional online discussion forums.

According to Rosen (2001), opinion leaders are interested in trying new things and sharing their experiences with others, and they are information-hungry and like to search for information online. According to Parasuraman and Colby (2001), both the perception of optimism and innovativeness are the contributors of technology readiness, and people with the perceptions of optimism and innovativeness about technology have higher technology readiness. Thus, the characteristics of opinion leaders are similar to those of the people who have higher technology readiness. Therefore, opinion leaders can be seen as people who usually have higher technology readiness.

According to the analysis results, it is found that people with the perception of optimism and innovativeness about technology usually refer to the electronic word-of-mouth before buying 3C products. This also means that opinion leaders are more willing to refer to the electronic word-of-mouth before purchasing 3C products. Therefore, dealing with the electronic word-of-mouth is essential for 3C products manufacturers. In order to utilize the power of the electronic word-of-mouth more effectively, the following suggestions are made for 3C products manufacturers.

1. 3C products manufacturers should focus more on the opinion leaders on the Internet. Although manufacturers could convey the information about their products directly to their customers by themselves, it is easy for customers to treat this kind of information as advertisements. Since opinion leaders have the ability to influence other people's decisions, manufacturers should cooperate with online opinion leaders and spread the information through them. There are many cooperation approaches, such as giving them free products, inviting them to the exhibitions, providing trial products, giving them a price discount and so on. Those online opinion leaders can affect other customers and other opinion leaders, so the electronic word-of-mouth about 3C products can be spread efficiently.

2. 3C products manufacturers should provide more technical support to those pioneers of purchasing new products. According to the analysis results, people with the perception of innovativeness about technology whose customer satisfaction and behavioral intention are not as high as expected. The possible reason is that there may not be enough technology support for the latest products from manufacturers. Since opinion leaders also have the perception of innovativeness about technology, 3C products manufacturers should be aware of their feedback and provide more advanced support to these pioneers in the first time. By providing them with more technical support and advanced information, these opinion leaders' customer satisfaction and behavioral intention can be improved. Furthermore, the positive word-of-mouth is created.

Limitation and future work

In this research work, due to the limited time and resources, the main limitation is that the samples of the questionnaires are not enough. There are only 160 available questionnaires

which are analyzed in this research. Among these questionnaires, there are 97% of the respondents whose ages are between 21 and 40, and there are 94% of the respondents who have Bachelor's or Master's degrees. Because the samples are not enough, the analysis results might not be able to reflect a real condition precisely.

In the future work, it is suggested considering more samples of the questionnaires. Besides, the research focuses on 3C products industry, so it is also suggested surveying different industries, for example the car industry, in order to understand the effect of the electronic word-of-mouth in different areas.

ABSTRACT

The paper sets out to present the results of a survey of customer satisfaction with regard to the strategy of Total Quality Management (TQM) adopted in a wheat flour milling company. This survey was conducted to learn more about customer expectations and satisfaction. The respondents were all customers of a flour-based food processor. Quality Function Deployment (QFD) was applied to improve customer service performance by focusing on Customer Satisfaction, Value and Retention. The results show that customer satisfaction has increased steadily over a period of three years. The QFD approach helped to design a competitive product by aligning the company resources to customers' needs. The findings are limited to a specific food manufacturing company and for this reason they cannot be generalized to the whole in service sector. Further research is needed for other service companies. The findings may support manufacturing companies hoping to achieve customer satisfaction by focusing on total quality management implementation efforts. Furthermore, companies can focus their efforts on improving the way in which they meet certain customers' needs if these needs are more extensively related to a certain component of quality management. It presents evidence to the managers of the value of implementing TQM strategy to effectively achieve customer satisfaction that ultimately leads to greater market share and profit maximization.

Keywords: Manufacturing, Total quality management, Quality function deployment, Customer satisfaction, Benchmarking

INTRODUCTION

Over the past two decades, companies have been experiencing dramatic changes in the business environment characterized by such phenomena as increasing consumer awareness of quality, the rapid transfer of technology, globalization and competition to reduce costs. In response to these challenges, many companies have joined the quality faction and implemented various quality improvement initiatives as a means to enhance competitiveness and ultimately business performance. While the business world also shifts its focus from product to customer, managers are discovering that profitable and sustainable revenue growth results from enhanced customer relations, because consumers nowadays are more informed, more demanding, and prone to change brands and

companies if their requirements are not met on time and at a price they are willing to pay (Andronikidis et al., 2009).

However, quality is considered the ability to meet the stated and implied requirements of customers and not an inherent feature (Shahin and Nikneshan, 2008). The effectiveness of quality initiatives resulting in sustainable competitive advantage and enhanced business performance has been a major subject of interest for business (Arumugam et al., 2009). Understanding customers' expectations is a prerequisite for delivering superior products, because they represent the implicit performance standards which customers use in assessing product quality (Parasuraman, 1998). Total Quality Management (TQM), as a set of management practices, focusing on customer satisfaction and constant organizational development, has been widely adopted (Dale, 1999; Yusof and Aspinwall, 2000).

Through TQM practices, companies have been trying to improve product quality to earn customer satisfaction, besides their overall performance (Bhat and Rajashekhar, 2009). But an image of the kind of TQM strategy which will efficiently earn this satisfaction in manufacturing industry is still vaguely presented. Most companies naturally focus on improving the quality of the product, while service quality – the steps taken to deliver the product – is not generally given priority. Thus, it is helpful for companies to know and understand the current practices and opportunities offered by TQM if they want pursue customer satisfaction by combining improvements in the product with those in the quality of service.

To provide a comprehensible image of TQM strategy in a manufacturing company, the present study collects data from a 'Voice of the Customer' survey, which describes how customers (in this case, of a small to medium-sized enterprise – hereafter, SME – in the food industry, processing wheat flour) appreciate quality in products and services. The main research question of this paper is as follows:

- How TQM can be implemented to achieve customer satisfaction in terms of quality of products and services?

The data are analyzed by the QFD method to gauge the level of customer satisfaction with products and service and to establish action plans for developing the potential of both. QFD is chosen since it is a form of strategic planning to accomplish TQM and is essential for quality initiatives to be successful (Juran, 1989).

In the light of the above, this paper is structured as follows. Section 2 reviews the theories laid down in the studies of customer satisfaction, with special reference to the case under review. Section 3 presents quality and TQM concepts by discussing the TQM implementation programme in the case company. Section 4 provides a snapshot of the analysis and measurement process of TQM success in the case company. Finally, Section 5 is devoted to conclusions and implications.

CUSTOMER SATISFACTION

Defining customer value and satisfaction

Customers choose products or services from a selection of different kinds on the basis of pre-perceived value for the product. Value can be defined as a ratio between what the customer gets and what he gives. The customers get benefits and assume costs. The benefits include functional benefits and emotional benefits. The costs include monetary costs, time costs, energy costs, and physics costs. Thus value is given by:

$$\text{Value} = \frac{\text{Benefits}}{\text{Costs}} = \frac{\text{Functional benefits + emotional benefits}}{\text{Monetary costs + time costs + energy costs + psychic costs}}$$

During and after the consumption and use of a product or service, customers will develop feelings of satisfaction or dissatisfaction (Kotler and Armstrong, 1996; Kotler, 2000). Customer (dis)satisfaction is defined as the overall attitude of customers toward a good or service after they have acquired and used it. It is a post-choice evaluation which results from selecting a specific purchase and the experience of using/consuming it (Malhotra, 1999). From the managerial perspective, maintaining and/or enhancing satisfaction is critical. Most studies reveal that satisfied customers positively influence a company's future cash flows (Pande et al, 2000). Managers should therefore in their overall business process create programmes to increase customer satisfaction.

However, it is necessary to recognize the factors which contribute to customer satisfaction or dissatisfaction. Figure 1 presents a model of customer satisfaction with regard to their consumption/use of product or service. On the basis of this experience, they evaluate its overall performance. This action has been found to relate precisely to the ratings of quality of product and/or service. Customers compare their perceptions of product/service quality after using the product with their expectation before they purchase it. It also depends on how far actual performance reflects expected performance; customers may that experience positive, negative, or neutral emotions. These emotional responses act as inputs into their overall satisfaction/dissatisfaction perception.

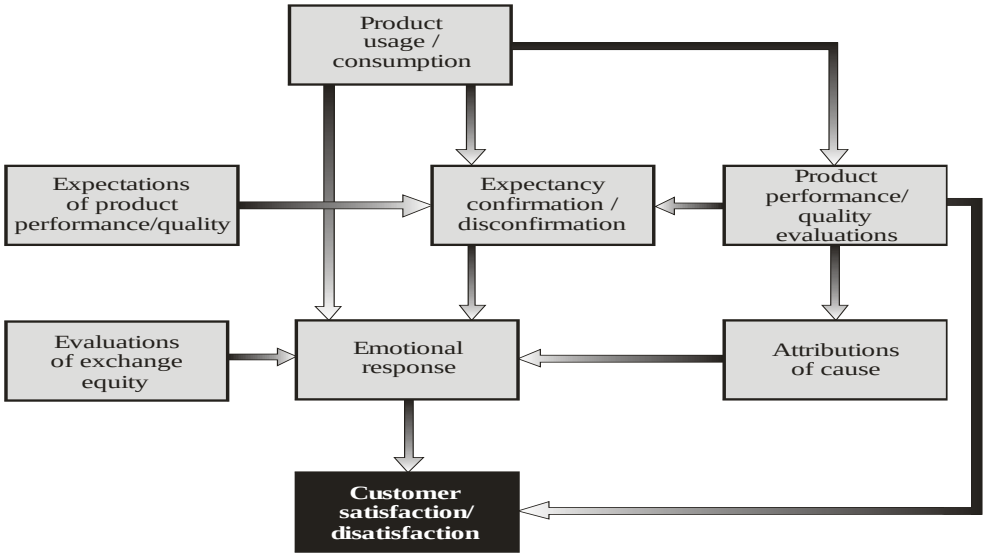

Figure 1: A model of customer satisfaction/dissatisfaction.

The level of satisfaction/dissatisfaction will also be affected by customers' evaluation of the equity of the exchange and also by their attributions of the cause of the product's performance.

IMPLEMENTING TOTAL QUALITY MANAGEMENT.

Quality and TQM.

Different specialists have defined quality as 'fitness for use', 'conformance to requirements' and 'freedom from variation'. One further short definition of quality is also 'customer satisfaction and loyalty'. We use two definitions of quality, for either products or services, as follows:

■ 'The totality of features and characteristics of a product or service that bear on its ability to satisfy stated or implied customers' needs' (Kotler, 2000).

■ Quality must provide goods and services that completely satisfy the needs of both *internal* and *external customers*. Quality serves as the 'bridge' between the producer of goods or services and the customer (Johnson & Weinstein, 2004).

Quality is the key to value creation and customer satisfaction. In a quality-centred company, a marketing manager has two responsibilities. First, he should participate in formulating strategies and policies designed to help the company win through the excellence of its quality. Second, he should deliver marketing quality alongside production quality. Each marketing activity – market research, sales training, advertising, customer service and so on – must be performed to high standards. Marketers play several roles in helping their companies to define and deliver high quality products and services to its target customers. Figure 2 shows the role of marketing between company and customer in this process.

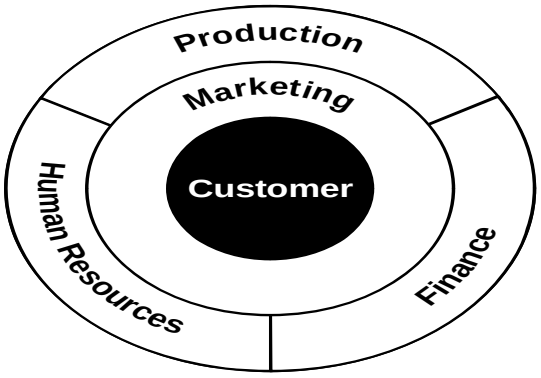

Figure 2: Evolving views about the role of marketing in the company (Kotler, 2000).

TQM is basically a strategy (towards continuous change), as well as an operationalized process, and can be also described as a holistic approach which seeks, through the improvement of quality, productivity and competitiveness (Pfau, 1989), to integrate all organizational functions and organizational objectives in a focus on meeting customer needs (Kumar et al., 2008) . It emphasizes the role of internal and external customers and suppliers, and the involvement of employees in a quest for continuous improvement (Oakland et al., 2002; Kanji, 2002; Karia and Asaari, 2006; Chang, 2006). TQM allows firms to obtain, on the one hand, a high degree of differentiation, satisfying customers' needs and strengthening brand image, and, on the other, to reduce costs by preventing mistakes and wasted time and by making improvements in the corporation's processes (Conca et al., 2004). It encompasses and facilitates all functional areas, processes and systems of businesses, including design, development, production, distribution and customer support (Jung et al., 2008). This holistic approach aims to maximize customer satisfaction upon a basis of repeating activities in the interests of innovation and advancement (Dessler, 2003; Ross, 1998; Yang, 2005).

According to Gill (2009), quality in a product makes sure that it can meet the present expectations of the customer takes account of or incorporates future needs. Indeed, the implementation of quality is the main focus in TQM philosophy. However, TQM companies need to define quality for themselves, whether the definition is intended to meet engineering standards, or is a leading edge definition to make a product which animates customers and which customers would not think of buying from competitors. With a clear definition of quality the company can start to focus on a target for change but if no one agrees on the definition of quality it is difficult to focus on implementing changes which will improve quality.

Scope of quality management

According to Klefsjö et al. (2008), the scope of quality management has changed in recent years from 'customer satisfaction' to something broader. This trend may be due to companies' increasing focus on their multiple bottom lines. What is vital is the way in which companies decide to define the concepts of (i) customers (ii) non-customer stake-holders and (iii) interested parties.

Bergman and Klefsjö (2003) describe customers broadly as 'those companies want to create value for'. The notion of value is here related to value chains, not to the financial chains in the organization. A transitional definition which may be constructive is that customers are individuals or organizations further downstream in the product life cycle process, that is, they are the receivers of a product (Johansson, 2008). Individuals or organizations upstream in the same process would accordingly be named suppliers. Customers and suppliers can be internal or external, depending on the organizational boundaries of the actual process.

Freeman and Reed (1983) attach the term 'stakeholders' with those persons or groups that have a stakes in the organization. Klefsjö et al. (2008) think stakeholders are those actors that provide necessary means or support to the organization, which could be withdrawn if their wants or expectations are not met. They further suggest the term 'primary stakeholder' to be used for those actors who provide the necessary means or support for the organization and could withdraw these, leading to significant consequences for the organization. Examples of primary stakeholders could include customers, employees, investors, shareholders and government.

According to Klefsjö et al. (2008) 'interested parties' are those who have any interest in the organizational activities, output or outcome, although these parties lack power or instruments to create unacceptable damage for the organization or to influence the primary stake-holders to do so. Some actors, although not directly providing any of the necessary means or support to the organization, may still have enough influence to justify considering them more than mere interested parties. Those 'secondary stakeholders' may include nongovernmental organizations, academics, media, fair-trade bodies, environmental pressure groups and other individuals or organizations which somehow may manipulate stakeholders to act on their behalf, if their needs and expectations are ignored.

Implementing TQM for customer satisfaction

What should marketers do in order to raise customer satisfaction and ultimately improve company performance? In the course of the improvement period, they should address it from two sides:

- Product quality side: developing Quality Management Systems (QMS), implementing International Standard Organization, implementing supplier evaluation programmes (in this case, as a provider of wheat and packaging materials and additive material) and providing food safety assurance through health certification.

- Services side: Providing a training centre for food processing, allocating technical representatives for after-sales services, running promotion activities and hotline services to develop customer relationships (Moven, 2001), developing business information for sales and distribution by using the ERP system for online customer orders, payment systems, production planning and scheduling and connecting R&D to customers in order to meet specific customer wants.

Measuring customer value and satisfaction

Quality Function Deployment (QFD) is used to assess the quality of products and services from the customer's standpoint and to identify the prioritized items of product quality and service which can affect the improvement of the SME and also to plan designs for products and services which give high advantage to both the customer and the company (Besterfield and Besterfield 1994; Cohen, 1995) by creating product uniqueness and shortening product life (Urban and Hauser 1993).

QFD is defined as 'how we understand the quality that our customers expect and make it happen in a dynamic way' (Martins and Aspinwall, 2001; Chow-Chua and Komaran, 2002). QFD is also referred to as a 'House of Quality (HOQ)'. The logic behind this is that the matrix in QFD fits together to form a house-shaped diagram (Kutucuoglu et al., 2001). QFD involves a team of people representing the various functional departments which combine in product development, such as marketing, design engineering, quality assurance, manufacturing/manufacturing engineering, test engineering, finance, product support, etc. (Crow, 1996). Figure 3 shows how QFD is used to benchmark organization technical capabilities against customer requirements. It shows that continuous improvement is the basic need for implementing QFD through the House of Quality.

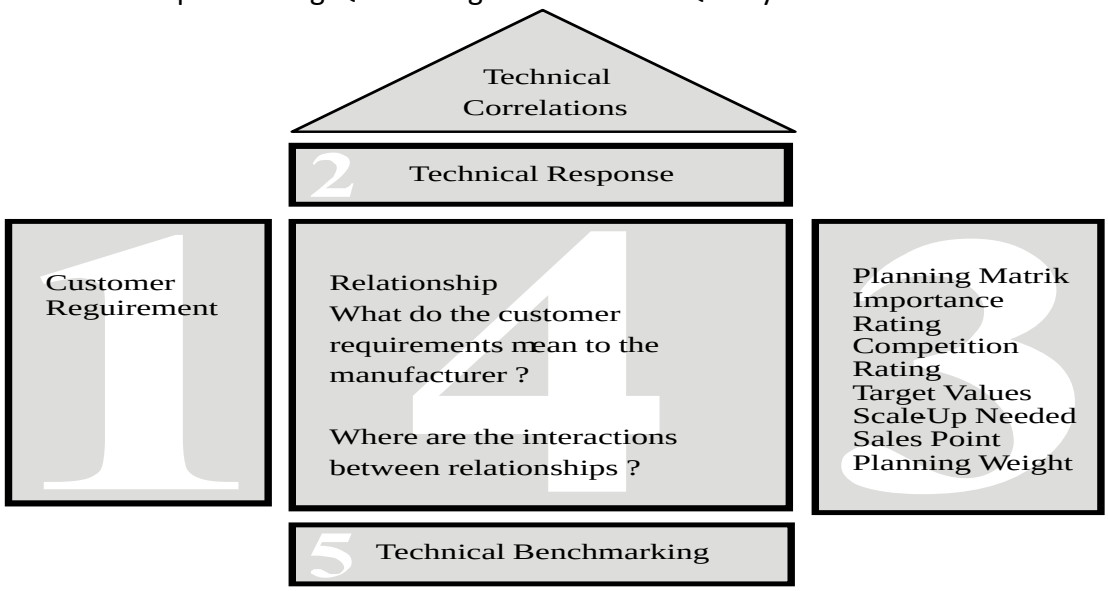

Figure 3: House of Quality for implementing QFD.

Customer satisfaction survey 2006

Observations were made of the case under review, a manufacturing company which is classified as an SME. Its main products are 3 classes of wheat flour products (high, medium and low protein content), divided into 16 brands with additional products, such as pellets, bran and pollard. We observed only wheat flour, since it accounts for 85% of the total sales. In addition, pellets, bran and pollard are consumed by the cattle and wood industries and are thus not as sensitive as those for the wheat flour customers. The product quality and customer service of the company were observed together with those of its three local

competitors and of the imported flour distributed in the market and the views of 150 customers were gathered; they bought various products (bread, noodles, biscuits, cakes, spring rolls, pastry and fried snacks) Sales regions and weekly consumption totals were also examined.

The observation was not concerned with the matter of product price. Surveys were conducted in 2006 and again in 2008.

Due to the low education levels of SME operators, the method was used of in-depth interviewing, on the recommendation of Churchill (1999), who suggests that this method is best suited to theory generation, in that in-depth interviewing allows the interviewer to change the wording of questions in accordance with the 'universe of discourse' (Gorden 1975), jargon and contextually specific phraseology and terminology of the informant.

The company used QFD for defining customer requirements (What), defining the technical correlation between customer requirements and technical response (How), planning the next improvement to meet customers' views and then defining which customer requirements should be prioritised, bearing in mind the manufacturing capability of the company. The following sections detail the steps of this process.

Defining "what" the customer requirements are (Step 1 in Figure 3)

Referring to customer value, functional benefits are defined as product quality attributes and emotional benefits are defined as service attributes. Table 1 presents both the product quality and service attributes that customers want ('what').

Table 1 was prepared by the marketing department of the company together with the product development section. The information was gathered in the course of discussion sessions. All the criteria in Table 1 are currently applied in the factory, marketing department and also in customer relationship management (CRM). Every Monday for three months the department heads of these sections held a management review meeting (MRM) convened by that was facilitated by the quality assurance (QA) department to formulate customer requirements. In addition, a quality consultant was also invited, whose job was to guide the managers in formulating these requirements through training and in-depth interviews.

Table 1: Customer requirements based on product quality and service quality.

Product Quality			Service	
Flour quality	Product Variety		Handling of customer complaints	Ease of calling
	Moisture			Responses
	Colour			Solutions
	Smoothness		Product availability	Anytime product taking
	Consistency			Reachable stations
	Foreign material (metal, plastic, yarn)			Ease of ordering
Hazard Protection	Brown spot			Delivery in place
	Product clump			Ease of getting information
	Insect		Product information	Production code
	Unpleasant odour			Brochure
Flour packaging	Variety of weights		Assistance	Training/exercise
	Stacking ability			Partnership
	Leak proof packaging			Entrepreneur consultancy
	Leak proof sewing			Sample product
	Imitation proof			Cookery contests
	Accuracy of weight			Cookery demos
Flour safety and quality warranties	Halal		Sales promotion	Advertising
	Healthy			Joint exhibitions
	International standard			Discounts
Fortification	Additive materials			Prizes
	Vitamin		Prize, bonuses & rewards	Rewards
				Credit terms and payment periods
Total	21 requirements		Total	22 requirements

Defining the technical correlation of "how" to meet the requirements (step 2 in Figure 3)

Once the customer requirements (22 requirements for service quality and 21 requirements for product quality) are listed (Table 1), the company should deploy the requirements into an action plan. Thus, a quantitative target should be established so that all the manufacturing, marketing and product development departments can carry out the plan. The company used a questionnaire for developing the action plan, containing 18 questions to cover product and service quality. Since the customers are not familiar with the Likert scale the salespersons of the company interviewed the customers and then interpreted the customers' answers in terms of the Likert scale.

The customers were asked how important the following needs were to them:

1. You need product information from a salesperson
2. You need a loan facility from the company
3. You need technical support for your production process related to the quality of the wheat flour

4. You need a quick response with delivery lead time of 1 day at maximum
5. You need a quick response with delivery lead time of 1 week at maximum
6. You need a transportation facility from the wheat flour manufacturer
7. You need direct access to the company's customer relationship management
8. You need online purchasing
9. You need wheat flour with low ash content for your product
10. You need finely-milled wheat flour for your product
11. You need wheat flour with neutral acidity of for your product
12. You are concerned about the protein content of the wheat flour used in your product
13. You are concerned about the fewer choices of wheat flours for your product
14. You need customised packaging of the wheat flour for your product
15. You need multi-purpose wheat flour for your product
16. You need wheat flour for your product which has been stored longer.

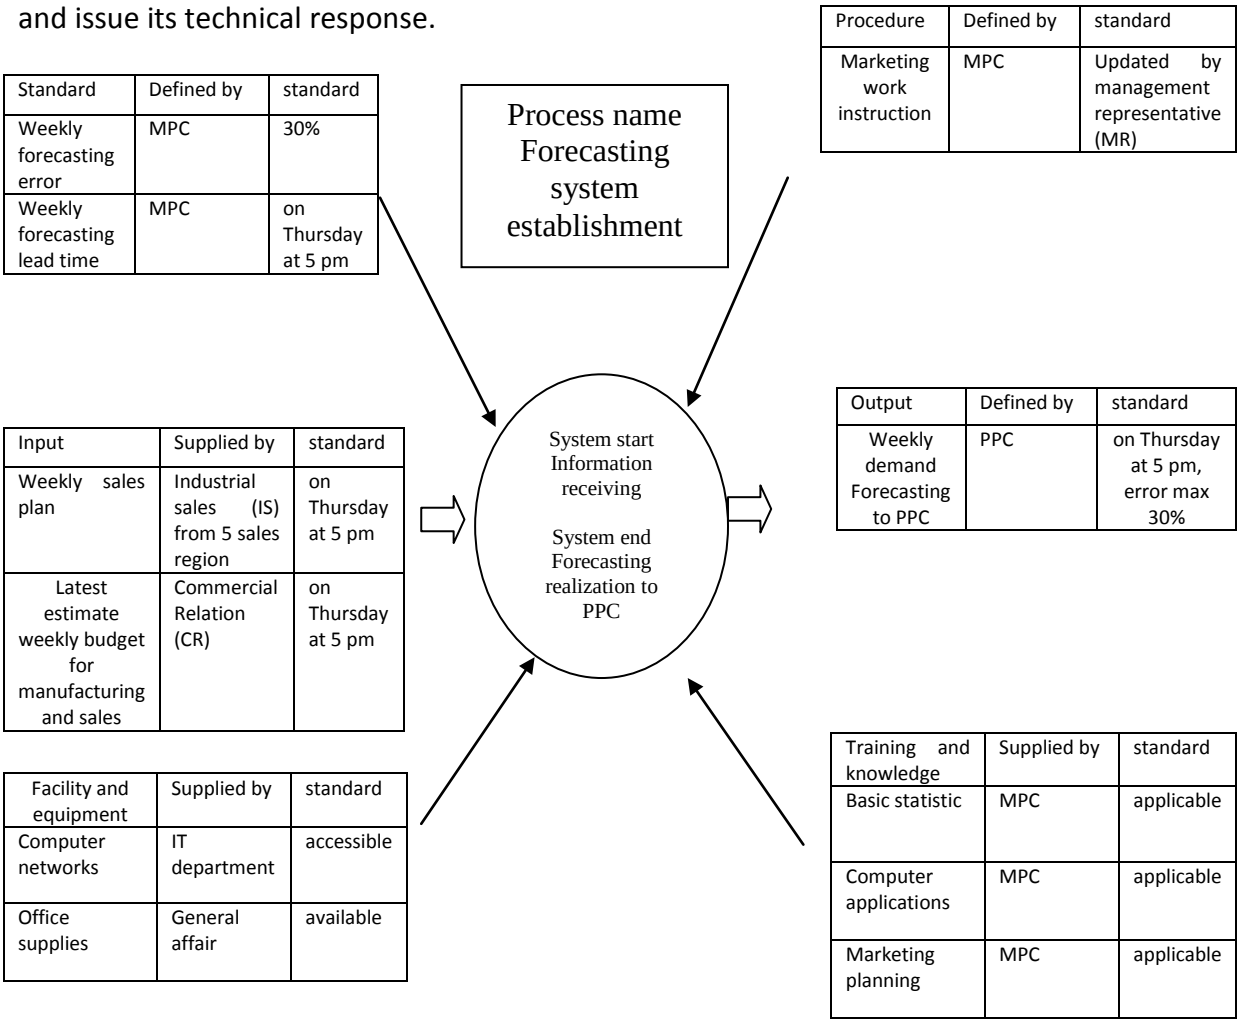
The answers to all these questions were scaled on a Likert scale from not very important, not important, fairly important and important to very important. The technical requirements arising from these answers guide a company in responding to customer wants and needs.

Developing a planning matrix and and building relationships between customer requirements and the company action plan (steps 3 and 4)

One of the important outcomes of the MRM was that a process model sheet replaced the analytical hierarchy process (AHP) which had always been used before in QFD implementation. This is because the company wanted to introduce a planning matrix of the simplest kind, to avoid confusion among the managers. In addition, the resulting technical response was meant to satisfy customer requirements; it had to be measurable and global in nature because it represents all the stakeholders of the quality attribute.

The first step is to construct a planning matrix. To take the example of product availability, we see from Figure 3 in the input/output analysis of the planning matrix, that resources (facility and equipment, training and knowledge, quality standards, working instruction and work plan) are benchmarked against customer requirements in the output matrix.

The company applies the process model sheet to determine and issue its technical response.



Standard	Defined by	standard
Weekly forecasting error	MPC	30%
Weekly forecasting lead time	MPC	on Thursday at 5 pm

Procedure	Defined by	standard
Marketing work instruction	MPC	Updated by management representative (MR)

Input	Supplied by	standard
Weekly sales plan	Industrial sales (IS) from 5 sales region	on Thursday at 5 pm
Latest estimate weekly budget for manufacturing and sales	Commercial Relation (CR)	on Thursday at 5 pm

Output	Defined by	standard
Weekly demand Forecasting to PPC	PPC	on Thursday at 5 pm, error max 30%

Facility and equipment	Supplied by	standard
Computer networks	IT department	accessible
Office supplies	General affair	available

Training and knowledge	Supplied by	standard
Basic statistic	MPC	applicable
Computer applications	MPC	applicable
Marketing planning	MPC	applicable

Figure 4: Process model sheet for meeting product availability requirement with manufacturer's capability.

Figure 4 develops step 4 for product availability ('how'); we see that the stakeholders in this step are the departments of production planning control (PPC), marketing planning control (MPC), information technology (IT) and the suppliers. The marketing department gathers information from the customers, which is then translated by the MPC according to its attributes. MPC then communicates the list of customer wants to the PPC in order to with the help of IT.

Making a development planning matrix (step 3 Figure 3) and prioritizing actions and finding the relationship of the matrix to the manufacturing strategy (step 4 Figure 3) are the result of a root cause analysis (Figure 4) and the development of action plans (Figure 5). These action plans are applied in the company where their effectiveness is periodically evaluated. This effectiveness will be the performance indicator of the success of QFD.

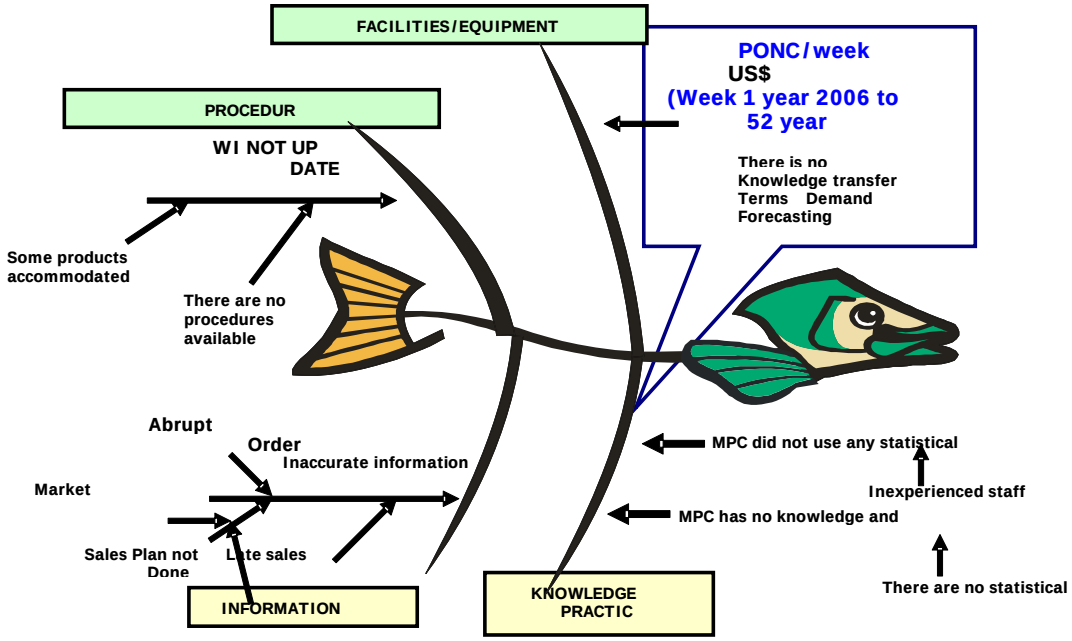


Figure 5: Root cause analysis of delivery lateness due to loss of product availability which incurs a price of non-conformance (PONC) as high as **US$ 20.987 per week**

Figure 5 shows the operability of root cause analysis by using a fish bone diagram. The company broke down the product availability problem into four areas, namely, facility and equipment problems, system and procedure problems, information flow problems and a resources (knowledge and practices) problem. From the Price of Non-Conformance (PONC) analysis, the company found that the biggest losses came from the knowledge sharing problem, which meant that lack of knowledge cost as much as US$ 20.987 per week. This loss came from, for instance, back orders, cancelled contracts, etc. From this analysis, the company created an action plan, as shown in Table 2.

Table 2: Action plans for accomplishing QFD.

What	Why	How	When	Where	Who
Statistical method	to produce good approximation of customer demand	by finding the most appropriate model	Early March 2006	MPC	MPC analyst
Working standard	to work properly	by following ISO 9000 requirement	Early march 2006	MPC	MPC section head
Sales plan	the current sales plan was not working due to product proliferation is not considered	building communication between CR and MPC	Early March 2006	CR and MPC	CR and MPC section heads
Practices and knowledge	to empower MPC worker in making forecasting	training and discussing	Early March 2006	MPC	MPC section head

Table 2 reveals the action plan of the stakeholders in the company. For instance, the sales plan must be communicated between Customer Relations (CR) and Marketing Planning and Control (MPC). The results of these action plans are then used in the customer satisfaction result in 2006, as shown in Section 3.3.3.

Customer satisfaction result 2006

After getting the result of the customer satisfaction survey, the data were plotted on the graph. Figure 6 presents the customer satisfaction rate, showing customer perceptions of product quality and service. This assessment compares the company's performance against that of its competitors (local and foreign).

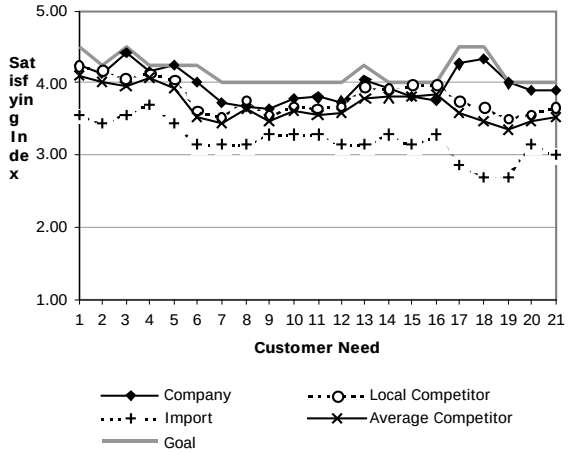

Figure 6a: Results of customer satisfaction survey: Product quality.

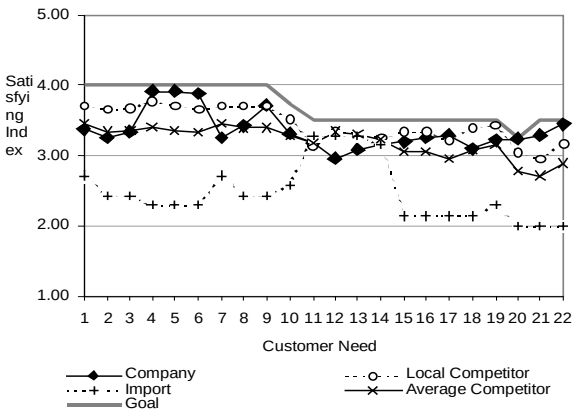

Figure 6b: Results of customer satisfaction survey: Service quality.

The satisfaction index measures customer satisfaction in relation to requirements, as in Table 1. During 2006, 200 questionnaires were distributed to customers in order to observe their satisfaction with the items in Table 1. The company used the same Likert scale, ranging between very weak, weak, fairly strong, strong and very strong.

The results of the above figures may be summarized as follows:

1. Customers give a high degree of importance to product quality (3,2-4,5). The results imply that the company has been a market leader in terms of product quality and needs only to keep its positioning strategy and continuously improve its quality to attain its goal.
2. Customers give a moderate level of importance to service quality (3,0-3,9). The results imply, however, that the company has been a market follower in terms of service quality and needs to continuously improve its service quality to attain its goal.
3. Comparing the organization's performance with that of its competitors suggests that:

- Generally, the company's performance in product quality is better than its competitors.
- In most areas the company's performance in terms of service is inferior to its competitors.

4. The benchmarking of performance between the case under review and other food manufacturing companies in the world shows that serious work must be done to improve its production process and cleaning standards. In most of these areas, the company lags behind its competitors. This means that a better system must be implemented and also more professional employees should be recruited to bring the company's flour mills to the benchmarked level.

This benchmarking encourages the company to apply TQM so as to improve its product and service quality. For the first action plan, the company prioritizes its top ten attributes as the most important attributes, as follows

- Product quality side: Quality Control/Quality Assurance, Implementation of Quality and Food Safety International Standard, Wheat provider, Packaging material, added iron & vitamins, Health certification.
- Services side: Training Centre Technical Representative, Promotion activities, sales & distribution, Depots, Hotline service, Quality Control/ Quality Assurance, Payment system, Production code and Research & Development.

The reason for focusing on the top ten priorities is that the company wants to cover improvement in terms of the importance of these attributes to the customers at the point of sale and also give the most benefit to the company.

ANALYSIS AND MEASURING THE SUCCESS OF TQM

Designing and implementing an effective performance measurement system in the TQM context is, however, not a straightforward task and numerous authors have tried to provide guidelines and recommendations for firms adopting TQM. Kaplan and Norton (2001) state that an effective performance measurement system should provide timely, accurate feedback on the efficiency and effectiveness of operations. To be effective, a performance measurement system must therefore be based on the drivers of organizational success, which in the context of TQM include, among other things, customer satisfaction and social impact (Claver et al., 2003). The long-term goals of TQM performance measurement should include the continuous improvement of performance and maximization of customer satisfaction by adapting to change in customer requirements and the general business environment. The implementation of performance measurement in the context of TQM depends on many factors: leadership, quality planning, specialized training, supplier management, process management and continuous improvement, as well as organizational learning (Claver et al., 2003).

Despite the vast amount of research on performance measurement in the TQM context, there is still a lack of empirical research seeking to discover what performance measures are actually being used by those who adopt TQM and how appropriate these companies find them. In order to bridge the gap properly, this study investigates the extent of use and appropriateness of the performance measurement systems applied in the TQM context within the domains of customer satisfaction and quality of products and services in food manufacturing SMEs.

The company measures the performance indicators to observe TQM's effectiveness from 2006 to 2008, as shown in Table 3 below. The second QFD is then developed to measure the effectiveness of the TQM programmes. The benchmarking results of the previous QFD (see Figure 6 a root cause analysis) are then used as inputs to the technical correlations of the new QFD. A new customer survey is then conducted in 2008 in order to measure the fitness of the TQM programme to the new customer survey results. The results are then summarized as shown in Figure 7.

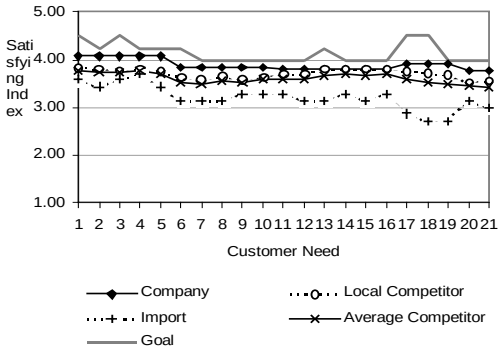

Figure 7a: Results of customer satisfaction survey: Product quality.

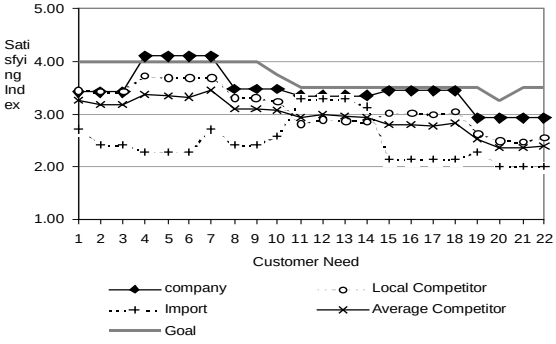

Figure 7b: Results of customer satisfaction survey: Service quality.

The Improvement Ratio for product quality has a lower value (1- 1.097), its mean company performance being very close to customer needs. Incidentally, the company needs to be serious about its performance in the matter of its services, because the improvement ratio for service is high in value.

Comparison of the company's performance in 2006 and in 2008 (Product Quality)

Based on the above comparison of customer satisfaction, the customer satisfaction index for product quality in 2008 is in general lower than in 2006. Some aspects, which have been successfully improved can be seen in point 7 (brown spots), 8 (product clumping), 9 (insects), 10 (unpleasant odour) and 16 (weight accuracy), but it has not yet reached its goal yet (check with Table 1). The company finally applied housekeeping and implemented good manufacturing practices for the food industry by considering that most of the unmet criteria fell under the heading of product cleanliness.

Comparison of the company's performance with that of its competitors in 2008 (Product Quality)

Generally, the company's performance was better than those of its competitors (whether for local or imported flour).

Comparison of company's performance in 2006 and in 2008 (Service Quality)

According to the above comparison of customer satisfaction, the customer satisfaction index for service quality in 2008 is generally higher than 2006, but it has not reached the designated goal in every component. Only 4 components succeeded as point 4 (Anytime product taking), 5 (Reachable station), 6 (Ease of ordering) and 7 (Delivery in place); other aspects, which need to be improved, are point: 9 (production code), 19 (discount), 20 (prize), 21 (rewards) and 22 (credit terms and payment period). The company finally improved their logistics networks by making contact with more autonomous distributors and attracting them by the offer of more rewards and quantity discounts.

Comparison of company's performance with that of its competitors in 2008 (Service Quality)

Generally, the company's performance is higher than those of its competitors (whether local or imported flour).

Table 3: Index growth of customer satisfaction with the company and its competitors between 2006 and 2008.

Flour Producer	**Product Quality**			**Service Quality**		
	2008	2006	Growth	2008	2006	Growth
Company	3.87	3.98	-2.71 %	3.46	3.35	3.29 %
Local Competitors	3.71	3.81	-2.79 %	3.12	3.45	-9.41 %
Foreign Competitors	3.21	3.21	0.00 %	2.47	2.47	0.00 %
Average Competitors	3.61	4.15	-2.31 %	2.96	3.20	-7.59 %

Table 3 shows that significant improvements were made in terms of company service quality (3, 29%). However, product quality went down, g. This reduction in product quality level is caused by the commitment of the local government to implementing the Hazard Analysis and Critical Control Point (HACCP) as a food safety standard. Thus this product quality reduction is not caused by inferior process performance. Indeed, the company has increased its product quality standard by adopting the HACCP standard.

Customer satisfaction index growth analysis

Referring to Table 3 above, the index growth of customer satisfaction indicates a shifting of customers' perception of the flour produced by the company and by its competitors. A shift in customer perception is shown in the decline of the customer satisfaction index of product quality against a rise in the customer satisfaction index of service. In this case, it is revealed

in the perception of quality in the flour produced by the company. This may have been influenced by any of the following factors:

- Management commitment and policy,
- Continual improvement in technology and innovation
- Management of the supply chain from supplier to end user

CONCLUSION

Most successful manufacturing companies have embraced TQM and realized its invaluable contribution. This acknowledges the importance of TQM as an effective method of achieving excellence in manufacturing, which cannot be denied. Embracing the concept of manufacturing excellence is considered a route to becoming the best manufacturer of a certain product. It refers to the ultimate goal of achieving the best manufacturing capabilities or being best-in-class in performance. Because of the pervasive use and reliance on business systems today, effective TQM strategy is much in demand to deal with all the activities of a company. The present paper brings together information from diverse sources to offer a common starting point and information base for quality assurance professionals. A comparison of customer satisfaction with product and service can help these professionals to apply this alternative method and tailor it to or integrate it in specific applications.

A continuous QFD needs to be deployed at the lowest level of operations. In addition, in order to make TQM work efficiently, companies need to build a corporate culture to replace continuous QFD. When this is applied, it should encourage people to apply the quality improvement programme more proactively. This shortens the life cycle of analysis between one QFD and another and the company becomes more competitive due to the increasing speed of its innovations.

ABSTRACT

This study aims to study the knowledge transfer pattern of success organizations in performing knowledge management in Thailand and construct the conceptual model of knowledge transfer in order to be the prototype for governance academic institute. Moreover, the pattern and procedure of knowledge transfer will be provided for governance academic institute in Thailand to be the success organization in performing knowledge management. The qualitative method was employed in this study. The in-depth interview was used as the data collecting tool. The sample of this study was four entrepreneurs from the medium and large companies where perform and succeed in the knowledge management. The topics of interview were focused on the success factors and patterns of knowledge transfer of entrepreneur in industrial sector. The results showed that the success key of knowledge transfer consisted of five factors which included the leadership perspective of each company in transferring knowledge, the use of information technology in transferring the knowledge, the team work system in knowledge transfer, knowledge transfer by experiential learning, and knowledge transfer by training system.

Keywords Knowledge Transfer, Key Success Knowledge Transfer

INTRODUCTION

The knowledge management (KM) in Thailand stands up to the serious problems about missing some of individual knowledge that accumulated during work until retire or leave completely that should be affected to the organizational operations. Many researchers attempt to solve this solution and find out the right method for capture that tacit knowledge from individual and additional into organizational system and examine the diffusion model for transfer tacit knowledge to the whole organization throughout building the learning organization (LO) and knowledge management simultaneously. Kumar et al. (2006) described the definition of knowledge management as: “Knowledge management is an umbrella term for making more efficient use of the human knowledge that exists within an organization It is essentially an industry trying to distinguish itself with specialized groupware and business intelligence (BI) products that offer a wide range of solutions. The major focus of knowledge management is to identify and gather content from documents,

reports and other sources and to be able to search that content for meaningful relationships."

It is necessary that the organization must manage the internal knowledge and convert into the own system and encourage the staffs' learning all the time. Managing the knowledge under non-learning atmosphere always failure immediately, beside the management of learning organization is more complicate than human development; education or training because of the consequence in process that have to implement after the people have the knowledge and skills enough. How organization convince those people for willing to transfer and share their knowledge to others. The last activity, organization should find the technique to keep that special knowledge and combine it into the organizational system and assessable effectively. There are many agencies from the governance and private sectors try to built the own model of knowledge management align their context and organizational culture that causes for top manager seeking the strategic to elicit the individual knowledge and share to the colleagues. Training is not the best way to transfer knowledge, majority obstruction of knowledge management is behavior "Possessive" prevent others from getting the knowledge and culture "Reject the personalization" should be the weak point of Thailand knowledge management and lead to underachievement.

Recently, the knowledge management in industry sector is strong and widely promoted focuses on human liken to human capital. The leading companies in KM importantly apply information technology (IT) like the main tools to build the model of knowledge transfer such as Siam Cement Group (SCG) in private sector and the Electricity Generating Authority of Thailand (EGAT) in government sector.

The study use comparison method to benchmark the process of management knowledge between academic institute and top company which are successful in KM from industry sector, capturing the knowledge from both initiate by staff and expertise into "Content or e-Library" found that only capturing is not enough for emerge the real succeed but also the right pattern of knowledge transfer to share within organization.

The result of the study found that most academic institute in Thailand tend to failure cycle in KM and knowledge transfer, especially governance academic institute that measure knowledge from "number of information that kept in knowledge base" without design process of learning organization i.e. building the curious environment to know, encouraging the "people" to share and emphasize the knowledge transfer to be clear, systematic and formal procedure.

The purpose of this paper is aim to explore the model of knowledge transfer in successful KM, case study of Thailand. Additional purpose is to initiate the pilot model for governance academic institute which they can apply this model, procedure and knowledge transfer system to get the explicit knowledge and encourage their KM successful.

OBJECTIVE OF THIS STUDY

The purposes of the study were;

1. To find out the knowledge transfer model in industry
2. To develop the knowledge transfer-pilot model for governance academic institute

SCOPE OF THIS STUDY

This study is quality research and collected data via in-dept interview technique: a simple of 4 entrepreneurs were undertaken regarding people who expert in the field of knowledge management and had worked at the successful company , in industry scale which are emphasized in medium and large enterprise defined in the classification from Thailand Office of Small and Medium Enterprises Promotion; wealth of asset or number of employees and they classify the type of business into production, service and trade.

The highlight of this study is to concentrate the successful factors and model of knowledge transfer for entrepreneur in industry scale which emphasizes the knowledge transfer model towards the successful goal.

BENEFIT OR VALUE OF THIS STUDY

This study shows the factors important to organizational knowledge transfer in industry that medium and large scale. This result guide to development the core competency of the government agency which need to build pattern up and pursuit knowledge transfer or for firms which interest to build knowledge transfer within organization and reinforce the special skill for knowledge transfer process i.e. seeking the knowledge and utilizing this tool for encourage the effective knowledge transfer.

CONCEPTUAL FRAMEWORK

The researcher of this study is to highlight the knowledge transfer model in knowledge management process.

The human understanding can be defined in four terms of knowledge level that differentiated and consequence; data, information, knowledge and wisdom, from apply processes of the consideration, separation, syntheses and analysis. The knowledge management process consists of 3 main compositions; knowledge generation, knowledge organization and storage and knowledge transfer (Awad and Ghaziri, 2004) and additional, the knowledge application (Natarajan and Shekhav, 2000) which is the most difficult step, then Laodon and Laodon (2006) have exhibited the diffusion of knowledge is shown in figure 1.

Figure 1: Knowledge management process (Laodon and Laodon, 2006).

The four steps of knowledge management are:

Step 1: Knowledge acquisition: get the knowledge from the variety sources i.e. both inside and outside the firm via knowledge conversion following the SECI model (Nonaka and Takeuchi, 1995)

Step 2: Knowledge storage: keep, syntheses, digest, collection and organize knowledge

Step 3: Knowledge disseminations: distribute the kept knowledge

Step 4: Knowledge application: utilization, apply the knowledge right

Along with the whole process need the right technology that suitable with the organization as the tools for communication and collaboration; knowledge exchange, knowledge transfer and including any activities which right tools i.e. community of practice (COP).

The researcher applies the knowledge management model (Laodon and Laodon, 2006) for the pilot study and there are the procedures as below.

RESEARCH PROCEDURE

Since the objective of the study was to explore and develop the knowledge transfer for governance academic institute. This study is qualitative research method and focus on seeking the important factors in knowledge transfer process from industry scale which has the steps as follows:

1. The study targeted the population who is the entrepreneur or top manager in industry scale who are expert or work in knowledge management field, successful business and work in medium and large firm as the definitions following the Thailand Small and Medium Enterprises Promotion that classify by wealth of asset, number of employees and classify type of business i.e. production, service, trade. A five of them were chosen by purposive sampling.
2. Methodology of data collection by in-dept interview with semi-structure that formulated from review literature.
3. Data analysis is the descriptive analysis by assesses the general information of entrepreneur then arranges the interviewed data and analysis linked the objectives, issues and related literatures.

RESULTS AND DISCUSSION

Case study of Firm A

The characteristic of firm A's work-style is learning center both academic and vocational train institute and join together between Thailand and Japan institute, formed organizational chart liken to mixed-structure association. There are three types of services i.e. Education and training, languages schools and calibration those are effected to the design of the knowledge transfer model that directly towards to the people in firm A who are smart expert and professional in variety issues, Firm expect that all people will transfer the tactic knowledge to explicit knowledge by sharing system. Firm A's knowledge transfer model has the characteristics as follow;

1. Apply the information technology (IT)system to support the knowledge transfer process via the variety tools as follows;
   1.1 E-learning Tools
   1.2 Electronic Yellow Pages
   1.3 E-mail
   1.4 Groupware
   1.5 Internet
   1.6 Intranet
2. Apply meeting system to exchange knowledge by build the environment which will be promoted the learning organization and encourages the staff to transfer or to participate in the knowledge transfer process such as set up the knowledge forum, mentoring program for new staff or new assignment or new project, and peer assistance system.
3. Child center management system that focus on the learner, the emphasize of firm A is education and training program aim to transfer knowledge. Therefore, the main strategic is concern the learner, this issue effects to get and gather knowledge and ability to transfer the knowledge requirement that seeking from variety sources i.e. inside and outside the classroom.
4. Teamwork system makes colleague received knowledge from multi-transfer method i.e. sharing from whom work together
5. Small group activity is one of exchange the ideas aim to solve the problem together in small group member to share between working
6. Job change management such as change the job description, rotation, exchange staff.

The conclusion of firm A's knowledge transfer model indicated that firm A did not emphasize on IT supporting system and built the environment for encourage learning but focus on people processed by self-learning with teamwork system and mentoring system. The key successful is leadership, the leader of organization deploy the policy and give priority to knowledge transfer process to staff and clearly identity mission and setting strategic in knowledge transfer.

Case study of Firm B

Firm B is a big manufacturer which product hard disk drive, such as Top Cover, Ramp, Crash stop, Latch and automobile electronic parts, was establish in 2001 by Japanese capitalist in Thailand and resisted 360 million bath.

Since the mission of firm B was set going to the world-class company in electronic parts with high accuracy made firm determined the procedure have to focus on how to produce with high accuracy. It is necessary to built learning organization (LO) for force the people know how-to and gain their ability. The significant supported tools is knowledge transfer model.

Firm B built thirteen patterns for the knowledge transfer model that align the firm's mission were;

1. Training

1.1 Team Work Training: Firm set up the activities for employee in military camp and trained by soldiers. This style aim to keep disciplinary regulations and teamwork.

1.2 IT Training: Firm join with Microsoft by educating and training by Microsoft to meet Microsoft conditions and will be certified by Microsoft.

1.3 Language Training: Firm emphasize in English and Japanese, and give more incentive to whom that has this skill.

2. Working Environment

2.1 Firm apply the concept of quality tools i.e. 5S to run the business beyond the steady state condition of "Cleanliness is The Heart of Our Business"

3. Communication

3.1 Firm use multi-channel for communication within organization and publish relationship (PR) via the variety tools such as electronic board, whiteboard, curriculum, magazine, brochure and radio

4. Activity

4.1 Core activities that all people must be done and kept as the rule of conduct such as 5S, total prevention management (TPM), PIZ.

5. SGA : Small Group Activity

The SGA of firm B is shown as the figure 2

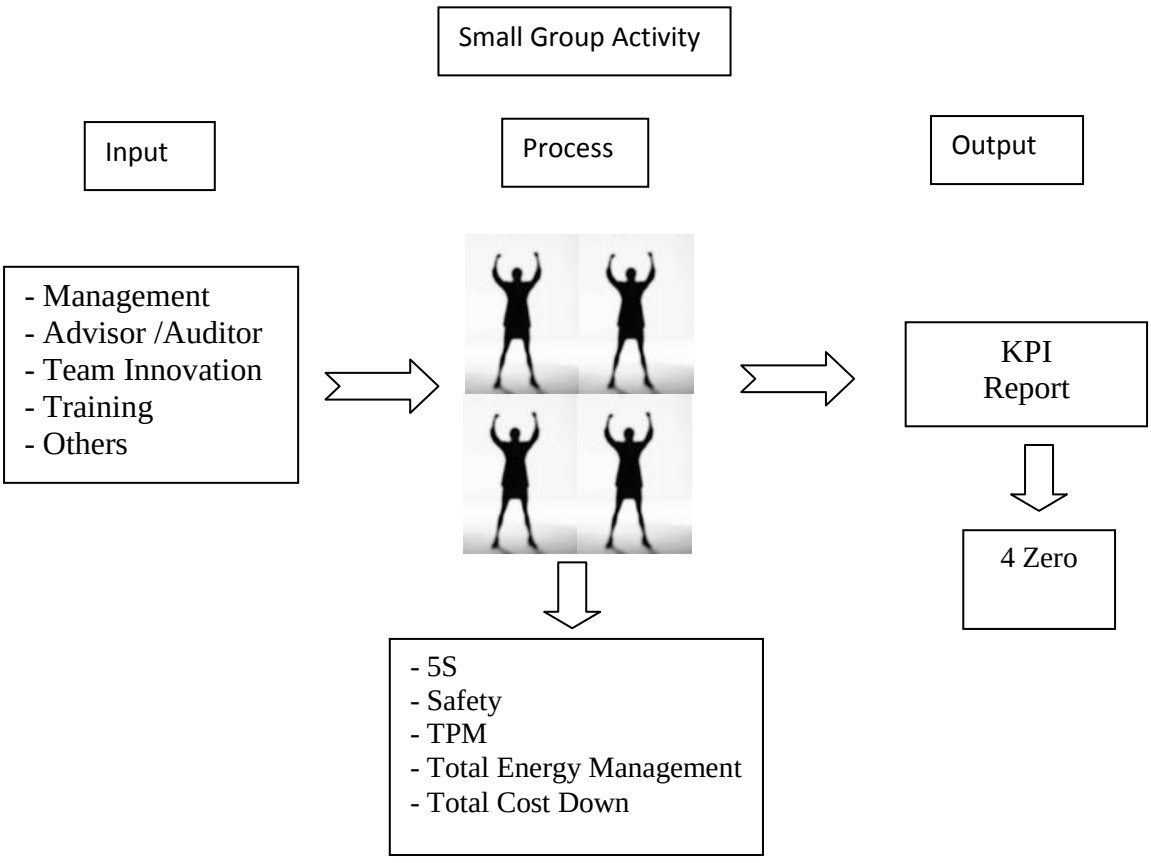

Figure 2: Firm B's Small Group Activity (Source: Contact the author.)

There are any activities and competitions between SGA, each group should be always prepare itself and meeting for setting their action plan to challenge winner and get the rewards and motivation.

6. Master Program
   6.1 Master Program is providing the priority activities for competitiveness within organization for building the learning organization and encouraging the people curiously to know and learn by themselves.
7. International Standard
   7.1 Firm want people understand the quality via the procedure of internal standard such as ISO 9001 and ISO 14000 which firm required and always push them to get it.
8. Customer Requirement
   8.1 Firm underline the customer feedback and always communicate to customer and get their comments via multi-channel such as call center, company webpage.
9. Problem & Solving
   9.1 Firm focus on the special R&D which solving the problems from production process or product.
10. Outside Visit
    10.1 Firm organize knowledge transfer technique broadly via multi-tools such as field trip outside firm or aboard and benchmarking
11. Technical Knowledge
    11.1 Firm highlight technical knowledge among production line via quality control activities i.e. Quality Control Cycle (QCC), Kaizan suggestion System (KSS) which is the sharing tool among the team.
12. Internal Trainer
    12.1 Firm will survey topics from staff and create the activity accord with their requested.
13. International Audit
    13.1 Due to this firm was invested by Japanese company which has their own standard and implemented in any places, firm B must have quality policy to control the quality meet the Japanese standards.

The conclusion of firm B's knowledge transfer model is shown that the background of firm B was invested by Japanese company lead the organizational culture to emphasize on staff's learning process within organization. Firm B has launched policy and strategic for building the learning underline the people via teamwork system by formed a big and small group that they can do whatever together such as learn, share, transfer something maybe sources from internal group or cross-boarder. Moreover, firm apply IT supporting system to knowledge transfer tools. Additional, the knowledge transfer process via learning by doing under the rule of quality assurance system in each product standard and transfer knowledge from linking among standard of each part.

Case study of Firm C

Firm C is the multinational business consultant which has head quarter in New York and 83 branches around the world, and there are 5 offices in South-East Asia. Firm C is outstanding in knowledge management and being a world-class leader in knowledge management.

Corporate' mission statements are "To build a grate firm that will attract, develop, excite, and retain exceptional people", and "To help our clients make distinctive, lasting, and substantial improvement in their performance"

Firm C is big and a top range in management consulting firms in the world, its business is to delivery the advanced solution to enhance client. There are the enormous capability people from diversified places on over the world transfer the numerous solutions and share the experience together, but it is not easy because of the site and locations. Firm C was built the organizational culture as the tools for seeking the knowledge from other people within organization, additional the mind of transfer the tactic knowledge diffuse to others in different places. The state of art to build the organization culture those were:

1. Value

The state condition of organization is important to employee that is approach the people is the wealth asset of organization.

2. Teamwork

There are separate the level of authority to access the knowledge significant into 3 levels; partner, part-time and steering group that were;

- Partner is the client who had ever worked and supports each other.
- Part-time is the temporary team for solving the problem.
- Steering group is consulting group who screen and contribute the knowledge in the database.

Knowledge management technology and Collaboration Tools for sharing experience and information should be supported by information technology (IT) system, those were;

1. Explicit knowledge sharing system
    - Intranet
    - Publish i.e. Knowledge map; if topic of petroleum required, seeking at petroleum catalog which there are many indeed sub-topics or search with customize search style.
2. Community of Practice (COP)
    - Practice network
    - Internal communication: Mckipedia, Blogs, forums
3. Center of Excellence (COE)
    - Industry practice expert
    - Function practice expert
    - Special initiatives
    - First alert

To evaluate knowledge transfer of Firm C by evaluating from follow up the understanding of monitoring in order to stimulate of sharing knowledge system or create new knowledge

such as setting the number of time and minimum time used the accessing knowledge by working system.

The conclusion of Firm C, that is the big multinational business consultant around the world as well as high quality of staff. All staff came from many countries which had different cultures so company has target of exchange knowledge management among staff. That why company make new culture as the tool for knowledge management. By the specific on person and create teamwork system in order to have knowledge sharing system by connecting of each staff in different countries. Company has emphasized on IT which is the tool of connecting knowledge management and transfer knowledge management of company.

Case study of Firm D

Firm D is the small and medium enterprise (SMEs) in which concern the research and development (R&D) for industrial of aquaculture, cattle, pet and agriculture. Currently firm start to research and development in kind of the cosmetics, customer goods and health care products. In according to firm has studying about applied research and experimental development in order to create innovation and making the economic valve for organization. In case, firm need to collect data arrangement and keep all data in appropriate system which can reduce loss information of organization as most as possible.

To operate and have strategies of firm D for building learning organization of this company by using knowledge to create knowledge organization. The process and model of transfer knowledge of firm D were;

1. Firm emphasis on the developing the employee by use knowledge widely and open mind for creative and operation themselves.
2. Firm give the knowledge opportunities for staff to training or seminar inside-and-outside the organization.
3. Top manager have deploy the policy and motivate for the staff making the creative project for organizational development.
4. Company has to install the data base server and intranet system of organization for all staff sharing knowledge.
5. Sharing the knowledge from job skills among the department by a monthly meeting.

Idea of operating's Firm D

- Personal level: the executive managers give the knowledge opportunities and challenge for the staff to enlarge themselves by participating the seminar from outside. In order to apply the right knowledge and utilization it in the organization as well as support all staff for new project at organization.

- Group level: the top managers have deploy the policy of "small group activities" for staff every week, about 2 hours. Let staff in same department t or other department share the ideas of organizational development front to the top managers such as the staff in academic department initiated and has presented the course of training the product's qualification.

Sale manager offer negotiation project training, accounting and technology department offer ERP: Enterprise project for minimizing risk, and additional, have contest for good project and stimulated by reward of creative project.

Structure

Organizational

Organizational structure has flexible and flat chain of command for adjust to the dynamic of the knowledge management of company as well as compatible with changing of knowledge.

Job

The characteristics of working as teamwork and able to work with cross-functional management, the people can rotate job or change the position in order to transfer knowledge among staff during working together.

Technology

Install the infrastructure in organization for basic knowledge such as the data base server and system for able to access knowledge easier.

The conclusion of Firm D as industrial company as kind business of research and development of aquaculture, cattle, pet and agriculture. Furthermore, company will product in line of the cosmetics, customer goods and health care products. Company need to depend on knowledge system in order to competitive with the foreign company by using company as knowledge organization to create model of knowledge.

Company emphasis on staff to develop knowledge by themselves and present as reality project. To train staffs share idea and how to solve problem. Moreover, company aim to work as teamwork for sharing idea and knowledge transfer.

CONCLUSION

The pattern of knowledge transfer of selected company was link with the knowledge disseminators of Laodon and London (2006). This can be concluded as shown below;

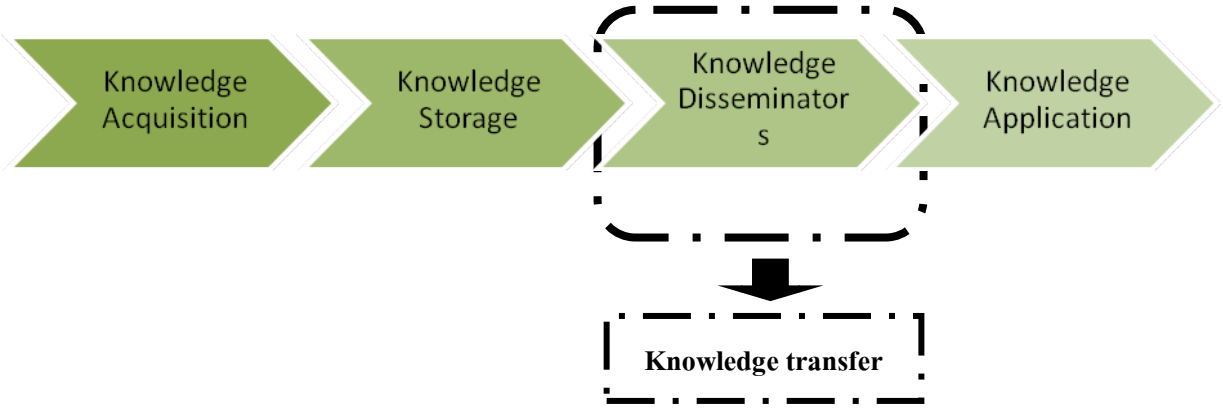

Figure 3: Knowledge management process (Laodon and Laodon , 2006) Focus on Knowledge Disseminator.

The step of knowledge transfer of each company was in the third step of knowledge management (Laodon and Laodon, 2006) which was the knowledge disseminator step. Moreover, this step was the “disseminate and transfer knowledge”. In this study, each company has their own strategy of knowledge disseminator as shown in Table 1.

Table 1: Key Success Knowledge Transfer case study of various companies.

Company A	Company B	Company C	Company D
Supporter	Supporter	Supporter	Supporter
IT System	Training	Culture creator	Education development of staff by experiential learning
Knowledge Sharing system with modified atmosphere	Working Environment	Team working system	Training Attended the seminar outside the company
Company A	**Company B**	**Company C**	**Company D**
Student base learning	Communication	IT System	IT System
Team working system	Activity	Explicit knowledge sharing system	Data Base Server and Intranet networking
Small-Group Activity	SGA : Small Group Activity	Community of Practice (CoP)	Project meeting
Rotation of Work	Master Program	Center of Excellence (COE)	Team working system
	International Standard		
	Customer Requirement		
	Problem & Solving		
	Outside Visit		
	Technical Knowledge		
	Internal Trainer		
	International Audit		

From Table 1, can be summarized the successful factors of Key Success Knowledge Transfer as below

1. The company leadership always focused on knowledge transfer
2. Knowledge transfer by the used of IT tool
3. Knowledge transfer by team working system
4. Knowledge transfer by experiential learning
5. Knowledge transfer by training system

From the summarized of Knowledge Transfer can identified that the importance factor effected to success of knowledge transfer comprise of 5 main topics and can be use as a conceptual model (Figure 4)

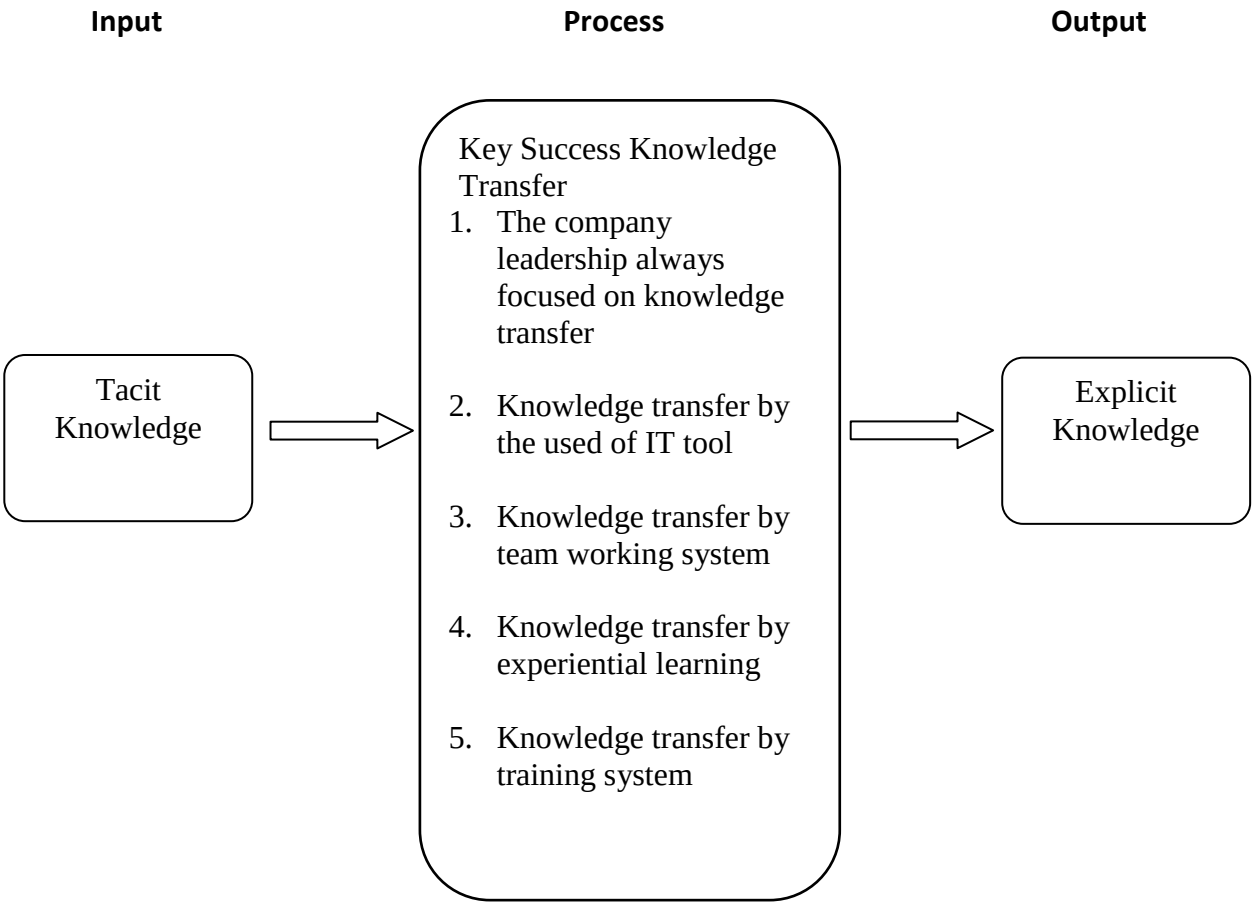

Figure 4: Conceptual Model of Knowledge Transfer.

From the conceptual model of knowledge transfer (Fig) can be finalized the key success knowledge transfer which is use as guideline for education and government sectors knowledge transferring, cause of, at present both sectors not yet success in KM to learning organization.

FURTHER RESEARCH

From the research found that Key Success Knowledge Transfer consists of 5 items:

1. The company leadership always focused on knowledge transfer
2. Knowledge transfer by the used of IT tool
3. Knowledge transfer by team working system
4. Knowledge transfer by experiential learning
5. Knowledge transfer by training system

This Key Success Knowledge Transfer has use for successful private company. The research tend, need the Key Success Knowledge Transfer to implement with the education sector to

proof that the Conceptual Model of Knowledge Transfer can be used with the education sector or not.

ABSTRACT

New technology environments provide a simpler way to manage knowledge. Social technologies are becoming the preferred method of communication of new generations and communication styles are evolving into a more collaborative approach.

Effective knowledge sharing depends on several factors like mentality, technology availability and detectable personal advantage. The advent of the enterprise 2.0 phenomenon offers new opportunities to implement knowledge management, but a structured approach is needed to fulfill its vast potential.

This study presents a methodology for the application of social technologies to provide companies with an implicit knowledge real time map. The innovation elements of the methodology are given by the deep analysis of criticalities, needs, behaviors, perceptions and trends, helpful to continuously improve the application.

The methodology consists of three key elements which are analyzed in depth: the gap analysis, the toolkit selection and the action plan. Through these components this approach allows to effectively capture users' perceptions and behaviors adapting the tools to the context specificity.

This paper aims to take up the challenges of examining the issues of knowledge sharing and transfer. It presents a first empirical application of this approach in Eni, an integrated energy company, active in more than seventy countries all over the world. The analysis includes the choice of indicators which help to monitor users' trends and engagement.

Keywords: social technology, enterprise 2.0, knowledge management, knowledge sharing.

INTRODUCTION

New technology backgrounds are transforming the way knowledge is experienced (Norris et al., 2003). Moreover the standards of today's fast and hyperactive world are far from the

context of the initial studies about KM. Traditional KM is characterized by a primarily top down approach and by specifying all contents structures in advance (Davenport, 2008). This approach is becoming not suitable anymore, even inside big companies with a consolidated culture (Leidner, et al. 2006). Today firms are very complex environments. Information technology has experienced many cycles of innovation, producing always more complex and integrated set of technologies to respond directly to business needs (Koplowitz, 2010). In spite of this, the huge quantity of documents produced daily can create innumerable silos of information. As a consequence knowledge capture and sharing can be too difficult and ineffective (Alberghini, et al., 2010).

The advent of the enterprise 2.0 phenomenon offers new opportunities to implement KM, but a structured approach is needed to fulfill its vast potential. The term "Enterprise 2.0" was first coined in 2006 by Andrew McAfee in an article about the use of emergent social software platforms within companies, or between companies and their partners or customers (McAfee, 2006). Even if there is still a debate about the relationship between Enterprise 2.0 and KM, applying web 2.0 technologies and emerging social behaviors can help to add greater interactivity into the KM environment. Social networking capabilities are providing vital information in a way that is adaptive and user-driven. Moreover new generations are used to dealing with social technologies, choosing them as their preferred method of communication with peers (De Gennaro, 2010).

This paper aims to take up the challenges of examining the issues of knowledge sharing and transfer in an energy company operating across all the world. More in detail, this study aims to provide with an applicative example of the structured approach which reckons with the context, people maturity level and KM purposes. The paper examines the steps of this approach, from the analysis of new needs to the application of social technologies. The methodology arises from the necessity to evaluate tools and the way to make use of them and the study present a set of analyses applied in Eni, an integrated energy company. Eni operates in the oil and gas, electricity generation and sale, petrochemicals, oilfield services construction and engineering industries. In these businesses it has a strong edge and leading international market position. Eni is active in 77 countries with a staff of about 78,400 employees.

At the beginning, the study concentrates on the modalities of the assessment phase, in which the target is represented by the deduction of new behaviors, perceptions and needs and by the evaluation of the lacks of the extant technology situation. The analysis is carried on through the observation of users trends, present technologies' availability and colleagues satisfaction surveys. The results allow to gain awareness of the internal fragmented environment and the rapidly evolving external landscape. Moreover the results represent a useful starting point to define the strategy to get the most from knowledge sharing and to guide the choice of indicators which help to monitor users' trends and engagement.

In this study the choice was oriented towards a social network in which everything was set up in a very modular way, in order to better follow employ needs to facilitate their job. Global networking sites bring people with common interest together increasing engagement. Choosing a technology target should be not enough to ensure a success. Old

generations tend to be skeptical about social technologies, so it is important to implement something very useful, in working terms, and that should become a habit and a necessity at work. For this reason a golden rule is monitoring the user engagement to nurture and build the community.

The paper is organized as follows. Section 2 provides a literature review about KM tools. Section 3 defines and analyses the methodology split into perception and qualitative/quantitative analyses. Section 4 describes the findings and includes guidelines about what to do and not to do depending on empirical data. Moreover, this Section presents a way to diagnose new demands to continuously improve the implemented system and achieve higher benefits. Section 5 describes the research implications and limitations. Finally, Section 6 highlights and summarizes the application of the methodology.

LITERATURE BACKGROUND

In work environments increasingly permeated by internet, KM tools are becoming an important mediator in the way knowledge is managed (Rao, 2005). Global organizations have invested heavily in KM programs in order to facilitate the transfer process of best practices, (Davenport and Prusak, 1999). They support the achievement of organization's strategic objectives (Hackett, 2000; Sveiby, 1995) and the nature of these programs differs from a technological view to a people view (Perrin, 2007). The power of KM is in allowing organization to explicitly enable and enhance the productivity of processes and to leverage their value for the group as well as for the individual (Ruggles, 1997).

KM theory is evolving to a more human orientation and new challenges of KM tool usage are emerging. One of the classic works in the field of computer-mediated workspaces address the "social information" (Brown and Duguid, 2000). Knowledge sharing enables people in virtual communities to access relevant knowledge (explicit or tacit) from broader scope of resources (Yang, Chen, 2007). The purpose of socialization combines both technological and personalization (Perrin et al. 2007).

The factors affecting sharing and transfer of knowledge in an organization concern the motivation for sharing (Kalling, 2003), the ability of the source to share (Foss and Pedersen, 2002), knowledge tacitness (Argote and Ingram, 2000; McEvily and Chakravarthy, 2002), and the ability of the recipient to accept knowledge (Dilek and Ulku, 2008). According to Wenger (1999), knowledge is often shared with the help of the technology. Now technology is even more powerful, easy and helpful, anyway, according to Malhotra (2005), there is nothing new in technology-induced change. Companies should never begin their transitions with pioneering technology, because to make good use of technology it is necessary to know which technologies are relevant (Malhotra, 2005). Management strategies need to shift from command and control to sense and respond (Rao, 2005). To confirm this theory, surveys conducted by analysts such as Forrester Research demonstrate that social technologies continue to grow popularity inside the enterprise, in particular wiki adoption is in the lead, followed by social networks.

The potential of Social Technologies

Social Technology is technology for social purposes or with a social basis. Social software encloses a range of software systems that allow users to interact and share data. In the last years online communities have been getting increasingly. At the same time, community members seem to rapidly lack loyalty, as they tend to use their community less over time (Bae and Jan, 2008). To survive and thrive, online communities must meet members' needs. People are more likely to participate in innovation initiatives that are well publicized and transparent (Koplowitz, 2010). From users' perspective social technologies increase the desire and the need of knowledge sharing. As a consequence, one of the most important tangible benefits inside an organization is the unlocking innovation. This kind of technologies has exploded into the business world, but they are still vastly misunderstood. Many organizations are either blocking their use, or simply experimenting the hypothetical benefits. It's a fact that organization are only recently starting to appreciate the full collection of capabilities that exist under the social technologies. Tools like Facebook, Twitter, and LinkedIn appeared with personal use, but recent surveys have demonstrated that inside an organization users employ social technologies to improve their job not just for personal matters (Forrester Reasearch, 2009).

Each day, more and more people are choosing social technologies as their preferred method of communication with peers. Just as email and instant messaging replaced the phone call, social technologies could have a similar effect in changing communication dynamics (De Gennaro, 2010).

In an always more hyperactive world, people can feel immediate benefits in connecting with the right peers, getting answers to questions and finding information. According with Forrester analysts as De Gennaro and Fenwick, there are key trends that will make the inclusion of social technology in the IT management tool set a necessity. These trends are the physical distance between and the entrance of Millennials into the workforce (De Gennaro, 2010). Telecommuting can strongly help to lower costs due to physical distance between teams. This strategy makes improved collaboration absolutely critical. For what concerns the Millennials, also known as the Millennial Generation (Generation Y), they are people born between 1980 and 2000. They are now entering the workplace. These new employees bring very different needs, experiences, and expectations to the job and often meet a seasoned workforce that has very different work styles (Schooley, 2009). Anyway, what Millennials want to support their work, such as flexible work schedules, social media tools, or a collaborative environment are work features that other employees can benefit from, too (Schooley, 2008). Web 2.0 tools allow people to ask questions, share ideas, and discover people skills regardless of the hierarchy. Such these tools help to break down organizational and cultural barriers such as time differences (Koplowitz and Owens, 2010).

THE TAILOR MADE METHODOLOGY

The methodology arises from the necessity to evaluate tools and the way to make use of them. It consists of three key elements which are analyzed in depth: *the gap analysis and*

monitoring, the toolkit selection and customization and finally *the action plan.* Through these components this approach allows to effectively capture users' perceptions and behaviors adapting the tools to the context specificity.

The research has been conducted within Eni, a multinational integrated energy company. This company was of particular interest because it is characterized by a consolidated culture, even if it operates all over the world and in many activities.

At the beginning the study concentrates on the gap analysis, with the target of detecting new behaviors, perceptions and needs and evaluating the lacks of the extant technology situation. To be always useful and to follow user needs, most of the time available tools need to be integrated, customized and adapted to the existing context. The results allow to gain awareness of the internal fragmented environment and the rapidly evolving external landscape. They guide the action plan, that must be carry out by exploiting the chosen tools, eventually after a customization. Moreover the results represent a useful starting point to define the strategy to get the most from knowledge sharing and to guide the choice of indicators which help to monitor users' trends and engagement.

It is extremely important planning future steps. The action plan must take into account people maturity level respect to current technologies and utilization expectations in the same way that a sailor always steers the course. A golden rule is that the approach should be gradual, especially in a consolidate context. In this case three phases were chosen: firstly *supporting individual needs*, then *improving the collaborative culture* and finally *enhancing the collective intelligence.* This study concerns mainly the first phase and put the basis for the others. This is a first long term approach. Of course the evolution of the context will bring an evolution of the approach itself.

Figure 1: The framework of the methodology.

Gap Analysis and monitoring

This phase consists of different kinds of analysis: perceptive, qualitative and quantitative analysis. These analyses permit to assess and monitor the current situation. Qualitative and quantitative analyses are strictly correlated in this study.

Perceptive analysis
To measure attitudes and perceptions about available technology a questionnaire based on Likert scales has been applied to a representative sample of 153 employees working in the information and communication technology (ICT) area. A Likert scale is a psychometric scale widely used in questionnaires and it was named after its inventor, psychologist Rensis Likert (1932).

In this survey of about 80 items, the individual was invited to define his attitude towards each statement by choosing among a number of four scores (“*strongly disagree, disagree, agree, strongly agree”*). In this way the choice method was forced since the middle option of "*neither agree nor disagree*" was not available. On the contrary the “*not sure/not applicable*” option was available.

The gap between users expectations and experience is analyzed through eight dimensions*: general perception of KM, knowledge creation and capitalization, diffusion, utilization, utility expectation, utility perception, tangibles, expectations respect to strategic objectives.*

The results emphasize on the need for collaboration and sharing experience. The following charts summarize the aggregate results about users’ perceptions. For what concerns the general perception, KM is seen as a way to share knowledge by the 66% of people and it is recognized a great importance in growth and change management. In this case results about KM importance are quite good. An interest aspect is that only 4% of people see KM as an IT tool.

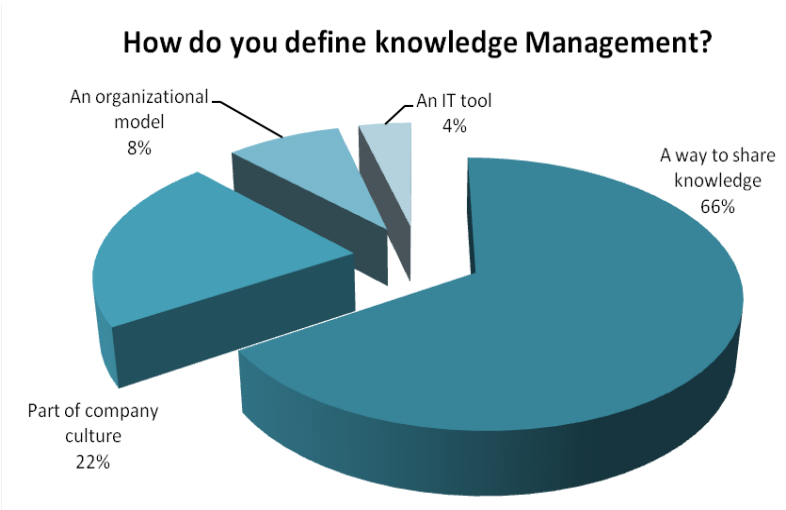

Figure 2: General perception of KM definition.

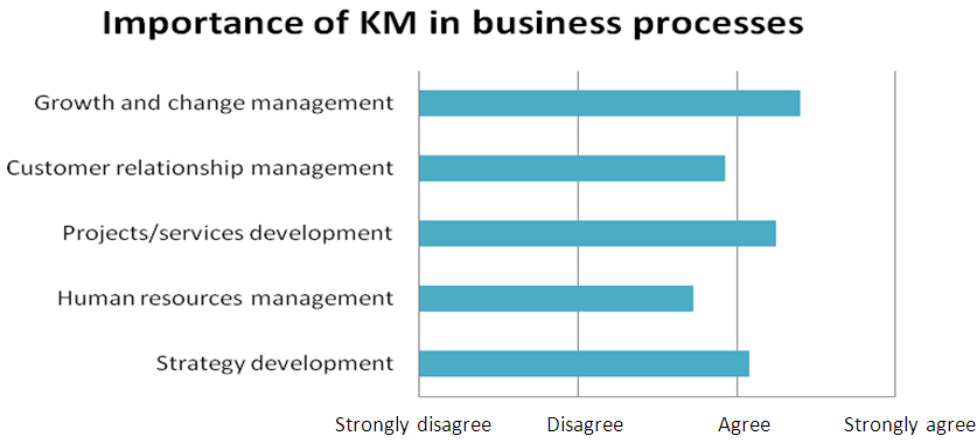

Figure 3: General perception of KM processes.

Sharing experience with other people and workshops have been recognized as the main sources of knowledge creation and capitalization. It is interesting to note that top down tools as collection of communications are in the bottom. It is the same also for what concern the knowledge diffusion dimension, in which results are very similar. In fact, sharing experience with other people and workshops have been recognized as well mostly relevant in favoring knowledge diffusion, while surveys and periodic communication are in the last positions.

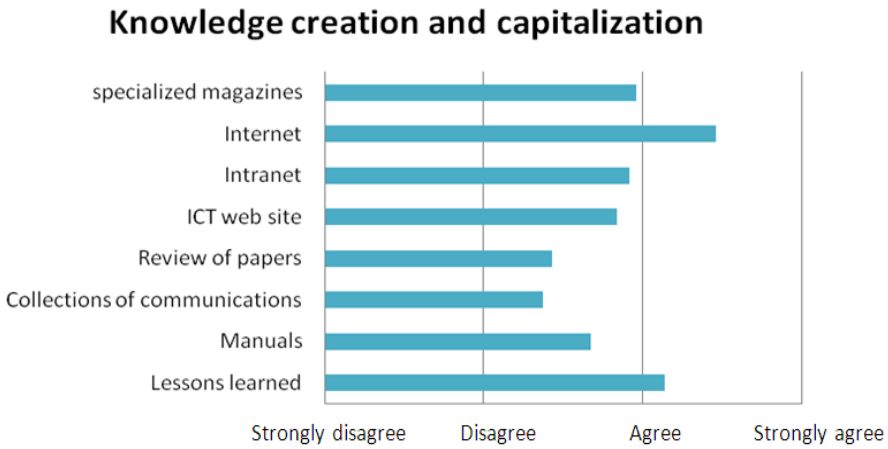

Figure 4: Knowledge Creation and Capitalization.

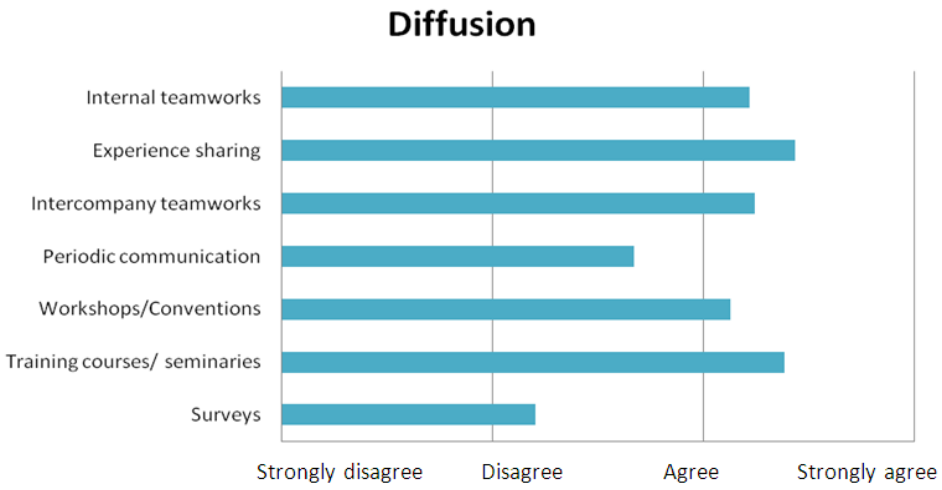

Figure 5: Knowledge Diffusion.

Internet, chat, instant messaging and email are the most used technologies. This result will be confirmed also by the quantitative analysis. People still use email as the preferred method of communications but there is an increasing interest in new technologies such as instant messaging and desktop sharing.

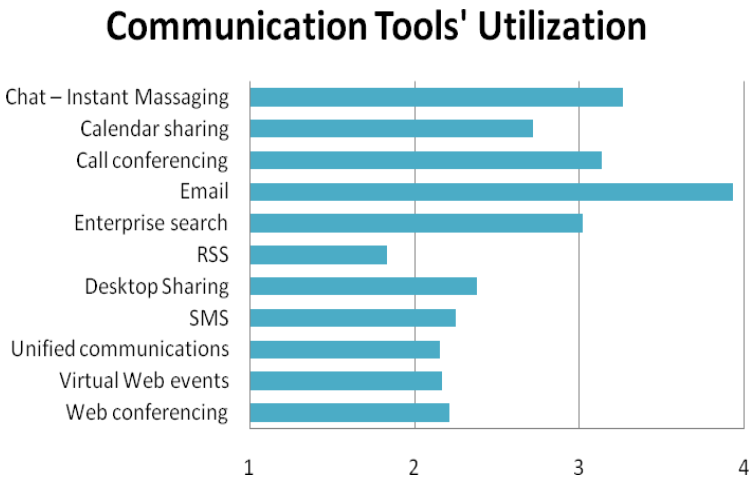

Figure 6: Tools' Utilization.

People were invited to choose on seven parameters about real perception and expectation of KM utility. These parameters are collaboration, competence, sharing knowledge, culture, change, content and connectivity. Expectations about KM utility are very high for all the aspects, in particular for collaboration and sharing knowledge. This means that people are definitely aware of KM importance. On the contrary the perceptions about what it is really available are quite low, especially for the competence map. Finding the right person with the right competence is one of the most important issue facing companies today, but it is not an easy task to be implemented. For what concern connectivity and collaboration they

are enough effectively perceived. The introduction of new collaboration tools provided an improvement in satisfaction.

Tangible activities confirm low perceptions, especially for the competence mapping and the easy accessing to lesson learned and process documentation. In fact, tangible activities are a sort of specification of some aspects of utility perceptions. The main expectations respect to strategic goals are about the improvement of the easiness of search and quality of information.

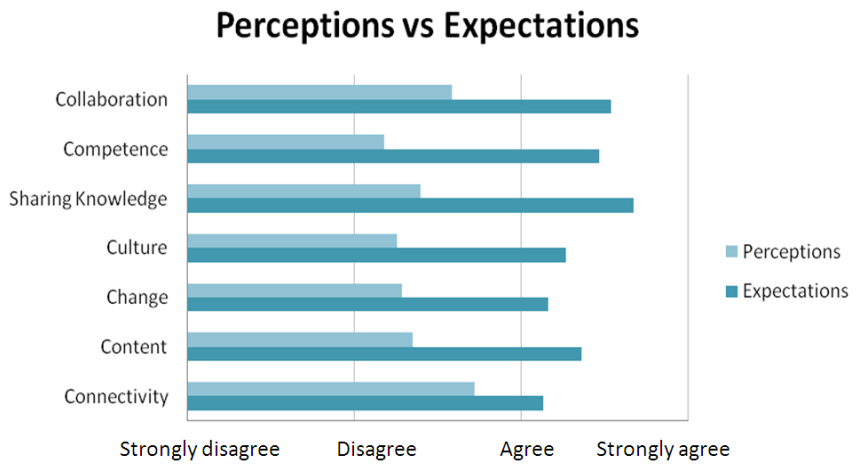

Figure 7: Utility Perceptions vs Utility Expectations.

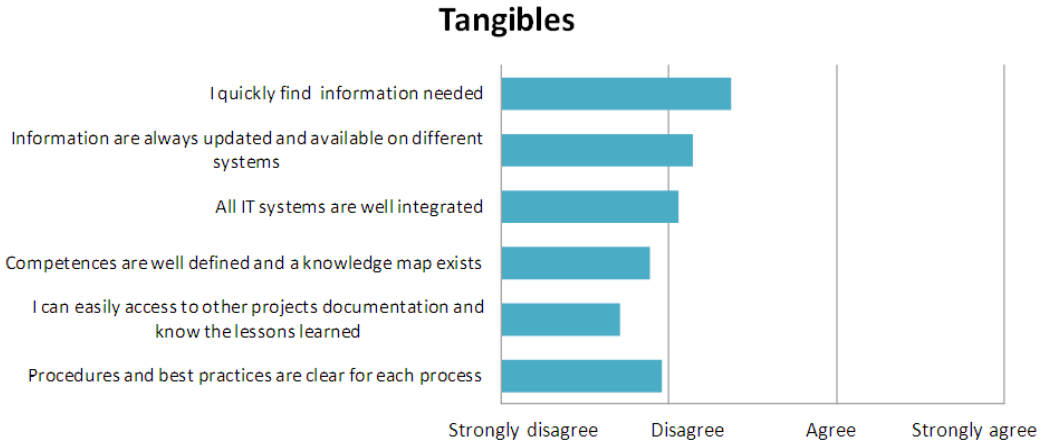

Figure 8: Tangible activities.

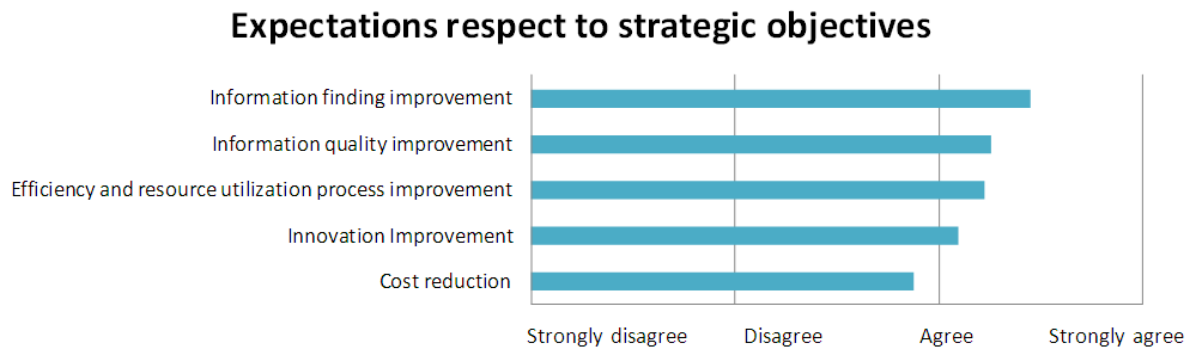

Figure 9: Expectations respect to strategic Goals.

Through the analysis of these results, it is possible to observe that people are ready to collaborate and that they strongly perceive the importance of sharing knowledge and collaborating. They have great expectations, because they feel the potential of new technologies and they are aware of innovation. They find some difficulty with the actual available systems, especially in mapping people skills, experiences and lesson learned.

Qualitative and quantitative analysis
Both qualitative and quantitative analyses contribute to corpus study. Current technologies and their real employment have been detected by specific tools able to collect and present information about user behavior on web sites as well as mobile devices running various operating systems. The quantitative analysis has been applied to a sample of 27.000 employees working in different Business Units. The quantitative results have been analyzed in a qualitative way to understand effective user needs.

Results revealed that users are constrained to employ many tools to reach their goals. Mostly they use IT tools to search people, find contacts and information about colleagues' positions and to communicate.

The introduction of new collaboration tools demonstrates a growing trend of utilization. The following chart shows utilization statistics concerning principal basic intranet tools.

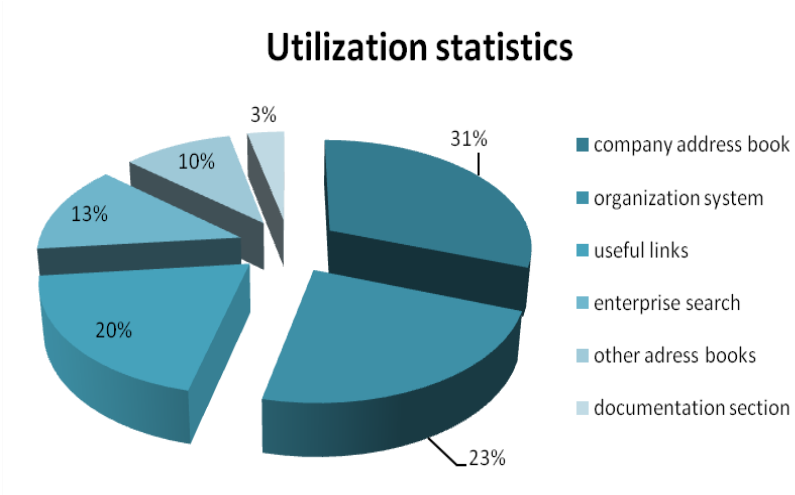

Figure 10: Utilization statistics of a group of application.

The following diagrams highlight the utilization trends after the introduction of an enterprise communication tool for instant messaging, web conferencing and sharing desktop sessions.

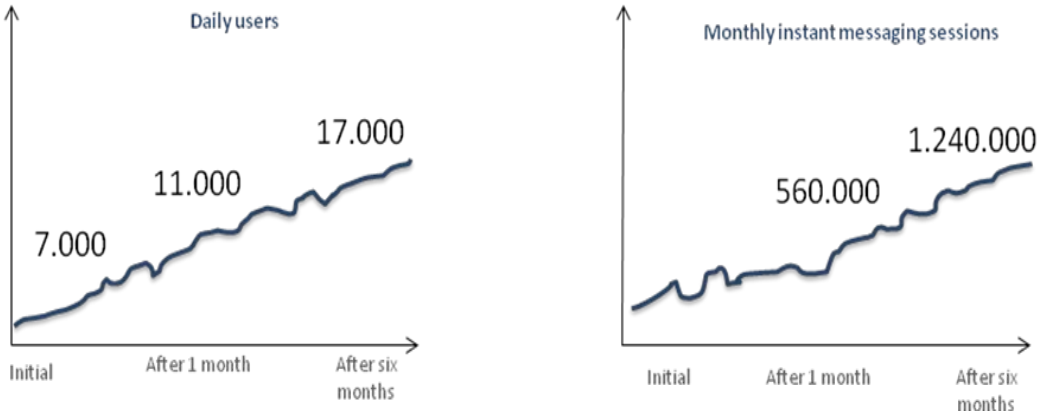

Figure 11: User Trends.

The target of this approach is to support knowledge sharing and transfer by exploiting current technology potentialities. Tools must be useful, easy and well integrated. It is extremely important to monitor utilization dynamics and the user engagement in order to intervene when necessary and to incentivize participation.

User engagement refers to the degree that a viewer or consumer has been positively influenced by a product and it bring participation and involvement. To monitor user engagement, it is necessary to select the right key performance indicators (KPI). In the case of social network KPI are quite different from the classical web sites KPI.
User engagement main objectives are to *enhance the sense of belonging* and to *increase user participation and involvement.* The chosen KPIs are the following ones.

- *Total time spent on site*: shows how thoroughly users are consuming the content.
- *Geographic segmentation*: the audience is divided according to geographic units. It can be useful to tailor programs to fit the needs of individual geographic areas, localizing the effort to geographic differences in needs and wants.
- *Single service utilization statistics*: shows how much users are consuming the single widget/service
- *Inbound and outbound links evolution*: The link analysis display all internal and external links of the website. This metric could be particularly useful for ongoing features helpful to build a regular user base for.
- *Profile completion level*: shows user psychological site loyalty
- *Number of added services*: shows how thoroughly users are interested to the content.

Toolkit selection and customization

Even if "KM activities are all over the map" (Malhotra, 2005), no IT tool can work unless the participants fully understand the benefits and unless employees have incentives to participate (Grant, 2007). Current technologies offer a wide range of products and possibilities. Given the variety of contexts and situations, choosing the right way to apply technology is extremely important, besides the choice of them. For this reason being able to always catch and understand user needs is crucial, especially in a complex environment such as a multinational company.

In this study a social network was selected to better follow employ needs and to facilitate their job. Social networking sites are not only simple tools. They allow users to create their own personal virtual space and a relationship network. This happens through psychological and social dynamics that encourage connections creation and maintenance.

The best way to apply a social network is from learning about the way the web works, through understanding the right innovation metrics and the focus. The new trends of innovation are made by passionate people that move more than in any time in history. Reasons that leaded to a social networks are the given by three social media and web Innovation metrics. The first one is the *return on attention* which is a key metric of attention scarcity and refers to the value we get in return for the time spent looking for what we want and need. Communities demonstrated wide cost reductions and a huge returned value in change of attention. The second one is the *return on information* metric, which is based upon the value of relevant data returned through search. Communities are an ideal pool to find information about people, needs and preferences. The third one is the *return on skills*. Communities are able to attract users with high capabilities and social networks make possible to build a knowledge map. The previous metrics represent the starting strategic objectives of the selected tool, namely generating relationships and engagement and letting the competencies emerge. User participation is favored by the capability of inducing and gratifying the joining pulse, going through the daily user flow. Realization has to be gradual and respect all kinds of needs.

The focus model was the *shelf*. A shelf can be personalized as preferred, can contain own and other objects, can hold working and extra-working contents.

Social networks are not all the same. In this particular case the main purpose was to realize a useful job tool able to create an open and connected place where ideas and discussions could grow in support of innovation and creativity. After the firsts analyses it was decided to make a modular offer to better address the social business needs of diverse users. By delivering a modular software approach, a new working environment, both effective and motivating at the same time, could be introduced. Modules follows users needs detected by the gap analyses and add further advantages. The basic modules allow total collaboration and involvement of the employees. It represents the initial stage to transform conversations into tangible initiatives. The other modules are designed to facilitate interaction, discussion and an exchange of information and to allow the submission of ideas to be commented on, including documents so as to work in a collaborative manner on new content. Additional advantages are given by the reduction of the numerous meetings and of the amount of emails, or simple by retaining a memory of past projects. The main feature is that individuals exchange views between each other in real time and even more accurately *the right information with the right people*.

Action Plan

The collected results give the basis to start to work. The main objective is to improve knowledge sharing and transfer by putting the individual at the center and analyzing social usability and relational motivations. In the current situation systems are very fragmented, but the perception survey shows that people are ready to share knowledge. Quantitative and quality analyses shows people tendencies, which represents the critical factor of the further implementation. First of all people want to find contacts and information about colleagues' position and competences, then they need an integrated system.

According to Malhotra (2005), best practices recommend not to pioneer new technology. For this reason the solution is in exploiting existent social technologies' feature in an integrated way always close to employees needs. The identified solution is a modular social network rich of functionalities. People themselves are ready, but we should move gradually to not counteract the benefit of social technologies. Three phases with different targets have been identified. The first phase's target is to support individual needs, the second phase's target is to improve the collaborative culture, and the third one is to enhance the collective intelligence.

To build a success social network it is necessary to follow a process. The main steps of this action plan are given by the active listening, strategic concept and governance, interface design, implementation, launch and promotion, participation and dynamics monitoring.

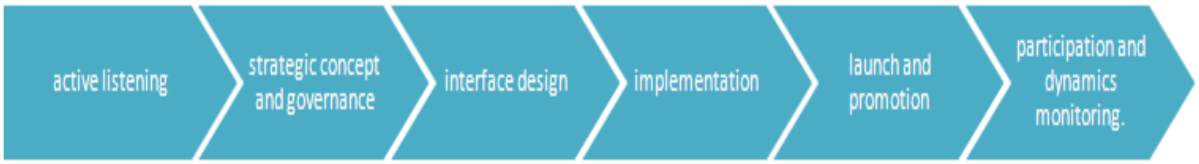

Figure 12: The Process.

Active listening is fundamental to discover people needs. Blowing up the needs permits to choose the right technology to enable. Brainstorming, focus group and AS IS analysis are key aspects of this stage that permit to formalize the contents. The strategic concept is a statement of what is to be done. Focus drivers are given by a shared and informal place, workability, practicalness, community and shared job.
The model is complex and it is necessary to move gradually. First of all it is necessary to work on the needs. Providing a not requested functionality can lead to the *empty room effect*, or rather users don't feel compelled to come back because the conversations doesn't seem active. A problem creates a need, a need asks for a solution. The solution should be delivered on time to not frustrate people, while the interface should be easy, usable and pleasant. Communication is crucial. This new tool aims to be an evolution of communication services and a development of social relationship. In particular the target is to create an informal space where it is possible to share interests, passions, personal skills and achieve actual leadership. It is absolutely important simulate and organize feedbacks to steer the course accurately as in a sailboat.

FINDINGS

The empirical study evaluated the effectiveness of current KM tools in achieving knowledge transfer in an integrated energy company. The paper proposes a tailor made methodology and some best practices to encouraged knowledge sharing in a more structured manner. In particular the paper proposes to use social networks, which are consolidated technologies, by this time.

Social network are strategic tools as they bring a change in organization dynamics. They represent a breaking point such as email introduction was at the beginning. Electronic mail was in fact a crucial tool that allowed multiple users to log from remote places. It started in 1965 and this new ability encouraged users to share information in new ways. In many cases resistance to change was encountered in introducing email inside the companies, as everyone could be able to communicate directly with the CEO, by that time. Now we are facing to another revolution: social networks allow users to create their own personal virtual space in which it is possible to show personal implicit competencies and communicate the own status.

In this study some main aspects are emerged about enterprise 2.0. There are principal reasons why community users decrease in their participation over time. Those are the lack of interest, low quality content, low usability, low trust, merely boring. Every context is different and it is absolutely important take into account people maturity level about new technologies. It is important to carry out every initiative in a gradual way and choose the

strategic objective for each phase basing on people perceptions and needs. Then monitoring is crucial to steer the course on every little change and the emerging of new needs.

To summarize best practices in the application of enterprise 2.0 the golden rule is always analyzing data to be ready to support new requirements and changes. Tools should be usable, easy and well integrated. It is important a continuous and active listening to people and the monitoring of keyword analysis and behavior patterns. To make the transition from individual to enterprise usage, web 2.0 products need to be able to scale to large groups and to operate across the entire enterprise. The enterprise search tool has to be very powerful, as search solutions are blending traditional approaches with web 2.0 functionality.
Effective design is crucial. It presents KM tools in context to enable and encourage usage and contribution. Effective design simplifies functions such as search and browse and also provides efficient contextual access to collaboration tools.

Table 1: what to do and not to do summary.

TO DO	NOT TO DO
Move gradually	Pioneer new technologies
Continuous and active listening	Give soon unrequested functionality risking the empty room effect
Analyze data	Underestimate user feedbacks and perceptions
Provide modular tools	Monitor only the initial KPIs
Monitor keyword analysis	Block people creativity
Be ready to change	
Follow a process	
Design usable and easy interface	
Integrate systems and enhance search tools	

RESEARCH IMPLICATIONS AND LIMITATIONS

These findings revealed the large number of factors impacting on knowledge transfer. It is not so much the knowledge existing in an organization but rather the firm's ability to effectively apply this knowledge that goes a long way to creating new knowledge (Alavi and Leidner, 2003). Social technologies help to leverage knowledge sharing and transfer, but a structured approach should be applied through many steps and different kinds of analysis, ready to always follow user needs.

The paper is based on an application of the described approach to a single, even large, company, which limits the possibility of making general conclusions. The representative nature of the survey group, together with the data collection methods employed, were key strengths of the study approach. However, there is a key limitation of the survey group due to the participation of only a little representative sample of people. Next steps are represented by the analysis of the trends of the utilization of this social network inside this multinational Company.

CONCLUSIONS

In an even more complex world, more openness is required to better understand and integrate expectations of internal stakeholders. Eni demonstrated a great farsightedness

and passion for continuous improvement. Social technologies can help to capture critical information, designing an implicit knowledge real-time map and apply a qualitative and dynamic analysis of people trends. Avoiding their use can be a missed opportunity for the companies, also because people can use external tools like Facebook to state their opinion and show their skills.

KM has evolved to the point where collaboration and contribution is as much a priority as information access. By now the linchpins of KM are not only the ability to lead users to relevant knowledge, but also the capability to promote participation.

ABSTRACT

Knowledge is a key resource in determining competitive advantage and market place success in the knowledge based society. Knowledge creation is a crucial part that develops the building of the Knowledge Management (KM), since it is concerned with the creation, storage, dissemination, and application of organizational knowledge (Meixell, Shaw and Tuggle, 2002). Since knowledge creation is a mature and established field, a variety of concept and approaches are available to explain them (Nonaka and Nishiguchi, 2001) and were adopted by numerous bodies in nurturing knowledge for their own special purposes. The paper discusses a dialectic movement and its model. The paper suggests a model so called A Dialectic Model in promoting competitive advantage in Islamic banks in order to soften the major challenge of lack in financial engineering and innovation within the framework of Islamic banking. The model applies Thesis-Antithesis-Synthesis Approach, which consists of four main components – thesis, antithesis, analysis, and synthesis. The antithesis component always goes against the thesis. The analysis component is a process in which the thesis and antithesis are taken into consideration in order to enable a Muslim to transact with a bank practicing an interest-free banking system. The analysis part is conducted by reviewing major ideas and precedents or fatwa given by previous scholars seen relevant to the matters without sacrificing the main principle of interest-free transaction as well as the products. A case study on Islamic Bank of Thailand (IBT) in developing a product will be included at the end of the discussion.

Keywords: Dialectic Model, Competitive Advantage, Knowledge Management, Product Development, Islamic Banking

INTRODUCTION

The introduction of Islamic banking system in dominant Muslim countries offers an alternative banking system to conventional one. Muslims perceive that conventional banking system is noncompliant with *Islamic Law (Shariah)* where the current banking practice of offering interest is prohibited by Islam.

The first Islamic financial institution, Saving Bank of Egypt, was established in 1963 by Ahmad El Najjar (Ariff, 1988). It was the first known modern experiment with Islamic banking. This financial institution first operated without projecting an Islamic image due to fear of being seen as a manifestation of Islamic fundamentalism. He pioneered an Islamic banking service in the form of a saving bank based on profit sharing in the town of Mit Ghamr (Siddiqi, 1988).

In 1971, The Nasir Social Bank declared its first interest free commercial bank although its charter made no reference to Islam or Islamic law *(Shariah)* (Ariff, 1988). This is viewed as the second effort to introduce Islamic banking in the world of banking services. The decade of 70's appeared to experience a significant surge of Islamic banking services in the world. Several Islamic banks came into existence in the East, for instance Islamic Bank for Development in Saudi Arabia (1974), Islamic Bank of Dubai (1975), Feissal Islamic bank of Sudan (1977), Bank of Finance in Kuwait (1977) and Feissal Islamic Bank of Egypt (1977) (Ariff, 1988).

Meanwhile, in the Southeast Asia region, the Philippine Amanah Bank (PAB) was established in 1973 by Presidential Decree as a response to the Muslim rebellion in the south. It was designed to serve the banking needs for the Muslim community. However, the primary aim of PAB was to construct Mindanao, Sulu and Palawan in the south (Mastura, 1988). PAB is not a pure Islamic banking based on Shariah since interest based operations continue to coexist with the Islamic mode of finance. PAB operates two 'windows' for conventional and Islamic counters.

Some Islamic financial institutions were also established in countries where Muslim community is minority. There was a proliferation of interest-free saving and loan in India during the seventies (Siddiqi, 1988). The Islamic banking system in Luxembourg was established in 1978, an Islamic Bank International of Denmark, the Islamic Investment Company of Australia (Ariff, 1988) and Islamic Bank of Thailand in 2003.

BACKGROUND TO RESEARCH

The uniqueness of Islamic banking products and services is its interest free banking which is offered to both Muslims and non Muslims customers. However, the study in Malaysia found that non Muslim customers accounted only 2 percent of the total number of its depositors (Man, 1988). This is an indication that Islamic bank's products and services in the early year of its operation in Malaysia failed to attract non Muslim customers. Metawa & Al Mossawi (1998) found that the religious belief and economic became the main factors for Muslims in selecting products and services of Islamic banks. The relationship between Islamic bank and customers cannot depend solely on religious factors. It might not be a problem for a nation where Muslims

are majority, country where Muslims are minority, religious factor is insignificant for competitive leverage.

Numerous studies revealed that religion is no longer the main factor in attracting depositors. Hence, Islamic bank should recognize this by offering products and services compatible to conventional banks (Erol & El-Bdour,1989; Haron & Planisek,1994; Gerrad & Cunniham,1997). A study conducted by Haron and Shanmugam (1995) and Haron and Norafifah (2000) shows that there are negative relationships between interest rate and the total interest free deposits. This clearly displayed that economic factor influences the customers' choice of products and services offered by a bank. This finding is supported by another study done by Radiah (1993). She found that Muslim and non Muslim customers give priority to time value of their saving. This group of customers constitutes sixty percent of Bank Islam Malaysia's depositors.

Thailand is a country where Muslims are a minority. Muslim community constitutes only 10 percent of her population of 63 million. Most of the Muslim community is at the deep south provinces of Thailand of Narathiwat, Pattani, Yala and Satun. Muslim community in these provinces is about 5 million. The rest is staying in other parts of Thailand. Islamic Bank of Thailand was established in 2003, giving an alternative to both Muslims and non Muslims for interest-free products and services. In order to attract non Muslim customers, the Islamic bank must be competitive relative to their conventional counterparts.

However, there are limited researches done on Islamic Bank of Thailand in terms of products and services offered. Therefore, this research aims to study on the competitiveness of Islamic banking products and services in a Non-Muslim nation by using knowledge management model in products and services development. This paper is a conceptual study as a Ph.D. thesis. An empirical investigation is not conducted yet. This paper tries to highlight that the product development process in Islamic banking follows the dialectic model of knowledge creation.

PROBLEM STATEMENT

Knowledge becomes an important asset in creating competitiveness (Fama & Jensen, 1983). If the knowledge of market forces is structured in an appropriate way and by proper utilization of knowledge, the bank can develop more competitive products and services. According to Pitt and MacVaugh (2008), knowledge management (KM) can enhance the effectiveness of new product development but more importantly, it is necessary to manage knowledge in a more structured way. The lack of awareness about knowledge management might lead to the failure of product development (Ferrari & Teledo, 2004). A certain knowledge technique is used in KM and Artificial Intelligence (AI). A study conducted on Taiwanese high companies implementing KM found that there is positive effect on new product development performance and its effective method will lead to the success of new product development (Liu, Chen & Tsai, 2005).

The product and services of Islamic Bank of Thailand are found to be less competitive (IBT annual report, 2010). They are offered to the market without proper understanding and are ill-informed of the market forces and needs. They lack of understanding, awareness and

information that could leverage their offers relative to their conventional banking counterparts This research addresses on the issue by promoting the knowledge creation techniques that should be applied in understanding the whole scenario, creating necessary knowledge within Islamic bank thus addressing the issue of gain competitive leverage. As an attempt to eliminate the constraints faced by Islamic bank, the research proposes the Dialectic Model (Approach) where Thesis, Antithesis and Synthesis techniques are used. However, this model has not been studied yet in the field of banking product development. The model was studied in a manufacturing organization in Japan. The model was successfully formulated a policy effecting both the employers and employees. The outcome is the formulated policy allows a win-win situation for both parties.

RESEARCH OBJECTIVES

1. To study the factors influencing the competitiveness of the Islamic banking products and the services in a nation where non-Muslims are majority.
2. To study dialectic model of knowledge management in developing competitive products in Islamic banking in a country where Muslims are minority.

RESEARCH QUESTIONS

1. What are the factors that will influence the competitiveness of Islamic banking products and services in a country where Muslim are minority?
2. How far can Dialectic Model contribute towards increasing competitive advantages in products and services of Islamic banking?

SIGNIFICANCE OF RESEARCH

1. The model will become a source of reference in developing Islamic banking products and services in Muslim minority countries.
2. The model will become a case study to other parts which are similar in its nature.
3. The outcome of this research will make Islamic banking products and services more competitive in their marketing efforts.

LITERATURE REVIEW

Islamic bank offers unique products and services compared to the conventional one. The uniqueness of Islamic banks is its interest-free banking facility to both Muslim and non-Muslim customers. Depository schemes, similar to conventional banks, are offered by Islamic banks. Islamic banks around the world offer three main types of depository services such as current accounts, saving accounts and investment accounts. Current and saving accounts guarantee depositors the nominal value of the deposit but provide no guarantee on returns. The investment accounts operate fully under the Profit Loss Sharing (PLS) scheme where capital is not guarantee neither any pre-fixed return.

In the case of Bank Islam Malaysia Berhad (BIMB), the products and services failed to attract non Muslim community. Non-Muslim depositors accounted for only two percent of the total number of depositors (Man, 1988). Even though the bank had a network of 533 branches as at the end of September, Islamic banks were used to be unpopular among Malaysian customers.

In Malaysia, there are two main types of depositors among Islamic banking customers. The first group represents those who strictly adhere to the Islamic faith and thus desire to follow strictly the Islamic teaching at any cost. The second group consists of moderate Muslims and non-Muslim customers. Haron and Planisek (1994) found that the former represents only forty percent of the Muslim customers. The later constitutes sixty percent and often consider time value is more important. The authors suggested that the top management of Islamic banks should realize the needs of time value of money and do not solely depend upon Muslims for deposit or as their fund users. Non-Muslims should be included as potential customers. This remark was also supported by Norafifah & Haron (2002).

RESEARCH VARIABLES

Islamic banking system is an alternative banking system to the conventional one. The products offered should be in compliance with *Shariah* law that is interest free. A study conducted by Haron and Wan Azmi (2008) found that religious belief plays an important role for Muslim customers in selecting products and services offered by Islamic banks. Most clients select products and services offered by Islamic bank because they desire to conform to *Shariah* or Islamic principles (Al-Ajmi, Abo Hussain, & Al-Saleh, 2009; Metawa & Almossawi, 1998).

Cooper (2001) stated that one of the common attributes in developing successful products is listening to the customer. Customer inputs can be used to improve and develop product (Plumlee & Little, 2006). According to Goffin and New (2001) customer support is an essential element in successful marketing of products. The prerequisite in ensuring product success in market is the need to understand customer requirement and expectations (Zang, 1998). A product which does not reflect customer needs will lead to the failure (Zirger & Maidique, 1990).

The key changes required of a firm in order to be competitive are its customers and competitors. Firm should determine customer's needs and be informed of the competitors' products. Products should reflect customer's needs and be differentiated from that of competitors (Homburg, Grozdanovic & Klarmann, 2007). By understanding customer's needs and competitors, firms can deliver a product that can give benefits to customers and have advantages over the competitors (Hoonsapon & Ruemroom, 2009). Product Differentiation is a source of competitive advantage. Differentiation means firms offer unique or superior benefits to their customers that competitors do not have (Porter, 1985).

According to Driva, Pawar and Menon (2000), an effectively managing and measuring the product development process is seen as a means of ensuring business survival through reduced time to market, increase quality and reduced costs. This fact is supported by Valle & Avella (2003) in his study on the innovative industries in Spain. They found that an effective product development process is indicated by better development time and cost and superior product. However those indicators can be achieved through an effective leadership.

A competitive product in a market should fulfill demands on quality, performance and cost (Ottoson, 2004). According to Jang, Dickerson and Hawley (2005), the combination of consumer acceptance and financial performance, sale and profitability, served as critical measures for product performance.

The selected variables are as follows:
Independent variables (IV): Shariah, customers' expectation, competitors' products information and product differentiation.
Dependent variables (DV): Customers' acceptance, market shares and profitability
Mediating variable (MV): Leadership

THEORETICAL FRAMEWORK

This section discusses the techniques that could be used, as an attempt to understand the issue and to nurture appropriate knowledge for specific use. It is necessary to be familiar with the techniques regularly used in creating knowledge, so that the strength and weaknesses could be identified.

DIALECTIC MODEL

The research identifies and proposes the Dialectic model (Takeuchi & Nonaka, 2004) for overcoming difficulties, eliminating constraints and solving the problem of creating new product within Islamic Bank. The justifications of the selection is that Dialectic approach takes verbal communication, direct conversation and dialog in its process, where all these have been a normal practice within banking institutions. Dialectic approach is proposed to strengthen and to formalize the current practice.

The Ba and Care, Cooperation, Cross Border and Symbiotic Co-Evolution are focus on learning from other organizations, local and abroad. It could be observation and adaptation from other's experiences and practices, to be implemented locally upon appropriate modification and adjustment to suit organizational needs. While, Induction, Deduction, Abduction and Self Reflection techniques is thought to be logical inference and monologue, without direct responses from personnel of authority. This is inappropriate in order to establish a solution that requires feedback and authorization from others, and thus Dialectic approach seems very promising for this study.

Dialectic Model for Knowledge Creation

This section discusses a dialectic movement and its model. The term "dialectic" originates from Greek *dialektos*, meaning discourse or debate. Plato (428-324 BC) referred dialectic as binary opposites, tensions and contradictions among ideas. The principle developed to include the idea that all levels of knowledge advance through a process of Thesis, Antithesis and Synthesis (Singer, 2003). According to Hegel's dialectic, it comprises three dialectical stages of development: a thesis giving rise to its reaction, an antithesis which contradicts or negates the thesis and the tension between the two being resolved by means of a synthesis.

According to Tekeuchi & Nonaka (2004) dialectics emphasizes two characteristics. The first is its emphasis on change in which it talks about process and movement. Secondly, it emphasizes on opposites. Change takes place through conflict and opposition. It is looking for contradictions within people or situations as the main guide to what is going on and what is likely to happen.

The core in dialectics is the notion of the world as being full of contradictions (Skirbekk & Gilje, 2001). The dialectical movement begins with thesis as the original state. The next stage is for this thesis to show itself to be inadequate or inconsistent. It is the opposite or negation of the first stage and hence is known as antithesis. It is the reaction against the thesis. The second stage also shows to inadequate or inconsistent. So, it results in third stage known as synthesis. It solves the oppositions between the thesis and the antithesis. The previous thesis and antithesis are reconciled and transcended (Takeuchi & Nonaka, 2004; Lind & Melin, 2003). The synthesis is a combination of the best thesis and the best of antithesis. However the synthesis will serve as the thesis for a new dialectic movement. The dialectic movement is illustrated in Figure 1 and Figure 2.

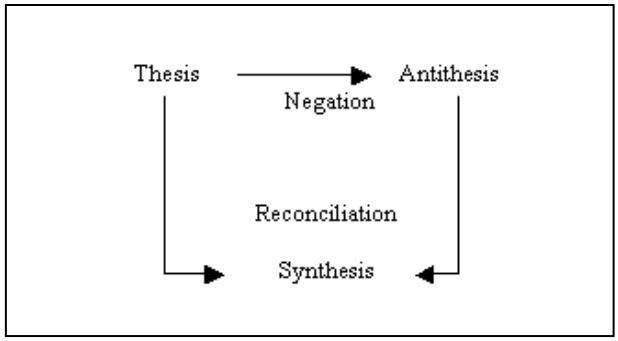

Figure 1: Dialectic Model (Tekeuchi & Nonaka, 2004).

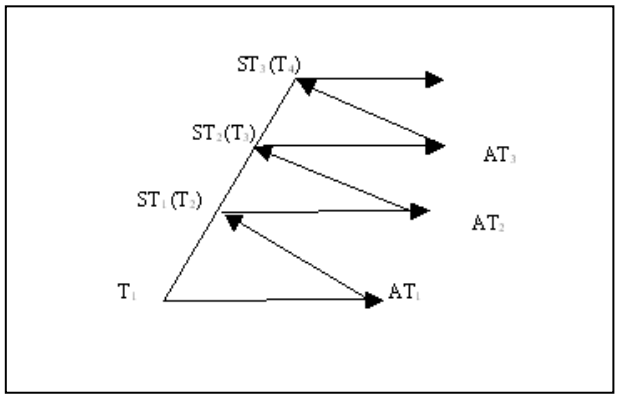

Figure 2: Thesis-Antithesis-Synthesis Movement (Tekeuchi and Nonaka, 2004).

Knowledge creation in dialectic thinking accepts what appear to be opposites and tries to synthesize them by transforming and uniting them. A new reality is created through synthesis. The process involves taking a thesis (T_n) and an antithesis (AT_n) and creating a new reality (ST_n). ST_n is separate and independent of T_n and AT_n. A synthesis (ST_n) is neither something in between nor something in the middle of a thesis (T_n) and an antithesis (AT_n). This relationship is illustrated in figure 2 above. A thesis (T_n) may represent interest or culture or practice of an individual or an organization meanwhile an antithesis (AT_n) may represent the interest or culture or practice of a community or a customer in which both are contradict to each other. In order to solve the problem or the conflict between a thesis and antithesis, the organization has to come up with a solution (ST_n). It is not a compromise, but has a higher or broader view of reality. It is a "super-proposal" that encompasses the conflicting thesis and antithesis in it. The process involves dynamic interaction for self-realization (Buss, 1979). Discovering a new knowledge it needs critical thinking by considering all possible internal and external variables of an organization that lead to "super-proposal".

Critical thinking or critical reasoning is a major topic on enhancing the effectiveness of human judgment and decision making (Ennis, 1992). Critical thinking is a skill for many complex problems in which normal procedures cannot be successfully used to solve a decision problem. Critical thinking is used to search for alternative solution, procedures or beliefs to arrive at innovative solution. Halpern (1984) defines critical thinking as thinking with a purpose and a goal. Critical thinking involves reflective and healthy skepticism requires deepening the background knowledge about the decision problem, and calls for a greater cognitive effort in selecting facts and assumptions to use (McPeck, 1992).

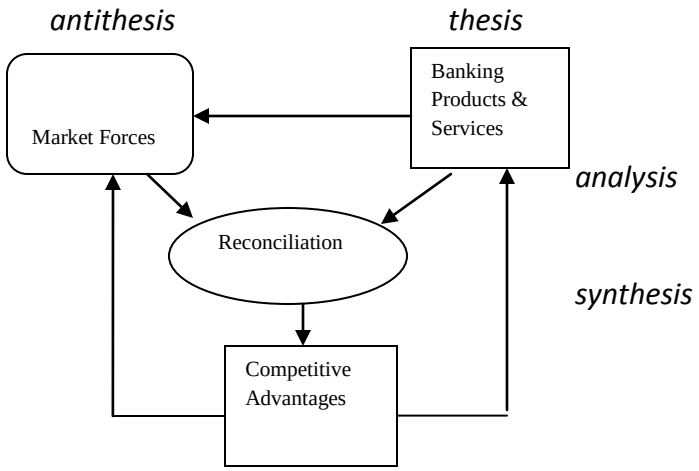

Figure 3: Conceptual Framework of the Study based on Dialectic Model.

The above figure represents a dialectic model which consists of several components of thesis, antithesis, analysis and synthesis. Thesis represents the products and services of Islamic bank which are interest free and have an equitable distribution of income and wealth and to increase equity participation in the economy (Chapra, 1982). Second component is antithesis, which represents the market forces. In this case thesis and antithesis always negate each other and there is a contradiction between those interests. The bank's interest is always driven by high profitability with low cost meanwhile the customers are driven by a high return from their savings and investments. They will deposit their money to banks that offer a high return (Erol & El-Bdour, 1989; Haron & Planisek, 1994 and Gerrad & Cunningham, 1997).

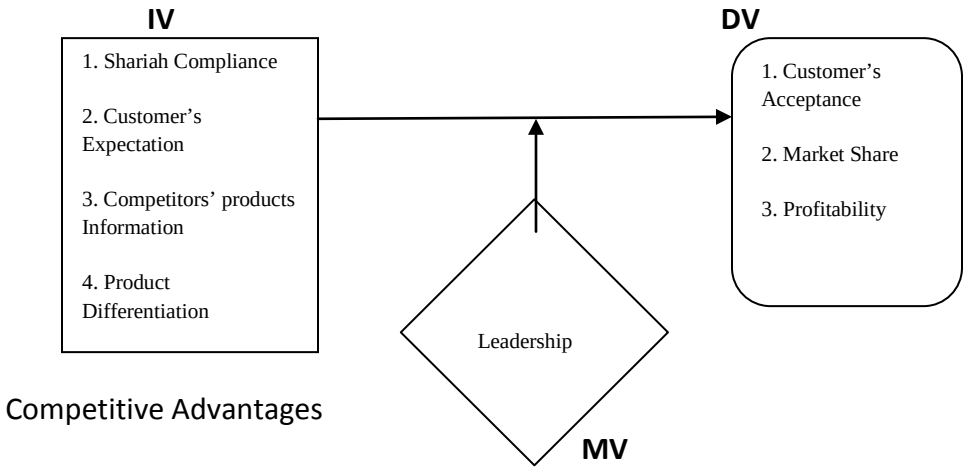

Figure 4: Research Variables.

The analysis is a process of reconciliation between those thesis and antithesis components. The process of analysis will consider several factors that can offer the best products and services without sacrificing the organization's interests and goals as well as customers' expectation. In order to formulate a new product, several variables are taken into consideration including

internal and external factors. The external factors represent the market force that can influence a product development. Those internal variables represent products and services offered by the bank.

DATA COLLECTION METHOD

The research will use qualitative in collecting data due to time constraint and some financial data are confidential. The qualitative method will study the effectiveness of the model in product development. Secondary data will be analyzed and interview will be used to identify its competitiveness.

A STUDY ON ISLAMIC BANK OF THAILAND (IBank)

The establishment of the Islamic Bank in Thailand was initiated by the Muslim entrepreneur living in the three southern provinces. They are formed to adhere to the Islamic way of life, following the principles of Islamic teachings. In 1998 the government propelled the development of Islamic banking system in many forms, especially to serve the Muslims' banking activities in conformity with the Shariah principle. The government's intention was to set up an Islamic Bank under her jurisdiction and managed under its own sets of law. The Ministry of Finance was then assigned to draft 'The Islamic Bank of Thailand Act' which was later approved by the parliament in October 2002.

During the initial stage of incorporation Islamic Bank focused solely on Muslim market segmentation. However IBank believes that Shariah banking system can serve anyone and thus creates and develops more innovative and competitive products. IBank then embarks on the rebranding exercise by offering the best services to customers. The Bank promotes ethical culture, social responsibility, Islamic principle and good governance through its operational framework. IBank is able to differentiate from the other conventional banks while offering new alternative banking for everyone regardless of religion. Currently IBank is a state owned enterprise and has 29 branches throughout the country (IBank, 2009).

Islamic Bank of Thailand is set up under the Islamic Bank of Thailand Act 2002 and regulated by the Ministry of Finance. The Bank commenced operations in June 2003 with paid-up capital of 1 billion baht and had its head quarter and the first branch in Klongton. The Bank continued to open more branches, especially in Bangkok and Southern provinces and by the end of 2005 the Bank had total of 9 branches. The expansion of the Bank's business continued through the acquisition of Shariah Banking Services of Krung Thai Bank Pcl. in November 2005. It was conducted under the government's policy and led to the increase of the number of branches increased from 18 to 27. In order to facilitate the growing business and increase competitive effectiveness the bank relocated the head quarter from Klongton to Asoke, a prime business area, in August 2005 (Islamic Bank of Thailand, 2011).

According to the market share report of IBank as on March 2011, The bank has 1.25% market share in financing (85.4 billion baht) and 1.32% (94.3 billion baht) of market share in deposit

(Market Share of Bank in Thailand, 2011). Table 4 shows the IBank profit. The profit rose up to 355.2 million baht in 2009 from 2.08 million baht in 2008. This represents an extreme 16,905 % increase in profit. The IBank deposit significantly went up to 40.8 billion baht in 2009 compared to 19.9 billion baht in 2008, which was 100 % increased in proportion (Islamic Bank of Thailand, 2009).

Table 1: Market Share of Bank in Thailand on March 2011.

BANK	Financing		Deposit	
	Amount (Million Baht)	Market Share (%)	Amount (Million Baht)	Market Share (%)

IBANK'S CORE PRODUCTS

The products, which are offered by The Islamic Bank of Thailand, are similar to the products offered by other conventional banks. However, the main different principle is all IBank's products are interest-free. Due to the global economic downturn, economic growth in Thailand drastically slowed down. There were unfavourable signs of the economic situation of the Thai people. The Islamic Bank of Thailand realized the difficulties and needs of customers, so the bank adjusted the features of two credit products namely, home financing, home refinancing, and created additional refinancing on credit card debt and personal financings. These three

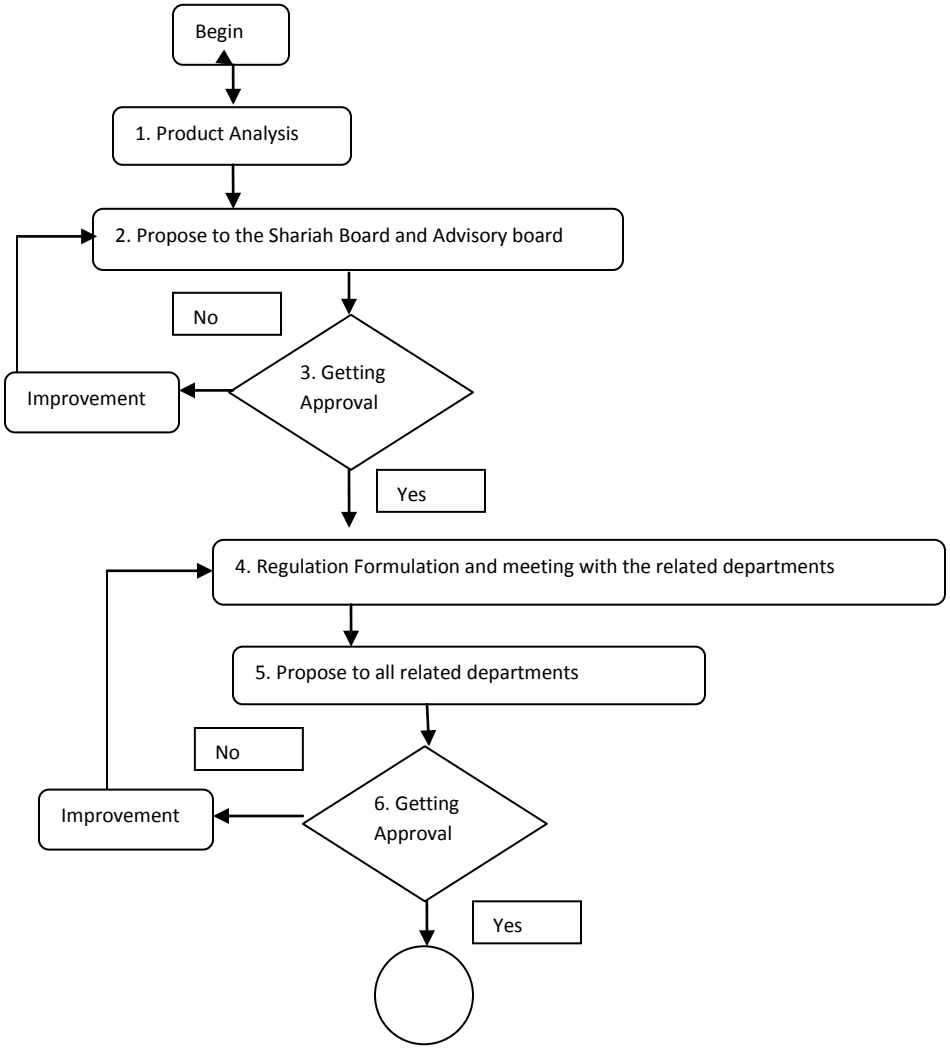
products are on packaged under the relief credit project, with the distinguishing characteristic of grace periods of principal repayment as long as three years for home financing and six months for the refinancing of credit card debt and personal financing. The rate of profit was less than half when compared to the burden of instalment payments to the original institutions of customers. These three products turned out to be well-received by the Bank's customers, making the total sales volume of these three products exceed 50% of the total amount of personal financing, and making this project well-known as a product champion of the year for the Bank.According to an interview with Mr. Shah Fahad Yousufzai, the vice president of product development department on 24th March 2011, these products are considered the most competitive products due to the amount approved and the number of customers.

PRODUCT DEVELOPMENT PROCESS

Figure 5 shows the flow of a product development process. All products offered by IBank must go through the above flow. The most important variable in IBank's product's offering in the market is compliance with Shariah law. The process of designing a new product begins with product development analysis. There are several factors taken into consideration in designing a new product. The process requires gathering several information such as the information from sale department, competitors products, rules and regulation of Bank of Thailand, information from every business sector, market needs, customers' behaviors, domestic and international market and economic tendency and the interest rate tendency both for deposit and loan. Although a new product has fulfilled the required analysis but does not meet the Shariah compliance, the products are not allowed to enter the market. New product must be pre-approved by the Shariah board before getting the approval from the executive committee and the board of directors. When a new product does not get the approval from the Shariah board, it should be revised and to realign with Shariah as recommended by the Board of Shariah.

The Board of Shariah will look at the Shariah law according to the verdicts revealed by the Muslim scholars of Sunni sect from the four main schools. They are Maliki, Hambali, Hanafi and Syafie schools of thought because these opinions are considered the most influential verdicts in Sunni sect. The Shariah board will choose the most flexible verdict from the opinions in order to make sure that the business can run smoothly and accordance with Shariah. However, the products and opinions might be different from one Islamic bank to the other in different countries. It is based on which opinions are chosen by the board of Shariah. For example, Bai Inah (sale of cash) personal refinancing is offered only by Islamic Bank of Thailand based on Bai Inah principle. In the Middle East countries, the product is considered doubtful to Shariah compliance. According to Maliki, Hanafi dan Hambali schools, Bai Inah is a void contract but it is acceptable with discourage in Shafie and Zahiri schools (Saiful Azhar Rosley, 2005).

Figure 5: The flow of product development process (Islamic Bank of Thailand, 2011).



CONCLUSION

Gaining competitive advantage should be following some schema of knowledge creation. Having sufficient and appropriate knowledge that are created and tailored to specific needs of a banking institution would be very useful so that it could create, refine, improve and eventually offer product and services at customers' preferences. The research shows that the most influential factor in Islamic banking is Shariah. The product must meet the requirement of Shariah first before offering to a market. Secondly, the Islamic Bank of Thailand is following the model in developing a competitive product in order to fulfill market's needs. Even though Islamic products have to be compliant to Shariah but the law is flexible and can create competitiveness by looking at different schools of thought. The research proves that the Dialectic Model is an appropriate approach for creating new knowledge and the necessity of that knowledge in assisting Islamic banking institutions gaining competitive advantage. However, the main obstacle for Islamic Bank of Thailand is a regulation regarding taxation. We recommend for a further research to conduct a research in finding a solution to wave tax for the Islamic banking system because the bank has to pay double taxes, which are social obligation (zakat) and company income tax. The current Banking Act in Thailand makes the bank becoming less profitable.

KNOWLEDGE MANAGEMENT AND PROJECT MANAGEMENT

Radosław Paliszkiewicz, Business Excellence, Poland

joanna_paliszkiewicz@sggw.pl

ABSTRACT

On a global basis, organizations are recognizing the importance of knowledge as a means of gaining or sustaining competitive advantage. Researchers have concluded that the only thing that is sustainable for successful businesses in the New Millennium – is what it knows, how it uses what it knows, and how fast it can know something new. Many organizations are primarily knowledge-focused and project oriented. They obtain data and information and produce either a product or service. In the project management process they use their own, and other's, knowledge and information. Much of the knowledge in an enterprise is grounded in the minds of employees. Past experience and internal learning create processes, insights, methodologies, know-how and understanding that represent what the business is and how it adds value. Since knowledge is the most basic of all competencies, its localization, acquisition and development, transfer, codification and application should be a critical success factor for attainment of a competitive advantage. In the article the knowledge management and project management concepts are described.

Keywords: knowledge management, project management, knowledge, information

INTRODUCTION

The role of knowledge as the key source for competitive advantage in enterprises has become very important. The idea that knowledge can be managed is fundamental to the related notions of the knowledge-based business, the learning enterprise and the management of intellectual capital. The recent interest in these overlapping concepts reflects important phenomena, which enterprises have to deal with, such as perceptions of increased competition, rates of change and market turbulence. Enterprises are hence looking for new ways to remain in business or compete effectively. One crucial way to achieve effectiveness is to recognize or rediscover assets the enterprise already has but is not utilizing to their full potential. Knowledge is a vital resource in project-based industries such as aerospace, construction, shipbuilding and software. If managed effectively, knowledge can be used to reduce project time, improve quality and increase customer satisfaction. However, the management of intellectual assets is a new and challenging process for project-based industries.

Identification of critical knowledge and the ability to utilize it is a challenge for any project organization. Successful project management is based on accumulated knowledge, and, on the other hand, on individual and collective competences.

In this paper knowledge management and project management concepts were described. The differences and possible synergies between these two conceptions were presented.

THE CONCEPT OF KNOWLEDGE MANAGEMENT

A useful way of arriving at a definition of what knowledge is can be achieved by differentiating it from what it is not. One of the most common distinctions in the contemporary knowledge literature is between knowledge, information, and data. Data is a set of discrete, objective facts about events. Information is a message, usually in the form of a document or an audible or visible communication. As with any message, it has a sender and a receiver. Information is meant to change the way the receiver perceives something, to have impact on his judgment and behavior. Knowledge is broader, deeper, and richer than data or information. Knowledge can be understood to emerge from the application, analysis, and productive use of data and/or information. In other words, "knowledge can be seen as data or information with further layer of intellectual analysis added, where it is interpreted, meaning is attached, and is structured and linked with existing systems of beliefs and bodies of knowledge" (Hislop, 2005).

In organizations, knowledge often becomes embedded not only in documents or repositories but also in organizational routines, processes, practices, and norms. Knowledge is a mixture of various elements; is fluid as well as formally structured; is intuitive and therefore hard to capture in words or understand completely in logical terms. Knowledge exists within people, part and parcel of human complexity and unpredictability.

There are many definitions of knowledge management, for example Gupta et al. (2000) defined it as "a process that helps organizations find, select, organize, disseminate and transfer important information and expertise necessary for activities such as problem solving, dynamic learning, strategic planning and decision making". According to Awad and Ghaziri (2004) knowledge management is a newly emerging, interdisciplinary business model that has knowledge within the framework of an organization as its focus. It is rooted in many disciplines, including business, economics, psychology, and information management. It is ultimate competitive advantage for today's firm. Knowledge management involves people, technology, and processes in overlapping parts. Liebovitz (2003) considered it as dealing with capturing, sharing, applying and creating knowledge in an organization to best leverage this resource internally and externally. Dunn and Neumunster (2002) define knowledge management as a systematic approach to managing and leveraging an organization's knowledge assets, which may include knowledge of the organization's customers, products, markets, processes, finances and personal services. Novins (2002) shortens the definition to simply say knowledge management can be thought of as packaging the right content and delivering it to the right people who can make use of it at the right time.

Organizations possess two kinds of knowledge: external and internal. External knowledge reflects awareness of regulations, competition and market trends, as well as the ability to anticipate a market. Internal knowledge includes an understanding of core competencies, know-how, strengths, weaknesses and lessons learned from past experiences (Frappaolo 2000).

All organizations generate and use knowledge. As organizations interact with their environments, they absorb information, turn it into knowledge, and take action based on it in combination with their experiences, values, and internal rules. Without knowledge, an organization could not systematize itself; it would be unable to maintain itself as a functioning enterprise. Knowledge generation means the knowledge acquired by an organization as well as that internally generated and developed within it. Acquired knowledge does not have to be newly created, only new to the organization. There are five modes of knowledge generation in organization (Davenport, Prusak, 1998):

1. Acquisition. The most direct and often most effective way to acquire knowledge is to buy it – that is, to buy an organization or hire individuals that have it. Outside knowledge can be leased or rented. A common type of acquisition is a firm's financial support of university or institutional research in exchange for exclusive rights to commercial use of promising results. Renting knowledge really means contracting a knowledge source. Hiring a consultant for a project is an obvious example. Using reputation as a key measure of value, a company will pay a consultant fee to share in that consultant's knowledge or apply it to a particular project.
2. Dedicated resources. A customary way to generate knowledge in an organization is to establish units or groups specifically for that purpose. 'Research and development' departments are the standard example. Their whole aim is to gather and come up with new knowledge – new ways of doing things.
3. Internal fusion. Knowledge generation through internal fusion purposely introduces complexity and even conflict to create new synergy. It brings together people with different perspectives to work on a problem or project, forcing them to come up with a joint answer.

   Here are five knowledge management principles that can help make fusion work effectively:
   - Foster awareness of the value of the knowledge sought and a willingness to invest in the process of generating it.
   - Identify key knowledge workers who can be effectively brought together in a fusion effort.
   - Emphasize the creative potential inherent in the complexity and diversity of ideas, seeing differences as positive, rather than sources of conflict, and avoiding simple answer to complex questions.
   - Make the need for knowledge generation clear so as to encourage reward, and direct it toward a common goal.
   - Introduce measure and milestones of success that reflect the true value of knowledge more completely that simple balance – sheet accounting.
4. Adaptation. A company can adapt new products from competitors or new technologies. A firm's ability to adapt is based on two principal factors: first, existing internal resources and capabilities that can be utilized in new ways, and second, being open to change or having a high "absorptive capacity." The most important adaptive resources are employees who can acquire new knowledge and skills easily.
5. Networks. Knowledge is also generated by informal, self-organizing networks within organization that may over time become more formalized. Communities of knowers, brought together by common interests, usually talk together in person on the

telephone, via e-mail and groupware to share expertise and solve problems together.

Alavi and Leidner (2001) note that knowledge may be viewed from five different perspectives:

- state of mind perspective, emphasizing knowing and understanding through experience and study;
- object perspective, defining knowledge as a thing to be stored and manipulated;
- process perspective, focusing on knowing and acting;
- condition perspective, emphasizing access to knowledge;
- capability perspective, viewing knowledge as a capability with the potential for influencing future action.

These different views of knowledge lead to different perspective of knowledge management:

- IT perspective, focusing on the use of various technologies to acquire or store knowledge resources (Borghoff, Pareschi, 1998). As knowledge is viewed as an object, knowledge management should focus on ensuring that explicit knowledge, available in the form of knowledge items, is widely accessible across an organization;
- Socialization perspective, focusing on understanding the organizational nature of knowledge management (Gold, Malhotra, 2001; Becerra-Fernandez, Sabherwal, 2001). Knowledge management should focus on supporting the processes of sharing, creating, and disseminating knowledge;
- Information system perspective, focusing on both IT and organizational capability and emphasizing the use of knowledge management systems (Schultze, Leidner, 2002; Tiwana, 2001). The right knowledge management strategy should be put in place to develop and nurture core organizational competencies, and create intellectual capital.

Thus far, a number of researchers have attempted to classify the major activities of knowledge management. For example Nonaka and Takeuchi (1995) focused on the dynamics of knowledge activities and suggested that the four major activities of knowledge management are socialization, externalization, combination and internalization. Despite its seminal contribution, this list of activities is too conceptual and even philosophical to be used in actual practice. Other versions are abundant. For instance, Tiwana (2000) suggested three fundamental activities, acquisition, sharing and utilization. Ruggles (1997) proposed such activities as generation, codification and transfer. Marquardt (1996) suggested four activities, acquisition, creation, utilization and storage. Wigg's (1993) version consists of four activities: creation and sourcing, compilation and transformation, dissemination, and application and value realization. Van der Pek and Spikervet (1996) proposed four activities: developing, securing, distributing and combining. Some other researchers presented more extensive frameworks consisting of six activities, namely acquire, select, internalize, use, generate and externalize (Holsapple, Joshi, 2002), or eight activities: identify, capture, select, store, share, apply, create and sell (Liebowitz, Beckman, 1998).

According to Paliszkiewicz (2007) knowledge management consists of five processes: localization, acquisition and development, transfer, codification, and usage. Knowledge

localization includes all activities, which indicate, where knowledge exist. Knowledge acquisition and development includes the knowledge acquired by an organization as well as that developed within it. Acquired knowledge does not have to be newly created, only new to the organization. Knowledge transfer is transmission of knowledge (experience, lessons learned, know-how) and use of transmitted knowledge. It is conveying the knowledge of one source to another source. Knowledge codification is the capture of knowledge so that it can be re-used either by an individual or by an organization. The aim of codification is to put organizational knowledge into a form that makes it accessible to those who need it. If knowledge management is to thrive, organizations must create a set of roles and skills to do the work of using knowledge.

Lin and Kim (2001) propose that organizational capability of knowledge management grows through the following four stages: initiation, propagation, integration, and networking. The stages in life cycle theory are sequential in nature and hierarchical in progression (Quinn, Cameron, 1983; Van de Ven, Poole, 1995). Therefore, each stage of the suggested model can be seen as a necessary precursor of the succeeding stages.

The first stage is an initiation stage in which organizations start to recognize the importance of organizational knowledge management and prepare for enterprise-wide knowledge management efforts. Environmental pressures such as rapidly changing socioeconomic and technical factors, globally increasing competition, and changing customer demands for knowledge-intensive products or services enforce the implementation of knowledge management (Demarest, 1997; Myers, 1996; Prusak, 1996). Consequently, organizations should clearly specify shared visions and goals of knowledge management and disseminate them over the whole organization through diverse communication channels.

The propagation stage is a stage where organizations start to invest in building their knowledge infrastructure to facilitate and motivate knowledge activities such as creating or acquiring, sharing, storing, and utilizing. Since organizations have already prepared for their knowledge management initiatives in the previous stage, the real enterprise- level efforts for knowledge management can start from here.

The integration stage is where organizational knowledge activities are institutionalized as daily activities over the whole organization. Management focus is placed on the integration of organizational knowledge and knowledge activities. As all organizational members become familiar with knowledge activities, the level of knowledge activities and knowledge accumulation reaches its highest levels.

The final networking stage is an external integration stage where organizational knowledge is networked not only within an organization but also with external entities such as suppliers, customers, research firms, and universities. As more and more organizations initiate knowledge management efforts, sustainability of competitive advantage from knowledge management becomes harder to come by. Generally, under the more severe competition, organizations usually concentrate its resources and executive time on core activities where it can perform at the best-in-the-world levels (Quinn et al., 1996). Organizations at this stage will also start to focus their organizational efforts on specialized core knowledge and outsource other needed knowledge from outside.

Organizations need to establish teaching and dissemination standards for their business to enable them to manage their knowledge assets better.

They are required to meet the following conditions (Macintosh, Filby, Kingston, 1999).

1. Promote the importance of knowledge management and the awareness of how knowledge management is to be achieved within, and across, operational divisions.
2. Create an awareness of a framework to achieve knowledge management.
3. Develop a skill base of personnel who have knowledge management skills to enable them to facilitate the development, use and sharing of the organization's knowledge assets.

Management of knowledge assets is difficult for reasons such as the following (Macintosh, Filby, Kingston, 1999).

- Knowledge exists at different levels of abstraction whose relevance depends on the user;
- The value and acceptability of knowledge varies greatly depending on the user;
- Knowledge does not have a fixed quality, it becomes out of data as time elapses;
- Knowledge is intangible and often incomplete, and is therefore very difficult to describe.

THE CONCEPT OF PROJECT MANAGEMENT

According to definition, a project is a complex, non-routine, one-time effort limited by time, budget, resources, and performance specifications designed to meet customer needs (Gray, Larson, 2006). It can also be viewed as a set of temporary activities conducted by an ad hoc organization (Olson, 2004). A project has a definite beginning, definite ending, and has several interdependent tasks. Unfamiliarity and uniqueness are also often described as characteristics of a project. As a discipline, project management is assuming importance similar to other disciplines in an organization such as engineering (Rad, Levin, 2002).

Organizations that support such non-routine, one-time efforts are known as project organizations, where functional lines of authority are not key to organizational success. The project organization is highly conducive to innovation, since new products and processes evolve from new ideas discovered during cross-functional, team-working interaction. This type of environment is often viewed as a vehicle for change and improvement, generally resulting in significant benefits for the company.
Project organizations are generally composed of many project teams carrying out several projects for an organization at once. Project teams are groups of people with the unique, specialized skills that come together to accomplish a particular assignment. The core of a project team includes the roles of project manager, task leaders and project expediters (or coordinators).

According to Microsoft's Sure Step Methodology, there are six phases in IT projects: diagnostic, analysis, design, development, deployment and operations. Every phase is defined by activities and products delivered by involved parties.

1. Diagnostic phase – starts simultaneously with the sales and quoting process, while basic requirements for customer's project are being gathered. The main target of

this phase is definition of key requirements, project goals, pointing of key business processes included in the project and presentation of rough project plan and scope. As the result of the phase is signed contract between parties and formal decision of project startup.

2. Analysis phase – is official start of the project. Detailed business analysis is being conducted to gather definition of customer's requirements in context of new project. The main target of this phase is creating and approval of Functional Requirements Document, which is the basis of design and development work. Also formal documents are created, such as Project Charter and Project Schedule.
3. Design phase – starts after the functional requirements (business analysis) are approved and signed. The phase covers design of specific system solutions for every identified process and procedure. The key products of the phase are Functional Design Document describing mappings of recognized procedures to standard system features and Technical Design Documentation describing adjustments of standard system for every identified functional gap.
4. Development phase – covers configuration and programming for every identified and planned business processes. The products of this phase are: prepared technical infrastructure and finalized solution, including programming of extensions, integrations and required data migration modules.
5. Deployment phase – is preparation of the company for startup of new system, what includes final set up of environments, users training and data migration. Main products of the phase is go-live-plan, results of acceptance and performance tests. The final step of the phase system Go Live.
6. Operations phase – focuses on support for the customer in the first period of system usage. The project is being closed and transited to service and maintenance. Main products of the phase are Project Closing Document, Lessons Learned and Service Level contract for support services.

KNOWLEDGE MANAGEMENT AND PROJECT MANAGEMENT

Project management and knowledge management disciplines are related. Both the disciplines have some common aspects and differences. Some of these aspects (*purpose, focus area, time, functions, communication, organizational structure, technology, organizational knowledge, investment*) are discussed below to develop a better understanding of both the disciplines and their relationship.

Purpose

The purpose of project management and knowledge management differ as their goals differ. From its definition, it is clear that project management is concerned with completing a project on time, within budget, and according to the project specifications while satisfying both the customer and project team expectations. A knowledge-based organization attends to two related processes that underline these direct processes: the effective application of existing knowledge and the creation of new knowledge. The goal is fourfold: to ensure that knowledge from one part of a company is applied to activities in other parts; to ensure that knowledge is shared over time so that the company benefits from past experience; to make it possible for people from various parts of the organization to find one another and collaborate to create new knowledge; and to provide opportunities and incentives for

experimentation and learning. Knowledge management is a deliberate effort to develop knowledge and apply it to improve performance throughout the enterprise.

Focus area

The focus areas of project management are: schedule, cost, scope, performance, and customer satisfaction. Knowledge management focus areas are: delivering innovating products and making process more innovating, faster work, cheaper work, better quality, and respecting customer needs. Both project management and knowledge management are practical and action-oriented disciplines. Though projects aim is to meet organization goals, the focus level of project management is confined to projects whereas knowledge management focuses on enterprise level and improvements in performance.

Time oriented perspective

The project aim is to realize the goal in the given time by the project team. Knowledge management is requiring a long-term time period and significant organizational resources such as human power, capital and managerial efforts (Davenport, Prusak, 1998; Prusak, 1996). Therefore, organizations need to make a long-term plan for organizational change into a knowledge management paradigm strategically and systematically. Building a special team for initiating knowledge management and the acquisition of the needed human resources and budget are prerequisite activities.

Functions

Project management is a discipline that involves planning and controlling functions in the process. Project management is very much concerned with working together in teams, learning from each other, sharing knowledge, and collaborating on efforts to improve efficiency and effectiveness of projects. The activities - working in teams, learning from each other, and collaborating to improve efficiency and effectiveness - are also an integral part of knowledge management. Mentoring and shadowing are examples of knowledge sharing techniques that project managers can use in order to transfer tacit knowledge for improved succession planning, leadership, and teamwork. Equally important are the issues of the role of the project manager in selection and recruitment, performance management, contract administration, and the importance attached to individuals and subcontractors with requisite knowledge, competencies, and wisdom as part of the wider intangible assets. Knowledge management should play an integral part of an organization's human capital strategy to encompass the various types of knowledge from these individuals and organizations (Liebowitz, Megbolugbe, 2003). Knowledge management uses activities connected with knowledge sharing to accomplish its objectives of improving efficiency and effectiveness.

Communication

Effective communication is a critical success factor for both project management and knowledge management disciplines. The larger and more complex the project is, the greater importance assumes the communication, as the number of communication channels is associated with the number of people and disciplines involved in a project. The main functions of knowledge management – localization, acquiring and developing knowledge, transfer, storing the knowledge efficiently, and utilizing knowledge – rely on communicating effectively and efficiently. While project communications are generally real-time, knowledge

management communications can be real-time and can happen after the knowledge has been discovered originally. Knowledge management may help improve communications and provide more informed knowledge to the project manager and project team. In this manner, project goals and objectives could be better articulated and shared among the team members. Additionally, knowledge management systems could be created to ensure a better sharing of best practice documents, lessons learned, project management and systems engineering methodologies.. For example, it can be done by building a Project Management Web Site to have a repository of documents to help the various flight programs and projects in seeing what others have done. These documents are being linked to each stage of project development.

*Organizational Stru*cture

Both of the disciplines influence the structure of an organization. However, project management's influence in changing organization structure is more obvious. Many organizations, which are routinely involved in multiple projects, changed their organizational structures from functional organizations to pure project or matrix organizations.

In knowledge management the main concerns of organizational managers at this point are how to build knowledge structure efficiently and how to expand knowledge activities. The organizational structure includes a measurement and reward system (Tampoe, 1996), human resource management such as training and education, promotion, recruiting policies (Quinn et al., 1996), flexible organizational structure (Nonaka, 1994), and guidance oriented leadership (Von Krogh, 1998; Senge, 1990). Additionally a complete knowledge management process is defined and applied enterprise-wide, including the related rules and policies as well as a permanent team for enterprise knowledge management. In creating appropriate knowledge structure also important are informal networks such as communities of practices.

Technology

Contrary to common beliefs, both are not dependent on technology as it has only a supportive role for these disciplines. Project management uses technology tools such as project management application software and risk analysis software to plan, monitor, analyze, and control project performance. Knowledge management uses information technologies, especially communication and database technologies, to facilitate and support the knowledge management activities (Earl, 1996). The most popular and common approach is implementing a knowledge management system or knowledge repository system to help organize the enterprise-wide knowledge resources (O'Leary, 1998; Liebowitz, Wilcox, 1997; Ruggles, 1998). The computational power of computers has little relevance to knowledge work, but the communication and storage capabilities of networked computers have made them 'knowledge enablers.'. Through e-mail, groupware, Internet, and Intranets, computers and networks can indicate people with specific or required knowledge and connect those people who need to share given knowledge over a distance. Desktop videoconferencing and multimedia computing that transmit voice and video, as well as text, make possible to interface the richness and subtlety of one person's knowledge with others. What we must remember is that this new information technology is only a pipeline and storage system for knowledge exchange. However, these technology tools in both the cases (project management and knowledge management) do not create knowledge and cannot

guarantee or even promote knowledge generation or knowledge sharing in an organizational culture that doesn't endorse such interfacing activities.

Organizational knowledge

People involved in projects are not only organizationally but also geographically dispersed. They have diverse backgrounds and may speak several languages. For example, in order to develop a new product, a company may bring in people from suppliers, clients and universities. But projects are temporally limited, and the people involved, and the lessons learned are dispersed when the project ends. The people often join or leave project during its time being. Sometimes it is difficult to find people who have been involved in a project from its beginning. Combined with employee empowerment and information decentralization typical to project organizations, this results in organizational knowledge fragmentation and loss of organizational learning (Jarvenpaa, Ives, 1994). Knowing about sources and types of knowledge and people who create it in each phase of project can guide for better feedback system. One of the main challenges of project management should be recording knowledge from the projects. In knowledge management there are two basic strategies for storing knowledge (Hansen, Nohria, Tierney, 1999). The codification strategy is based on codifying the knowledge and storing it in artifacts and databases where it can be accessed. In the personalization strategy, the knowledge is tied to persons who develop it and it is shared by personal interaction. In the codification strategy the firms do big investments in information technology, which enable them to gather, codify and transfer the formal knowledge into documents and reports. In the personalization strategy the companies have moderate investment in information technology, they are more interested in sharing knowledge between people.

The projects interact with knowledge base of the firm in three principal ways:

1. Knowledge mobilization. Because even the existing knowledge of the firm is not always sufficient to meet project objectives, projects often have to act to mobilize and absorb knowledge from the wider environment;
2. Knowledge creation. Projects often create new knowledge. This knowledge may take several different forms depending on whether it is embodied in new products and services, designed into new processes or institutionalized as new practices. This new knowledge may be created both directly as one of the deliverables from the project, and indirectly through the learning involved in achieving that deliverable;
3. Knowledge integration. Project implementation often requires combining skills and ideas from disparate sources. In many instances, this combination is short-term and project-specific. In other words, knowledge is combined to serve the goals and deliverables of the project, but is thereafter allowed to disperse. In some instances, however, the combination produces a synthesis that is of long-lasting value to the organization.

Investment

Both project management and knowledge management disciplines need investment and demand results. While a project size determines the resources and investment needed, investment on project management within an organization depends on the goals of project performance excellence set by the organization. The scope - what we intend to accomplish - of knowledge management determines its investment needs. For successful implementation

of project management and knowledge management, we need to make changes in policies, practices, and procedures train people at all levels make changes to accounting and finance control systems. While project management demands project-based finance and cost control mechanisms, knowledge management introduces innovative cost measuring concepts such as recognizing and accounting for intellectual capital.

CONCLUSIONS AND IMPLICATIONS TO MANAGERS

In such a changing environment modern organizations have to react fast and be flexible, so organizing by projects is on a strong increase. They need to use knowledge management in their projects to manage knowledge such as other tangible resources. In different phases of projects, types of knowledge and involved people and varieties and amount of information need special policies and tasks for management. Knowledge creation can be seen in all phases. According to the authors integrating knowledge management with project management could be desirable and result-oriented because the integration improves project management performance and meets its objectives of time, cost, performance, and customer satisfaction more effectively. There can be several examples highlighting the benefits of integrating knowledge management within project management. Utilizing actual cost data and earned value data of previously executed projects to improve project cost estimating is an example of how a knowledge management concept of learning can help improve project management performance. Knowledge management can enhance the project manager's activities by being better able to leverage knowledge internally and externally through improved knowledge sharing techniques among the project team.
It is important that project-based organizations progress their knowledge management initiatives. This means:

- Ensuring that the organizations start to explicitly identify their knowledge assets and knowledge management related processes;
- Ensuring that the organization starts to control and manage these assets and processes;
- Ensuring that professionals in the organization are aware of the importance of the organization's knowledge assets and are aware of existing knowledge management related processes.

ABSTRACT

In today's rapidly changing market and technological environment, manufacturing companies often raise questions about the most efficient way of product commercialization. In times of global crisis and situations of increasingly competitive struggles, product managers should take proactive product strategy with the potential of far-reaching effects in the future. It seems that product trainings also play a crucial role. Product trainings allow all actors participating in marketing mix related processes to acquire appropriate knowledge about product and its components. They increase productivity and flexibility, enhance work skills and influence the product management efficiency. Results of a research among Slovenian domestic appliance companies show a direct impact of a combination of trainings and training transfer factors on marketing mix. We believe that support provided by product managers and supervisors strongly impacts the sales revenue.

Keywords: product management, training, training transfer factors, marketing mix

INTRODUCTION

In the last decade domestic appliance industry is facing with a challenge of explosive demand for new and improved products as well as the availability of new technologies for production and delivery of such products which generates additional demands on the system (O'Connell, 1996). This situation accelerates the rate of a change and it produces an "evolved" system which attempts to respond to changes on marketplace (Katsanis and Pitta, 1995). The product and technology complexity which is actually the base for communication with customers, addresses external and internal marketing needs as well. Therefore many companies are of the opinion that product training is a top priority for them (Neff, 2002). Despite the importance of the role product managers have for the marketing function and for new product introduction, there has been little research conducted on the matter of product managers' training.

TRAINING

Training is defined as the systematic development of skills that individuals need to perform their work (Miglič, 2002). Individuals should take their own responsibility for their professional development but realise their learning needs in partnership with their colleagues at work and their direct superiors using different teaching methods (Torrington, Hall and Taylor, 2008). Armstrong (2003) and Torrington et al. (2008) identify a range of different approaches to training. They state that the training may be based on different

methods of teaching – both off-the-job teaching methods (formal education, consultancy courses, outdoor-type courses, in-house courses, dramas and improvisations, role-plays, simulations etc.) as well as on-the-job teaching methods (instructions, mentoring, self-development, self-development teams, the use of learning logs and learning contracts, e-learning, blended learning etc.)

The volume of trainings in an organisation relates to the degree of uncertainty and unpredictability of the products, markets and R&D (Blandy et al., 2000). By means of various trainings organisations reduce the possibilities of unpleasant surprises and enhance the well-being of their employees (Armstrong, 2003). Trainings increase the value of individuals in the labour market; enhance their satisfaction with the current work and thus their loyalty to the organisation (Torrington et al., 2008). Consequently training reduces staff turnover (Blandy et al., 2000) and increases organisation's revenues and profits (Bontis, 2003). Because of these potential benefits a significant rise in the amount of training inside the organisations (Campbell, 2006; Sugrue, 2003) and in the number of the participants could be expected (Blandy et al., 2000).

Dechawatanapaisal and Siengthai (2006) consider that adequate opportunities for training should be offered to the employees. Garvin, Edmondson, and Gino (2008) say as well that all the employees in an organisation should receive periodic training. In particular, they highlight the importance of training for new employees and training in cases of special events in the organisation and emphasise the need to train employees when new business or work initiatives emerge, as well as in cases of employees' transfer to other posts or changes to the content of existing jobs. Jarvis, Holford, and Griffin (2006) consider that training in the past was highly stratified. Mostly the upper levels of organizational hierarchies benefited from the training, and on the other side the lower levels very little or nothing. Situation in the last 50 years has changed (Trunk Širca et al., 2009). Blandy et al. (2000) for example, reported that the majority of organisations train 80-85% of their employees. On the other hand problems in smaller organisations due to weak attitude towards training are still present. Managers in small businesses are often unaware of the potential benefits of training (Storey and Westhead, 1997) and afraid that their well trained staff could be head-hunted by bigger and more powerful corporations (Carter and Jones-Evans, 2006).

TRAINING TRANSFER FACTORS

Practice and theory of training acknowledge a variety of so called training transfer factors. These factors encourage transfer of knowledge acquired within a certain training context to a certain work context and thus positively contributing to the performance of individual employees and an organisation as a whole (Holton III, Hsin-Chih, and Naquin, 2003). The causal link between changes in behaviour and performance of individuals and organisational performance is anticipated also by Kirkpatrick's training evaluation model (Kirkpatrick 1998). Regarding the training transfer some authors emphasise the need for systematisation of training activities, for careful planning of training events and for the use of monitoring activities. Externalisation and recording of tacit knowledge seems to be important as well, and the use of adequate teaching methods including reflexive thinking, team-based approaches to learning, practical work tasks and project work (Bader and Bloom, 1995).

Baldwin, Magjuka, and Loher (1991) among the others, note that performing some specific managerial activities before the training could have a relevant influence on the perception of the importance of training, on learning motivation and later on also on training transfer. Standpoints of managers and superiors and their actions can be a significant signal for the employees since they affect not only the process of learning but individual and organisational behaviour as well (Wieland Handy, 2008). So, we certainly need to emphasise the meaning of training support provided by both work colleagues (peers) and direct superiors in an organisation.

THE ROLE OF PRODUCT TRAINING IN COMPANIES

Meža (2009) defines product management as a kind of a messenger of a market. It directly transfers clear information about a market and market happenings to different departments in a company which need such information to make their business decisions. Nowadays, in the times of severe competition and constant price pressures, this should be a permanent activity of product managers to care for cost reduction of product cycles.

Each product in a company has to be closely related to the wishes and needs of the customers and to the market as a whole. It should also be compared to the competitive products on the market to see and stress out its advantages and to solve possible problems related to its weaknesses. The product position on the market can be defined as the combination of product quality and its characteristics perceived by the customers. Adequate product positioning on the market is necessary in order to successfully carry out company strategy.

Summing up the activities of the product management, the product managers are responsible for:

- collecting and analysis of market information, information about competitors and the perception of new trends,
- working on development of new programs,
- supporting the sales department when new products, product families and product lines are launched onto the market,
- price positioning and setting the prices for new products,
- performance monitoring of a product group.

Product management core activities are by no means focused on a product and/or on management activities. They are related to direct participation in project development and in planning of new products. The outcomes of the product management work can be judged by the product quality or the level its success. Certainly, we should note, that there are some products which are more likely to be successful on the market, and there are others, which might be unsuccessful as well.

On the other hand, domestic appliance industry is facing a crisis nowadays. Some authors (Meža, 2009) suggest variety of possibilities to solve or even prevent such product crises. Product management and product training could play an important role in avoiding and preventing potential product crises resulting in inefficient market communication, weak commercialization of novelties/changes (due to poor advertising start and inadequate

advertising strategy). Therefore product training is inherently related to cycle time reduction activities. When considering trainings for new salespeople and customer about product, the implicit assumption is, that the benefits of such training should be improved product sales, better product introduction on market, improved brand image, etc. By our opinion product training in the industry of domestic appliances plays an important role.

THE MODEL OF PRODUCT TRAINING

Product managers should understand that they have to use multiple marketing tools (product, price, place, promotion) to enhance the quality and relevance of product training. Actually, the very well known 4Ps should represent an important tool for influencing customers' choices (Kotler, 2009). On the other hand, from the customer's perspective, each marketing tool is supposed to deliver a customer benefit ("C") (figure 1). We propose to use these two approaches in a way which enables the product training to play an important, active role in connecting 4Ps and consumer's 4Cs and consequently in the customer value creation. In general, product training should be designed in a way to affect all the categories of 4Cs customer needs, customers' perception of costs, convenience/choices customer have and communication possibilities for maximizing the possibilities for influencing the customer choices.

Product training should be based on proper training content and on appropriate training methods as well. When designing the training, these two ingredients should be considered at the same time and should be carefully discussed with product managers as well. We propose the following four-outcome measurement schema for designing the product training:

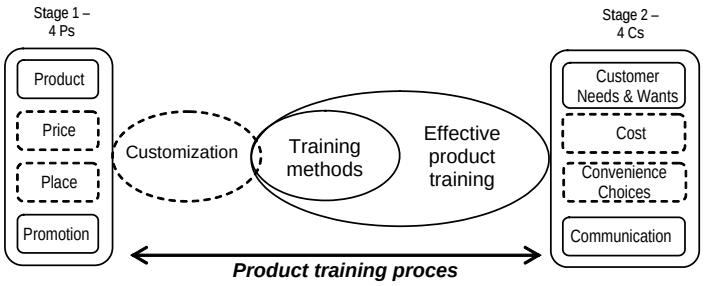

Figure 1: Model of Product training system.

As already mentioned, at the same time as the training content is outlined and the relations between 4Ps and 4Cs identified, training methods should be selected as well. In our case a training method is a strategy or tactics that a product manager (trainer) uses to deliver the message to the participants of the training so that the product training achieves its objectives. There are, however, a variety of techniques for conveying information to 4C and therefore one or a mix of several training methods can be used. These are shortly described in table 1.

Table 1: Training methods for Product training (adapted from Carey, 1999).

Training method	Description
Lecture	• Mostly an oral presentation, but may be supplemented with visual aids or handouts. • The technique is generally confined to presenting only the expert's point of view. • Often used because it is easier to organize and a great deal of information can be presented in a short period of time. • Useful when there are large groups of trainees.
Lecture/Discussion	• Variation of the lecture where the trainer increases trainee participation through facilitation of discussion at set times during the session. • Discussion is often initiated through the use of questions. • Trainer must plan the discussion and carefully choose the questions to lead the discussion
Demonstration	• Oral explanations combined with visual activities. • Method demonstrations show processes, concepts and facts and are especially effective in teaching a skill that can be observed. • A result demonstration shows the outcome of some practice or innovation, such as unique sales features, product operation etc.
Group discussion	• Trainer leads the trainees as a group through a discussion of a given topic. • May or may not be preceded by a short explanatory lecture.
Symposium	• A series of lectures presided over by a moderator. • Allows for the presentation of several points of view or several related topics.
Panel	• A dialogue among several experts sitting in front of the room. • A moderator coordinates the discussion. • Differs from a symposium because panel members have an opportunity to discuss and interact with each other's ideas and views.
Forum	• Following one or more presentations, the audience interacts and discusses the topic(s), bringing up a wider range of views
Discussion groups	• Involves every member of the audience in a small group (4 to 20 people per group). • Groups may have a pre-selected or self-elected leader. • The groups may be given a specific topic or asked to develop a list of problems, issues, priorities, questions, etc. and report back to the main group. • Discussion groups encourage/allow everyone to participate, even if the audience is large. • Groups should be monitored to insure that one person is not dominating the activities.
Case studies	• Information is given to the trainees detailing a specific situation or problem and the trainees are assigned (as individuals or discussion groups) the task of making recommendations for the most appropriate action to solve the problem. • Introduces a practical aspect to the training environment and creates a problem solving situation similar to that many trainees may face after returning to work.
Field visits	• A visit to an organization or workplace, such as a production plant or trade show, that demonstrates the practical application of the ideas under discussion. • Care must be taken that the place to be visited is aware of the objectives of the field trip. • Adds a practical aspect to the training • Trainees need to be properly prepared for the visit and should be encouraged to make specific observations.

METHODOLGY

To evaluate the product training issues incorporated in marketing mix categories, a study was commissioned. Project managers in 7 companies were chosen as product training providers. The purpose of the research and data collection was to find actual and relevant training methods for different 4Ps categories (see table 2) described and presented in the Model of Product training system (see fig. 1) and also key contents which are relevant for each of the 4Ps categories and consistent with the chosen methods of teaching.

We developed an interview approach to find out which training methods are relevant to each one of the 4Ps categories. The target population of the training were customers. The results of the study are presented in table 2

Table 2: Training methods utilized by 4P components.

Element of 4 P	Training method	Content
PRODUCT		
Assortment	Lecture, Lecture/Discussion, Field visits	Workbooks/manuals, Market/customer knowledge
Quality	Lecture/Discussion, Demonstration, Case studies, Field visits	Workbooks/manuals, Company policy
Design	Lecture/Discussion, Field visits, Group discussion, Symposium, Panel, Forum, Discussion groups	Product education Team work
Feature	Lecture, Lecture/ Discussion, Demonstration , Field visits	Workbooks/manuals, Product education
Brand	Lecture/Discussion, Group discussion, Panel, Forum, Field visits,	Workbooks/manuals, Product education, Team work, Sales techniques
Service/Warranty	Lecture/ Discussion, Group discussion	Workbooks/manuals, Company policy
PRICE		
Price-value	Lecture/Discussion, Demonstration, Discussion groups, Field visits	Product education, Workbooks/manuals, Market/customer knowledge
Discount	Discussion groups, Field visits	Team work, Sales techniques
Payment terms	Discussion groups, Field visits	Sales techniques, Company policy
PLACE/DISTRIBUTION		
Sale channels	Discussion groups, Field visits	Sales techniques, Company policy, Market/customer knowledge
Market share	Lecture/Discussion, Demonstration, Discussion groups, Field visits	Market/customer knowledge, Company policy
Public relation	Lecture/Discussion, Symposium, Panel, Forum, Field visits	Product education, Workbooks/manuals, Market/customer knowledge, Company policy
PROMOTION		
Advertising	Lecture/Discussion, Demonstration, Discussion groups, Field visits	Workbooks/manuals, Product education, Sales techniques, Company policy

After the best training methods and training contents had been gathered, we focused our research into finding out which training methods should be used at each stage of New Product Introduction (NPI) project phases (see table 3). The majority of the training methods used in different phases of NPI are participant focused demanding high level of their participation. This is an important guideline for the organisation of such events because such approaches to product trainings require trainers with appropriate social skills.

Table 3: Training methods provided in NPI project phases.

Phase of NPI project	Training method used	Project objective
Scoping phase	Case studies, Field visits, Group discussion	Scope project & develop concepts
Feasibility phase	Case studies, Case studies, Group discussion	Detailed investigation & prototyping
Justification phase	Group discussion, Panel, Demonstration	Develop business case
Development phase	Group discussion, Panel	Product development
Manufacturing phase	Group discussion, Panel	Operational Ram-Up
Launch phase	Lecture/Discussion, Demonstration, Case studies, Field visits, Group discussion, Symposium, Panel, Forum, Discussion groups	Commercial phase

CONCLUSIONS

Product training seems to be an important mechanism for introduction of new products in domestic appliance industry. This is especially important because the competition in this industry is getting stronger nowadays. In our paper we recognise a variety of training methods which influence customers' needs, lower their perceptions of costs, enhance their convenience/choices and communication possibilities. They stem from marketing mix components and have the power for maximizing the possibilities for influencing the customer decisions. The training methods should be related to training contents as well. The findings of our research are especially important to product managers who are usually responsible for organising such trainings.

In this paper, when referring to the Model of Product training system, we recognize the training methods and contents which could help the companies to successfully introduce new products. In the literature there aren't practically any studies examining such issues – studying the causal links or correlations between the new product introduction and training. Therefore, we recommend conducting further research related to product trainings, because the findings may have a significant impact on the strategies/tactics of new product introduction.

ASSESING CORRELATED RISK USING THE MULTIVARIATE PROCESS INCAPABILITY INDICES

chunyilee1@gmail.com

ABSTRACT

Process capability indices have been widely used in industry today since they provide quantitative measures for evaluating process performance. Instead of using process capability index, the process incapability index C_{pp} has an advantage of separating the information of process accuracy and precision for a symmetric tolerance. Using C_{pp} process incapability index, the process performance and its risk level can easily be understood by quality practitioners. Recently, a new process incapability index C''_{pp} (s,t) is developed based on the desirability function to correctly measure the process performance for an asymmetric tolerance.

In this paper, due to the fact that the quality of an industrial product is determined by two or more interrelated quality characteristics, we propose new multivariate incapability process indices by taking the correlation among multiple quality characteristics into account. Analogous to univariate process incapability index, the multivariate process incapability index can be viewed as an extension of the univariate process incapability index and thus the manufacturing/environmental risk for a multivariate process can be evaluated accordingly. The major advantage of using the multivariate process incapability indices is that the correlated risk for a multivariate process and its expected losses can be evaluated in a more precise way. Finally, the correlated risk assessment using the new multivariate incapability indices and their associated interval estimates is further demonstrated by two numerical examples.

Keyword: multivariate process incapability indices, desirability function, symmetric and asymmetric tolerances, correlated risk assessment.

INTRODUCTION

In today's business environment, it is becoming more and more important for companies to evaluate the risks associated with their processes to improve the product quality and system safety as well as to reduce hazardous waste from their facilities. Traditionally, engineers perform process capability studies to analyze the performance of key quality characteristics. Quality improvement actions will be taken if the process is not capable of meeting specifications. Statistical process control tools, such as univariate and multivariate process capability indices have been widely employed in the assessment of manufacturing performance. According to Ayyub (2003), risk is commonly evaluated as the product of likelihood of failure occurrence and its impact, namely, RISK= LIKELIHOOD$\times$ IMPACT. This equation presents risk as an expected value of loss or an average loss. There are several methods currently being used for risk assessment in the manufacturing and chemical process industries. The most well known technique for quantitative risk assessment is failure mode and effect analysis (FMEA), as described in Montague (1990) and Ayyub (2003). This involves identifying each process step that may fail, then assigning rankings for occurrence, severity, and detectability. The "occurrence ranking" indicates how likely a failure is considered to occur (where higher scores correspond to higher probabilities), and is related to the process capability indices. The "severity ranking" shows the potential impact of a failure. The "detectability ranking" indicates how likely it is that a failure can go undetected until its full impact materializes. The three rankings are then multiplied, and higher total scores indicate higher risk priority number (RPN). Apparently, the ranking is purely subjective, and determined by quality practitioners.

Process capability indices (PCIs), on the other hand, have been widely used in industry today. They provide quantitative measures of process performance and thus lead to the direction of quality improvement. Instead of using process capability index, the process incapability index, $C_{pp} = (\mu - T)^2/D^2 + \sigma^2/D^2$ where $D = \min(D_l, D_u)/3$, $D_l = T - LSL$, $D_u = USL - T$, LSL is the lower specification limit, USL is the upper specification limit, T is the target value, μ is the process average and σ is the process standard deviation, introduced by Greenwich and Jahr-Schaffrath (1995) has the advantage of separating the information of accuracy and precision for symmetric tolerances. If the key characteristic of a process Y has mean μ and variance σ^2, then the expected valued of square loss, $E(Y-T)^2$, equals to $(\mu - T)^2 + \sigma^2$ where T is target value. Thus, according to Ayyub's (2003) definition of risk (i.e. Risk can be treat as an expected value of loss or an average loss), the process incapability index C_{pp} can be treated as a

standardized risk index since $C_{pp} = E(Y-T)^2/D^2$. Using the process incapability indices, the process risk level can easily be understood by quality practitioners. In addition to symmetric tolerances, asymmetric tolerances are frequently encountered in aerospace and auto industries. To measure the process performance for an asymmetric tolerance, the process incapability index C''_{pp} was proposed by Chen (1998). However, those process incapability indices are inappropriate since they can't correctly reflect the true process incapability for asymmetric tolerance. Pan and Lee (2009) proposed a new univariate process incapability index $C''_{pp}(s,t) = C''_{ia}(s,t) + C_{ip}$ using the concept of desirability function, which can properly reflect the actual non-conforming rate.

Recently, the serious ecological problems caused by an pollution and other contaminations, almost all the Environmental Protection Agencies (EPA) around the world have imposed regulations or laws, such as air pollution control act to reduce and control air pollution problems. Among them, the NO_x and SO_x emission and their potential loss at a chemical company located in Kaohsiung county of Taiwan (see Pan and Chi, 2008) is a good practical example for the application of correlated risk assessment. Moreover, due to the fact that the quality of a process output is often measured by the joint level of several correlated process quality characteristics, it is useful to develop a multivariate process incapability index to correctly reflect the correlated risk in terms of process inaccuracy and process variation. The major advantages of using the multivariate process incapability indices is that the correlated risk for a multivariate process and its expected losses can be evaluated in a more precise way. Thus, it is necessary to develop accurate multivariate process incapability indices for assessing the correlated risk occurred in either a manufacturing or environmental multivariate process.

LITERATURE REVIEW

Greenwich and Jahr-Schaffrath (1995) proposed an incapability index called C_{pp}, which can be considered as a simple transformation of the process capability index C^*_{pm}.

$$C_{pp} = \left(\frac{1}{C^*_{pm}}\right)^2 = \left(\frac{\mu - T}{D}\right)^2 + \left(\frac{\sigma}{D}\right)^2 = C_{ia} + C_{ip}, \qquad (1)$$

where $C_{ip} = (\sigma / D)^2$, $C_{ia} = ((\mu - T)/D)^2$ and $D = \min(D_l, D_u)/3$. The advantage of using C_{pp} index is that it provides separate information concerning the process accuracy and

precision, which is not available in C_{pm}^{*} index. Therefore, this information separation is highly beneficial because it indicates to what degree the process inaccuracy contributes the process being incapable of meeting the specification.

Chen (1998) found that C_{pp} index is incorrect for asymmetric tolerances. In order to overcome the drawback, he proposed the $C_{pp}^{"}$ index as shown in Equation (2) to deal with asymmetric tolerances.

$$C_{pp}^{"} = \left(\frac{A}{D}\right)^2 + \left(\frac{\sigma}{D}\right)^2 = C_{ia}^{"} + C_{ip}, \tag{2}$$

where $D = \min(D_l, D_u)/3$, $A = \max\{(\mu - T)d/D_u, (T - \mu)d/D_l\}$, $d = (USL - LSL)/2$, $D_u = USL - T$ and $D_l = T - LSL$.

Pan and Lee (2009) further showed that Chen's process incapability index is inappropriate since it can't properly reflect the actual non-conforming rate for asymmetric tolerance. Hence, they proposed a new univariate process incapability index $C_{pp}'''(s,t) = C_{ia}'''(s,t) + C_{ip}$ using the concept of desirability function. Due to the fact that manufacturing risks are inversely proportional to the distances between the target and specification limits, their relationship can be reflected by an appropriate selection of s and t values. To facilitate the assessment of manufacturing risks, a decision rule for determining s and t is derived. Pan and Lee (2009) proved that $C_{pp}'''(s,t)$ index is more accurate than C_{pp} and C_{pp}''' indices in assessing the manufacturing risks.

THE DEVELOPMENT OF A MULTIVARIATE PROCESS INCAPABILITY INDEX

To develop a multivariate process incapability index, we first assume that the two key quality characteristics are independent. According to the definition of C_{ia}''' index, it can be shown by using the following indicator function:

$$C_{ia}''' = 1_{\{\mu \le T\}}(\mu) \left(\frac{T - \mu}{D_l}\right)^2 \frac{d^2}{D^2} + 1_{\{\mu > T\}}(\mu) \left(\frac{\mu - T}{D_u}\right)^2 \frac{d^2}{D^2}, \tag{3}$$

where indicator function 1_A is defined as

$$1_A(x) = \begin{cases} 1, & x \in A \\ 0, & x \in A^c. \end{cases} \tag{4}$$

Since Equation (3) has a quadratic form, a matrix presentation of the bivariate process incapability index MC_{ia} can be defined as

$$MC_{ia}=\begin{bmatrix} \mu_1 - T_1 \\ \mu_2 - T_2 \end{bmatrix}'\begin{bmatrix} \frac{1_{\{\mu_1>T_1\}}d_1^2}{D_1^2 D_{1u}^2}+\frac{1_{\{\mu_1\le T_1\}}d_1^2}{D_1^2 D_{1l}^2} & 0 \\ 0 & \frac{1_{\{\mu_2>T_2\}}d_2^2}{D_2^2 D_{2u}^2}+\frac{1_{\{\mu_2\le T_2\}}d_2^2}{D_2^2 D_{2l}^2} \end{bmatrix}\begin{bmatrix} \mu_1 - T_1 \\ \mu_2 - T_2 \end{bmatrix}, \quad (5)$$

where μ_j, T_j, USL_j and LSL_j, $j = 1, 2$, are the process average, target value, upper and lower specification limit of *j*th key quality characteristic respectively, $D_j = \min(D_{jl}, D_{ju})/3$, $D_{jl} = T_j - LSL_j$ and $D_{ju} = USL_j - T_j$. By matrix computation, Equation (5) can be rewritten as

$$\begin{aligned} MC_{ia} &= (\mu_1 - T_1)^2\left[\frac{1_{\{\mu_1>T_1\}}d_1^2}{D_1^2 D_{1u}^2}+\frac{1_{\{\mu_1\le T_1\}}d_1^2}{D_1^2 D_{1l}^2}\right]+(\mu_2 - T_2)^2\left[\frac{1_{\{\mu_2>T_2\}}d_2^2}{D_2^2 D_{2u}^2}+\frac{1_{\{\mu_2\le T_2\}}d_2^2}{D_2^2 D_{2l}^2}\right] \\ &= C''_{ia1} + C''_{ia2} \end{aligned}, \quad (6)$$

where C''_{iaj} is the C''_{ia} indices of *j*th key quality characteristic, $j = 1, 2,$ respective. It is straightforward to extend Equation (6) to a general case in which the product has p key quality characteristics. Thus, the multivariate process inaccuracy index MC_{ia} for p characteristics can be defined as

$$MC_{ia} = (\boldsymbol{\mu} - \mathbf{T})'\mathbf{C}_{ind}^{-1}(\boldsymbol{\mu} - \mathbf{T}), \quad (7)$$

where $\boldsymbol{\mu} = [\mu_1, \ldots, \mu_p]'$ is the vector of the process average and $\mathbf{T} = [T_1, \ldots, T_p]'$ is the target vector and $\mathbf{C}_{ind}^{-1}$ is a cost matrix that be defined as

$$\mathbf{C}_{ind}^{-1} = \begin{bmatrix} \frac{1_{[\mu_1>T_1]}d_1^2}{D_1^2 D_{1u}{}^2}+\frac{1_{[\mu_1\le T_1]}d_1^2}{D_1^2 D_{1l}{}^2} & 0 & \cdots & 0 & 0 \\ 0 & \ddots & & & 0 \\ \vdots & & \frac{1_{[\mu_i>T_i]}d_i^2}{D_i^2 D_{iu}{}^2}+\frac{1_{[\mu_i\le T_i]}d_i^2}{D_i^2 D_{il}{}^2} & & \vdots \\ 0 & & & \ddots & 0 \\ 0 & & \cdots & 0 & \frac{1_{[\mu_P>T_P]}d_P^2}{D_P^2 D_{Pu}{}^2}+\frac{1_{[\mu_P\le T_P]}d_P^2}{D_P^2 D_{Pl}{}^2} \end{bmatrix}$$

If we consider that the p quality characteristics are independent, then the multivariate process inaccuracy index, MC_{ia}, has an additive property, i.e.

$$MC_{ia} = \sum_{j=1}^{p} C''_{iaj}, \quad (8)$$

where C''_{iaj} is the C''_{ia} index of the *j*th key quality characteristic. The additive property in Equation (8) has a meaningful interpretation under the assumption of independence: the C''_{ia} index provides information about the process inaccuracy while only depending on process average μ, the location parameter. Thus, we can conclude that the multivariate process incapability index in Equation (8) is correct.

Next we consider the matrix presentation of the imprecision index MC_{ip} of a bivariate process which is similar to Equation (7).

$$MC_{ip} = \left| \begin{bmatrix} (D_1^2)^{-1} & 0 \\ 0 & (D_2^2)^{-1} \end{bmatrix} \begin{bmatrix} \sigma_1^2 & 0 \\ 0 & \sigma_2^2 \end{bmatrix} \right|, \tag{9}$$

where $|\cdot|$ is a determinant notation, σ_j^2, T_j, USL_j and LSL_j are the process variance, target value, upper and lower specification limit of *j*th key quality characteristic, $j = 1, 2$, $D_j = \min(D_{jl}, D_{ju})/3$, $D_{jl} = T_j - LSL_j$ and $D_{ju} = USL_j - T_j$. By a matrix computation, Equation (21) can be rewritten as

$$MC_{ip} = \left| \begin{bmatrix} \frac{\sigma_1^2}{D_1^2} & 0 \\ 0 & \frac{\sigma_2^2}{D_2^2} \end{bmatrix} \right| = C_{ip1} C_{ip2}, \tag{10}$$

where C_{ipj} is the *j*th index C_{ip} of key quality characteristic, $j = 1, 2$. Equation (10) can be extend to a general case in which the product has p key quality characteristics. Thus, the multivariate process imprecision index MC_{ip} for p characteristics can be written as:

$$MC_{ip} = |\mathbf{D}_{ind}^{-1} \boldsymbol{\Sigma}|, \tag{11}$$

where $\boldsymbol{\Sigma}$ is the variance-covariance matrix and $\mathbf{D}_{ind}$ is defined as

$$\mathbf{D}_{ind} = \begin{bmatrix} D_1^2 & 0 & \cdots & & 0 \\ 0 & \ddots & & & \\ \vdots & & D_j^2 & & \vdots \\ & & & \ddots & 0 \\ 0 & & \cdots & 0 & D_P^2 \end{bmatrix}$$

Now we consider p quality characteristics under the independent assumption, the

multivariate process imprecision index, MC_{ip}, has the following multiplicative property.

$$MC_{ip} = \prod_{j=1}^{p} C_{ipj}, \tag{12}$$

where C_{ipj} is the C_{ip} index of the *j*th key quality characteristic. The multiplicative property in Equation (12) also has a meaningful interpretation under the assumption of independence: the C_{ip} index provides information about process imprecision while only depending on the process variance σ^2, scale parameter. Thus, we conclude that the imprecision index of a multivariate process in Equation (12) is correct.

Based on Equations (7) and (11), the multivariate process incapability index can be written as

$$MC''_{pp} = (\boldsymbol{\mu} - \mathbf{T})'\mathbf{C}_{ind}^{-1}(\boldsymbol{\mu} - \mathbf{T}) + |\mathbf{D}_{ind}^{-1}\boldsymbol{\Sigma}| = MC''_{ia} + MC_{ip}, \tag{13}$$

To develop a general index for evaluating correlated risk, we relieve the independent assumption to a dependent one and consider the following quadratic loss function proposed by Pignatiello (1993) that has several correlated quality characteristics. Pignatiello (1993) proposed a quadratic loss function as shown in Equation (14) for manufactured products that has several correlated quality characteristics.

$$loss(\mathbf{Y}) = (\mathbf{Y} - \tau)'\mathbf{C_q}(\mathbf{Y} - \boldsymbol{\tau}), \tag{14}$$

where $\mathbf{Y}$ is the vector of quality characteristics, $\boldsymbol{\tau}$ is the vector of target values and $\mathbf{C_q}$ is a positive definite cost matrix. When $\mathbf{C_q}$ is a diagonal matrix, the loss function is the sum of p single-response quadratic loss functions. For non-diagonal $\mathbf{C_q}$ matrices, the off-diagonal elements are related to the incremental losses that are incurred when pairs of quality characteristics are simultaneously off-target. In the bivariate case, the loss can be written as

$$\begin{aligned} loss(\mathbf{Y}) &= \begin{bmatrix} y_1 - \tau_1 \\ y_2 - \tau_2 \end{bmatrix}' \begin{bmatrix} c_{11} & c_{12} \\ c_{12} & c_{22} \end{bmatrix} \begin{bmatrix} y_1 - \tau_1 \\ y_2 - \tau_2 \end{bmatrix} \\ &= c_{11}(y_1 - \tau_1)^2 + c_{22}(y_2 - \tau_2)^2 + c_{12}(y_1 - \tau_1)(y_2 - \tau_2), \end{aligned} \tag{15}$$

where y_i is the *i*th key quality characteristics, τ_i the *i*th target value for quality characteristics and c_{ij} is the cost parameter. The first two terms on the right hand side in Equation (16) are the univariate quadratic loss function values. The last term is non-zero only when both quality characteristics are off-target and $c_{12} \neq 0$. The coefficient c_{12} is related to the additional incurred loss when both y_1 and y_2 are off-target. Hence, we can modify

the $\mathbf{C}_q$ matrix in Equation (15) to develop an inaccuracy index of a multivariate process. Based on Pignatiello's (1993) multiple response loss function, a multivariate process inaccuracy index, without an independent assumption, can be defined as

$$MC_{ia} = (\boldsymbol{\mu} - \mathbf{T})'\mathbf{C}^{-1}(\boldsymbol{\mu} - \mathbf{T}), \tag{16}$$

Then, the diagonal and off-diagonal entries of matrix $\mathbf{C}$ can be written as:

$$1_{\{\mu_i \le T_i\}} c_{il}^2 + 1_{\{\mu_i > T_i\}} c_{iu}^2$$

and

$$\rho_{ij}(1_{\{\mu_i \le T_i\}} 1_{\{\mu_j \le T_j\}} c_{il} c_{jl} + 1_{\{\mu_i \le T_i\}} 1_{\{\mu_j > T_j\}} c_{il} c_{ju} + 1_{\{\mu_i > T_i\}} 1_{\{\mu_j \le T_j\}} c_{iu} c_{jl} + 1_{\{\mu_i > T_i\}} 1_{\{\mu_j > T_j\}} c_{iu} c_{ju})$$

where $1_{\{\mu_i \le T_i\}}$ is the indicator function, $c_{il} = (D_i D_{il})/d_i$ and $c_{iu} = (D_i D_{iu})/d_i$, $i = 1, \ldots, p$, are the cost parameters and ρ_{ij} represents the correlation coefficient between *i*th and *j*th quality characteristics. The coefficients $c_{il}c_{jl}$, $c_{il}c_{ju}$, $c_{iu}c_{jl}$ and $c_{iu}c_{ju}$ are related to the additional incurred loss when both the *i*th and *j*th quality characteristics are off-target.

Using the concept of the univariate process capability index C_p, the MC_p index proposed by Taam et al. (1993) will be equal to 1 if the manufacturing process region falls completely within an engineering tolerance region and the manufacturing process follows a multivariate normal distribution. Pan and Lee (2010) proved that the calculation of the MC_p index proposed by Taam et al. (1993) can be simplified to:

$$MC_p = |\boldsymbol{\rho}|^{-1/2}, \tag{17}$$

where $\boldsymbol{\rho}$ is a correlation matrix. Equation (17) implies that the value for the MC_p index might be greater than 1 (an overestimation occurs) since the determinant for the correlation matrix is between 0 and 1. In other words, the value of the MC_p index will be greater than 1 if the quality characteristics are not independent, which results in an overestimation of the true process performance. Similarly, for the $MC_{pm} = MC_p/D$ index proposed by Taam et al. (1993), the same drawback could occur when the multiple quality characteristics are not independent. Thus, by adopting similar multivariate control region concepts shown in Montgomery (2001), we further revise Taam's modified engineering tolerance region so that the shape of the ellipsoid within the engineering tolerance region can be flexibly adjusted by the correlation of multiple quality characteristics. The relationship between

Taam's modified regular tolerance region and our revised slanted tolerance region for a bivariate quality characteristic is illustrated in Figure 1.

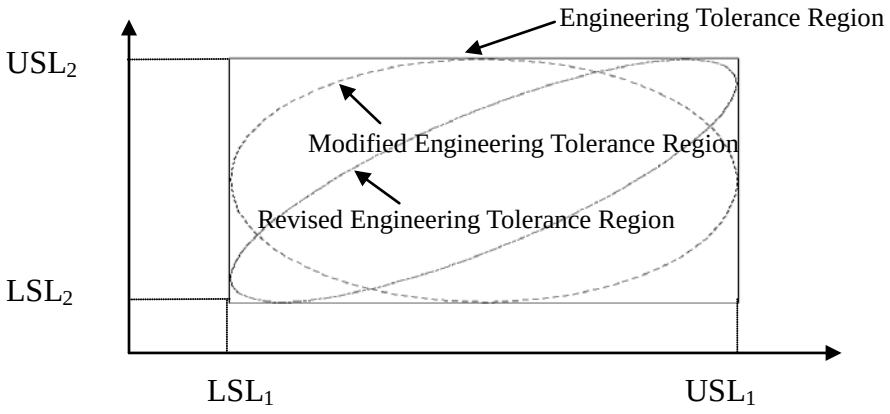

Figure 1: Relationship between Taam's modified region and our revised engineering tolerance region.

To overcome the drawback of overestimation using the MC_p and MC_{pm} indices, a revised engineering tolerance region is proposed as below:

$$E_{d_E,\mathbf{A}^*,\mathbf{T}} = \{\mathbf{X} \in \mathbf{R}^p | (\mathbf{X}-\mathbf{T})'(\mathbf{A}^*)^{-1}(\mathbf{X}-\mathbf{T}) = d_E^2\}, \tag{18}$$

where the elements of matrix $\mathbf{A}^*$ are given by

$$\rho_{ij}\left(\frac{USL_i - LSL_i}{2d_E}\right)\left(\frac{USL_j - LSL_j}{2d_E}\right) \quad i,j = 1,\ldots,p, \tag{19}$$

$\mathbf{T}$ is the target vector, ρ_{ij} represents the correlation coefficient between the *i*th and *j*th quality characteristics and $(USL_i - LSL_i)$ denotes the *i*th specification width for each side of rectangle circumscribed to the ellipsoid $E_{d_E,\mathbf{A}^*,\mathbf{T}}$. Similar to the MC_{pm} ratio of the two volumes shown in Taam et al. (1993), our proposed multivariate process capability index can be written as

$$NMC_{pm} = \frac{Vol.(E_{d_E,\mathbf{A}^*,\mathbf{T}})}{Vol.(E_{d_E,\mathbf{\Sigma},\boldsymbol{\mu}})}\left(1 + (\boldsymbol{\mu}-\boldsymbol{T})'\mathbf{\Sigma}^{-1}(\boldsymbol{\mu}-\boldsymbol{T})\right)^{-1/2}$$

Let $d_E^2 = \chi^2_{p,1-\alpha}$ and $\chi^2_{p,1-\alpha}$ is the $100(1-\alpha)$*th* percentile of a chi-square distribution with p degrees of freedom, then the NMC_{pm} index can be rewritten as

$$NMC_{pm} = \frac{|\mathbf{A}^*|^{1/2}}{|\boldsymbol{\Sigma}|^{1/2}} \left(1 + (\boldsymbol{\mu} - \boldsymbol{T})'\boldsymbol{\Sigma}^{-1}(\boldsymbol{\mu} - \boldsymbol{T})\right)^{-1/2} = NMC_p / D_{ev},$$

where $NMC_p = (|\mathbf{A}^*|/|\boldsymbol{\Sigma}|)^{1/2}$ and $D_{ev} = (1 + (\boldsymbol{\mu} - \boldsymbol{T})'\boldsymbol{\Sigma}^{-1}(\boldsymbol{\mu} - \boldsymbol{T}))^{1/2}$. Notice that the term D_{ev} in NMC_{pm} index denotes a function of Mahalanobis distance between the process mean and target vector and it can be used to measure the process deviation from target $\mathbf{T}$. Furthermore, C_p and C_{pm} indices can be considered as a special case of our NMC_p and NMC_{pm} indices if $p = 1$ and $1 - \alpha = 0.9973$. Based on the concept of univariate process incapability index C_{pp}, the transformation of NMC_p index can be rewritten as

$$\left(\frac{1}{NMC_p}\right)^2 = \frac{|\boldsymbol{\Sigma}|}{|\mathbf{A}^*|}, \tag{20}$$

By a matrix computation, the Equation (20) can be rewritten as below

$$MC_{ip} = |\mathbf{D}_{ind}^{-1}\boldsymbol{\Sigma}| = \frac{|\boldsymbol{\Sigma}|}{|\mathbf{D}_{ind}|}, \tag{21}$$

According to Equations (20) and (21), the matrices $\mathbf{A}^*$ and $\mathbf{D}_{ind}$ have the same structure. We can modify the matrix $\mathbf{D}_{ind}$ in Equation (21) to develop an imprecision index for the multivariate process by considering the correlation among several key quality characteristics. Thus, relieving the independence assumption, the imprecision index for a multivariate process can be defined as

$$MC_{ip} = \frac{|\boldsymbol{\Sigma}|}{|\mathbf{D}|}, \tag{22}$$

where the elements of matrix $\mathbf{D}$ are

$$(\rho_{ij} d_i^* d_j^*)/\chi^2_{p,1-\alpha}, \; i, j = 1, \ldots, p, \tag{23}$$

ρ_{ij} is the correlation coefficient between the *i*th and *j*th quality characteristics, $d_i^* = \min(D_{il}, D_{iu})$, $D_{il} = T_i - LSL_i$, $D_{iu} = USL_i - T_i$ and $\chi^2_{p,1-\alpha}$ is the $(1-\alpha)$th percentile of a chi-square distribution with p degrees of freedom. Based on the results of Equations (16) and (22), the multivariate process incapability index for evaluating the correlated risk can be written as

$$MC_{pp} = MC_{ia} + MC_{ip} = (\boldsymbol{\mu} - \mathbf{T})'\mathbf{C}^{-1}(\boldsymbol{\mu} - \mathbf{T}) + \frac{|\boldsymbol{\Sigma}|}{|\mathbf{D}|}.$$

In order to evaluate the performance of our proposed multivariate process incapability indices, a simulation study has been conducted and random samples with various sample sizes are generated from the multivariate normal distribution $N(\boldsymbol{\mu}, \boldsymbol{\Sigma})$. To evaluate process performance by using our proposed multivariate process incapability indices, five hypothetical bivariate processes listed in Table 1 are considered.

The specifications and target values are assumed to be $(LSL_1, USL_1) = (-3.4393, 3.4393)$, $(LSL_2, USL_2) = (-3.4393, 3.4393)$ and $\mathbf{T} = (0, 0)$.

Table 1: The mean vector and covariance matrix of five bivariate processes.

	Hypothetical bivariate processes				
	I	**II**	**III**	**IV**	**V**
Mean vector ($\boldsymbol{\mu}$)	$\begin{bmatrix}0\\0\end{bmatrix}$	$\begin{bmatrix}0\\0\end{bmatrix}$	$\begin{bmatrix}0\\0\end{bmatrix}$	$\boldsymbol{\Sigma}^{1/2}\begin{bmatrix}1\\1\end{bmatrix}$	$\boldsymbol{\Sigma}^{1/2}\begin{bmatrix}1\\1\end{bmatrix}$
Covariance matrix ($\boldsymbol{\Sigma}$)	$\begin{bmatrix}1 & \rho\\ \rho & 1\end{bmatrix}$	$\begin{bmatrix}1 & \sqrt{2}\rho\\ \sqrt{2}\rho & 2\end{bmatrix}$	$\begin{bmatrix}2 & 2\rho\\ 2\rho & 2\end{bmatrix}$	$\begin{bmatrix}1 & \rho\\ \rho & 1\end{bmatrix}$	$\begin{bmatrix}0.5 & 0.5\rho\\ 0.5\rho & 0.5\end{bmatrix}$

According to Equation (23), the matrix $\mathbf{D}$ is given by

$$\begin{bmatrix}1 & \rho\\ \rho & 1\end{bmatrix},$$

where ρ is the correlation coefficient between two quality characteristics.

Due to the fact that a 99.73% process region $E_{\chi^2_{2,\,0.9973},\boldsymbol{\Sigma},\mathbf{T}} = \{\mathbf{X} \in \mathbf{R}^2 | (\mathbf{X} - \mathbf{T})'\boldsymbol{\Sigma}^{-1}(\mathbf{X} - \mathbf{T}) \quad = \chi^2_{2,\,0.9973}\}$ and a 99.73% revised engineering tolerance region $E_{\chi^2_{2,\,0.9973},\mathbf{D},\mathbf{T}} = \{\mathbf{X} \in \mathbf{R}^2 | (\mathbf{X} - \mathbf{T})'\mathbf{D}^{-1}(\mathbf{X} - \mathbf{T}) = \chi^2_{2,\,0.9973}\}$ are equivalent, the values of MC_{ia} and MC_{ip} indices for process I should be nearly equal to 0 and 1 when the process mean is equal to the target. Moreover, process II represents the

variation of one quality characteristic is greater than 1, process III represents the variations of two quality characteristics are greater than 1, process IV represents the process mean vector is deviated from the target vector and process V represents both the variations of two quality characteristics are less than 1 and the process mean vector is deviated from the target vector respectively. Notice that the Mahalanobis distances between target vector and process mean vector are equal to 2 for process IV and V. A simulation study has been conducted 5,000 times and the results are summarized in Table 2.

Table 2: The simulation results of our multivariate process incapability indices for different correlation coefficients ρ.

	100	**0.0153**	**1.0155**	**0.0227**	**2.0325**	**0.0308**	**4.0270**	**1.5421**	**1.0012**	**0.7670**	**0.2546**

In Table 2, all the values of our MC_{ia} index for processes Ⅰ, Ⅱ and Ⅲ are close to zero for various correlation coefficients and all the values of our MC_{ia} index for processes Ⅳ and Ⅴ are greater than zero for various correlation coefficients. In addition, all the values of our MC_{ip} index for processes Ⅰ and Ⅳ are close to 1 for various correlation coefficients and all the values of our MC_{ip} index for processes Ⅱ and Ⅲ are greater than 1 for various correlation coefficients. Moreover, all the values of our MC_{ia} index are greater than zero and all the values of our MC_{ip} index are less than 1 for process Ⅴ, which reflect the properties of process Ⅴ. Therefore, we can conclude that the process precision and accuracy can correctly be reflected by our proposed MC_{ia} and MC_{ip} indices.

The estimation of MC_{pp} index and its sampling distribution

Assume that the key characteristics of a multivariate manufacturing process are normally distributed. Let $\mathbf{X}_1,\cdots,\mathbf{X}_n$ be a random sample of *n* measurements with p quality characteristics from a multivariate normal distribution with mean vector $\boldsymbol{\mu}$ and covariance matrix $\boldsymbol{\Sigma}$. In order to estimate the MC_{pp} index, the natural estimator of MC_{pp} index is defined as

$$\widehat{MC}_{pp} = \widehat{MC}_{ia} + \widehat{MC}_{ip} = (\bar{\mathbf{X}} - \mathbf{T})'\hat{\mathbf{C}}^{-1}(\bar{\mathbf{X}} - \mathbf{T}) + \frac{|\mathbf{S}|}{|\mathbf{D}|},$$

where $\bar{\mathbf{X}}$ is the sample mean vector, $\mathbf{S}$ is the sample covariance matrix and the diagonal and off-diagonal entries of matrix $\hat{\mathbf{C}}$ are

$$1_{\{\bar{X}_i \le T_i\}}c_{il}^2 + 1_{\{\bar{X}_i > T_i\}}c_{iu}^2$$

and

$$\rho_{ij}(1_{\{\bar{X}_i \le T_i\}}1_{\{\bar{X}_j \le T_j\}}c_{il}c_{jl} + 1_{\{\bar{X}_i \le T_i\}}1_{\{\bar{X}_j > T_j\}}c_{il}c_{ju} + 1_{\{\bar{X}_i > T_i\}}1_{\{\bar{X}_j \le T_j\}}c_{iu}c_{jl} + 1_{\{\bar{X}_i > T_i\}}1_{\{\bar{X}_j > T_j\}}c_{iu}c_{ju})$$

Since the $\widehat{MC}_{ia}$ index for asymmetric tolerances is a quadratic form and its sampling distribution is very complicated for asymmetric tolerances, we consider the MC_{ia} index for symmetric tolerances and its estimator can be written as

$$\widehat{MC}_{ia} = (\bar{\mathbf{X}} - \mathbf{T})'\mathbf{C}_s^{-1}(\bar{\mathbf{X}} - \mathbf{T}),$$

where the elements of matrix $\mathbf{C}_s$ are

$$\rho_{ij}D_iD_j,\ i,j = 1,\ldots,p, \qquad (24)$$

ρ_{ij} is the correlation coefficient between the *i*th and *j*th quality characteristics and $D_i = \min(D_{il}, D_{iu})/3$. Then, the sampling distribution of $\widehat{MC}_{ia}$ for symmetric tolerances can be written as

$$f(y) = \sum_{k=0}^{\infty}(-1)^k c_k \frac{y^{p/2+k+1}}{\Gamma(p/2+k)},$$

where

$$c_0 = \exp(-\frac{1}{2}\sum_{j=1}^{p} b_j^2) \prod_{j=1}^{p} (2\lambda_j)^{-\frac{1}{2}},$$

$$c_k = \frac{1}{k}\sum_{r=0}^{k-1} d_{k-r} c_r,\ k \geq 1,$$

$$d_k = \frac{1}{2}\sum_{j=1}^{p} (1 - k b_j^2)(2\lambda_j)^{-k},\ k \geq 1,$$

$$\mathbf{P}'\mathbf{\Sigma}^{\frac{1}{2}}\mathbf{C}_s^{-1}\mathbf{\Sigma}^{\frac{1}{2}}\mathbf{P}/n = diag(\lambda_1, \ldots, \lambda_p),\ \mathbf{P}'\mathbf{P} = \mathbf{I} \text{ and } \mathbf{b}' = (\mathbf{P}'(\mathbf{\Sigma}/n)^{-\frac{1}{2}}(\boldsymbol{\mu} - \mathbf{T}))'$$

(see Mathai and Provost, 1992). Furthermore, the *r*th moment of $\widehat{MC}_{ia}$ is derived below:

$$E(\widehat{MC}_{ia})^r = \left\{ \sum_{r_1=0}^{r-1} \binom{r-1}{r_1} g^{(r-1-r_1)} \sum_{r_2=0}^{r_1-1} \binom{r_1-1}{r_2} g^{(r_1-1-r_2)} \ldots \right\}, \text{ where}$$

$$g^{(k)} = 2^k k! \{ tr(\mathbf{C}_s^{-1}\mathbf{\Sigma}/n)^{k+1} + (k+1)(\boldsymbol{\mu} - \mathbf{T})'(\mathbf{C}_s^{-1}\mathbf{\Sigma}/n)^k \mathbf{C}_s^{-1}(\boldsymbol{\mu} - \mathbf{T}) \},\ k = 0, 1, 2, \ldots$$

Then, the expected value and variance of $\widehat{MC}_{ia}$ can be simplified to:

$$E(\widehat{MC}_{ia}) = MC_{ia} + tr(\mathbf{C}_s^{-1}\mathbf{\Sigma}/n)$$

$$Var(\widehat{MC}_{ia}) = 2tr(\mathbf{C}_s^{-1}\mathbf{\Sigma}/n)^2 + 4(\boldsymbol{\mu} - \mathbf{T})'\mathbf{C}_s^{-1}(\mathbf{\Sigma}/n)\mathbf{C}_s^{-1}(\boldsymbol{\mu} - \mathbf{T}))$$

Note that the estimator $\widehat{MC}_{ia}$ is asymptotically unbiased.
Since the sampling distribution of $\widehat{MC}_{ia}$ is too complicated to use, an approximate sampling distribution of $\widehat{MC}_{ia}$ is given by

$$\frac{\theta_3}{\theta_2}\chi_v^2 - \frac{\theta_2^2}{\theta_3} + E(\widehat{MC}_{ic}), \tag{25}$$

where $\theta_k = \sum_{j=1}^{p} \lambda_j^k (1 + k b_j^2)$, $k = 1, 2, 3$ and χ_n^2 is a chi-square distribution with $v = \theta_2^3/\theta_3^2$ degrees of freedom (see Mathai and Provost, 1992). Based the approximate sampling distribution of $\widehat{MC}_{ia}$ in Equation (25), we further prove that an approximate 100(1-α)% confidence interval for the MC_{ia} index is

$$\left[\widehat{MC}_{ia} - L_{MC_{ia}},\ \widehat{MC}_{ia} + U_{MC_{ia}} \right], \tag{26}$$

where $L_{MC_{ia}} = w\chi^2_{v,1-\alpha/2} + u + b_{MC_{ia}}$, $U_{MC_{ia}} = -(w\chi^2_{v,\alpha/2} + u + b_{MC_{ia}})$, $w = \theta_3/\theta_2$, $u = -\theta_2^3/\theta_3$, $b_{MC_{ia}} = tr(\mathbf{C}_s^{-1}\mathbf{\Sigma}/n)$ and $\chi^2_{v,\alpha}$ is the 100αth percentile of a chi-square distribution with v degrees of freedom. Since θ_k and $\mathbf{\Sigma}$ are usually unknown and it can be estimated by $\hat{\theta}_k = \sum_{j=1}^{p} \hat{\lambda}_j^k (1 + k\hat{b}_j^2)$ and sample covariance matrix $\mathbf{S}$ respectively, an approximate 100(1-α)% confidence interval for the MC_{ia} index can be written as

$$\left[\widehat{MC}_{ia} - \hat{L}_{MC_{ia}},\ \widehat{MC}_{ia} + \hat{U}_{MC_{ia}}\right], \tag{27}$$

where $\hat{L}_{MC_{ia}} = \hat{w}\chi^2_{\hat{v},1-\alpha/2} + \hat{u} + \hat{b}_{MC_{ia}}$, $\hat{U}_{MC_{ia}} = -(\hat{w}\chi^2_{\hat{v},\alpha/2} + \hat{u} + \hat{b}_{MC_{ia}})$, $\hat{w} = \hat{\theta}_3/\hat{\theta}_2$, $\hat{u} = -\hat{\theta}_2^3/\hat{\theta}_3$, $\hat{b}_{MC_{ia}} = tr(C_s^{-1}\mathbf{S}/n)$ and $\hat{v} = \hat{\theta}_2^3/\hat{\theta}_3^2$.

In order to assess the performance of the approximate confidence interval in Equation (27), a simulation study has been conducted and random samples with various sample sizes are generated from the multivariate normal distribution $N(\boldsymbol{\mu}, \mathbf{\Sigma})$. The specification limits and the target values are assumed to be $(LSL_1, USL_1) = (10, 16)$, $(LSL_2, USL_2) = (10, 16)$ and $\mathbf{T} = (13, 13)$. For each combination, 1,000 random samples are generated and the corresponding approximate 95% confidence intervals are computed for each sample. The observed coverage probability (i.e. the fraction of 1,000 computed confidence intervals which contain the actual value of the index) is recorded accordingly. When the interval estimates perform adequately, the observed coverage probability should be close to 95%. The observed coverage probabilities of an approximate 95% confidence interval for MC_{ia} index are given in Figure 2. Thus, a 99% confidence interval for the coverage probability of 0.95 is $0.95 \pm Z_{0.005}\sqrt{0.95 \times 0.05/1000} = 0.95 \pm 0.0178$. Hence, one can be 99% confident that a “true 95% confidence limit” will have a proportion of coverage from 0.933 to 0.967. According to the results of Figure 2 we can find that the approximate confidence interval for our MC_{ia} index in Equation (27) does not perform well when both the sample size and the value of MC_{ia} index are small. We conclude that with lower value of MC_{ia} index, larger sample sizes are required to have the 95% coverage probability. To reach a steady state as shown in Figure 2, eighty (80) samples are needed when $MC_{ia} \geq 1.0$.

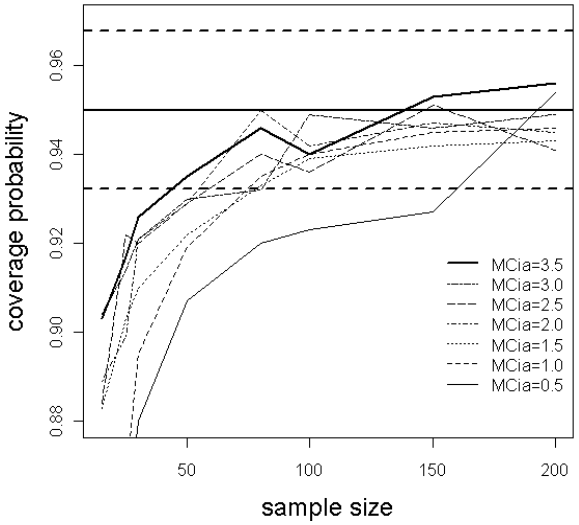

Figure 2: Observed coverage probabilities of the approximate 95% confidence interval.

Since $|\mathbf{S}|/|\mathbf{\Sigma}|$ is the distribution of $\prod_{i=1}^{p}\chi^2_{n-i}/(n-1)^p$ (see Maman, 2005), the estimator $\widehat{MC}_{ip}$ is distributed as $MC_{ip}\prod_{i=1}^{p}\chi^2_{n-i}/(n-1)^p$, where χ^2_{n-i} is an independent chi-square distribution with $(n-i)$ degrees of freedom. Thus, the *r*th moment of $\widehat{MC}_{ip}$ is derived as below:

$$\frac{1}{b_r}(MC_{ip})^r,$$

where

$$b_r = \left(\frac{n-1}{2}\right)^{\frac{rp}{2}} \prod_{i=1}^{p} \frac{\Gamma(\frac{n-i}{2})}{\Gamma(\frac{n-i}{2}+r)}$$

and the expected value and variance of $\widehat{MC}_{ip}$ can be simplified to:

$$E(\widehat{MC}_{ip}) = \frac{1}{b_1}MC_{ip}\ ,\ Var(\widehat{MC}_{ip}) = (\frac{1}{b_2} - \frac{1}{b_1^2})(MC_{ip})^2.$$

Note that the estimator $\widehat{MC}_{ip}$ is biased and $b_1\widehat{MC}_{ip}$ is an unbiased estimator. Based on the sampling distribution of $\widehat{MC}_{ip}$, we further prove that a 100(1-α)% confidence interval for MC_{ip} index is

$$\left[\frac{\widehat{MC}_{ip}}{w_{1-\alpha/2}}, \frac{\widehat{MC}_{ip}}{w_{\alpha/2}}\right], \tag{28}$$

where w_α is the 100αth percentile of the distribution of $\prod_{i=1}^{p}\chi^2_{n-i}/(n-1)^p$.

Numerical Examples

Example 1:

Sultan (1986) discussed an example in which the Brinell hardness (*H*) and tensile strength (*S*) are two quality characteristics for an industrial product. The engineering tolerances for *H* and *S* are given by (112.7, 241.3) and (32.7, 73.3) respectively and the target vector for *H* and *S* is (177, 53). After collecting 25 measurements listed in Table 3, a process capability study is conducted assuming the process is in control.

Table 3: The 25 data sets of Brinell hardness (H) and tensile strength (S) for an industrial product.

H	S	H	S	H	S
143	**34.2**	**141**	**47.3**	**178**	**50.9**
200	**57.0**	**175**	**57.3**	**196**	**57.9**
160	**47.5**	**187**	**58.5**	**160**	**45.5**
181	**53.4**	**187**	**58.2**	**183**	**53.9**
148	**47.8**	**186**	**57.0**	**179**	**51.2**
178	**51.5**	**172**	**49.4**	**194**	**57.5**
162	**45.9**	**182**	**57.2**	**181**	**55.6**
215	**59.1**	**177**	**50.6**		
161	**48.4**	**204**	**55.1**		

Based on the 25 measurements listed in Table 3, the sample mean vector $\overline{\mathbf{X}}' = [177.2, \quad 52.316]$ and the sample covariance matrix $\mathbf{S}$ are calculated, where

$$\mathbf{S} = \begin{bmatrix} 338 & 88.8925 \\ 88.8925 & 33.6247 \end{bmatrix}.$$

According to Equations (23) and (24), the matrices $\mathbf{D}$ and $\mathbf{C}_s$ can be obtained as below:

$$\mathbf{D} = \begin{bmatrix} 349.5213 & 92.0102 \\ 92.0102 & 34.8372 \end{bmatrix}$$

$$\mathbf{C}_s = \begin{bmatrix} 459.3878 & 120.9322 \\ 120.9322 & 45.7878 \end{bmatrix}$$

The actual relationship among the 99.73% process region, the 99.73% revised engineering tolerance region and engineering tolerance region are shown in Figure 3.

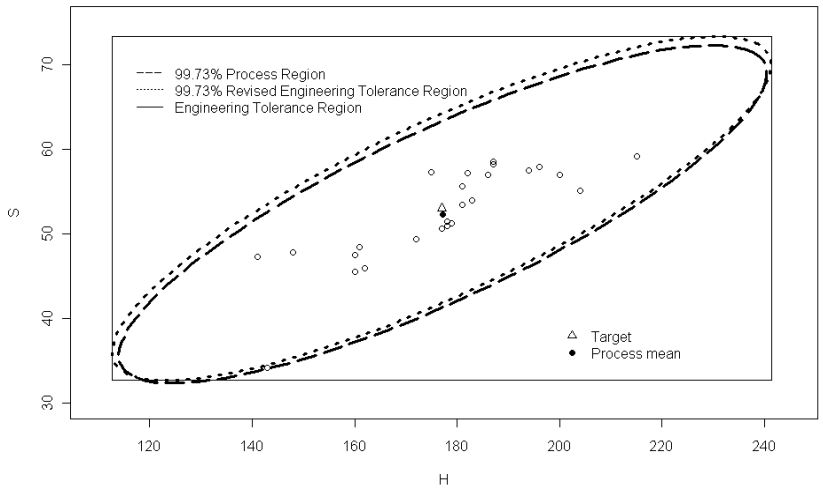

Figure 3: Relationship among 99.73% revised engineering tolerance region, 99.73% process region and engineering tolerance region.

Apparently, the process mean is close to the target and the "99.73% process region" is approximately equal to the "99.73% revised engineering tolerance region". Since the estimated conforming rate for this example is 99.91% under the assumption of multivariate normality for the underlying process distribution and our proposed indices are $\widehat{MC}_{ia} = 0.04$ and $\widehat{MC}_{ip} = 0.93$ respectively, the results show that the 99.73% process region is close to the 99.73% revised engineering tolerance region, and that the process mean is close to the target (see Figure 3). Thus, our proposed indices, $\widehat{MC}_{ia}$ and $\widehat{MC}_{ip}$, indicate that the multivariate process is capable and the true process performance is reflected.

Example 2:

In this example, a historical aircraft data sets collected by Pratt and Whitney Company (Niverthi and Dey, 2000) is used for illustration. The data set has measurements on ten (10) different aircraft features which are taken from a component hub of the engine. After performing the Shapiro-Wilk test, one can find out that three (3) of ten (10) different aircraft features in this data set are multivariate normally distributed with the mean vector $\overline{\mathbf{X}}' = [22.0492, 1.8544, 3.04675]$ and the covariance matrix

$$\mathbf{S} = \begin{bmatrix} 9.2016\times10^{-8} & 1.9592\times10^{-8} & -6.9796\times10^{-8} \\ 1.9592\times10^{-8} & 1.1755\times10^{-7} & -3.5510\times10^{-8} \\ -6.9796\times10^{-8} & -3.5510\times10^{-8} & 3.7879\times10^{-6} \end{bmatrix}.$$

Since our proposed index is based on the normality assumption for the underlying distribution, we only consider three aircraft features which follow multivariate normal

distribution. Given the engineering tolerances of the three aircraft features (22.047, 22.051), (1.852, 1.856) and (3.038, 3.052) and the target vector (22.049, 1.854, 3.045), the matrices $\mathbf{D}$ and $\mathbf{C}_s$ can be obtained as below according to Equations (16) and (23).

$$\mathbf{D} = \begin{bmatrix} 2.8256\times10^{-7} & 5.3228\times10^{-8} & -1.1692\times10^{-7} \\ 5.3228\times10^{-8} & 2.8256\times10^{-7} & -5.2629\times10^{-8} \\ -1.1692\times10^{-7} & -5.2629\times10^{-8} & 3.4614\times10^{-6} \end{bmatrix}$$

$$\mathbf{C}_s = \begin{bmatrix} 4.4444\times10^{-7} & 8.3723\times10^{-8} & -1.8390\times10^{-7} \\ 8.3723\times10^{-8} & 4.4444\times10^{-7} & -8.2781\times10^{-8} \\ -1.8390\times10^{-7} & -8.2781\times10^{-8} & 5.4444\times10^{-6} \end{bmatrix}$$

The incapability indices and their associated interval estimates are summarized in Table 4. The two components of a multivariate process incapability index, $\widehat{MC}_{ia} = 1.03$ and $\widehat{MC}_{ip} = 0.15$, indicate that this multivariate manufacturing process exhibits a fairly high risk mainly due to the process inaccuracy. After performing the baseline analysis, quality practitioners can focus their improvement efforts on reducing the risk caused by process inaccuracy. Therefore, the information of process inaccuracy and process variation revealed by $\widehat{MC}_{ia}$ and $\widehat{MC}_{ip}$ indices can be served as a useful guideline for pointing out the directions for future quality improvements.

Table 4: The process incapability indices and their associated interval estimates.

	Process Incapability Indices		
	$\widehat{MC}_{ia}$	$\widehat{MC}_{ip}$	$\widehat{MC}_{pp}$
Indices	**1.03**	**0.15**	**1.18**
Interval Estimates	**[0.88, 2.16]**	**[0.09, 0.34]**	**[0.97, 2.504]**

Note: Values within bracket represent the 95% confidence intervals for respective indices.

CONCLUSIONS AND FUTURE RESEARCH

In many industries, the quality of the process is often determined by several quality characteristics, some of which are correlated. To assess the risk of correlated multiple quality characteristics, new multivariate process incapability indices are proposed by considering that the key quality characteristics are independent first and then relieving the independent

assumption to a dependent one. Based on the concepts of Pignatiello's (1993) multiple response loss function and slant ellipsoid-shaped regions, the two components of a multivariate process incapability indices, MC_{ia} (the inaccuracy index) and MC_{ip} (the imprecision index), are developed respectively. Moreover, the statistical properties of the estimators of MC_{ia} and MC_{ip} indices, such as their *r*th moment, expected value and variance are derived. The confidence intervals for MC_{ia} and MC_{ip} indices are also constructed by taking sampling error into account. Finally, in two numerical examples, we have demonstrated that the correlated risk for a multivariate manufacturing process as well as its expected losses can be evaluated in a more precise way by using the new multivariate process incapability indices.

In this paper, the development of multivariate process incapability indices is based on the assumption of normality. The future researchers may consider developing non-normal process incapability indices for both univariate and multivariate cases. Another research area is to further explore the relationship between the multivariate process incapability indices and their associated non-conforming rates. In addition to two-sided specification limit, one-sided specification limit are often encountered in the environmental research and service industries. Thus, the development of a new process incapability index for one-sided specification limit is the third potential research area needs to be further studied.

EFFICIENT INTERVAL GOAL PROGRAMMING FOR ARBITRARY PENALTY FUNCTION

Hao-Chun Lu*, Fu Jen Catholic University, Taiwan

Tzu-Li Chen, Fu Jen Catholic University, Taiwan
chentzuli@gmail.com

ABSTRACT

Penalty function is a key factor in interval goal programming (IGP), especially for decision-maker weighing resources vis-à-vis goals. Many approaches have been proposed for treating several types of penalty function in the past several decades. The recent approach proposed by Chang (2009) considers the S-shaped penalty function. Although there are many approaches in literatures, all are complicated and inefficient. This paper proposes a novel and concise uniform model to treat any arbitrary penalty function in IGP. The efficiency and usefulness of the proposed model are demonstrat by several numeric examples.

Keywords: interval goal programming, penalty function

INTRODUCTION

The goal programming (GP) model is a well-known aggregating procedure for solving multi-objective decision problems. This takes into account many objectives simultaneously, which can be conflicting. GP was firstly proposed by Charnes and Cooper (1961) and has been applied to many real-world problems in areas like management, marketing, economics, engineering, transformation, finance, government, and internal context (Schniederjans, 1995; Lai and Hwang, 1994). It is an important technique in considering several objectives for finding an acceptable solution. It can be said that GP is the most widely used technique for solving multi-criteria and multi-objective decision-making problems. It can be formulated in the following traditional form:

$$\begin{aligned} \text{Min} \quad & \sum_{i=1}^{m} (w_i^- n_i + w_i^+ p_i) \\ \text{s.t.} \quad & f_i(\mathbf{x}) + n_i - p_i = g_i, \ i = 1,...,m, \\ & \mathbf{x} \in \mathbf{F}; \ n_i, p_i \geq 0 \ \forall i. \end{aligned}$$

where $\mathbf{x}$ is a vector of decision variables, $\mathbf{F}$ is a feasible set of constraints, $f_i(\mathbf{x})$ and g_i are the goal function and its aspiration level, n_i and p_i are negative and position unwanted deviations from its target value, respectively. Any unwanted deviation with respect to its target is penalized according to the marginal constants w_i^- and w_i^+.

Many approaches (Jones and Tamiz, 1995; Vitoriano and Romero, 1999; Romero, 2004; Chang, 2006; Chang, 2009) have been proposed for treating different shapes of penalty function in the past few decades. Different penalty functions require different approaches to solve the IGP problem. Although there are many approaches in literature, there is a lack of a concise uniform model to treat any arbitrary penalty function in IGP. This paper proposes a novel model to solve this practical problem and has the following features:

(*i*) Regardless of the complexity of the penalty function, this model will easily treat any type of penalty function in a uniform way.

(*ii*) This uniform model is more concise and efficient than current ones.

CURRENT RELATED IGP MODEL

The idea of IGP proposed by Charnes and Collomb (1972) was first developed by Jones and Tamiz (1995). Increasing penalty and reverse penalty models were introduced in their article. For example, take an IGP problem with m goals. Suppose there are $k1+k2$ attribute values (the points of position on to the related target value) in penalty function of the *i*th goal. The attribute values are $a_{i,k1},...,a_{i,1},b_{i,1},...,b_{i,k2}$ where $a_{i,k1}<...<a_{i,1}<b_{i,1}<...<b_{i,k2}$. Then, the marginal penalty rates for each segment between adjacent attribute values are $\alpha_{i,k1-1},...,\alpha_{i,1},0,\beta_{i,1},...,\beta_{i,k2-1}$. This U-shaped penalty function (Fig. 1) can be expressed by Jones and Tamiz (1995) as follows:

Jones and Tamiz's model (1995):

$$\text{Min} \quad \sum_{i=1}^{m}\left[\alpha_{i,1}n_{i,1}+\sum_{j=2}^{k1-1}(\alpha_{i,j}-\alpha_{i,j-1})n_{i,j}+\beta_{i,1}\rho_{i,1}+\sum_{j=2}^{k2-1}(\beta_{i,j}-\beta_{i,j-1})\rho_{i,j}\right]$$

s.t.
$$f_i(\mathbf{x})+n_{i,j}-p_{i,j}=a_{i,j},\ j=1,...,k1-1,\ i=1,...,m, \tag{1}$$
$$f_i(\mathbf{x})+\eta_{i,j}-\rho_{i,j}=b_{i,j},\ j=1,...,k2-1,\ i=1,...,m, \tag{2}$$
$$n_{i,j}\le Mu_{i,j},\ p_{i,j}\le M(1-u_{i,j}),\ j=2,...,k1-1, \tag{3}$$
$$\eta_{i,j}\le Mv_{i,j},\rho_{i,j}\le M(1-v_{i,j}),\ j=2,...,k2-1, \tag{4}$$
$$\mathbf{x}\in\mathbf{F};\ n_{i,j},p_{i,j},\eta_{i,j},\rho_{i,j}\ge 0\ \forall i,j,$$

where $u_{i,j}$ and $v_{i,j}$ are binary variables, M is a big enough constant, and $n_{i,j}$ and $\rho_{i,j}$ present deviation variables for the left U-shaped penalty function and the right U-shaped penalty function, respectively .

For this U-shaped penalty function, two cases can be used in the Jones and Tamiz's model. One is increasing penalty case ($\alpha_{i,j+1}>\alpha_{i,j},\beta_{i,j+1}>\beta_{i,j}\ \forall i,j$), which only require Constraints (1) and (2). The other one is reverse penalty case ($\alpha_{i,j+1}<\alpha_{i,j},\beta_{i,j+1}<\beta_{i,j}\ \forall i,j$), which uses Big-M Constraints (3) and (4) to avoid both $n_{i,j}$ and $p_{i,j}$ ($\eta_{i,j}$ and $\rho_{i,j}$) becoming zero simultaneously, since the coefficients of $n_{i,j}$ ($\rho_{i,j}$) in achievement function are negative.

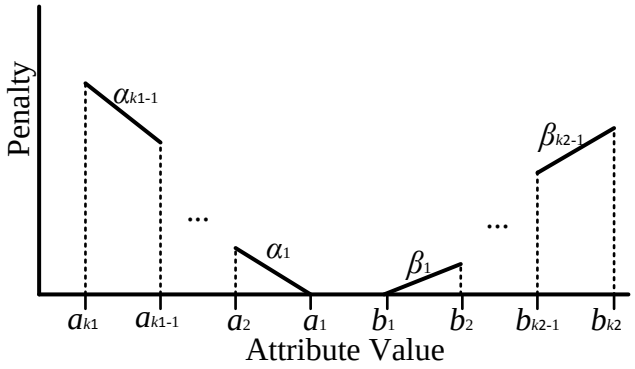

Figure 1: A U-shaped penalty function.

Recently, Chang (2006) proposed a new model of increasing penalty function for improving efficiency. The two aforementioned models (Jones and Tamiz, 1995; Chang, 2006) solve the penalty function regardless if marginal penalty rates for sequence segments are increasing or decreasing. However, these cannot solve the complex penalty function in an IGP. Yang et al. (1991) proposed a model for solving fuzzy programming problems with S-shaped membership function. Li and Yu (1999) showed that Yang et al.'s (1991) model is correct only for a specific type membership function and proposed their own model for other types of membership functions. Lin and Chen (2002) generalized the model of Yang et al. (1991) and indicated that the model of Li and Yu (1999) is inapplicable to a fuzzy programming problem involving more than one membership function. Recently, Chang and Lin (2009) proposed a complex formulation to solve the simplest S-shaped penalty function in an IGP problem.

However, when the models of Jones and Tamiz (1995) and Chang and Lin (2009) meet the reverse penalty case, they will become inefficient and complicated because of the Big-M constraints. Although there are many approaches in literature, all have been complicated and inefficient up to now. This paper proposes an efficient and concise uniform model to treat any arbitrary penalty function in IGP.

PROPOSED IGP MODEL FOR ARBITRARY PENALTY FUNCTION

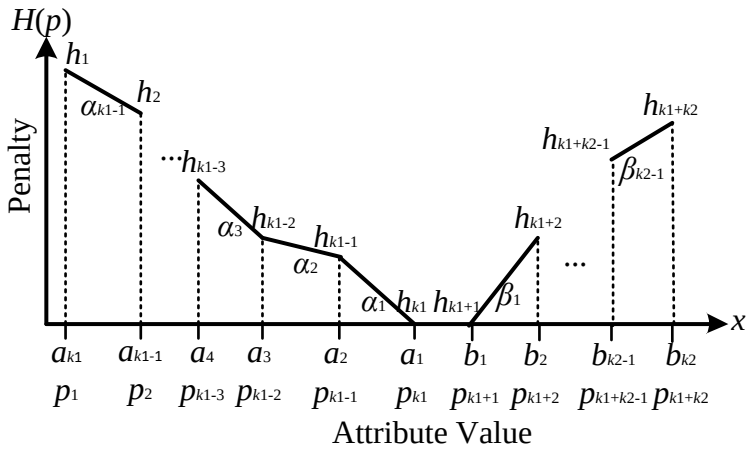

Figure 2: An arbitrary penalty function.

An arbitrary penalty function in IGP is a difficult problem (Fig. 2) since DMs can choice their preferred the marginal penalty rates for each segment between adjacent attribute values. As such, the slopes of each segment can be any arbitrary value, either positive or negative. For convenient modeling, another symbol is used to denote the original attributed values. Hence, $p_1 = a_{k1}$, …, $p_{k1} = a_1$, $p_{k1+1} = b_1$, …, $p_k = b_{k2}$ ($k = k1 + k2$). The arbitrary penalty function can be expressed by Proposition 1.

Proposition 1 *The penalty function* $H(p)$ (*Fig. 2*)*,* h_j *is the penalty value related to the attribute values* p_j *where* $j = 1,...,k$ $(H(p_j) = h_j)$ *.* k *positive continuous variables* $(\lambda_1,...,\lambda_k)$ *and* $k-1$ *binary variables* $(u_1,...,u_{k-1})$ *are introduced in this model.* $H(p)$ *can be expressed by the following linear equations and inequalities:*

$$p = \sum_{j=1}^{k} \lambda_j p_j , \tag{5}$$

$$H(p) = \sum_{j=1}^{k} \lambda_j h_j , \tag{6}$$

$$\sum_{j=1}^{k} \lambda_j = 1, \tag{7}$$

$$\sum_{j=1}^{k-1} u_j = 1, \tag{8}$$

$$\lambda_1 \le u_1 , \ \lambda_j \le u_{j-1} + u_j , j = 2,...,k-1 , \ \lambda_k \le u_{k-1} . \tag{9}$$

Proof It is trivial. □

In Proposition 1, the value of penalty in (6) will be zero when $u_{k1} = 1$ because the goal value between a_1 and b_1 meets the aspiration level that DMs choose. Afterwards, the penalty will be continuously increasing depending on the marginal penalty rates when the goal value is far away from the aspiration level. The model in Proposition 1 has an improvement over current models since there are no Big-M constraints. However, Constraint (9) requires $k-1$ binary variables and k constraints to construct the model. It still seems inefficient for solving the arbitrary penalty function in IGP. Vielma and Nemhauser (2010) proposed a technology that constructs Constraint with a logarithmic number of binary variables and constraints. Therefore, Vielma and Nemhauser (2010)'s technology is used to reduce the required binary variables and constraints and conduct the concise uniform model for treating any arbitrary penalty function. The proposed model is described in Proposition 2.

Proposition 2 *The penalty function $H(p)$ in Proposition1 can be expressed by the following linear equations and inequalities:*

$$\text{Min} \quad \sum_{i=1}^{m}\sum_{j=1}^{k}\lambda_{i,j}h_{i,j}$$

$$\text{s.t.} \quad f_i(\mathbf{x}) = \sum_{j=1}^{k}\lambda_{i,j}p_{i,j},\ i=1,...,m,$$

$$\sum_{j=1}^{k}\lambda_{i,j}=1,\ i=1,...,m, \tag{10}$$

$$\sum_{j\in J_l^+}\lambda_{i,j}\le v_{i,l},\ \sum_{j\in J_l^-}\lambda_{i,j}\le(1-v_{i,l}),\ l=1,...,r,\ i=1,...,m, \tag{11}$$

$$\mathbf{x}\in\mathbf{F};\ \lambda_{i,j}\ge 0\ \forall i,j;\ v_{i,l}\in\{0,1\}\ \forall i,l, \tag{12}$$

where

(i) $p_{i,j}$ and $h_{i,j}$ are the attribute values and related penalty value for goal i

$(p_{i,1}<...<p_{i,k})$,

(ii) J_l^+ and J_l^- are same in Proposition 2,

Proof It is similar to Proposition 1. □

NUMERICAL EXAMPLES

To demonstrate the usefulness and efficiency of the proposed model, three examples are presented here and are solved by CPLEX 11 (ILOG 2008) on a PC with 3.16 GHz Core™2 Duo CPU and 4GB RAM.

Example 1 The example is modified from the IGP problem of Vitoriano and Romero (1999). The problem is expressed as follows and the three goal penalty scale data are listed in Table 1.

$$\text{Goals:} \quad (f_1(\mathbf{x}))\ 3x_1+2.5x_2+2.5x_3=100$$
$$(f_2(\mathbf{x}))\ 4x_1+3x_2+3.5x_3=100$$
$$(f_3(\mathbf{x}))\ 3.8x_1+5x_2+3.5x_3=100$$

$$\text{s.t.} \quad x_2+x_3\ge 10, \tag{13}$$

$$x_1\ge 0,\ x_2\ge 4,\ x_3\ge 0. \tag{14}$$

Only two models (Chang and Lin, 2009; proposed model) can solve this IGP because those penalty functions are U-shaped, S-shaped, and arbitrary shaped respectively.

By referring to Chang and Lin (2009), this example can be formulated as a complicated and inefficient model. For the arbitrary penalty function (Goal 3), this model uses much binary

variables and Big-M constraints to restrict the domain of $n_{i,j}$ and $\rho_{i,j}$. Each of non-linear term ($u_{2,3}f_2(\mathbf{x})$, $v_{2,3}f_2(\mathbf{x})$, $u_{3,2}f_3(\mathbf{x})$, $v_{3,2}f_3(\mathbf{x})$, $u_{3,3}f_3(\mathbf{x})$, $v_{3,3}f_3(\mathbf{x})$) also require an additional binary variable and four Big-M constraints for linearization. The efficiency of this model will be hampered by the Big-M constraints. Compared to Chang and Lin's (2009) model, the proposed model is concise and efficient for treating any arbitrary penalty function in IGP. The respective computational times, iterations, binary variables, additional constraints, and solution are listed in Table 2.

Table 1: Penalty scale for the three goals.

Goals	Description	Interval (Unit %)	Marginal penalty
1	U-shaped increasing penalty function	10~80	3
		80~90	2
		90~100	1
		100~110	0
		110~120	1
		120~130	2
		130~200	3
2	S-shaped penalty function	10~80	0.9
		80~90	2
		90~100	1
		100~110	0
		110~120	1
		120~130	2
		130~200	0.9
3	Arbitrary penalty function	10~80	2
		80~90	1
		90~100	2
		100~110	0
		110~120	2
		120~130	1
		130~200	2

Table 2: The Computation Results for Example 1.

Item	Chang and Lin's model	Proposed model
CPU Time(sec)	0.11	0
No. of iterations	47	16
No. of 0-1 variables	12	9
No. of constraints	60	21
Solution (x_1, x_2, x_3)	(18.33, 4, 6)	
Goal (1,2,3)	(80, 106.33, 110.67)	

CONCLUSION

This paper proposes an efficient and concise model to treat any arbitrary penalty function in IGP. Regardless of the complexity of the penalty function, this model can efficiently solve any arbitrary penalty function in a uniform way, and with binary variables and constraints that only require logarithmic numbers of original ones. Numerical examples show that this novel model for treating arbitrary penalty function in IGP has favorably tight properties, while computational results demonstrate that it significantly outperforms current models, especially when the scale of a problem is large.

ABSTRACT

Seaports are important nodes in modern supply chains and have a large impact on national wellbeing. A disruption in these links can have a high impact on the whole society. Preparation is important if crises want to be handled efficiently. This paper analyzes how logistical emergency situations can be modeled with hybrid simulation modelling. Simulations are one possible way to analyze, how complex systems develop through time. The focus is on maritime transportation in the Gulf of Finland. Queuing models from Discrete-Event Simulation was combines with Agent-Based Modelling to have more realistic models. This paper provides an overview, how it is possible to model individual ships using available data and creating a network of connections between potential seaborne routes. The simulation model estimates, how long queues will develop to backup seaports, if some seaports cannot be used due to disruptions. Also, the importance of coordination is highlighted in this paper. Practical action points, like importance of weekend work and amount of working shifts at the seaports in the time of emergency are highlighted by the simulation results.

Keywords: Agent-Based Modeling, Simulation, Logistics, Containerization, Risk management

INTRODUCTION

During the spring of 2010 there was a huge oil spill in the Gulf of Mexico. Nearly 5 million barrels of oil spilled out (Achenbach and Fahrenthold 2010) and it will have a long-term impact for both the environment and the economy. Repeating similar negative outcome to Exxon Valdez oil tanker accident in Alaska during 1989 (, where 0.35 mill. barrels were spilled out to fragile Northern nature; BBC, 2011a), as well as Erika and Prestige oil spills in the France/Spanish coast-line during years 1999 and 2002 (BBC, 2011b; Rainsford, 2010). Spillages also create pressures for logistical systems as a spillage can force a seaport to be closed for the duration of the cleaning operations. The Gulf of Finland is especially a sensitive area as the passage is narrow and there is a heavy traffic flow of oil ships from the port of Primorsk, but also from Estonian seaport, Muuga (Tallinn) (Kämärä 2010).

Seaports act as important nodes in global supply chains (Panayides and Song 2008). Congestion is one important category in port competitiveness (Yeo et al. 2008; Tongzon and

Heng, 2005) and they have a large impact on national wellbeing as well. A disruption in port operations might have a big impact as many nations are heavily dependent on seaborne transportation. On global scale over 40 % of all trade is conducted using seaports (World Trade Organization 2009) and in some countries the share is even larger. In Finland roughly 80 – 90 % of all trade in tons is through seaports (Finnish Customs 2011),

Preparation is critical in crisis situations (Long 1997). Preparation phase is the strategic planning for the operations during the actual crisis. This paper will concentrate on developing a method to analyze logistical system in these types of situations. However, it is not an easy task. If no other method can be used to analyze a complex system, simulation can be used as a final method (Law 2006). Agent-Based Modelling has started to gather more interest in the academia, but models in Operational Research are still scarce (Siebers et al. 2010). However, it can provide improved understanding on systems, which were earlier too complex to be modelled by using other, more traditional, approaches (Macal and North, 2006).

The research question in this paper is: "*How can logistics emergency situations be simulated with Agent-Based Modelling?*" In this study we use a hybrid simulation model to analyze how logistical flows will function in a crisis situation. A hybrid approach is used as Discrete-Event Simulation provides many good ways to model queuing systems. However, it lacks the versatility of Agent-Based Modelling. As such, hybridization was our chosen approach.

This paper is structure as follows. In the second section information about risk management is presented. The third section provides an overview about simulations. The section presents general information from simulation, as well as the used simulation approaches. The fourth section concentrates on the research background. The research project behind this study is presented. The fifth section gives an overview about the simulation model, while the sixth section analyzes the model's results. The final section concludes this study and provides further avenues for research.

SUPPLY CHAIN RISK MANAGEMENT

Most research on intermodal supply chains concentrated on efficiency and capacity estimation prior of 9/11. This research included optimal scheduling of container terminal construction (Fung 1998), impact of insufficient capacity on commodity prices (Terahara 1999), and fine tuning operational strategies in intermodal train operations (Newmann 1998). Since 9/11 risk management has started to gather more interest. Vandiver (2006) identified critical infrastructure in the U.S. Computers, telecommunication equipment, and pharmaceutical preparations were seen to be most critical cargo as they have a high impact to other sectors and are difficult to substitute. Direnzo (2007) estimated maritime risk related to different regions. Trade and passenger flows in the US were used to estimate the high risk areas. Handley-Schachler and Navare (2010) highlight the importance of identifying risk allocation and sustainability in port systems, as they are usually partially owned by public sector and operated by the private sector. According to de Langen (2004) the port governance structure also has a great impact on seaport performance.

A related issue is the handling of different types of goods. Some dangerous goods (such as flammable liquids, dangerous gases, etc.) require special attention. A risk management framework for dangerous goods transportation has been proposed by Batarlienė (2008). However, recently 100% inspection for containers has been suggested by U.S. officials and it might have a big impact on port operations (Bakshi et al. 2011). Figure 1 shows the most important variables regarding risk management within nodes in supply chains. The whole supply chain consists then from many nodes which each with their own risk management as well as the actual transportation between the nodes. This requires coordination between the partners. The coordination consists of contracts, information technology, information sharing, and joint-decision making (Arshinder et al. 2008). Figure 2 represents the risk management in a supply chain.

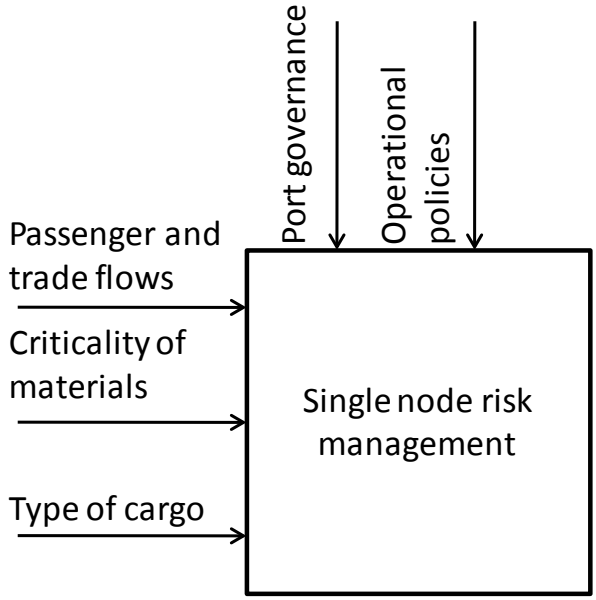

Figure 1: Variables impacting risk management in transportation nodes.

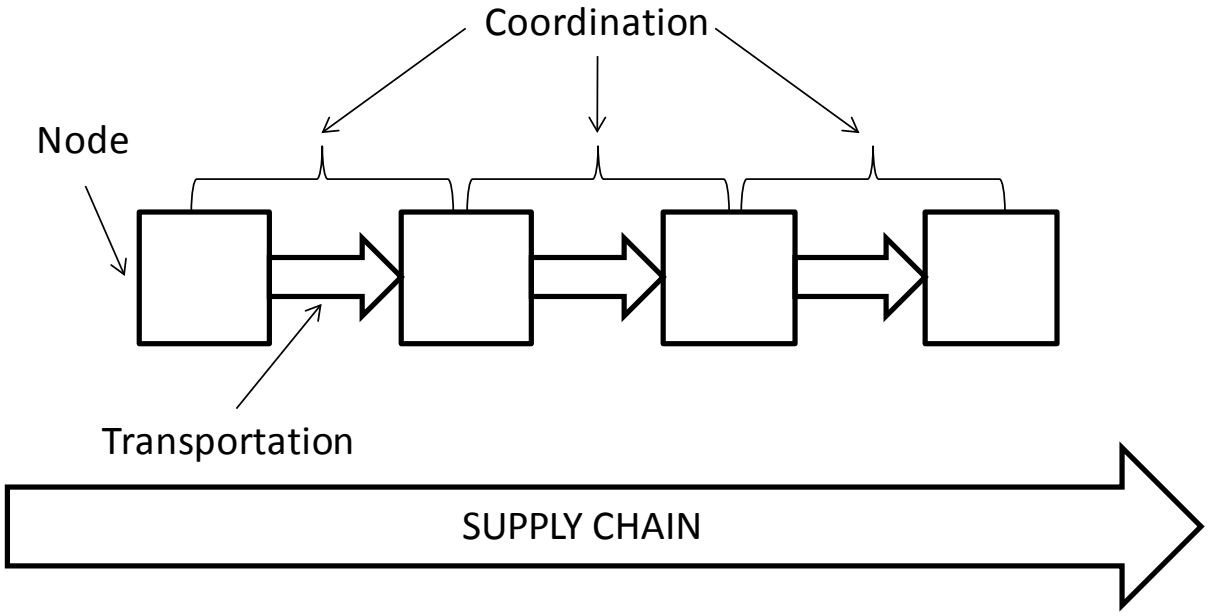

Figure 2: Supply chain risk management.

Mansouri et al. (2010) have proposed a framework to create resilient port infrastructure systems. In the first phase the vulnerabilities are assessed. During the second phase resilience strategies are developed. In the final phase investment strategies are valued. The resilience of the whole system will not only depend on the resilience of individual nodes but strong interdependencies between nodes exist. For instance, if there is a stoppage in one part of the chain, it might ripple through the whole chain. If one train is missed, it is possible to miss a connecting ship and the whole delivery is delayed.

SIMULATION MODELLING

Simulation as a Part of the Operations Research Toolkit

Simulation is one possible tool in operations research (Hillier and Lieberman 2005). The purpose of operations research is to improve organizational performance by finding best possible (or good) solutions to problems. Robinson (2004, p.4) has defined simulations as "Experimentation with a simplified imitation (on a computer) of an operations system as it progresses through time, for the purpose of better understanding and/or improving that system". Simulation does not guarantee improvement, but it can be combined with heuristics and/or optimization (Ivanov 2009).

According to Robinson (2004), three key issues separate simulation from other modelling approaches. Many traditional modelling approaches do not contain stochastic elements, which might have a big impact on the final results. Secondly, simulation does not contain restrictive assumptions, which might be difficult to take into account in other modelling approaches. Thirdly, simulation models have an animated display, which allows more transparency than a large set of equation or large spreadsheet models.

Many different simulation approaches exist. According to Jahangirian et al. (2010), the most widely used approaches in manufacturing and business are discrete-event simulation (DES), system dynamics, hybrid models, and agent-based modeling (ABM). The approaches used in this paper (ABM and DES) are introduced in the following sections.

Agent-Based Modelling

Agent-Based Modelling is a relatively new approach in simulation modeling. The original concept trace back to von Neumann machines but it started to gather more interest in the 1990s as computational power started to increase rapidly (Macal and North, 2005). One of the first applications was Schelling's segregation model (Schelling, 1969). The model consisted of a grid of household. Each household had preferences regarding their neighborhood. If too many neighbors were of different condition (this could be income level, education, race, etc.), the household decided to move to a new location. Eventually the system reaches a equilibrium where different types of households live in segregated environments.

According to Macal and North (2006) there are four primary reasons for the increased interest in Agent-Based Modelling. Firstly, observed systems are becoming more complex in

terms of interdependence. Secondly, some systems have been too complex to model using other approaches. Thirdly, even more data exists in a higher level of granuility. Finally, the rapid increase in computational power has made the simulations possible. According to Davidsson et al. (2005) and Hilletofth et al. (2010), most of the work in Agent-Based Modelling is still on a conceptual level and only few empirical models exist.

Many different classifications for agents have been presented but there are no agreement regarding the subject (Schieritz and Milling 2003). Few basic principles still apply to the actual modeling approach. The main area of interest is the agents and their decisions. The agents exist in an environment and gather local information for simulation system. The agents will then interact with other agents and the system's behavior emerges from the interaction. (Wooldridge and Jennings 1995)

Discrete-Event Simulation

The main focus in DES is discrete-events, which occur during the simulation run. The events are located in a calendar. As soon as the simulations time reaches an event, it will be executed. Each event will be executed one at a time. White and Ingalls (2009) provide an overview about the most important aspects in DES. They are presented in Table 1.

Table 1: Concepts in discrete-event simulation (White and Ingalls 2009).

Concept	Description
Inputs	Actions of environment on the system
Outputs	Measured quantities
State	Internal condition of the system
Entities	Dynamic entities which flow through the system's structure
Attributes	Unique characteristics of an entity
Activities	Processes and logic in the model
Events	Conditions occurring during the simulation, which causes a change in the system's state
Resources	Anything which has a constrained capacity
Global variables	Variable containing information about the system
Random number generator	Generates randomized values to be used during the simulation
Statistics collector	Collects statistics on conditions

Servers and queues are heavily used within DES. Entities enter the model through various sources and wait in queues to be served by different servers. There is a delay when the server handles the entity and the entity then moves to a new queue. Eventually the entities exist through sinks. (Banks et al. 2005)

RESEARCH BACKGROUND

This research was conducted during an EU funded (Interreg IV A programme) STOCA project (Study of Cargo Flows in the Gulf of Finland in Emergency Situations). The project consisted of many work packages conducted by different organizations. One package concentrated on creating simulation models for emergency situations. This paper presents one of these

models. Prior to the model construction interviews were conducted. The interviewees consisted from various logistical operators in the Gulf of Finland area. The models were constructed based on the interviews. More information from the interviews can be found in Karttunen et al. (2010).

Simulation was chosen as the research methodology as the problem domain is extremely complex and it might be difficult to include all of the important dimensions in analytical model. In these cases simulation is a justified approach (Law 2006). Agent-Based Modelling has started to gather more interest in the academia but models in Operational Research are still scarce (Siebers et al. 2010). However, it can provide improved understanding on systems, which were earlier too complex to be modelled by using other, more traditional, approaches (Macal and North, 2006). During the project System Dynamics models were as well constructed, but they will not be presented in this paper.

Gulf of Finland is located between Finland, Estonia, and Russia in the Baltic Sea Region. The largest seaports of the region are located in Russia. The largest one, Primorsk, handles 75+ million tons of oil products each year. The second largest, Port of Saint Petersburg, handles over 50 million tons of various cargo. Other major seaports in the area include Vysotsk (Russia), Ust-Luga (Russia, in the medium-term planned to reach 100+ mill. tons handling volume), Sköldvik (Finland), Helsinki (Finland), Kotka and Hamina (Finland), and Tallinn (Estonia). The map of the area is presented in Figure 3. (Kämärä 2010)

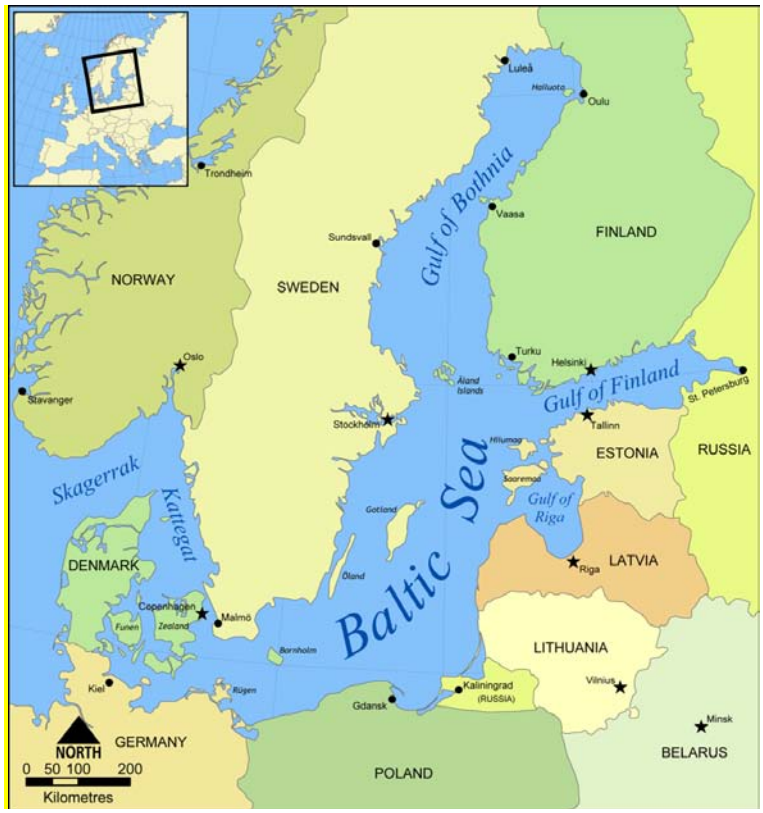

Figure 3: Baltic Sea Region (Map from Wikimedia Commons).

A relatively large part of the demand in Fnnish and Estonian seaports are due transit traffic to/from Russia. Estonian seaports handle a great deal of Russian oil products. The port of Tallinn handles over 20 million tons of oil each year. The oil is transported to Tallinn via

railways. The ports of Hamina and Kotka also handle a good deal of Russian oil products. The east-bound transit to Russia consists mostly from containers and cars. (Kämäräinen 2010; Posti et al. 2009)

SIMULATION MODEL

The simulation model combines Agent-Based Modelling with Discrete-Event Simulation. The model was coded using Anylogic. The main elements in the simulation model are the individual ships. Each ship represents one container ship, which has its own route to follow. The data for the ships has been gathered from Fossey (2009). The ships move in the Baltic Sea Region according to their route. When a ship arrives to its location, it spends there a stochastic amount of time. The time comes from a triangular distribution with a minimum time of 8 hours, mode of 12 hours, and a maximum of 24 hours. Figure 4 shows a schematic of the ship agents.

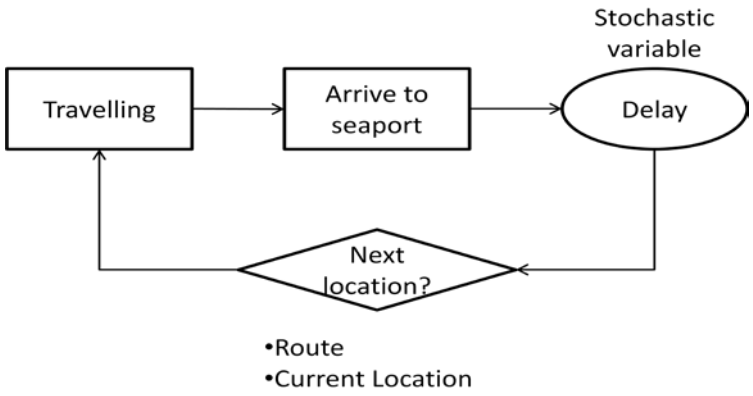

Figure 4: Schematic of the ship agents.

The travelling time uses a graphical information system (GIS) to calculate the time between the seaports using a fixed speed. The model contains a layer of networked connections in the region. This layer works as the GIS inside the model. The software has automatic algorithms, which choose the fastest route inside the network between the desired nodes. The layer is also incorporated to the user interface and the individual ships move on this layer. This is presented in Figure 5.

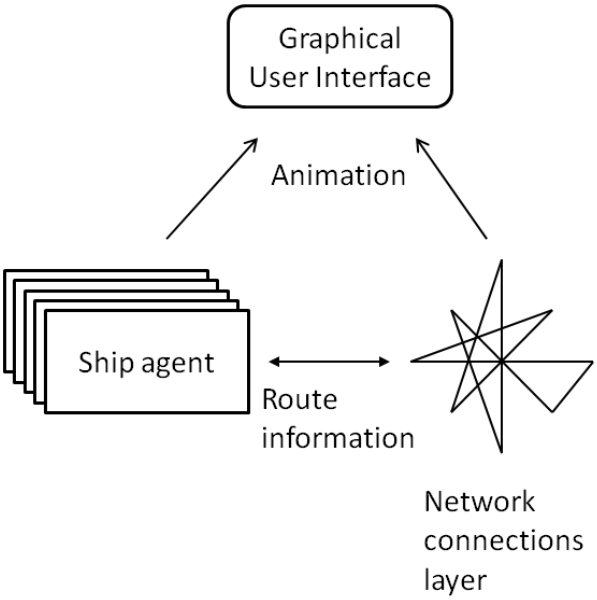

Figure 5: Schematic of the ship agents, network connections layer and graphical user interface.

During the normal run time no seaport has any issues with capacity. This is why the delays in the ship agents are modelled using stochastic variables. Figure 6 shows the model during the normal run-time.

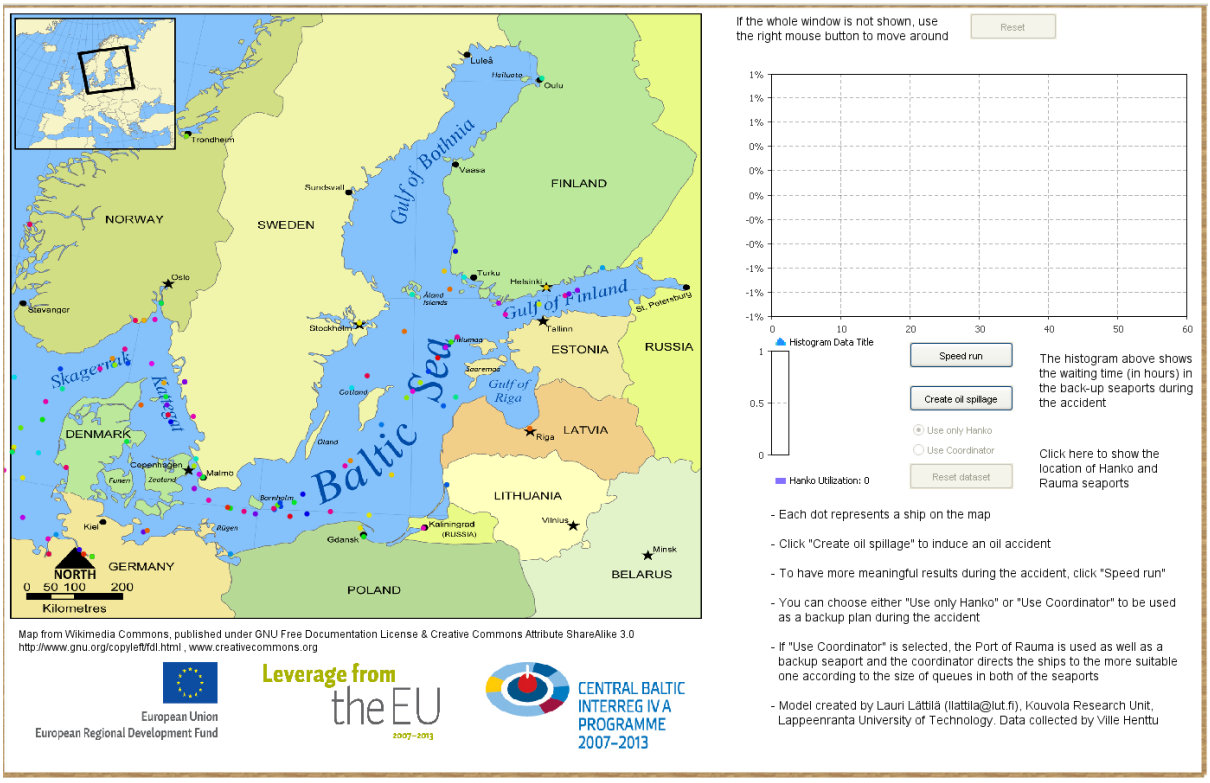

Figure 6: Model interface during normal runtime.

During the simulation it is possible to induce an oil accident in the region. The ports of Helsinki, Kotka, and Hamina cannot be used as the oil is seen to block the seaport completely. The ships start to re-route to Hanko as it is the closest seaport with a meaningful amount of container capacity. It is also possible to use a coordinating agent during the accident. This coordinator is able to gather information from various sources and in the Finnish context it could represent the Finnish National Emergency Supply Agency. The co-ordinator will route the ships to the most suitable location during the crisis. The co-ordinator will use Rauma as another potential backup seaport. It has a lot of container capacity but it is located further away on the west coast of Finland. The information used by the co-ordinator is presented in Table 2.

Table 2: Information used by the coordinator.

Amount of ships in Hanko
Amount of ships in Rauma
Ships arriving to Hanko
Ships arriving to Rauma
Capacity available at both seaports

During the oil-accident the capacity of Hanko and Rauma becomes constrained. The capacity of the seaports depends on the amount of container cranes on the seaports, as well as the working hours. In Finland seaports generally operate two shifts during weekdays and one shift during Saturday. Hanko has 2 cranes operating and Rauma has 9. Also, the seaports do some overtime work. Each ship will be handled even if the seaport has to use overtime.The model contains a graphical-user interface where the user can induce the oil accident. Also, the user can decide whether a coordinator is used or not. Figure 7 shows the model during the oil-accident.

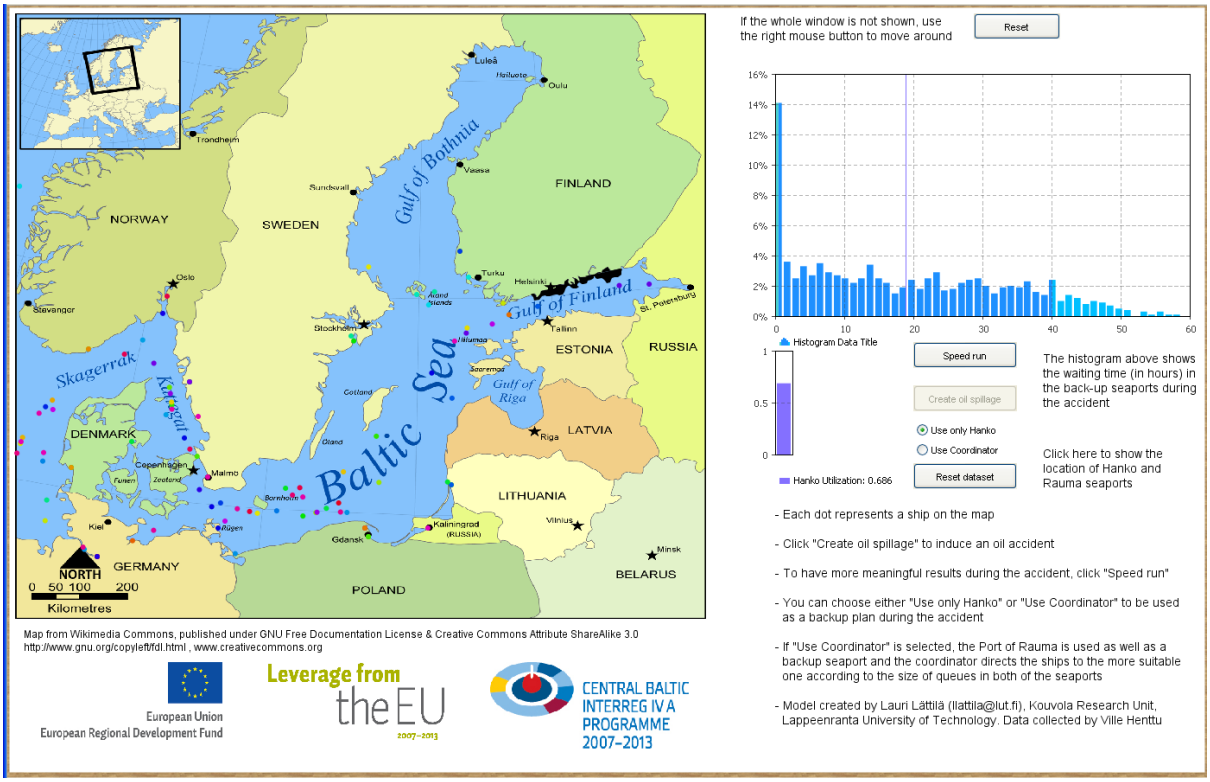

Figure 7: Model interface during the oil accident.

The ports of Rauma and Hanko are modeled using DES. The ships will first arrive into a queue and wait for a server. During the normal working hours all of the servers are available. Figure 8 shows the schematic for the ship agents during the oil accident

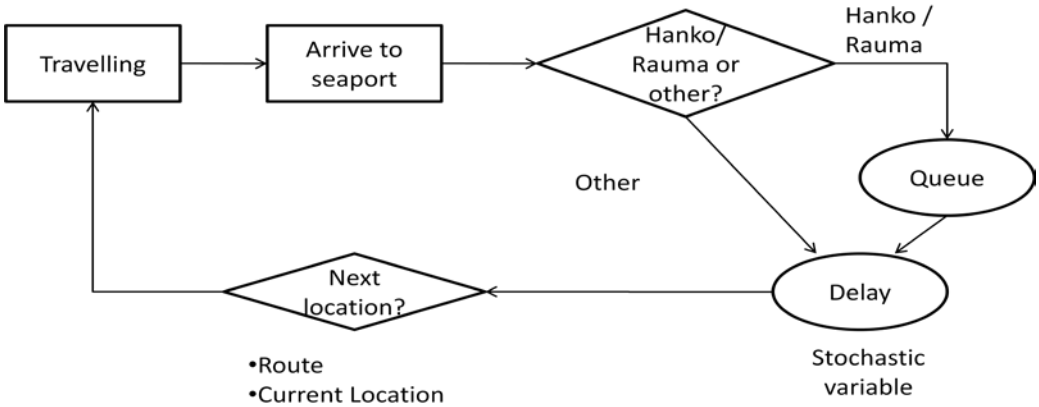

Figure 8: Schematics for the ship agents during the oil accident.

All of the ships at the port of Kotka, Hamina, and Helsinki are “trapped” inside the oil and cannot leave their respective seaports. They are removed from the model. The other ships start to reroute to Hanko or ask the coordinator for the appropriate seaport.

RESULTS FROM THE MODEL

The main area of interest in the simulation study is the queuing time in the system during the accident. In the long run the demand is below the system's capacity as the amount of ship is limited. However, the ships might have to wait long times before the seaports can take the ships in during the accident. Figure 9 shows results during one simulation run.

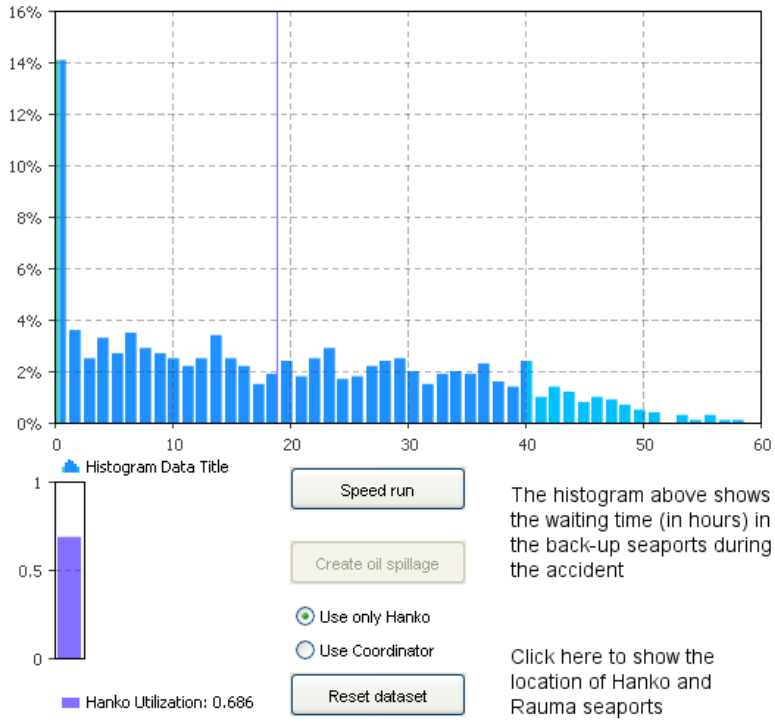

Figure 9: Waiting times for ships when only Hanko is used.

About 14% of the ships get immediately to handling as there are no ships in queue. However, most of the ships have to wait for some time and the average waiting time is 19 hours. Some ships even have to wait nearly 60 hours. It should be noted, that some of the waiting time is simply due to weekends. During this time no servers will be available and this is shown up as excess waiting time. The situation improves significantly when the coordinator is included in the model. The results for this are presented in Figure 10.

The average waiting time drops from 19 hours to ten hours. Also, as this situation also includes the seaport operating hours, large part of the queue is most likely due to waiting for working hours, not waiting for a server. Nearly 45% of the ships do not have to wait in queue at all.

The waiting time were compared statistically. As the waiting times are not normally distributed, a non-parametric test was chosen. In this case Mann-Whitney's U-test was used. The test was conducted with SPSS and the results are presented in Table 3.

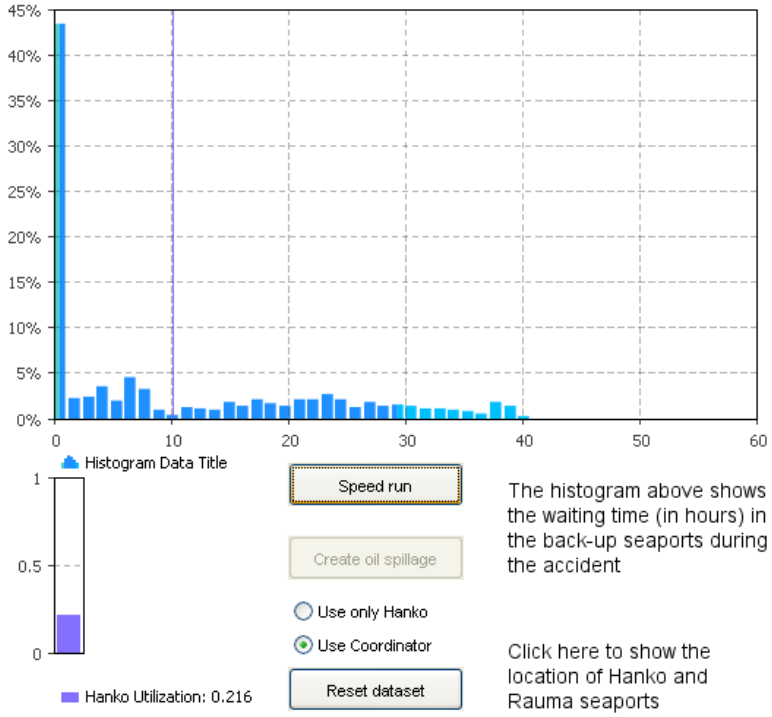

Figure 10: Waiting time for ships when coordinator is used.

Table 3: Mann-Whitney's test for the waiting times.

Ranks

	Chosen scenario	N	Mean Rank	Sum of Ranks
Excess waiting time	No coordinator	1000	1162,49	1162494,50
	Coordinator	1000	838,51	838505,50
	Total	2000		

Test Statistics[a]

	Excess waiting time
Mann-Whitney U	338005,500
Wilcoxon W	838505,500
Z	-12,680
Asymp. Sig. (2-tailed)	,000

a. Grouping Variable: Chosen scenario

The waiting times are clearly smaller when the coordinator is used. The ships are able to get through the system a lot faster and the damage to society is clearly smaller. However, in order to have more meaningful results, a Monte Carlo module was included in the model. The module will create oil accidents of various length and analyzes the mean waiting time. These results are presented in Figures 11 and 12.

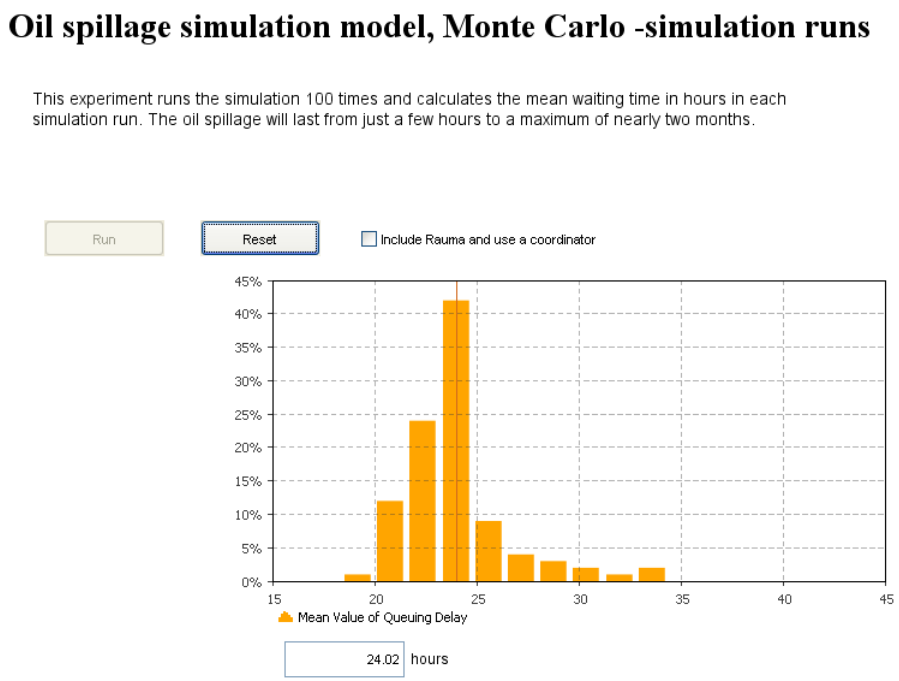

Figure 11: Monte Carlo run results without using a coordinator.

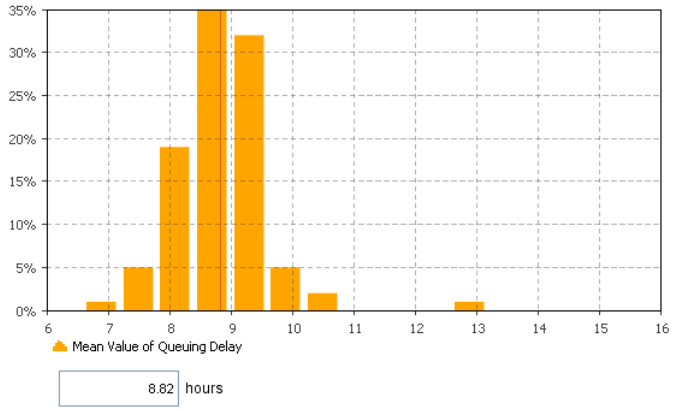

Figure 12: Monte Carlo run results with using a coordinator.

The Monte Carlo runs results confirm the observations. It is possible to significantly reduce the excess waiting time by using a coordinating actor who gathers the relevant information regarding potential back-up seaports. This is also reflected in the respective utilization statistics. Using only Hanko the utilization can be as high as over 70% (theoretical maximum without overtime is 52 % so significant over time is used in the model) but drops to 25 %, when a coordinator is used.

DISCUSSION AND CONCLUSIONS

The research question in this paper was "How can logistics emergency situations be simulated with Agent-Based Modelling?" Hybridization of ABM and DES seems to provide a good platform to analyze logistical systems in emergency situations. Individual nodes (such as seaports and warehouses) can be modeled using servers and queues, while actual transportation between the nodes can be modeled using ABM. This is in line with the

conceptual framework presented in Figure 2. Simulation provides a good way to estimate the interconnectness of the system as individual supply chain are connected. Supply chains can share same transports (especially large container ships) and they can use the same nodes. Coordination was also included in the model.

This research has some limitations. Firstly, only containerships in the Containerization International Yearbook were analyzed. If a significant portion of containerships are not presented in the book, then the demand on the seaports is too small. Also, different types of cargo were not analyzed in the model. Even though dry or liquid bulk ships would not use the same loading/unloading equipment, they require pilots to get to the seaports. Piloting should be as well included in the model and then incorporate demand from other sea vessels than container ships. Secondly, hinterland capacity was not analyzed in the model. This might create bottlenecks in the nodes, which would further increase the waiting time at the seaports.

Further research includes expanding the model to include different types of ships and pilots. However, it might be difficult to get information from the dry bulk shipping lines. One possible way is to include them as random arrivals to the servers according to the seaport current demand. Hinterland capacity also plays a vital role in emergency situations. It should also be included in the model. Hybridization of various simulation approaches provides many benefits and should be strongly encouraged in logistics research.

ABSTRACT

The main objective of this paper is to deal with a single item lot sizing problem with fuzzy parameters, which is called the fuzzy single item lot sizing problem (F-SILSP). Since F-SILSP does not meet the crisp deterministic assumption, it cannot be solved by traditional mathematical programming. In this paper, the possibility approach is chosen to convert the fuzzy model to be an equivalent crisp single item lot sizing problem (EC-SILSP). The equivalent crisp model from this transformation procedure is in the form of mixed integer linear programming (MILP). It can be solved by traditional solver to find an optimal solution for each pre-specified possibility level. A numerical example with both trapezoidal and triangular fuzzy parameters is illustrated to demonstrate that an equivalent crisp model can be used. In addition, the equivalent crisp model is employed in inventory planning in a case study of inventory planning for bituminous coal with trapezoidal fuzzy demand and triangular fuzzy unit price in a power plant of an example petrochemical company.

Keywords: Modeling, Inventory Planning, Lot Sizing Problem, Fuzzy Set Theory, Possibility Theory, Petrochemical Company

INTRODUCTION

Lot sizing problems are production planning problems with order quantity between purchasing or production lots (Brahimi *et al.*, 2006). Small lot sizes lead to many orders and low inventory levels. On the other hand, big lot sizes lead to few orders and high inventory levels (Lee *et al.,* 1991). Thus, the consideration of lot sizes is an economic problem in that the objective of inventory models is to minimize total inventory cost, which comprises unit price, ordering cost, and inventory holding cost, while satisfying demand (Lee *et al.,* 1991; Brahimi *et al.*, 2006). The first inventory planning model, namely Economic Order Quantity (EOQ), was proposed by Harris (1913). It is used to find an optimal order quantity in the case of an uncapacitated single stage and single item of inventory control with a well-defined demand pattern. However, sometimes the demand pattern cannot be defined. Wagner and Whitin (1958) proposed an inventory model with time-vary demand, namely dynamic lot sizing, and used dynamic programming techniques to find an optimal order quantity. Subsequently, other inventory models have been constructed, based on the above models, such as the Economic Manufactured Quantity (EMQ) model, the EOQ with backorder, the EOQ with price breaks, EOQ based period order quantity, the EOQ for multiple items with capacity constraints, the lot sizing problem for lead time minimization, the run-out time

model, the lot sizing problem in the case of shortages causing lost sales, the order-level system with a power demand pattern, the uncapacitated single item lot sizing problem, the capacitated single item lot sizing problem, the uncapacitated multiple item lot sizing problem, the capacitated multiple item lot sizing problem, and so on (Baracsi *et al.*, 1990; Askin and Goldberg, 2002; Brahimi *et al.*, 2006).

USILSP is a type of inventory model with time-vary demand. Brahimi *et al.* (2006) stated that there are four basic formulations of USILSP in the form of mixed integer linear programming (MILP), i.e., aggregate formulation (AGG), formulation without inventory variables (NIF), the shortest path formulation (SHP), and facility location-based formulation without inventory variables (FAL). They gave three reasons that motivate us to study USILSP, i.e., some industries can aggregate products to obtain a single product, USILSP is a basic model and can be extended towards a more complex model, and many solution approaches for solving complex lot sizing problems must use USILP as sub-problems. As a result, the authors focus on the AGG model in USILSP which is shown in equations (1)-(4).

Notations

The following notations are used in the paper:

t, the t^{th} period in the planning horizon t = 1, 2,…, T,
y_t, the ordering (or setup) variable, which is 1 when order or setup occurs in period t, and 0 otherwise,
S_t, the ordering (or setup) cost in period t,
x_t, the purchasing (or producing) quantity in period t,
I_t, the inventory level at the end of period t,
p_t, the unit price (or production cost) in period t,
h_t, the inventory holding cost in period t,
d_t, the demand in period t,
d_{kT}, the sufficiently large number, where $d_{kT} = \sum_{t=1}^{T} d_t$; ∀t.

Focused on the AGG model in USILSP, assume that there are no beginning and ending stocks of the planning horizon ($I_0 = I_T = 0$), and inventory parameters i.e., s_t, p_t, h_t, and d_t are deterministic. The AGG of USILSP in a form of MILP is as follows:

(USILSP-AGG) Min TC = $\sum_{t=1}^{T}(s_t y_t + p_t x_t + h_t I_t)$ (1)

Subject to:

$I_{t-1} + x_t - I_t = d_t$; ∀t, (2)

$y_t d_{kT} \geq x_t$; ∀t, (3)

$y_t \in$ binary variables, $x_t \geq 0$, $I_t \geq 0$; ∀t. (4)

The objective function of USILSP-AGG in equation (1) is to minimize the total cost over the t period horizon. Constraints in equation (2) are inventory balance equations. Demand in period t (d_t) can be satisfied when it is equal to the beginning inventory of period t (I_{t-1}) plus the purchasing or producing quantities in period t (x_t) minus the available on-hand inventory at the end of period t (I_t). Constraints in equation (3) are used to control ordering variables. Since d_{tT} is a large number, then y_t is treated as 1 when inventory is ordered in period t ($x_t > 0$), and y_t is treated as 0 when inventory is not ordered in period t ($x_t = 0$).

To answer how much inventory is required to minimize total cost and satisfy demand in each period, the inventory models are a good choice of approach. When a classical inventory model is used, a crisp deterministic assumption is required. However, sometimes, this assumption does not hold. In real-world problems, there are two types of uncertain parameter in the inventory model, i.e., randomness and fuzziness, which respectively lead to the fuzzy inventory model and the stochastic inventory model. Most information stochastic inventory models are described by statistical or probabilistic information, which deals with probability distributions of inventory parameters. Since statistical information is collected from a lot of sampling data, high cost and time lost for data collection must be considered. There are many researchers who use verbal information based on the experiences of veterans, and model these experiences to be fuzzy parameters (Mandal *et. al.*, 2005; Yao *et al.,* 2006; Dutta *et. al.*, 2007; Tutuncu *et. al.*, 2008). For these reasons, this paper used fuzzy set theory and deals with SILSP with fuzzy parameters.

FUZZY UNCAPACITATED SINGLE ITEM LOT SIZING PROBLEM (F-USILSP)

Fuzzy set theory was first proposed by Zadeh (1965). It is a mathematical tool to describe imprecision in the fuzzy environment. Imprecision refers to the sense of vagueness rather than the lack of knowledge about the value of parameters. The vagueness is due to the unique experiences and judgments of decision makers. For example, demand is classified as two verbal sets, medium and high. When a classical set is chosen to classify this demand as verbal classes, the range of 10,000-15,000 units of demand is defined as medium, and 15,001-20,000 units of demand is defined as high. The exact boundary of medium and high is 15,000 units of demand. It means that 15,000 units of demand is assigned to the set of medium, but 15,001 units of demand is assigned to the set of high. This classification shows that when an event is classified by the judgment of decision maker(s), an exact set boundary is inappropriate. On the other hand, the fuzzy set boundary is not an exact demarcation but an area of boundary. Members in a fuzzy set must be linked with a degree of possibility in the range of [0, 1], which is called a membership function.

The fuzzy set was designed for vagueness and uncertainty, which are found in real life. In addition, there are many fields which are built based on fuzzy set theory, such as fuzzy logic and control, fuzzy clustering, fuzzy mathematical programming , etc. (Zimmermann, 1996). Fuzzy mathematical programming or fuzzy optimization, which was proposed by Zimmermann (1976, 1978, and 1983), is one application of fuzzy set theory. It was extended to many fields in production planning and control, such as transportation, scheduling, flexible manufacturing system (FMS), location, aggregate planning, inventory planning, and

so on (Zimmermann, 1996; Klir *et al.*, 1997). There has been a lot of research which deals with vagueness in inventory models. For example, Yao and Lee (1999) introduced a group of computing schemata for the fuzzy EOQ of inventory with or without backorders. Hsieh (2002) used fuzzy arithmetical operations of the function principle to find the fuzzy total production inventory costs, and used Graded Mean Integration Representation and the Extension of the Lagrangean method to defuzzify and find optimal solutions for the inventory models. Pai (2003) applied fuzzy sets theory to solve capacitated lot size problems with fuzzy capacity. Yao and Chiang (2003) compared the results obtained by centroid and signed distance methods in the case of the total cost of inventory without backorders. Mandala *et al.* (2005) focused on fuzzy cost parameters, objective functions, and constraints in a multi-item multi-objective inventory model with shortages and demand dependent unit cost with storage space, number of orders and production cost restrictions. Chang *et al.* (2006) used fuzzy concepts to optimize total inventory cost in the case of a mixture inventory model involving variable lead time with backorders and lost sales. Chen and Chang (2008) studied the fuzzy EPQ in the case of unrepairable defective products with fuzzy opportunity cost and trapezoidal fuzzy costs under crisp or fuzzy production quantities in order to extend the traditional production inventory model to the fuzzy model. Halim *et al.* (2011) developed fuzzy production planning models for an unreliable production system with fuzzy production rate and stochastic/fuzzy demand rate.

The AGG model is selected to show how the possibility approach can transform the fuzzy inventory model into an equivalent crisp inventory model. Let the unit price, ordering cost, inventory holding cost, and demand be fuzzy variables. Thus the F-USILSP can be modeled as follows:

$$\text{(F-USILSP) Min TC} = \sum_{t=1}^{T}(\tilde{s}_t y_t + \tilde{p}_t x_t + \tilde{h}_t I_t) \quad (5)$$

$$\text{Subject to } I_{t-1} + x_t - I_t = \tilde{d}_t;\ \forall t, \quad (6)$$

$$y_t \tilde{d}_{kT} \geq x_t;\ \forall t, \quad (7)$$

$$y_t \in \text{binary variables},\ x_t \geq 0,\ I_t \geq 0;\ \forall t. \quad (8)$$

The F-USILSP in equations (5)-(8) is in a form of fuzzy MILP. Thus, this model cannot be solved by classical mathematical methods.

EQUIVALENT CRISP UNCAPACITATED SINGLE ITEM LOT SIZING PROBLEM (EC-USILSP)

The possibility approach in the context of fuzzy set theory was introduced by Zadeh (1978) to deal with non- stochastic imprecision and vagueness. According to Dubois and Prade (1988) and Dubois (2006), the possibility approach appropriately was used to model various kinds of information, such as linguistic information and uncertain formulae, in logical settings. In this section, the possibility approach will be used to convert the F-USILSP to the EC-USILSP.

Let $\tilde{a}$ and $\tilde{b}$ be fuzzy variables, and $\tilde{a}'$ and $\tilde{b}'$ be the complements of $\tilde{a}$ and $\tilde{b}$, respectively. Operation * means any one of the operators >, $\geq$, =, $\leq$, <. The possibility and necessity measure of fuzzy event $\tilde{a} * \tilde{b}$ are respectively defined by (Zimmermann, 1990).

$$\pi(\tilde{a} * \tilde{b}) = \sup\{\min(\mu_{\tilde{a}}(x), \mu_{\tilde{b}}(y))/x * y; x, y \in \Re\} \quad (9)$$

$$\mathrm{Ness}(\tilde{a} * \tilde{b}) = 1 - \pi(\tilde{a}' * \tilde{b}') \quad (10)$$

where $\pi(\tilde{\bullet})$ and $\mathrm{Ness}(\tilde{\bullet})$ means possibility and necessity of fuzzy variable $\tilde{\bullet}$.

Let $\tilde{a}_i$ for i = 1,…, n be n fuzzy variables, the right hand side $\tilde{b}$ becomes a crisp variable, and let $f : \Re^n \to \Re$ be a real-value function. The possibility of fuzzy event $f(\tilde{a}_i) * b$ is defined by (Zimmermann, 1996).

$$\pi(f(\tilde{a}_i) * b) = \sup_{x_i \in \Re}\{\min_{1 \leq i \leq n}\{\mu_{\tilde{a}_i}(x_i)\} / f(x_i) * b; x_i, b \in \Re, \forall i\} \quad (11)$$

In this paper, Chance-Constrained Programming (CCP) (Charnes and Cooper, 1959), which is normally used to confront stochastic linear programming (SLP), is adopted as a way to convert the F-USILSP to the EC-USILSP. The concept of CCP guarantees that the probability of stochastic constraints is greater than or equal to a pre-specified minimum probability. Let $\hat{c}_j$, $\hat{a}_{ij}$, and $\hat{b}_i$ for j = 1, …, n and i = 1, …,m be continuous random variables, and x_j be decision variables. The relationship between standard SLP and its probability SLP is given by Min Z = $\sum_{j=1}^{n} \hat{c}_j x_j$; subject to constraints, $\sum_{j=1}^{n} \hat{a}_{ij} x_j \leq \hat{b}_i$; $x_j \geq 0$ for all x_j if and only if Min Z = f; $\Pr\left(\sum_{j=1}^{n} \hat{c}_j x_j \leq f\right) \geq 1 - \alpha$; $\Pr\left(\sum_{j=1}^{n} \hat{a}_{ij} x_j \leq \hat{b}_i\right) \geq 1 - \alpha_i$; f and $x_j \geq 0$ for all x_j, where f is an artificial variable, which should be the minimum value when it is not greater than the objective function of standard SLP, Pr means probability, $1 - \alpha$ and $1 - \alpha_i$ are pre-specified minimum probabilities. The researchers who are interested in the field of SLP can refer to Birge and Louveaux (1997) for further details. In the same way, the F-USILSP becomes the following possibility USILSP:

(Poss-USILSP) Min TC = Θ (12)

Subject to $\pi\left(\sum_{t=1}^{T} (\tilde{s}_t y_t + \tilde{p}_t x_t + \tilde{h}_t I_t) \leq \Theta\right) \geq \alpha$; $\forall t$, (13)

$$\pi(I_{t-1} + x_t - I_t = \tilde{d}_t) \geq \alpha; \forall t, \quad (14)$$

$$\pi(y_t \tilde{d}_{kT} \geq x_t) \geq \alpha; \forall t, \quad (15)$$

$y_t \in$ binary variables, $x_t \geq 0$, $I_t \geq 0$, $\Theta \geq 0$; $\forall t$. (16)

Based on the possibility ranking in equation (11), Lertworasirikul *et al.* (2003) proved and proposed the Lemma 1, as follows:

Lemma1. Let $\tilde{a}_i$ for i = 1,..., n be fuzzy variables with normal and convex membership functions and b be a crisp variable. The lower and upper bounds of the α-level set of $\tilde{a}_i$ are denoted by $(\tilde{a}_i)_\alpha^L$ and $(\tilde{a}_i)_\alpha^U$, respectively. Then, for any given possibility levels α_1, α_2 and α_3 with $0 \le \alpha_1, \alpha_2, \alpha_3 \le 1$,

(i) $\pi(\tilde{a}_1 + \cdots + \tilde{a}_n \le b) \ge \alpha_1$ iff $(\tilde{a}_1)_{\alpha_1}^L + \cdots + (\tilde{a}_n)_{\alpha_1}^L \le b$,

(ii) $\pi(\tilde{a}_1 + \cdots + \tilde{a}_n \ge b) \ge \alpha_2$ iff $(\tilde{a}_1)_{\alpha_2}^U + \cdots + (\tilde{a}_n)_{\alpha_2}^U \ge b$,

(iii) $\pi(\tilde{a}_1 + \cdots + \tilde{a}_n = b) \ge \alpha_3$ iff $(\tilde{a}_1)_{\alpha_3}^L + \cdots + (\tilde{a}_n)_{\alpha_3}^L \le b$ and $(\tilde{a}_1)_{\alpha_3}^U + \cdots + (\tilde{a}_n)_{\alpha_3}^U \ge b$.

The Poss-USILSP is transformed into the EC-USILSP by the Lemma 1, as follows:

(EC-USILSP) Min TC = $$\sum_{t=1}^{T}\left((\tilde{s}_t)_\alpha^L y_t + (\tilde{p}_t)_\alpha^L x_t + (\tilde{h}_t)_\alpha^L I_t \right) \quad (17)$$

Subject to $I_{t-1} + x_t - I_t \ge (\tilde{d}_t)_\alpha^L$; $\forall t$, (18)

$I_{t-1} + x_t - I_t \le (\tilde{d}_t)_\alpha^U$; $\forall t$, (19)

$y_t (\tilde{d}_{kT})_\alpha^U \ge x_t$; $\forall t$, (20)

$y_t \in$ binary variables, $x_t \ge 0$, $I_t \ge 0$; $\forall t$. (21)

The special case of EC-USILSP, which is the EC-USILSP with trapezoidal and triangular fuzzy parameters, will be shown in next section.

EC-USILSP WITH TRAPEZOIDAL AND TRIANGULAR FUZZY NUMBERS

Since trapezoidal and triangular fuzzy numbers, which have linear membership functions, are basically fuzzy numbers, the F-USILSP with trapezoidal and triangular parameters will be examined in this paper. Let $\tilde{A}$ be the trapezoidal fuzzy number with a lower and upper crisp value at α = 0 and 1 at each corner point of trapezoidal membership function, which is denoted by $(\tilde{A})_0^L$, $(\tilde{A})_1^L$, $(\tilde{A})_1^U$, and $(\tilde{A})_0^U$, respectively (See Figure 1a). The membership function of $\tilde{A}$ is given by

$$\mu_{\tilde{A}}(r)=\begin{cases}\dfrac{r-(\tilde{A})_0^L}{(\tilde{A})_1^L-(\tilde{A})_0^L} & ;(\tilde{A})_0^L\le r\le(\tilde{A})_1^L\\ 1 & ;(\tilde{A})_1^L\le r\le(\tilde{A})_1^U\\ \dfrac{r-(\tilde{A})_0^U}{(\tilde{A})_1^U-(\tilde{A})_0^U} & ;(\tilde{A})_1^U\le r\le(\tilde{A})_0^U\\ 0 & ;\text{Otherwise}\end{cases} \quad (22)$$

where $\mu_{\tilde{A}}(r) \in [0, 1]$, and $r \in \mathbb{R}$. Thus, the lower and upper crisp value of $\tilde{A}$ at each α-cut are defined by $r_{Lower/\tilde{A}} = (\tilde{A})_1^L\alpha+(\tilde{A})_0^L(1-\alpha)$, and $r_{Upper/\tilde{A}} = (\tilde{A})_1^U\alpha+(\tilde{A})_0^U(1-\alpha)$. Let $\tilde{B}$ be a trapezoidal fuzzy number with $(\tilde{B})_1^L = (\tilde{B})_1^U = (\tilde{B})_1$, then $\tilde{B}$ is called a triangular fuzzy number (see Figure 1b). The lower and upper crisp value of $\tilde{B}$ at each α-cut are defined by $r_{Lower/\tilde{B}} = (\tilde{B})_1\alpha+(\tilde{B})_0^L(1-\alpha)$, and $r_{Upper/\tilde{B}} = (\tilde{B})_1\alpha+(\tilde{B})_0^U(1-\alpha)$.

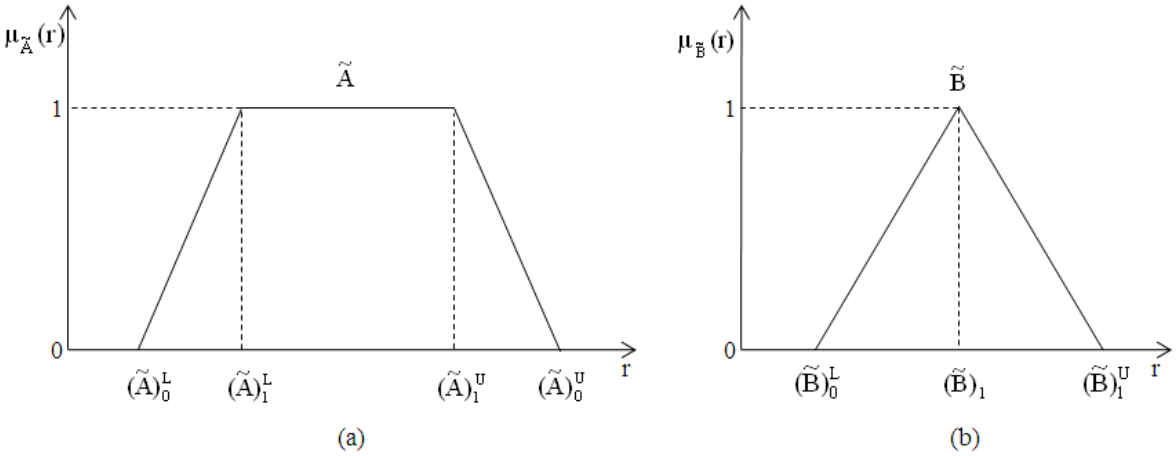

Figure 1: Membership Function of (a) Trapezoidal Fuzzy Number, and (b) Triangular Fuzzy Number

If the fuzzy parameters of F-USILSP $\tilde{s}_t$, $\tilde{p}_t$, $\tilde{h}_t$ and $\tilde{d}_t$ are trapezoidal fuzzy numbers, then the general model of EC-USILSP follows mixed integer linear programming.

$$\text{(EC-USILSP-Trapezoidal) Min TC} = \sum_{t=1}^{T}\left(\left(\alpha(\tilde{s}_t)_1^L+(1-\alpha)(\tilde{s}_t)_0^L\right)y_t+\left(\alpha(\tilde{p}_t)_1^L+(1-\alpha)(\tilde{p}_t)_0^L\right)x_t+\left(\alpha(\tilde{h}_t)_1^L+(1-\alpha)(\tilde{h}_t)_0^L\right)I_t\right) \quad (23)$$

$$\text{Subject to } I_{t-1}+x_t-I_t \ge \alpha(\tilde{d}_t)_1^L+(1-\alpha)(\tilde{d}_t)_0^L;\ \forall t, \quad (24)$$

$$I_{t-1}+x_t-I_t \le \alpha(\tilde{d}_t)_1^U+(1-\alpha)(\tilde{d}_t)_0^U;\ \forall t, \quad (25)$$

$$y_t\left(\alpha(\tilde{d}_{kT})_1^U + (1-\alpha)(\tilde{d}_{tT})_0^U\right) \geq x_t \text{; } \forall t, \quad (26)$$

$y_t \in$ binary variables, $x_t \geq 0$, $I_t \geq 0$; $\forall t$, (27)

Note that a triangular fuzzy number is a trapezoidal fuzzy number with $(\tilde{\bullet})_1^L = (\tilde{\bullet})_1^U$. Thus, EC-USILSP with triangular fuzzy parameters can be modeled as EC-USILSP with triangular fuzzy parameters. The numerical example with triangular fuzzy parameters is illustrated to show how to use this model in the next section.

NUMERICAL EXAMPLE

To show how to use the EC-USILSP model, a numerical example with trapezoidal fuzzy unit price and demand and triangular fuzzy inventory holding and ordering cost is discussed in this section. Assume that the beginning and ending stock of the planning horizon are both zero. Let the trapezoidal fuzzy unit price be classified as three levels, i.e., cheap, normal and expensive. It is respectively denoted by $\tilde{p}_c$ = (10, 15, 20, 25), $\tilde{p}_n$ = (20, 25, 30, 35), and $\tilde{p}_e$ = (30, 35, 40, 45). The trapezoidal fuzzy demand is classified as three levels, i.e., low, medium, and high. It is respectively denoted by $\tilde{d}_l$ = (60, 80, 100, 120), $\tilde{d}_m$ = (100, 120, 150, 170), and $\tilde{d}_h$ = (150, 170, 180, 200). The triangular fuzzy ordering cost is classified as three levels, i.e., low, medium, and high. $\tilde{s}_l$ = (200, 300, 400), $\tilde{s}_m$ = (300, 400, 500), and $\tilde{s}_h$ = (500, 600, 700). The triangular fuzzy inventory holding cost is classified as three levels, i.e., low, medium, and high. $\tilde{h}_l$ = (1, 2, 3), $\tilde{h}_m$ = (2, 3, 4), and $\tilde{h}_h$ = (3, 4, 5). Based on the experience of the decision maker, the parameter levels of the F-USILSP in terms of the verbal classification for five periods are shown in Table 1.

Table 1: Verbal Estimation of F-USILSP parameters for Five Periods.

Period t	Unit Price	Demand	Ordering Cost	Holding Cost
1	Cheap	Medium	Medium	High
2	Expensive	High	High	Medium
3	Cheap	Low	Low	High
4	Normal	Medium	Low	Medium
5	Expensive	High	High	Low

From Table 1, the F-USILSP of this example is modeled as follows:

$$\begin{aligned}\text{(F-USILSP) Min TC} = {} & (\text{Medium})y_1 + (\text{High})y_2 + (\text{Low})y_3 + (\text{Low})y_4 + (\text{High})y_5 \\ & + (\text{Cheap})x_1 + (\text{Expensive})x_2 + (\text{Cheap})x_3 + (\text{Normal})x_4 + (\text{Expensive})x_5 \\ & + (\text{High})I_1 + (\text{Medium})I_2 + (\text{High})I_3 + (\text{Medium})I_4 + (\text{Low})I_5 \quad (28)\end{aligned}$$

Subject to

$x_1 - I_1$ = Medium, (29) $I_1 + x_2 - I_2$ = High, (30)

$I_2 + x_3 - I_3$ = Low, (31) $I_3 + x_4 - I_4$ = Medium, (32)

$I_4 + x_5$ = High, (33) $y_1\tilde{d}_{15} \geq x_1$, (34)

$y_2\tilde{d}_{25} \geq x_2$, (35) $y_3\tilde{d}_{35} \geq x_t$, (36)

$y_4\tilde{d}_{45} \geq x_4$, (37) $y_5\tilde{d}_{55} \geq x_5$, (38)

$y_t \in$ binary variables, $x_t \geq 0$, $I_t \geq 0$ for t = 1, 2, …, 5 (39)

In accordance with the extension principle, fuzzy numbers $\tilde{d}_{tT}$ for all t = 1, …, T are given by $\tilde{d}_{15} = \left[\sum_{t=1}^{5}(\tilde{d}_t)_\alpha^L, \sum_{t=1}^{5}(\tilde{d}_t)_\alpha^U\right] = \left[\left(\alpha\sum_{t=1}^{5}(\tilde{d}_t)_1^L + (1-\alpha)\sum_{t=1}^{5}(\tilde{d}_t)_0^L\right), \left(\alpha\sum_{t=1}^{5}(\tilde{d}_t)_1^U + (1-\alpha)\sum_{t=1}^{5}(\tilde{d}_t)_0^U\right)\right]$, then the crisp interval of $\tilde{d}_{15}$ is $(\tilde{d}_{15})_\alpha^U = 760\alpha + 860(1-\alpha)$. So, $(\tilde{d}_{25})_\alpha^U = 610\alpha + 690(1-\alpha)$, $(\tilde{d}_{35})_\alpha^U = 430\alpha + 490(1-\alpha)$, $(\tilde{d}_{45})_\alpha^U = 330\alpha + 370(1-\alpha)$, and $(\tilde{d}_{55})_\alpha^U = 180\alpha + 200(1-\alpha)$. Thus, the EC-USILSP with triangular and trapezoidal parameters is a crisp MILP as follows:

(EC-USILSP) Min TC = $(400\alpha + 300(1-\alpha))y_1 + (500\alpha + 400(1-\alpha))y_2 + (300\alpha + 200(1-\alpha))y_3$
$+ (300\alpha + 200(1-\alpha))y_4 + (500\alpha + 400(1-\alpha))y_5 + (15\alpha + 10(1-\alpha))x_1 + (35\alpha + 30(1-\alpha))x_2$
$+ (15\alpha + 10(1-\alpha))x_3 + (25\alpha + 20(1-\alpha))x_4 + (35\alpha + 30(1-\alpha))x_5 + (4\alpha + 3(1-\alpha))I_1$
$+ (3\alpha + 2(1-\alpha))I_2 + (4\alpha + 3(1-\alpha))I_3 + (3\alpha + 2(1-\alpha))I_4 + (2\alpha + (1-\alpha))I_5$ (40)

Subject to

$x_1 - I_1 \geq 120\alpha + 100(1-\alpha)$, (41) $x_1 - I_1 \leq 150\alpha + 170(1-\alpha)$, (42)

$I_1 + x_2 - I_2 \geq 170\alpha + 150(1-\alpha)$, (43) $I_1 + x_2 - I_2 \leq 180\alpha + 200(1-\alpha)$, (44)

$I_2 + x_3 - I_3 \geq 80\alpha + 60(1-\alpha)$, (45) $I_2 + x_3 - I_3 \leq 100\alpha + 120(1-\alpha)$, (46)

$I_3 + x_4 - I_4 \geq 120\alpha + 100(1-\alpha)$, (47) $I_3 + x_4 - I_4 \leq 150\alpha + 170(1-\alpha)$, (48)

$I_4 + x_5 \geq 170\alpha + 150(1-\alpha)$, (49) $I_4 + x_5 \leq 180\alpha + 200(1-\alpha)$, (50)

$y_1(760\alpha + 860(1-\alpha)) \geq x_1$, (51) $y_2(610\alpha + 690(1-\alpha)) \geq x_2$, (52)

$y_3(430\alpha + 490(1-\alpha)) \geq x_3$, (53) $y_4(330\alpha + 370(1-\alpha)) \geq x_4$, (54)

$y_5(180\alpha + 200(1-\alpha)) \geq x_5$, (55)

$y_t \in$ binary variables, $x_t \geq 0$, $I_t \geq 0$ for t = 1, 2, …, 5 (56)

This above crisp mixed integer linear programming is solved with α = 0, 0.1, 0.2, …, 1. Then the total cost, ordering variable in period t, buying quantity in period t, and inventory level at the end of period t for t = 1, 2, …, 5 are shown in Table 2.

Table 2: The result of numerical example.

Alpha Level	Total Cost	Period t	y_t	x_t	I_t

		5	0	0	0

From Table 2, at the lowest possible level ($\alpha = 0$), the inventory plan orders 250 units in period one to cover the first two periods and 310 units to cover periods three, four, and five. The total cost is 7,600.00 THB. At the highest possible level ($\alpha = 1$), the inventory plan orders 290 units in period one to cover the first two periods and 370 units to cover periods three, four, and five. The total cost is 12,950.00 THB. The trend of total cost from EC-USILSP, solving with $\alpha = 0, 0.1, 0.2, \ldots, 1$, is an increasing linear trend, which is illustrated by plotting TC and α in x and y axis, respectively. It means that when higher possible levels are required, the TC will increase.

CASE STUDY

The case study of this paper focuses on the inventory planning of bituminous coal in a power plant of a petrochemical company. The main purpose of this power plant is to produce electrical power for the company's petrochemical plants, which is the core business of this company. Bituminous coal is the main raw material for the generation of the electrical power. Demand for bituminous coal measured in metric tons is dependent on the demand for electrical power, which is required for petrochemical production. In this study, the demand for bituminous coal is classified as 5 trapezoidal fuzzy numbers, i.e., lowest, low, medium, high, and highest (see the membership function of fuzzy demand in Figure 2). Based on the experience of the production manager and the fuzzy information in Figure 2, the demand for bituminous coal in the planning horizon (12 periods) is predicted in the form of verbal demand, which is shown in Table 3. The price of bituminous coal per metric ton is classified as 7 triangular fuzzy numbers, i.e., the cheapest, very cheap, cheap, normal, expensive, very expensive, the most expensive (see the membership function of fuzzy unit prices in Figure 3). Based on the experience of the purchasing manager and the fuzzy information in Figure 3, the unit price of bituminous coal in the planning horizon is predicted in the form of verbal unit prices, which are shown in Table 3. The company has two outsourcers, namely companies A and B, which transport bituminous coal from the distributor to the inventory area. Focusing on the inventory area, there is a large area for the storage of 80,000 metric tons of bituminous coal. According to the company's policies, 20,000 metric tons of bituminous coal must be stored as a safety stock. It cannot be used up. Thus, the net inventory space is equal to 60,000 metric tons. The inventory level at the end of period 0, or the beginning stock of period 1, is equal to 15,000 tons. So the net demand of period 1 is equal to (20,000, 25,000, 30,000, 35,000) metric tons minus 15,000 metric tons, that is (5,000, 10,000, 15,000 20,000) metric tons. Company A charges 1 million Thai Baht (THB) per order, and the maximum transportation capacity of company A is 50,000 metric tons per period. Company B charges 1.5 million THB per order, and the

maximum transportation capacity of company B is equal to that of company A. Note that although the quantity of each order is less than the maximum transportation capacity of each company, companies A and B cannot discount the charge rate per order. Based on the policies of the company, the holding cost is fixed as a crisp value. It is equal to 200 THB per metric ton per period.

Table 3: Demand (x 1,000 Metric Tons) and Unit Price (x 100 THB per Metric Ton).

Period t	Demand		Unit Price	
	Verbal Prediction	Trapezoidal Fuzzy Number	Verbal Prediction	Triangular Fuzzy Number
1	Low	(20, 25, 30, 35)	Normal	(20, 25, 30)
2	Low	(20, 25, 30, 35)	Cheap	(15, 20, 25)
3	Medium	(30, 35, 40, 45)	Cheap	(15, 20, 25)
4	Medium	(30, 35, 40, 45)	Very Cheap	(10, 15, 20)
5	Medium	(30, 35, 40, 45)	Cheap	(15, 20, 25)
6	Medium	(30, 35, 40, 45)	Cheap	(15, 20, 25)
7	High	(40, 45, 50, 55)	Normal	(20, 25, 30)
8	High	(40, 45, 50, 55)	Expensive	(25, 30, 35)
9	Medium	(30, 35, 40, 45)	Normal	(20, 25, 30)
10	Low	(20, 25, 30, 35)	Expensive	(25, 30, 35)
11	Lowest	(15, 15, 20, 25)	Normal	(20, 25, 30)
12	Lowest	(15, 15, 20, 25)	Expensive	(25, 30, 35)

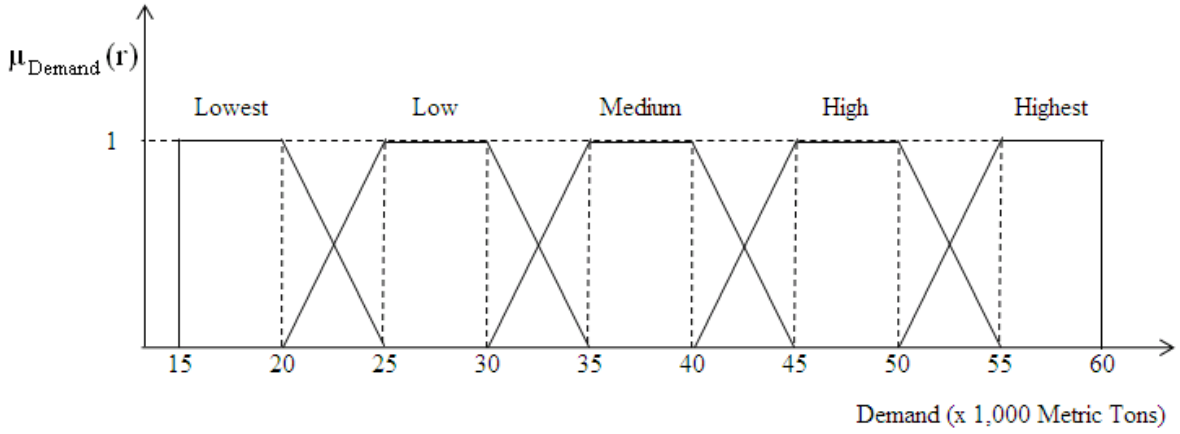

Figure 2: Membership Function of Fuzzy Demand.

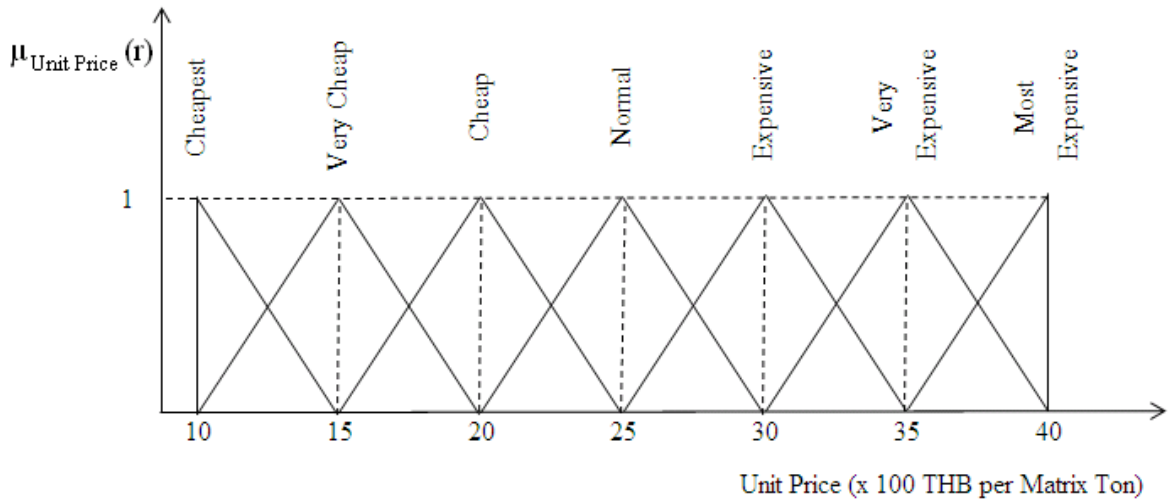

Figure 3: Membership Function of Fuzzy Unit Prices.

This case study is different from the numerical example. Since there are two transporters, and transportation capacity of them is limited, sometimes only company A can be selected (the service charge of company A is less than that of company B), but sometimes both companies A and B must be selected (when the buying quantity exceeds the transportation capacity of company A). Let decision variables x_{tA} and x_{tB} for t = 1,…, 12 be the buying quantities which are transported by companies A and B in period t, respectively. Thus, the equation of the bituminous coal price can be formulated as follows:

$$\begin{aligned}\text{Unit price} = {} & (2{,}500\alpha + 2{,}000(1-\alpha))(x_{1A} + x_{1B}) + (2{,}000\alpha + 1{,}500(1-\alpha))(x_{2A} + x_{2B}) \\ & + (2{,}000\alpha + 1{,}500(1-\alpha))(x_{3A} + x_{3B}) + (1{,}500\alpha + 1{,}000(1-\alpha))(x_{4A} + x_{4B}) \\ & + (2{,}000\alpha + 1{,}500(1-\alpha))(x_{5A} + x_{5B}) + (2{,}000\alpha + 1{,}500(1-\alpha))(x_{5A} + x_{5B}) \\ & + (2{,}500\alpha + 2{,}000(1-\alpha))(x_{7A} + x_{7B}) + (3{,}000\alpha + 2{,}500(1-\alpha))(x_{8A} + x_{8B}) \\ & + (2{,}500\alpha + 2{,}000(1-\alpha))(x_{9A} + x_{9B}) + (3{,}000\alpha + 2{,}500(1-\alpha))(x_{10A} + x_{10B}) \\ & + (2{,}500\alpha + 2{,}000(1-\alpha))(x_{11A} + x_{11B}) + (3{,}000\alpha + 2{,}500(1-\alpha))(x_{12A} + x_{12B}). \end{aligned} \quad (57)$$

Let binary variables y_{tA} and y_{tB} for t = 1,…, 12 be ordering variable, which is one when companies A and B receive orders, respectively, and 0 otherwise. The equation of the ordering cost can be formulated as follows:

$$\text{Ordering cost} = \sum_{t=1}^{12} 1{,}000{,}000 y_{tA} + \sum_{t=1}^{12} 1{,}500{,}000 y_{tB}. \quad (58)$$

Let decision variable I_t be the inventory level at the end of period t. The equation of the inventory holding cost can be formulated as follows:

$$\text{Inventory holding cost} = \sum_{t=1}^{12} 200 I_t. \quad (59)$$

Because the demand for bituminous coal for t = 1,…, 12 was based on the judgment of decision maker, it is a fuzzy demand. Therefore, there are 24 equivalent crisp inventory balance constraints of 12 periods, as follows:

$$x_{1A} + x_{1B} - I_1 \geq 10{,}000\alpha + 5{,}000(1-\alpha), \tag{60}$$

$$x_{1A} + x_{1B} - I_1 \leq 15{,}000\alpha + 20{,}000(1-\alpha), \tag{61}$$

$$I_1 + x_{2A} + x_{2B} - I_2 \geq 25{,}000\alpha + 20{,}000(1-\alpha), \tag{62}$$

$$I_1 + x_{2A} + x_{2B} - I_2 \leq 30{,}000\alpha + 35{,}000(1-\alpha), \tag{63}$$

$$I_2 + x_{3A} + x_{3B} - I_3 \geq 35{,}000\alpha + 30{,}000(1-\alpha), \tag{64}$$

$$I_2 + x_{3A} + x_{3B} - I_3 \leq 40{,}000\alpha + 45{,}000(1-\alpha), \tag{65}$$

$$I_3 + x_{4A} + x_{4B} - I_4 \geq 35{,}000\alpha + 30{,}000(1-\alpha), \tag{66}$$

$$I_3 + x_{4A} + x_{4B} - I_4 \leq 40{,}000\alpha + 45{,}000(1-\alpha), \tag{67}$$

$$I_4 + x_{5A} + x_{5B} - I_5 \geq 35{,}000\alpha + 30{,}000(1-\alpha), \tag{68}$$

$$I_4 + x_{5A} + x_{5B} - I_5 \leq 40{,}000\alpha + 45{,}000(1-\alpha), \tag{69}$$

$$I_5 + x_{6A} + x_{6B} - I_6 \geq 35{,}000\alpha + 30{,}000(1-\alpha), \tag{70}$$

$$I_5 + x_{6A} + x_{6B} - I_6 \leq 40{,}000\alpha + 45{,}000(1-\alpha), \tag{71}$$

$$I_6 + x_{7A} + x_{7B} - I_7 \geq 45{,}000\alpha + 40{,}000(1-\alpha), \tag{72}$$

$$I_6 + x_{7A} + x_{7B} - I_7 \leq 50{,}000\alpha + 55{,}000(1-\alpha), \tag{73}$$

$$I_7 + x_{8A} + x_{8B} - I_8 \geq 45{,}000\alpha + 40{,}000(1-\alpha), \tag{74}$$

$$I_7 + x_{8A} + x_{8B} - I_8 \leq 50{,}000\alpha + 55{,}000(1-\alpha), \tag{75}$$

$$I_8 + x_{9A} + x_{9B} - I_9 \geq 35{,}000\alpha + 30{,}000(1-\alpha), \tag{76}$$

$$I_8 + x_{9A} + x_{9B} - I_9 \leq 40{,}000\alpha + 45{,}000(1-\alpha), \tag{77}$$

$$I_9 + x_{10A} + x_{10B} - I_{10} \geq 25{,}000\alpha + 20{,}000(1-\alpha), \tag{78}$$

$$I_9 + x_{10A} + x_{10B} - I_{10} \leq 30{,}000\alpha + 35{,}000(1-\alpha), \tag{79}$$

$$I_{10} + x_{11A} + x_{11B} - I_{11} \geq 15{,}000, \quad (80)$$

$$I_{10} + x_{11A} + x_{11B} - I_{11} \leq 20{,}000\alpha + 25{,}000(1-\alpha), \quad (81)$$

$$I_{11} + x_{12A} + x_{12B} \geq 15{,}000, \quad (82)$$

$$I_{11} + x_{12A} + x_{12B} \leq 20{,}000\alpha + 25{,}000(1-\alpha). \quad (83)$$

Based on transportation capacity limitations, the maximum transportation capacity of companies A and B is 50,000 metric tons per period, the constraint for the control ordering variable can be formulated as follows:

$$50{,}000y_{tA} \geq x_{tA} \text{ and } 50{,}000y_{tB} \geq x_{tB} \text{ for t = 1,..., 12.} \quad (84)$$

Focusing on the inventory space limitations, the bituminous coal cannot be stored at a quantity greater than 60,000 metric tons. Thus the warehouse capacity constraints are added as follows:

$$I_{t-1} + x_{tA} + x_{tB} \leq 60{,}000 \text{ for t = 1,..., 12.} \quad (85)$$

The minimum total cost, binary variables, order quantity, and inventory level for each α-level set can found by solving MILP, min (57) + (58) + (59), subject to (60)-(85), where y_{tA} and $y_{tB} \in$ binary variables, x_{tA}, x_{tB}, and $I_t \geq 0$ for t = 1, ..., 12. The results at α = 0 and 1 are shown in Table 4.

Table 4: Inventory plan at α = 0 and 1.

If a decision maker wants to plan for the lowest total cost, the lowest of possible level ($\alpha = 0$) is chosen. The inventory plan orders 5,000, 20,000, and 30,000 metric tons of bituminous coal, which is transported by company A, in periods one, two, and three, respectively. To serve the demand of periods four and five, 60,000 metric tons must be refilled. Since the maximum transportation capacity of company A is less than 60,000 metric tons, an excess demand (10,000 metric tons) must be transported by company B. In period six, 60,000 metric tons of bituminous coal is ordered. An aggregate total of 30,000 metric tons, which is ordered in period seven, and 30,000 metric tons, which was transferred from period six, must be used to serve the demand of periods seven and eight. In period nine, 50,000 metric tons is ordered to cover periods nine and ten, and 30,000 metric tons is ordered in period eleven to cover the demand of the last two periods. The total cost is 540 million THB. On the other hand, when the highest possible level ($\alpha = 1$) is required, the total cost increases to 813 million THB. The inventory plan of this scenario orders 10,000, 25,000, and 35,000 metric tons in periods one, two, and three, respectively. To serve the demand of periods six, seven, and eight, 60,000 and 35,000 metric tons is ordered respectively, in periods six and seven. In period nine, 60,000 metric tons is ordered to cover periods nine and ten, and 30,000 metric tons is ordered in period eleven to cover the last two periods.

CONCLUSIONS

This paper used Possibility Approach to convert the fuzzy inventory model (F-USILSP) to an equivalent crisp inventory model (EC-USILSP). Consequently, the EC-USILSP can be solved by traditional mathematical programming methods. In addition, this EC-USILSP was adopted for inventory planning in the case study of inventory planning for bituminous coal with trapezoidal fuzzy demand and triangular fuzzy unit price in a power plant of a petrochemical company. The EC-USILSP is very flexible to solve problems, for example, before using EC-USILSP in the case study, the EC-USILSP could be modified to support additional restrictions on two issues; transportation capacity limitations and inventory space limitations. The results found higher possible levels are required, and the total cost will increase accordingly.

FUTURE STUDIES

In this article, SILSP with fuzzy parameters, which is the smallest problem, was selected as the sample to study. Future work could focus on, firstly, using other more sophisticated inventory models, such as a multiple item lot sizing problem in a single-stage and multiple-stage production; and secondly, a study of SILSP with several periods, where these problems would be more complex. Consequently, solving these problems requires a lot of time. Therefore, for future work, comparisons should be made between ‘optimization methods

and Meta Heuristics' and 'optimization methods or Meta Heuristics' to test which is more appropriate in these cases. Lastly, this article focuses only on inventory models with fuzzy parameters, but some parameters of inventory models may have variations in other characteristics, such as random variables or random fuzzy variables. Therefore, in future study, models should be developed to support other parameters.

ABSTRACT

Facing an atmosphere of the fierce global business competitiveness increasingly, if a company wants to employ the traditional manufacturing improvement method to significantly raise the business survival ability, it cannot achieve the objective. As a result, a company needs to review it's as-is logistics business and operation model from a whole viewpoint to develop a feasible innovative to-be logistics model between companies inside and outside domestic and foreign industrial zones. This research adopts the solar energy industry in Taiwan as an example to profoundly investigate the as-is logistics operation models between companies inside and outside industrial zones, including logistics business models, logistics operation models, inventory management and so on. At the same time, this research points out the shortcomings and provides the concrete and substantial suggestions of the as-is models for the solar energy industry. After understanding the status of integrating manufacturing between companies inside and outside domestic and foreign industrial zones, this study finds the critical success factors of integrating manufacturing inside and outside industrial zones for the solar energy industry. Then this study proposes the feasible models of integrating manufacturing inside and outside industrial zones and executes the difference analysis between the as-is model and the to-be model. After creating the business models of integrating manufacturing inside and outside industrial zones, we undertake the detail logistic operation model of integrating manufacturing inside and outside industrial zones. Finally, this research presents the concrete and valuable suggestions for implementing the logistics operation models of integrating manufacturing.

Keywords: Inside and outside domestic and foreign industrial zones, Logistics business model, Logistic operation model, The solar energy industry.

INTRODUCTION

Today enterprises have focused on reducing manufacturing costs by decreasing the inputs of human and manufacturing resources for achieving the aim of lean production. However, facing an atmosphere of the fierce global business competitiveness, it reaches the limits of this way to improve competitiveness of enterprises by using the global division of work and a high-quality production system to reduce production costs and shorten delivery. Furthermore, the rise of the concept of manufacturing services drives the current manufacturing to rethink whether as-is logistics operation models are able to quickly respond customer demands in order to grip the pulse of market demand. Therefore, enterprises must escape the operation of the current thinking to break the existing stereotype of the corporate business model in order to survive in the competitive industry environment. In this point of view, enterprises must develop innovative integrated logistics business model from the optimization of a entire system and considering different industry clusters and industrial properties in order to enhance their entire operational efficiency, enable them to shorten the delivery time, reduce costs and improve customer service quality vision.

THE INTEGRATION PROCESS AND THE STATUS OF DOMESTIC INDUSTRIAL PARK INSIDE AND OUTSIDE

The overview of solar energy industry

Looking at the current energy, using of new solar and wind power is the fastest growing and popular. Since 1997, the solar energy industry market has 33% growth per year [2]. So we know wind and solar at this stage will be the most promising of the green energy. Germany, Japan and Spain have better development in solar energy industry, such as promoting policies and larger solar market demand [1, 5]. China also have been pushed solar energy industry hardly in recent years [3]. Unfortunately, the price of international module continues falling, and the span of expected fall is 5% [4]. It means that manufacturing margins had squeezed, we must improve the logistics model to execute the cost down strategy.

However, solar power without fuel and waste, each unit of electricity can reduce carbon dioxide emissions 0.581 g, and the sun will light at least 50 billion years, solar power is an best options to substitute traditional fossil fuel.

Because a wide range of solar applications, this research takes the mono and poly-silicon solar energy industry as an example to profoundly investigate logistic operation models between companies inside and outside domestic and foreign industrial zones.

The as-is business models of integrated process between companies inside and outside domestic and foreign industrial zones

Because the differences among the specifications of solar applications are very small, the price is a critical factor for competing in the solar energy market. To ensure that the downstream solar energy manufacturers can obtain enough components and maintain price competitiveness, some solar energy manufacturers in Taiwan have begun toward the

direction of vertical integration. For example, Tatung Company has established an initial vertical integration business model for the solar energy industry.

This study collects the typical as-is business models of the solar energy industry; which can be divided into four models as follows:

a) *Partial vertical integration business model for the solar energy industry chain:*

A company has abundant capital to vertically integrate the up-stream, middle-stream and/or down-stream solar energy supply chain through transferring investment to set up subsidiaries or stock ownership means. For example, Tatung invested Sanchih Semiconductor Company, and then Sanchih Semiconductor Company invested to establish Green Energy Technology Company. Green Energy Technology Company is responsible for silicon ingots and silicon wafer manufacturing, but also engaged in the production of solar cells and modules. In the downstream of the solar energy supply chain, Tatung Company adopts the parallel strategy of OBM (Original Brand Manufacturing) and OEM (Original Equipment Manufacturing).

b) *The horizontal integration business model for homogeneous companies in the solar energy industry chain:*

For example, AUO Company aggressively start global deployment for solar cell modules including Taichung in Taiwan, Tianjin in China and Czech Republic and other places to set up factories in order to develop China, European and Asian markets. Since Europe is the largest solar energy market in the world, AUO applied the homogeneous horizontal integration business model to develop oversea solar module plants to amplify the market share in Europe.

c) *The horizontal integration business model for heterogeneous companies in the solar energy industry chain:*

Formosa Plastics Group utilizes its strong financial foundation and excellent R&D capabilities in the plastics industry to develop key materials of the solar energy industry chain. Development of these key materials is the high threshold, but the profit is abundant. For example, Formosa Energy & Material Technology Company is responsible for the production of lithium-iron battery material In addition, Formosa Plastics Company produces EVA film and Silane. AUO and component supplier of system integration perform the heterogeneous horizontal integration to provide final solar energy application solutions.

d) *Focusing on specific areas in the solar energy industry chain:*

Fuju Solar Energy Company in Taiwan will devote itself to poly-silicon production. The company is located in Pingtung Export Processing Zone in Taiwan, which meets market demands of silicon ingot and silicon wafer manufacturers in Tainan Science Park, Luchu Science Park, Hsinchu Science Park and Taoyuan area. Danone Technology Company focuses on silicon ingot and silicon wafer production and then sell solar silicon wafers to domestic and foreign solar cell manufacturers. Ritek Company at the Hsinchu Industrial Park in the

middle stream of the solar energy industry chain is responsible for solar module manufacturing.

The integrated process logistics model between companies inside and outside domestic and foreign industrial zones

Companies in the upstream solar energy industry chain adopt make-to-stock (MTS) model. First, manufacturers develop production plans based on sales forecasts. Then, the manufacturers begin preparing the required materials based on material requirement planning. Nowadays the manufacturers of poly-silicon materials in Taiwan have not begun mass production. Thus, the solar chip manufacturers in Taiwan purchase the required poly-silicon materials from foreign suppliers. Foreign suppliers deliver poly-silicon materials to bonded warehouses. When manufacturers start processing, they remove the required materials from the bonded warehouse. After finishing the manufacturing, semi-finished products will be placed in the warehouse. If companies receive domestic orders, the third party logistics service providers with a long term cooperation relationship deliver these semi-finished products. If the orders come from foreign customers, the customs brokers deal with customs operations, and then send the silicon wafer to foreign manufacturers by sea transportation. Figure 1 shows the logistics business model of the upstream solar energy industry chain.

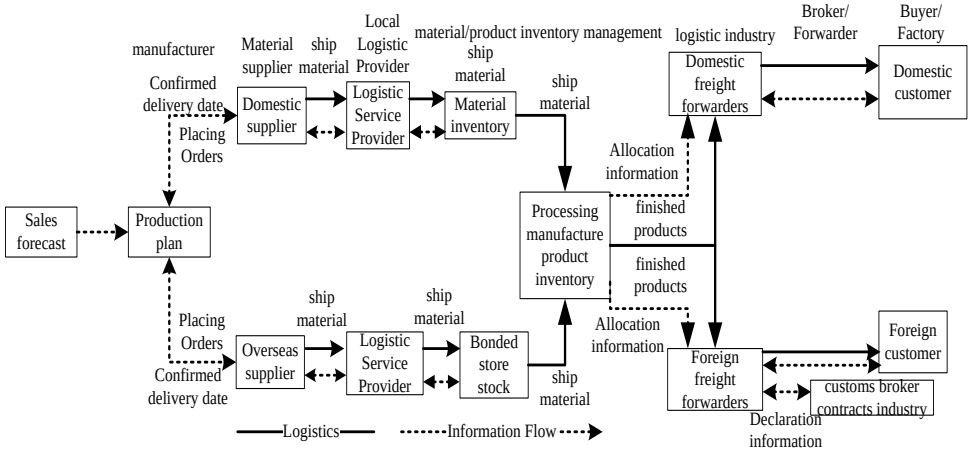

Figure 1: The logistics business model of the upstream solar energy industry chain.

With respect to the solar cell logistics, solar cell manufacturers purchase poly-silicon material from the suppliers in Europe, the United States and other countries. The small amount of solar silicon wafers come from the domestic manufacturers. The purchase of raw materials from foreign suppliers adopts the bonded way. Most solar cell customers come from foreign area. Because the salt could erode the solar cells, the volume of solar cells is small and sea transportation spends a lot of time, the majority of solar cells are delivered by air transport. When the customers abroad receive solar cells, they send confirmation to the solar cell manufacturers, and then complete the overseas orders. The domestic orders for solar cells are implemented by land transportation. Similarly, when domestic customers receive the goods, they will send a confirmation to the solar cell manufacturers to complete domestic orders.

Figure 2 and Figure 3 show the as-is models between companies inside and outside domestic and foreign industries zones for solar cell modules and solar energy application. As solar cell modules and solar application belong to the build-to-order (BTO) business model. When the companies get orders, they check whether the standard parts are enough. If inventory is not enough, then they start purchasing standard parts. Meanwhile, they also begin purchasing required non-standard components. However, owing to the considerations of quality and bond, they import components from Europe, the United States, South Korea and Japan. Figure 3 shows the purchasing logistics operation model of the solar cell modules and solar applications between companies outside and inside industrial zones.

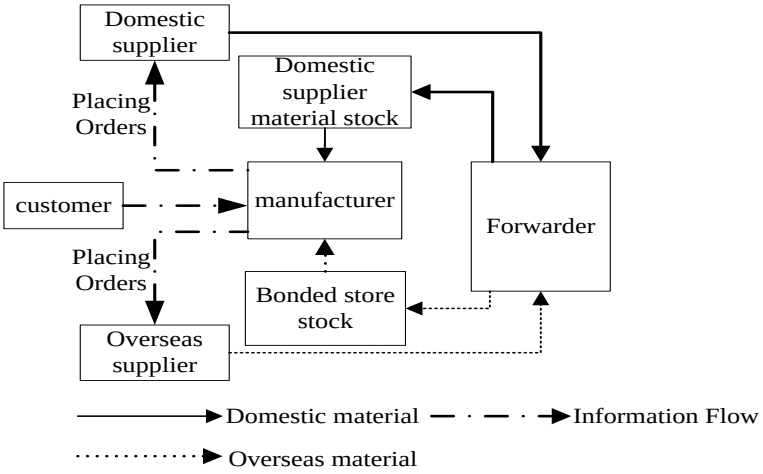

Figure 2: The solar cell modules and solar energy industry applications outside and inside integration of processing the feed mode of operation.

With regard to delivery logistics, first, domestic or foreign companies release orders to headquarters. The order information is passed to the manufacturing sector. When the manufacturing sector receives a manufacturing order, it starts picking and processing operations. After finishing the manufacturing process, finished products are briefly placed in storage area of finished goods. Finally, the operations department contacts with the forwarders immediately. If the product is exported to foreign manufacturers, it will inform the customs, and finished goods are to the seaport. On the other hand, if the products are delivered to domestic customers, it will transport directly to the destination by freight forwarder.

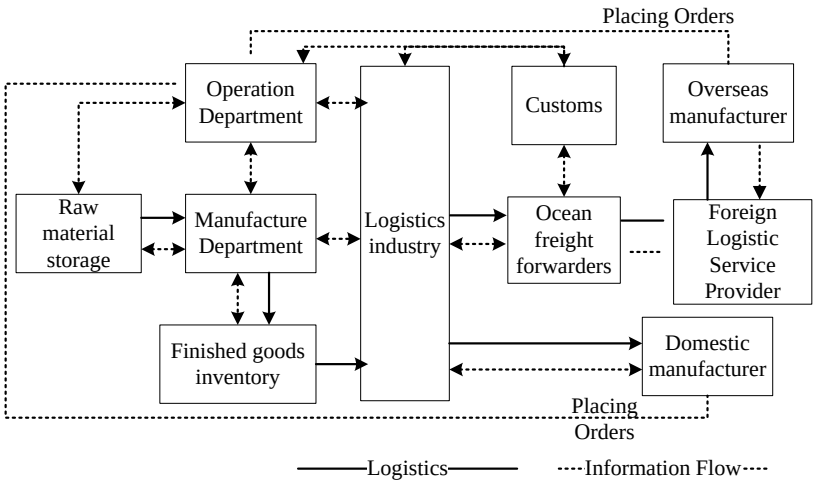

Figure 3: Solar application of industrial plant inside and outside the system integration process of the logistic model

The defects in the current situation and improvement recommendations for integrated process between companies inside and outside industrial zones

Nowadays, poly-silicon materials factories have not begun mass production yet. Solar silicon wafer manufacturers must rely on foreign imports, including the United States, Germany, Japan and Korea. Since the poly-silicon materials will spend a lot of time in set transport, the solar silicon wafer manufacturers need to prepare the high safe stock levels that lead to the increase of inventory cost. Owing to the manufacturing pollution, this research recommends poly-silicon material factory should be built at a lower population density like Pingtung Export Processing Zone. In addition, it can meet the requirement of the poly-silicon materials at the Tainan Science Park and Kaohsiung Science Park.

In regard to the middle-stream solar energy industry, the specification difference of solar cells is very small. Hence, most companies adopt make-to-stock (MTS) business model. In the down-stream solar energy industry, manufacturers adopt the build-to-order business model, so they don't storage finished product inventory. Because domestic solar energy chip manufacturers' capacity cannot meet the requirements of solar energy cell manufacturers, the main sources of solar chips come from foreign solar energy chip manufacturers. In respect of solar energy modules, the main components including solar cells, EVA films, backboards and low-iron glass also depend on foreign imports. Only the small portion of the purchase is by domestic manufacturers. Owing to the recent policy of the German government, the orders of solar application are significantly increasing to lead to shortages of materials and components. Therefore, foreign suppliers of raw materials and components have great influence on the solar energy industry in Taiwan. Furthermore, the down-stream solar energy industry companies face the delivery problem. Because the volume of a solar cell module is large, they are easy to injure in transportation process. Therefore, the solar cell module plants are suitable for the establishment of production lines near the market. As the domestic market of solar energy applications is smaller, solar cells and modules are export. This research suggests that Taiwan's solar cell and module manufacturers can use their superior production technology to cooperate with foreign factories to obtain a large solar energy power plant projects.

The above description shows the Taiwan's solar energy companies highly depend on foreign raw materials and components, regardless of up-stream, middle-stream or down-stream solar energy industry. Figure 5 shows which the supply relationships should be enhanced. In order to improve the competitiveness of Taiwan's solar energy industry, the raw material and component suppliers in the upstream solar energy chain need to provide the low price materials and components under the same quality condition to downstream manufacturers. The delivery time and production costs of the down-stream solar energy companies must be more competitive, and can be able to the effective helm of the up-stream material supply. In addition, the raw materials are imported through the Port of Keelung. Under the consideration of plant locations, if we can change to other ports such as the ports of Taichung or Kaohsiung to unload raw materials and components, we can reduce the transportation cost.

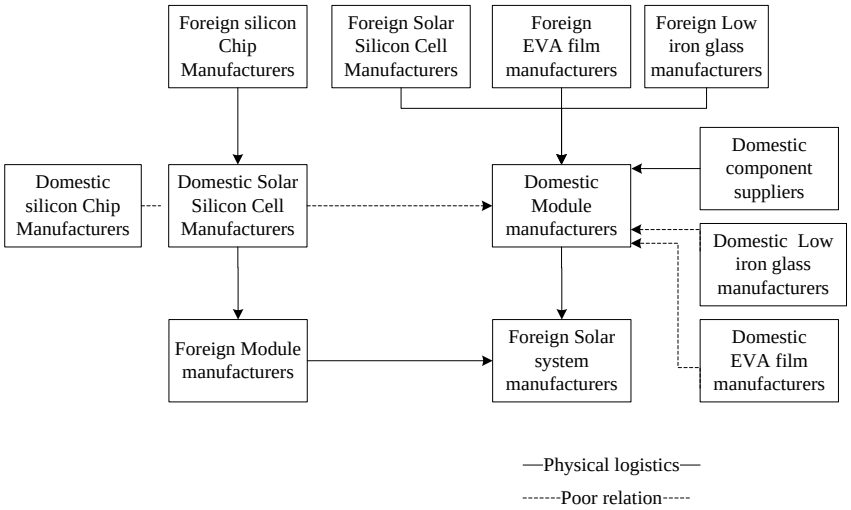

Figure 4: Shows strengthen the relationship between each other's supply diagram for current solar energy industry supply chain.

In addition, the manufacturing of both solar cells and modules in Taiwan has not reach economies of scale. Hence, compared with other international solar energy manufacturers, production cost in Taiwan's companies is still higher.

THE ANALYSIS OF THE FEASIBLE MODELS OF INTEGRATED PROCESS BETWEEN COMPANIES INSIDE AND OUTSIDE DOMESTIC AND FOREIGN INDUSTRIAL ZONES

This section depicts the feasible models of integrated process between companies inside and outside domestic and foreign industrial zones for solar energy industry. The details of integrated process are described in the following sub-sections.

The key factors for implementing the integrated processes between inside and outside solar industrial zones

The key factors to promote the integrated processes between inside and outside industrial zones for the solar energy industry are described as follow:

a) Because the sources of the poly-silicon materials and solar energy cells rely on foreign imports in Taiwan, the transportation cost and inventory cost are significantly increases. Hence, Taiwan's solar energy manufacturers should establish a complete the supply chain for the solar energy industry.

b) The solar manufacturing companies in Taiwan are distribured, it should integrate up-stream, middle-stream, and down-stream companies to become a regional industry cluster.

c) Because the market of the solar energy industry is very small in Taiwan, the solar energy industry belongs the export-oriented industry. The location of the manufacturers for the solar energy factories should is near the Free Trade Zones to reduce the cost and the time of land transportant.

d) Building solar plants in the Export Processing Zone and Free Trade Zone can reduce customs duties, commodity taxes, and operating costs significantly.

e) Because the solar cell modules are big in size, we suggest that solar module factories should be set up in the Free Trade Zones. The solar module factories can be easy to import needed components and export the solar energy modules.

f) If the solar energy industry can establish factories in the neighboring zone, it will be easy to implement VMI approach to decrease transportation costs, inventory costs, safety stock, and improve the efficiency of logistics operations.

The feasible model of integrated processes between inside and outside solar energy industrial zones

For the current status of the solar energy industry, this research proposes the feasible model and related regional planning to enhance the logistics efficiency of the solar energy industry.

The feasible model

So far, the solar energy companies do not completely integrate its supply chain throughout up-stream, middle-stream, and down-stream. Especially, the poly-silicon materials of the up-stream all rely on the foreign manufacturers. The domestic solar energy industry can't control the supply of raw materials. Meanwhile, the other critical materials, such as solar silicon wafers and solar cells, EVA film, need to rely on imports, so that it can't meet demand for order in the rush season. Besides, the solar energy industry chain has not yet formed a complete industry clusters and the solar energy manufacturers in Taiwan is too distributed. Owing to these causes, the solar energy industry in Taiwan must prepare high safety stocks. Hence, poly-silicon material manufacturers should be added and supply the domestic manufacturers so as to reduce the safety stock in the solar energy industry.

As the factors mentioned above, the operation cost in solar energy industry is increased significantly. In addition, to face the competition from China, the solar energy manufacturers in Taiwan can't adopt the low-cost competitive strategy. Therefore, Taiwan solar energy module companies need to be transformed into build-to-order business model and provide solar energy modules with technology aesthetics to significantly increase the value-added of products.

Location planning

Figure 5 shows the feasible model of the inside and outside domestic and foreign industrial zones for the solar energy industry. Because a solar energy industry needs vast land, and the Export Processing Zones and the Free Trade Zone in the south Taiwan have lower occupancy rate, land of the south Taiwan can satisfy the requirement of the solar energy industry chain. The up-stream solar energy industry with a lot of pollution, so we suggest poly-silicon plants materials and silicon wafer plants should be located in a lower population area such as Pingtung Export Processing Zone.

For the up-stream part, the Pingtung Export Processing Zone is 25 km away from the Kaohsiung Port and Kaohsiung International Airport. The silicon can be transported to the Pingtung Export Processing Zone from foreign mining areas. After the silicon ore is being processed to become poly-silicon materials, they can provide the poly-silicon materials to solar silicon wafer plants inside the industrial zone. The production of silicon wafers can conveniently meet the demands of solar cell factories in Kaohsiung Export Processing Zone.

For the middle-stream part, the solar cell plants are close to the Kaohsiung Free Trade Zone, they can use the convenient land, sea and air transport infrastructure to delivery products rapidly to domestic and foreign customers. Because of small size and light weight, the solar cell can be transported rapidly by air transportation.

For the part of down-stream, the surrounding materials of solar energy modules can be obtained from the Taichung Precision Machinery Park. Owing to the bulky solar energy modules, they may easily lead to damage in the transport process. Therefore, we suggest that solar energy module plant can be established in the Kaohsiung Free Trade Zone, and delivers their products directly to solar energy system manufacturers in foreign industrial areas by sea transport. The factories in Kaohsiung Free Trade Zone can obtain tax free, when they procure materials and components from tax districts in Taiwan or foreign countries.

In addition, the major markets of the solar energy industry are EU and USA. If the solar energy modules are shipped by sea transport to EU and USA, it would waste a lot of time and is hard to immediately response the customers' requirements. For this reason, domestic enterprises can build solar energy module plant at overseas to satisfy requirements of nearby markets. The feasible model proposed in this paper utilizes the convenient services provided by customs at the Export Processing Zone and the Free Trade Zone. In addition, the feasible model integrates land, sea and air transportation for importing raw materials and components, and exporting products. Hence, it will significantly raise the competitiveness of Taiwan's solar energy industry.

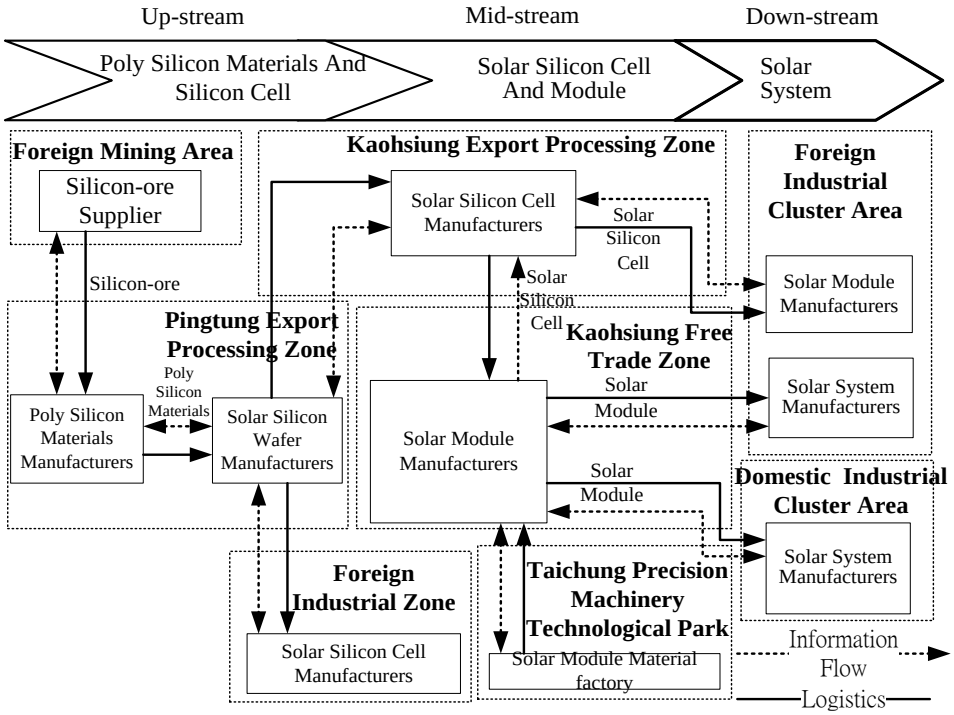

Figure 5: The feasible model of integrated processes between inside and outside domestic and foreign industrial zones for the solar energy industry in Taiwan.

Evaluation of the feasible model of integrated processes between inside and outside domestic and foreign industrial zones for the solar energy industry

The section elaborates the differences of the as-is and the to-be models as follows.

a) Industry cluster

In the as-is model, the members of solar energy industry chain are distributed in the north, central, and southern Taiwan. In the To-Be model, the companies gather in the southern industrial zones to become a domestic solar energy industry cluster.

b) Transport distance for semi-finished and finished products

In the as-is model, the members of the solar energy industry chain locate at the northern, central, and southern industrial areas in Taiwan, the semi-finished and finished products need the longer transport distances. In the to-be model, the members of industrial chain gather in the southern industrial zones to form the whole industry chain so as to shorten the delivery distances of semi-finished and finished products effectively.

c) Transportation cost

In the as-is model, because the providers for components of solar energy modules are not adjacent to the solar module plants, transportation costs are being raised significantly. In the to-be model, the transportation distance can be shortened through location planning because the solar energy module plants are located in the Free Trade Zone, and the suppliers of the solar energy modules are near the Free Trade Zone.

d) Global layout

In the as-is model, solar energy plants are located in Taiwan. Solar energy companies have not formed a global layout yet. For this reason, we suggest solar module plants should be adjacent to the nearby U.S. and Europe markets to understand and satisfy customer needs.

e) Import and export customs procedures

In the as-is model, because the manufacturers of solar energy industry chain are distributed in the domestic industrial zones, it is more complicated in the customs operations. In the to-be model, we suggest that the solar energy plants can be set in the Kaohsiung Free Trade Zone, the Pingtung Export Processing Zone and the Kaohsiung Export Processing Zone, to obtain convenient customs operations.

f) Probability of meeting the deadline

In the as-is model, the solar energy industry only has partial vertically integrated. At the same time, the critical raw materials may be shortage. Hence, these factors decrease the probability of meeting the deadline. In the to-be model, the solar energy industry has integrated completely, and can control critical raw materials. Hence, the to-be model can decrease the chance of shortage to increase the probability of meeting the deadline.

g) Vertical integration

In the as-is model, we lack the up-stream poly-silicon material manufacturers. In the to-be model, we suggest that the up-stream poly-silicon material manufacturers can be established in the Pingtung Export Processing Zone to form completely vertical integration.

h) Product Type

The solar energy companies just focus on standardized homogeneous products in the as-is model. However, this research suggests these companies should provide the solar energy products of customization and high efficiency conversion.

i) Safety stock

Because the as-is model lacks the up-stream poly-silicon material companies, it is hard to control the key raw materials. Hence, many companies keep higher safety stock. In the to-be model, the safety stock of the poly-silicon materials is reduced.

j) Inventory cost

Because of safety stock level is reduced in the to-be model, the solar energy companies can decrease the inventory cost.

k) Acquisition of key materials

In the as-is model, companies may lack poly-silicon materials. However, in the to-be model, the solar energy industry companies can effectively control the sources of poly-silicon materials.

CONCLUSION

According to the investigation of this research, original materials and major parts and components of Taiwan's solar energy industry depend on foreign import, especially poly-silicon materials. If the companies cannot ensure stable supplies of materials and components, they may face the shortage problems that can lead to interrupt the production line. Meanwhile, because the major suppliers of poly-silicon materials are EU & USA now, it takes a long purchasing time. Owing to fewer solar chip manufacturers in Taiwan, the capacity of solar chips cannot satisfy the demand of Taiwan's solar cell manufacturers. Therefore, solar cell manufacturers almost import solar chips. Concerning the solar cell modules, the major components including solar cells, EVA films, background boards, and low-iron tempered glass come from foreign manufacturers. The establishment of the solar energy supply chain is not complete yet. Hence, Taiwan's government should create the related laws to assist the sound development of the solar energy industry. Because the biggest solar energy market product is EU, Taiwan's solar energy companies should establish the solar energy module and system integration factories for reducing transportation cost and assuring quality.

In addition, by profoundly understanding the whole structure, the present situation, and the characteristics of the solar energy industry, this research finds the key success factors of integrated process between companies inside and outside industry zones for the solar energy industry, and then develops the feasible innovative to-be business model of solar energy industry. Because the solar energy industry needs a large land, this research suggests to integrate the neighboring Pingtung Export Processing Zone, Kaohsiung Export Processing Zone and Kaohsiung Free Trade Zone to built a integrated process business model between companies inside and outside industrial zones. At the same time, this research develops a detail logistic operation model of the solar energy industry based on the above-mentioned innovative business model.

ABSTRACT

Organisations, especially in the business sector, are in constant demand to improve their operations, competitiveness and efficiency. Systems thinking is one of the ways to meet this demand at least in larger organisations. Standard-based management systems related to areas such as environmental management, health & safety and quality have become important organisational building blocks. It can be argued that in order to avoid harm caused by overlapping structures and operations these systems should be integrated.

In this article, the evolution and effective integration of EHSQ (Environment, Health, Safety and Quality) management in a business organisation are studied. The evolutional development paths of environmental management, health and safety management and quality management are studied. A comparison between the development paths is made to find similarities and differences in the development of these management systems.

To understand how EHSQ integration should take place in an organisation, elements of an integrated management system are presented. The benefits and challenges arising from the implementation of an IMS are also studied. Together the study on EHSQ development paths and integrated management systems present a view on effective EHSQ integration.

Keywords: integrated management systems, IMS, environmental management, health and safety management, quality management

INTRODUCTION

The constant need of organisations to continuously develop their operations, competitiveness and efficiency has resulted in the need for system thinking. Fulfilling the diverse requirements of various stakeholders requires different approaches. The constant increase of these requirements has highlighted the need for a systematic approach to handle them. This has led to a dramatic increase in the development of management systems (MS). MSs help control systems and provide systematic ways to standardize functions. (Asif et al., 2010a) Different management systems offer an operating framework and procedure and simultaneously support continuous improvement. (Voutilainen et al., 2001)

These systems often share resources, processes and stakeholders, suggesting that integrating them could be beneficial. Zutshi and Sohal (2005) even state that "the integration of systems/standards is one of the major strategies for ensuring survival and savings (time, cost, resources) for the organizations in the twenty-first century". Integrated management systems (IMS) are being implemented at an exceeding pace, the most important motivations according Zeng et al. (2010) are satisfying customer requirements, responding to government appeal and remaining competitive. The most commonly integrated management systems are quality, environmental and occupational health and safety standards. They are often based on widely used standards such as ISO 9001, ISO 14001 and OHSAS 18001 that include common characteristics and starting points, which make them relatively easy to integrate. (Zeng et al., 2007; Jørgensen et al., 2006; Wilkinson and Dale 1999)

Along with business interest in management systems and their integration, research interest in them has increased dramatically during the last decade. This study aims to contribute in the field by summarizing the historical development of the aforementioned areas of environmental, health & safety and quality management (EHSQ) and looking at them in the context of integrated management systems. The research has been broken down into three research questions:

RQ1: What have been the development paths of different areas of EHSQ management?
RQ2: What elements does an integrated management system include and how can the efficiency of an IMS be assessed?
RQ3: What are the main benefits and challenges of IMS implementation on organizational success?

This study summarizes and continues the dissertation work of one of the authors (Tervonen, 2010). The research questions are answered through a literature review. The research results aim to present the historical development leading to the rise of integrated management systems, the current view on how IMS integration should take place and what benefits and challenges lie in the integration The structure of the research is demonstrated below in Figure 1.

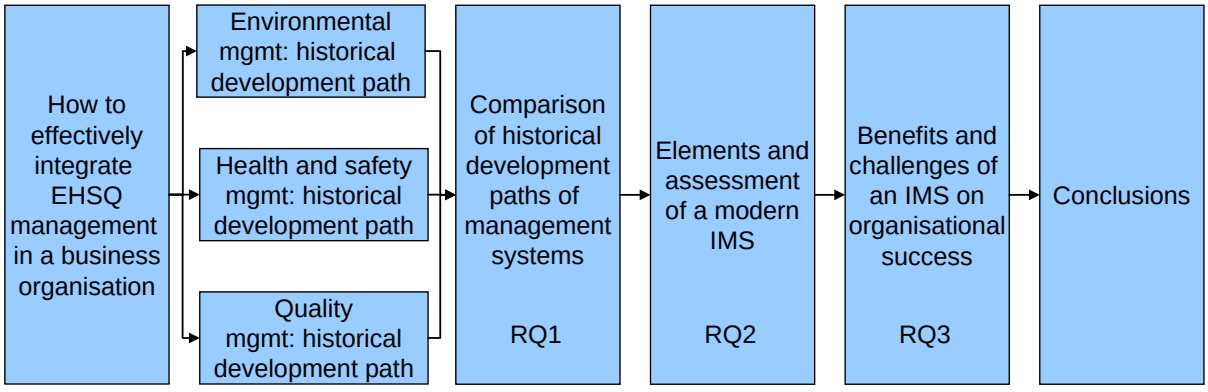

Figure 1: The outline of the study.

DEVELOPMENT PATHS OF EHSQ MANAGEMENT SYSTEMS

The current situation in different areas of EHSQ management becomes clearer through an understanding of historical development. The logic behind existing policies and the direction of development stems from the past. By recognizing the path leading to the current situation, it is easier to analyse the present and also future trends of development. The analysis results can be compared to the development and situation of an organization's EHSQ management to aid development.

Environmental management

Environmental issues raised public interest in the 1960's in a rather sudden and dramatic way. Rachel Carlson's book Silent Spring (1962) can be considered an important opening statement of the environmental discussion (Kallio, 2001). This started the process leading to the birth of environmental management (EM) in the 1970s. Before this, emission restrictions and environmental regulations were rather rudimentary in many fields, and pollution was practically considered a free commodity by companies.

A heated debate on the pros and cons of economic growth began in the beginning of the 1970's. An important initiator of the debate was the UN's first Conference on the Human Nature in Stockholm in 1972 and the Limits to Growth report of the Club of Rome published the same year. The oil crises in 1973 and 1979 resulted in an increasing concern for the sufficiency of natural resources. The environmental policy sector was created in the 1970's. Traditional environmental management, the first stage of environmental management, was a period of reluctant adaptation. Environmental factors were seen as restrictions on operations to which one had to adapt to when faced with external enforcement. The companies had to start adapting their operations to new regulations. A majority of multinational companies created their own environmental policies. Only a few companies included the goal of voluntarily exceeding the minimum levels required by legislation in their policies (Kallio, 2001).

The second stage of environmental management – passive appraisal – commenced in the mid-1980's when it was realised that no organisation could succeed in the long run if their operations were in major conflict with the requirements and values of the surrounding society. This stage was characterised by companies re-evaluating their approach to environmental issues and the recognition of their strategic potential. This stage can be considered the starting point of modern environmental management. (Kallio, 2001; Petulla, 1987)

Ministries of the Environment were established in the 1980's. Environmental activism found new forms as a result of internationalisation and professionalization and several environmental organisations were created. As a result of massive environmental accidents and an increasing concern for the environment in the 1980's new, increasingly strict environmental legislation and regulations were created. Growing demands of consumers, corporate clients, and investors also emerged as new factors. Previously passive companies had to readjust their attitude towards environmental issues. As a result environmental departments and monitoring systems were created and major companies even employed

environmental managers. The concept of sustainable development was created during the 1980s. (Kallio, 2001).

Only a few companies had reached the level of innovative EM by the beginning of the 1990's. The 1992 UN Rio de Janeiro conference can be considered as the highlight of the decade from an environmental viewpoint. The conference led to the creation of the international Climate Change Convention (Kallio, 2001). However, the green transformation of companies was only in a very early stage and no significant actions were made to reduce emissions or other environmental impacts. Procedures and practices only started to change towards the end of the 1990's as environmental management tools became more common through the introduction of ISO 14001.

In the 2000's, modern environmental management is still the most dominant trend. The field of environmental management has evolved from a mere reliance on linear stage models to more elaborate considerations of the determinants and components of management and performance. An increasing number of companies are adopting the practices of environmental management. In addition, the strategic opportunities of environmental management are becoming prominent (Kolk and Mauser, 2002). Eco-efficiency has become an important issue for companies. Pressure from legislation and markets, as well as globalisation, increasingly impact the environmental aspects of business. Climate change emerged as the most important environmental issue in the 2000's, resulting in emission trading becoming a significant EM factor. (Heiskanen, 2004).

Table 1 synthesizes the development path from the viewpoints of the (Finnish) state, companies, the civic society and nature. The focus of EM has been changing from traditional EM guided by laws and regulations to the more proactive modern EM. Environmental management has become a potential source of competitive advantage.

Table 1: Illustration of state, civic society and companies' relationship to environment (Kallio, 2001).

	State	Companies	Civic society	Nature
1960	Supporting industry Industry thinking	Investing in basic industries Territory thinking	Grass roots civic movements Global thinking	Water spoilage
1970	Water and toxic laws Sanction thinking	Concern for natural resources Expansion thinking	Environmental movement organisations, Life style thinking	Air pollution
1980	Nationalization of environmental protection Control thinking	Green transformation of enterprises Expansion thinking	Institutionalization of nature protection Consumer thinking	Tshernobyl Acid rain Exxon Valdes
1990	Sustainable Development Program thinking	Commercialization of environment Specialized thinking	Emphasizing consumer choices Eco-thinking	Climate change Ozone layer Logging of forests
2000	Implementation of programs Policy of natural resource	Increasing competition Survival strategies	Pattern of differentiation Differentiation of consumption	Climate change

Integration has developed EM closer to risk management and integrated process based management. Johnson and Walck (2004) suggest that the optimal way to achieve sustainability is to integrate sustainability values into the business values and strategies of a company. In recent years, business level organisations have been able to gain a competitive edge through the proactive utilisation of EM issues. Lanoie, Laplante and Roy (1998) found that capital markets react to the release of negative information and that large polluters are affected more significantly by such releases than smaller polluters. Niskala (1997) suggests that in order to support eco-competitiveness, the management of environmental issues must be holistic and consider all the operations of an organisation.

Health and safety management

The extent of health and safety (HS) management can be classified into three categories: person, machine or equipment and organisation levels (Figure 2). The classification also describes the increase of complexity when moving from a person level to machine and organizational levels. (Reason, 1997)

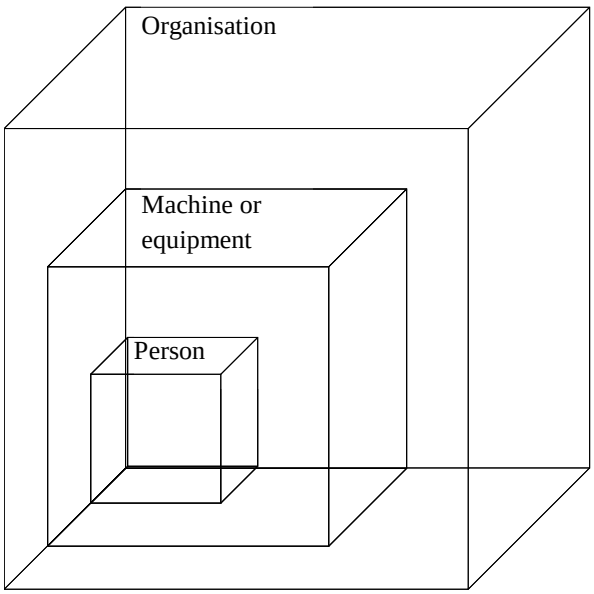

Figure 2: Classification of the scope and development level of health and safety management.

On the “person” level, the focus on observation is on whether the worker works in a safe manner or not. Failures are attributed to human actions, such as lack of motivation, lapses of memory or carelessness. Performance is often measured by means of accident frequency, and the safety organisation of work plays a key role. On the “machine or equipment” level failures are attributed to the interaction between humans and machines. Safety actions are characterised by risk analyses and the assessment of environmental impacts on human beings. According to the third category, a human error is a result of an identifiable cause in the system. This mode of thinking has common points with quality management, emphasising proactivity and continuous improvement. (Reason, 1997) The improvement of both quality and safety will result in a higher level of risk prevention, which creates the basis for an integrated management model. Herrero et al. (2002) suggest that the concepts of TQM can be applied to the practices of health and safety management.

The operating cultures in different sectors of health and safety management differ considerably, and legislation usually only governs the regulations of a single sector. This sets challenges for successful implementation. A view on the development path of legislation-making concerning different fields of HS management in Finland is presented in Table 2. It also reflects the general development of the content of HS management.

Table 2: The development path of legislation concerning different areas of HS management in Finland (Tervonen et al., 2009b).

Sectors	1930	1940	1950	1960	1970	1980	1990	2000
Personnel security*								x
Rescue operations	x		x	x	x		xx	xx
Safety against crime**								x
Information security							x	xxxx
Safety of buildings and premises						x		xx
Safety of production and operations			x	xx	xxx		xxxxx	xx
Occupational health and safety	x	x	x		xxxxx			xx
Safety of non-domestic operations***								x
Readiness planning				x	x		xx	x
Environmental safety					x	x	xx	xx

x = commencement and reform level of legislation
* is connected to occupational health and safety and information security
** is connected to general crime legislation
*** is connected to personnel security, safety against crime, rescue operations and safety of production and operations

Following regulations has meant passive organisational development- defined outside the organisation by the regulators and government. Only in recent years the development has took on a more active approach. Individual methods beyond authority regulations can lead to sustainable competitive advantages. These methods may overlap and support each others, and strict running after the regulations might result in unnecessary double work.

Several different parties participate in the HS operations of large companies, and the different sectors of health and safety, as well as risk assessment, is often treated in a number of places around the organisation. In addition, risk assessment often addresses risks from the viewpoint of only one sector of, and the results of a single assessment do not reach the different representatives of the safety organisation. Evaluation of the different sectors of may lead to a situation in which improvements are only made in the sector evaluated at a given time. The impacts of the measure on the overall level of health and safety of the organisation are not taken into consideration. In terms of overall performance, the best solutions can be found by assessing the impacts of an improvement on all sectors. The goal is to avoid overlapping work in risk assessment in different sectors of and waste of resources. More holistic management of health and safety issues can be achieved by increasing co-operation between people responsible for different sectors of safety. (Hill & Smith, 1995; Lanne & Tytykoski, 2004)

The first health and safety management system applications were based on the Occupational Health and Safety Management System (BS 8800) and the Dutch Safety Checklist for Contractors (SCC) standard. BS 8800 was replaced with the international OHSAS specifications in 2000. The Occupational Health and Safety Assessment Series specifications OHSAS 18001 supports the assessment and certification of the management systems of organisations. In addition, the International Labour Organisation (ILO) has published instructions on occupational health and safety systems (ILO-OHS 2001). The International Safety Rating System (ISRS 1996) is a method for auditing safety management procedures and the functionality of the systems. The safety practices self-assessment model

complements the European Quality Award model by taking the occupational health and safety issues into consideration in a more comprehensive manner. (Levä, 2003) Integration of e.g. occupational health and safety matters into environmental management systems can bring many benefits to industrial companies. They can avoid duplicated measures and find optimal solutions, because the principles of prevention are similar in environmental protection and health and safety management (Honkasalo, 2000).

Quality management

Total quality management is a philosophical entity of the concept of management and a compilation of quality management methods and techniques. Some studies refer to the hard and soft sides of TQM. Total quality management is an approach to the management of an organisation in which quality plays a central role and which is based on the participation of all of its members. The goal is long-term success, which can be achieved through customer satisfaction, and which benefits all members of the organisation as well as society. (Silen, 1998; Dale, 1999)

The development of quality management is often described in the literature as a four-stage process (Figure 3): the first stage inspection (I) can be considered to have started during the industrialisation and mass production. The second stage quality control (QC) began during the Second World War and especially in Japan after the war. The emphasis of the second stage lies in the manufacturing process, which is systematically developed.

The third stage, quality assurance (QA), incorporates the entire development and manufacturing process of a product as a factor affecting quality. In the fourth stage, total quality management (TQM), quality is seen in a holistic and strategic manner. At this point, the responsibility for quality was extended to include everyone in the organisation and the role of the corporate management becomes central. (Bounds et al, 1994; Dale, 1999; Hannukainen et al., 2006)

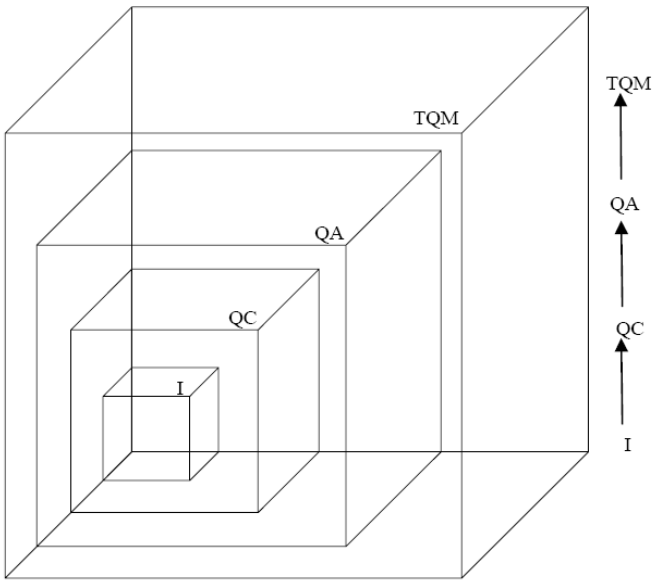

Figure 3: Development of quality management ideologies (Dale, 1999).

According to Hannukainen et al. (2006), the "Quality 2020" survey carried out by the American Society for Quality showed the following outlines: the application of quality thinking must become more innovative, more flexible and quicker to implement. The number of professionals working in the field of quality may decrease, but the need for quality-related skills will not. The trend seems to be towards the decrease of the importance of a quality department's role as a separate unit and making quality increasingly into everyone's concern. The challenge for specialists in the field of quality will be to develop to meet the needs of business and technology.

Comparison of the development paths

The development paths of EHSQ management areas are combined in Table 3. The comparison shows that each management area has, in slightly different pace, expanded during the last fifty years from a detail level to a holistic level. More viewpoints have been brought on every area, making them more complex to manage and affecting more functions and people in organisations. This inevitably leads to overlapping structures, which suggests that looking at these systems as a whole might result in improved efficiency and competitiveness.

Table 3: Overview of EHSQ development paths.

	Development of EM	**Development of H&SM**	**Development of QM**
-1950		1930s: Labor contract negotiations Rescue operations	I, 1931: Shewhart 1950s: Japan era in QM. QC; Deming et al.
1960	1962:Silent Spring published	1960-1970s: Many socio- and psychological theories of work developed	QA, Japan era continues 1962: Quality circles Ishikawa et al.
1970	Traditional EM - reluctant adaptation 1972: UN Stockholm conference and Limits to Growth	Research disciplines born Nordic model of occupational H&S 1975: Eurofound	TQM in Japan
1980	Modern EM - passive appraisal Sustainable development		TQM in America and Europe 1985: MBNQA 1986: Six Sigma 1987: ISO 9001
1990	1992: Rio de Janeiro UN conf. 1996: ISO 14001 Program thinking	1996: EU-OSHA 1996: BS8800, ISRS 1999: OHSAS 18001	1990s: "decade of quality" 1994: EFQM criteria
2000-	2004: Emission trading Program implementation Eco-competitiveness	2001: ILO-OHS Global safety and security Information safety	

The development of environmental and health & safety management has followed norms and regulations, while the development of QM has been driven by business needs of companies. Despite this, all three have developed towards similar holistic directions.

The historical development of EM and H&SM seem to be less researched than the development of QM in timeline format. This might be explained by the time span the areas have been developed intensively, the quality management begun roughly twenty years before the other two. EM and H&SM are also conceptually more diverse than QM, so describing them in a simple chronological way is more challenging.

INTEGRATED MANAGEMENT SYSTEMS

At the moment, there is no widely accepted standard equivalent to ISO standards for integrated management systems. The different integration levels in organisations pose a challenge for the making of a universal standard. (Jørgensen et al., 2006) The most commonly integrated management systems are quality, environmental and occupational health and safety standards. They are often based on widely used standards such as ISO 9001, ISO 14001 and OHSAS 18001 that include common characteristics and starting points, which make them relatively easy to integrate. (Zeng et al., 2007; Jørgensen et al., 2006; Wilkinson and Dale, 2001)

The organisation's culture and atmosphere must support the goals of integration and the willingness to combine different management systems. If not, integration will remain at the level of mere integration of documentation (Wilkinson and Dale, 2000). Jørgensen et al. (2006) also note the case-by-case nature of integration: there is no specific way to integrate management systems. The starting point is the organisation's culture and willingness to integrate. Successful integration depends on several factors, such as the content of the existing systems, field of operation, organisational culture and a number of other factors. (Wilkinson and Dale, 2001; Karapetrovic and Jonker, 2003)

The IMS model of Karapetrovic and Jonker (2003) is shown in Figure 4. It demonstrates how different management systems and the main interest group of the systems are linked. Like most model depictions of IMSs, the model has a continuous improvement circle built in it. It illustrates the idea that separate MSs should be first joined together at their interfaces enabling further integration into a holistic management system.

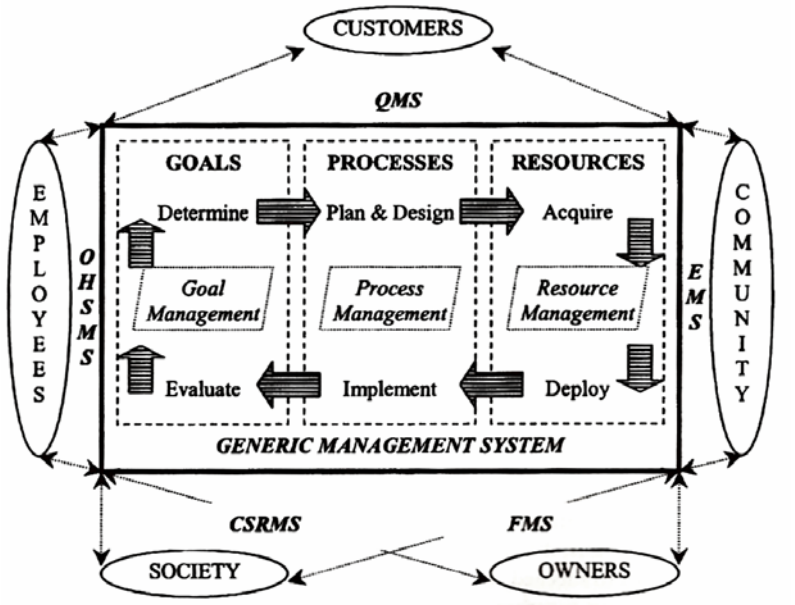

Figure 4: An IMS model of different management systems and their main interest groups (Karapetrovic and Jonker, 2003).

The IMS model by Wilkinson and Dale (2001) in Figure 5 highlights taking organisational culture into account in IMS implementation. In the model, the integrated quality, environmental and safety management systems are no longer independent and their role is to serve the entity in an integrated way, benefiting the entire organisation. Resources, personnel and processes have been divided between all previous systems. Goals are set and results measured jointly, which will create a circle of continuous improvement. The model joins all management systems tightly in order to create a common integrated system and cultural structure that are based on the key aspects of holistic quality management, such as teams, active participation and co-operation. In this way, it is possible to achieve a strong culture, which is divided between quality, environmental and safety issues, where core values and procedures of the entire organisation are based on holistic quality management. (Wilkinson and Dale, 2001)

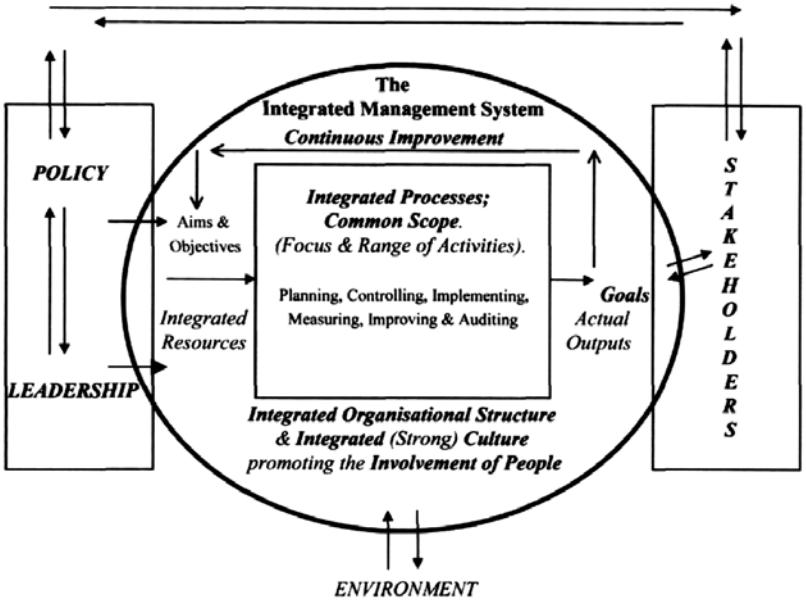

Figure 5: An IMS model highlighting the importance of culture (Wilkinson and Dale, 2001).

Where the previous models look at systems and organisational culture, the model by Zeng et al. (2007) in Figure 6 looks at IMSs from a synergy viewpoint. The levels included in the model are strategic synergy; organisational/resources, structural and cultural synergy; and documentation synergy. It demonstrates the flow in IMS implementation: from strategic synergy towards resources, structural and cultural synergy which lead to documentation synergy.

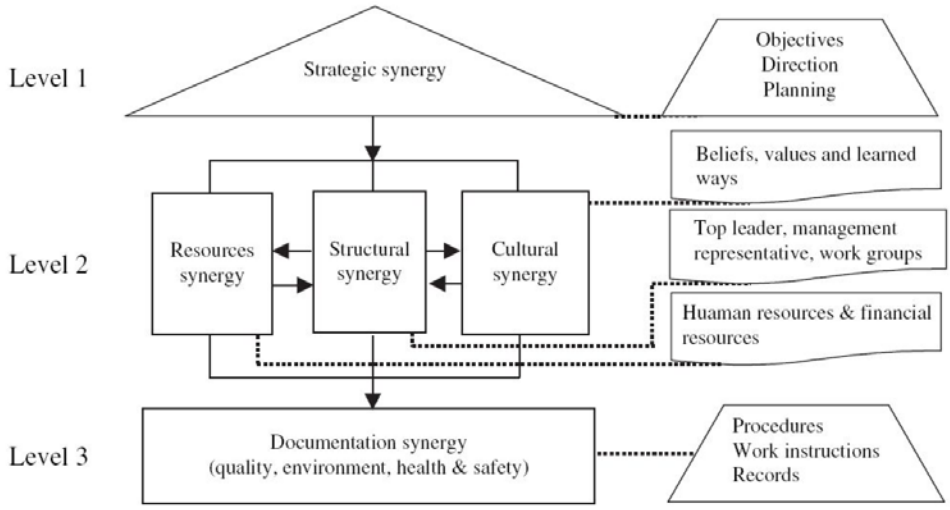

Figure 6: An IMS model from the synergy viewpoint (Zeng et al., 2007).

Asif et al. (2010b) recognise two strategies for implementing an IMS: a techno-centric approach and a systems approach. Their work suggests that maximum benefits are achieved through the systems approach, while the techno-centric approach mainly affects the organizational level. This finding supports the viability of the model proposed by Zeng et al. (2007).

Assessment of an IMS

How can the organization gain information on how its integrated management system is working? Setting and monitoring key performance indicators, both financial and IMS area specific metrics, can give information on this. This will give an idea if the system is working through whether the goals have been reached. It can also identify problem areas if goals are not met somewhere. However, metrics alone do not recognize improvement potential and synergies between different IMS areas. Metrics must be linked to the strategic processes in order to lead to results in an integrated way. (i.e. Zutshi & Sohal, 2005; Conti, 2006; Tervonen et al., 2009a)

There are several tools that can be used in order to reach the goals indicated in the organisational development model, such as models of business management excellence or holistic quality management such as the EFQM or the Malcolm Baldrige models. Regardless of the tool, the most critical point is the clear and accurate description of goals: what are the organisation's goals and what are the impacts of the organisation and its management system on the surrounding society (Conti, 2006). For the maintenance and progress of the system it is also necessary that a management review is held regularly with key personnel representing management from across the organization. (Zutshi & Sohal, 2005)

Figure 7 demonstrates a synthesis of EHSQ integration and their assessment as proposed by Tervonen et al. (2009a). The assessment is based on the CMMI maturity levels, against which the achievement of business goals is reviewed.

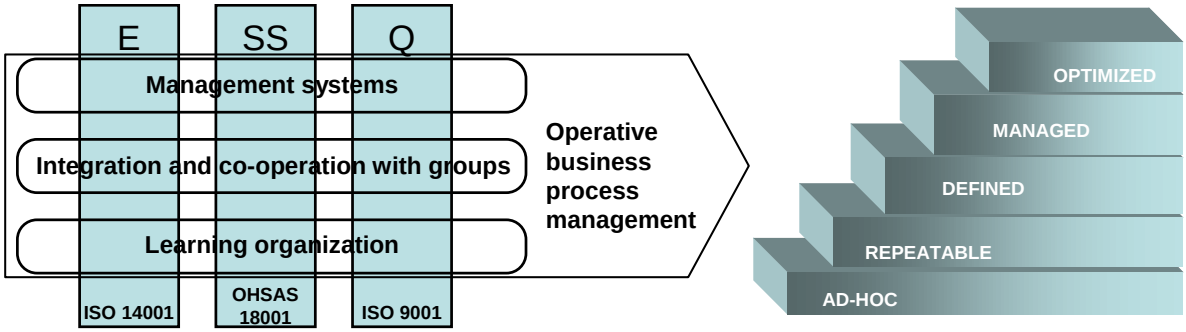

Figure 7: The integration of EHSQ management to operations and maturity levels.

BENEFITS AND CHALLENGES OF IMS

In figure n, Zeng et al. (2007) classified the synergies an IMS includes on three levels: 1) strategic synergy, 2) cultural, structural and resources synergy and 3) documentation synergy. Zwetsloot (1995) describes the synergies similarly, categorising them into common aspect synergy, management synergy and organizational synergy.

Casadesus et al. (2011) performed an empirical investigation on whether these synergies realise in practice using a sample of Spanish organizations with ISO 9001 and/or ISO 14001. Their results suggest that implementing them into an IMS brings greater benefits to the organization than having them as separate management systems. Their results showed a particularly large difference in customer satisfaction.

Zeng et al. (2010) identified the most significant benefits achieved by their case companies from IMS integration to be the simplification of certification processes, management cost savings and decreased paper work. In Zeng et al. (2011) two more benefits were pointed out: decreased complexity of internal management and facilitation of continuous improvement. Beckmerhagen et al (2003) suggest of prevalent benefits in more detail, the results of the Zeng et al. studies support these findings.

Zutshi and Sohal (2005) studied the IMS implementation of three Australian business organizations. The main IMS benefits they discovered were 1) Improved transfer of strategy to operations 2) Improved resource utililization 3) Better visibility for management through a holistic view 4) Improved acceptance and understanding of employees of different IMS areas 5) More effective integrated training programs 6) Enhanced communication 7) Positive bottom line and market image effect 8) Ease of auditing and housekeeping.

Beckmerhagen et al. (2003) point out that the integration of standards and the integration of systems is largely disconnected. Integration should be done gradually and the order of integration should be thought out. Full integration should include all the management systems of an organization and consist of an IMS core and function-specific modules. Their case study highlights an example in which safety management was not fully integrated, which led to non-conformance in that area.

Zutshi and Sohal (2005) found these challenges/impediments accompanied by integration: 1) People's attitudes and the resulting cultural resistance 2) Lack of a formal strategic plan and a planning process hinders MS integration 3) Lack of internal expertise to integrate, leading to the use of consultants which may not provide the desired results 4) Constantly changing regulations and guidelines 5) Insufficient capability of reporting results in a timely manner 6) Time-delays in integration.

CONCLUSION

The aim of the study was to look at the integration of HSEQ management from multiple perspectives. A view of what has caused the interest in integrated management systems and what is the current theoretical basis of integrated management systems was gained. The posed research questions were answered in the previous chapters. Below are the answers in a summarized form:

RQ1: What have been the development paths of different areas of EHSQ management?

Several observations can be made from the comparison of the historical development paths of the EHSQ management areas. The development paths have been led by different motivators. E and HS management areas have, especially in the past, been driven by laws and regulations, although recently a more active mode of development has been introduced, as the areas have become ways to gain competitive advantages. Quality management has from the beginning been motivated internally from the need to meet customer requirements effectively.

Despite different governing factors each area has progressed towards a more holistic view. The scope has shifted from a detail level, be it individual products, the operator of a machine or a single health or safety issue towards the organizational level. This increase in scope explains the need to adopt systems to handle these management areas. Multiple stakeholders, both internal and external, are constantly involved with each of the management areas and they become interlinked. The fact that this has happened only recently explains the IMS "boom" of the last decade.

RQ2: What elements does an integrated management system include and how can the efficiency of an IMS be assessed?

The current IMS view is to use existing MSs as building blocks that are combined into the organization's management process to form a holistic management system. As Beckmerhagen et al. (2003) stated, a fully integrated management system should include all the management systems of an organization and consist of an IMS core and function-specific modules. Through the strategy process, IMS goals and their indicators are defined and assessed through management reviews. It is possible to assess an IMS in more detail through the use of i.e. EFQM or CMMI models.

RQ3: What are the main benefits and challenges of IMS implementation on organizational success?

Integrated management systems aim to gain benefits for the organization by achieved synergy advantages. Zeng et al. (2007) classify these synergies on three levels: 1) Strategic 2) Cultural, resources and structural and 3) Documentation. Through synergy achieved through IMS implementation, concrete benefits such as simplification of certification, management cost savings, decreased paperwork, decreased complexity of internal management and facilitation of continuous improvement can be reached (Zeng et al., 2010; Zeng et al., 2011).

Challenges that need to be accounted for when implementing IMSs mostly relate to management actions and organizational culture. Recognizing the interfaces between different MSs during the implementation phase is important. Setting clear goals both for the implementation and the different IMS areas is crucial. Proper management support and leadership can lessen the cultural resistance to the implementation.

The framework presented in this study can be used to assess individual IMSs using the same structure: historical developments, elements and assessment and benefits and challenges. This can be seen as a well-balanced way to investigate an IMS.

This study focused on HSEQ management areas. Further insight could be gained by adding other areas in the analysis. An interesting topic would also be to analyse and compare several organizations using the history – elements and assessment – benefits and challenges structure.

USING THE BCFI METHOD TO IMPROVE IDEA MANAGEMENT

ABSTRACT

New Product Development is a starting point for many world-class innovations that originate in the minds of people. Along the development path they might become products or services that produce value for their developers, makers and users. The process where ideas become refined to start making (economical) sense to a company often begins unclear, fuzzy and completely unstructured. Companies and researchers today are doing what they can to clarify the processes therein in order to make innovation paths more structured, and to bind the activities to corporate strategies and existing technological roadmaps.

The case at hand was studied to improve the company's idea management in the front end phase. For this study, data was collected by means of a survey about the effects and importance of idea management to early-stage handling of new ideas. The results were then analysed with the Balanced Critical Factor Index method. For the method, specific information about the experiences and expectations of respondents in the case company was asked. The case company, a world-renown manufacturer, operates in the business-to-business market, and does business in several countries.

The Balanced Critical Factor Index (BCFI) method specifically showed that there were definite targets for development, according to the respondents' experiences and expectations. The study produced important information about the current state of idea management and the corporate culture around it. Based on the findings and the results, the corporate management will be able to focus attention to the critical areas, and enhance the knowledge culture by means of idea management. In the long run, the company's intention is to screen their ideas for feasibility already in their early stages, in order to pick the winning ideas for further development into world-class innovations.

INTRODUCTION

Corporate strategy dictates the guidelines for business in the modern company. The company management should be aware of the accordance of everyday to its chosen strategies at all times in order to run the business effectively and to make quality decisions. In order to accomplish this, the management needs timely information about the company's direction of development, both as historical statistics and future estimates. There are several ways to measure business activities, but selecting what to measure and the source for information are important to get eligible results that can be used for the purpose of business development.

The data was collected from a selected group of experts and managers who have a stake in the idea management process. Their future functions include coordinating the screening process for individual ideas, evaluating the ideas, and other supporting tasks. The intention has been to acquire data from several corporate levels in order to find out how the process measurement and the tools used in the process could be developed to match corporate requirements. The overall number of respondents for this study was 20 employees from both manager and non-manager levels.

THE BALANCED CRITICAL FACTOR INDEX METHOD

The Balanced Critical Factor Index (BCFI) method is used for data analysis. The method was first introduced as the Critical Factor Index (CFI) method by Takala and Rautiainen in 2003. Through further development by Takala & Ranta (2007) and Takala & Nadler (2010), the method has evolved to the BCFI method to de-emphasize the importance of standard deviations in the calculations. The method, originally developed to sense and respond to customer satisfaction, is used to find the critical attributes in business processes. It can be used for examining several types of different processes as a management tool to find the business-critical allocation targets for resources. (Nadler & Takala, 2010).

Data for this method is commonly collected by means of a questionnaire. However, because for each process within the company the attributes are individually applicable, a standardized questionnaire cannot be used. The questionnaire should rather be customized for each case in order to get reliable and accurate results (Nadler & Takala, 2010). The next section describes using the method in more detail.

Using the Balanced Critical Factor Index method

There are three separate phases in the BCFI method:

1) Assessing the current situation and making observations
2) Defining the appropriate attributes for critical factors
3) Data analysis and application of CFI tools

Phase 1 consists of preliminary research of the organization, its processes and the situation in general. This phase is meant for finding the appropriate phenomena and the correct organizational elements to research, in addition to getting acquainted with the processes and people whose input is required.

Phase 2 is about defining and selecting the relevant attributes to measure the business processes. The attributes are directly used in a questionnaire, sent to respondents that have key roles within the examined processes. The respondents are asked to respond their past experiences and future expectations about the processes, as represented through various attributes. They respond on a numerical scale where the higher end indicates better grading for attributes. Also, the opinion of respondents about past and future development is asked with the options 1) worse, 2) same and 3) better.

Phase 3 comprises calculating the following indices for data analysis, according to the BCFI method:

$$\text{SD expectation index} = \left(\frac{\text{SD of expectation}}{10}\right) + 1$$

$$\text{SD experience index} = \left(\frac{\text{SD of experience}}{10}\right) + 1$$

$$\text{Performance index} = \frac{\text{Average of experience}}{10}$$

$$\text{Importance index} = \frac{\text{Average of expectation}}{10}$$

$$\text{Gap index} = \left|\frac{(\text{avg.of experience} - \text{avg.of expectation})}{10}\right|$$

$$\text{Direction of future/past development index} = \left|\frac{(\text{b\%-w\%})}{100}\right|$$

The BCFI is calculated with the following equation, with values from the other indices:

$$\text{BCFI} = \frac{\text{SD expectation index} \cdot \text{SD experience index} \cdot \text{Performance index}}{\text{Importance index} \cdot \text{Gap index} \cdot \text{Direction of development index}}$$

Originally, the BCFI has been used with the indices for future and past development calculated together. However, depending on the results, it is more eligible to calculate them separately. Thus, it is possible to make a comparison between the perceived states of the attributes according to historical development and the future development direction. With this, it is possible to make a development statistic over time, as the attributes are measured in future instances.

Attributes are considered critical when their BCFI value is close to zero. If an attribute has a value significantly greater than others, it is also noteworthy. The separate indices can be weighted if there is need to emphasize them according to the prevalent circumstances (Nadler & Takala 2010, pp. 3–4).

The BCFI values are calculated individually for each attribute. The results can be presented as a bar graph that shows the BCFIs for both past and future development side by side. If results are needed for certain organizational elements (for example only manager-level personnel or for only certain units), the results can be divided accordingly and a separate graph should be made for each statistic.

RESULTS

The data was collected from a population of employees consisting of managers and experts. Their work locations are in Finland and other countries. A questionnaire with 28 attributes related to idea management was sent to the respondents. The results are presented in this section firstly as a summary of average scores, standard deviations and percentages for the direction of development (separately for future and past) for all questioned attributes. 21 replies in all were received for the survey. The table below shows the summarized raw data:

Table 1: Summarized raw data for the idea management survey

Idea management	Average of expectations	Standard deviation of expectations	Average of experience	Standard deviation of experience	Direction of future development			Direction of past development		
					Worse	Same	Better	Worse	Same	Better
Attribute 1	8,47	0,77	5,32	1,97	0,00 %	11,11 %	88,89 %	5,26 %	68,42 %	26,32 %
Attribute 2	7,82	1,07	6,56	1,86	11,76 %	35,29 %	52,94 %	0,00 %	75,00 %	25,00 %
Attribute 3	8,32	1,00	5,63	1,74	0,00 %	42,11 %	57,89 %	0,00 %	72,22 %	27,78 %
Attribute 4	8,05	1,08	5,05	2,09	5,26 %	21,05 %	73,68 %	5,56 %	83,33 %	11,11 %
Attribute 5	8,00	1,24	4,89	2,00	0,00 %	22,22 %	77,78 %	5,56 %	55,56 %	38,89 %
Attribute 6	6,69	1,78	4,13	2,09	0,00 %	50,00 %	50,00 %	6,25 %	62,50 %	31,25 %
General idea correspondence to strategy										
Attribute 7	7,61	1,04	5,67	2,17	0,00 %	66,67 %	33,33 %	0,00 %	83,33 %	16,67 %
Attribute 8	7,95	1,13	5,84	2,09	0,00 %	55,56 %	44,44 %	0,00 %	63,16 %	36,84 %

Attribute 10	8,05	1,78	5,95	2,34	0,00 %	26,32 %	73,68 %	0,00 %	42,11 %	57,89 %
Attribute 11	8,32	0,95	6,32	2,11	0,00 %	42,11 %	57,89 %	0,00 %	68,42 %	31,58 %
Attribute 12	7,58	1,71	5,56	2,25	0,00 %	31,58 %	68,42 %	0,00 %	57,89 %	42,11 %
Importance of idea management for solution/product development in these areas:										
Attribute 13	8,21	1,13	6,42	1,92	0,00 %	15,79 %	84,21 %	0,00 %	73,68 %	26,32 %
Attribute 14	7,63	1,50	5,58	2,04	0,00 %	27,78 %	72,22 %	0,00 %	78,95 %	21,05 %
Attribute 15	7,84	1,80	5,84	2,09	0,00 %	27,78 %	72,22 %	5,26 %	52,63 %	42,11 %
Importance of idea management for operational development in these areas:										
Attribute 16	7,05	1,43	5,17	2,20	0,00 %	55,56 %	44,44 %	11,11 %	77,78 %	11,11 %
Attribute 17	7,20	1,58	5,47	2,09	0,00 %	47,37 %	52,63 %	10,53 %	78,95 %	10,53 %
Importance of idea management for business development in these areas:										
Attribute 18	7,59	1,54	5,59	2,06	0,00 %	41,18 %	58,82 %	5,88 %	70,59 %	23,53 %
Attribute 19	7,76	1,52	5,63	2,45	0,00 %	25,00 %	75,00 %	0,00 %	68,75 %	31,25 %
Idea collection										
Attribute 20	8,50	1,05	4,75	2,17	0,00 %	10,00 %	90,00 %	5,00 %	75,00 %	20,00 %
Attribute 21	7,75	1,33	4,42	2,27	0,00 %	21,05 %	78,95 %	5,26 %	73,68 %	21,05 %
Attribute 22	7,79	1,69	3,94	2,75	0,00 %	22,22 %	77,78 %	5,88 %	76,47 %	17,65 %
Attribute 23	7,56	1,29	4,25	2,74	0,00 %	23,53 %	76,47 %	6,25 %	81,25 %	12,50 %
Improvements by idea management to these attributes										
Attribute 24	6,88	1,26	5,20	2,04	0,00 %	46,67 %	53,33 %	0,00 %	64,29 %	35,71 %
Attribute 25	6,95	2,32	5,28	2,44	21,05 %	52,63 %	26,32 %	5,88 %	82,35 %	11,76 %
Attribute 26	7,80	1,20	4,89	2,00	0,00 %	31,58 %	68,42 %	5,56 %	72,22 %	22,22 %
Attribute 27	8,00	0,97	5,18	2,32	5,88 %	23,53 %	70,59 %	6,25 %	68,75 %	25,00 %
Attribute 28	8,10	1,52	5,84	2,06	0,00 %	36,84 %	63,16 %	5,56 %	77,78 %	16,67 %

Some conclusions can already be made from the raw data. It seems that attributes 6, 24 and 25 have received the lowest average scores. Also, the standard deviation of attribute 25 is significantly larger than other attributes. This indicates that there is ambiguity about the attribute. Regarding past experiences, attribute 6 also had a very low average score, which means the expectations for this attribute are pessimistic, despite the direction of future development is expected to become either better or stay the same.

Attribute 20 has received the biggest average score, and its direction of future development has ultimately the most responses on “better”, which indicates this as a strongly noticeable attribute for future development.

Results from the BCFI method

The BCFI method yielded results for both the future and past development separately. From the shape of the figure below, it can be seen that there is more ambiguity and unawareness of the past circumstances in various attributes than in the expectations for the future. Although for such attributes as 4, 16, 17 and 25 the values for the past BCFI are significantly bigger than others, the scale values in the figure below are limited to 10 in order to keep the diagram readable. The results for both future and past BCFIs are displayed in figure below.

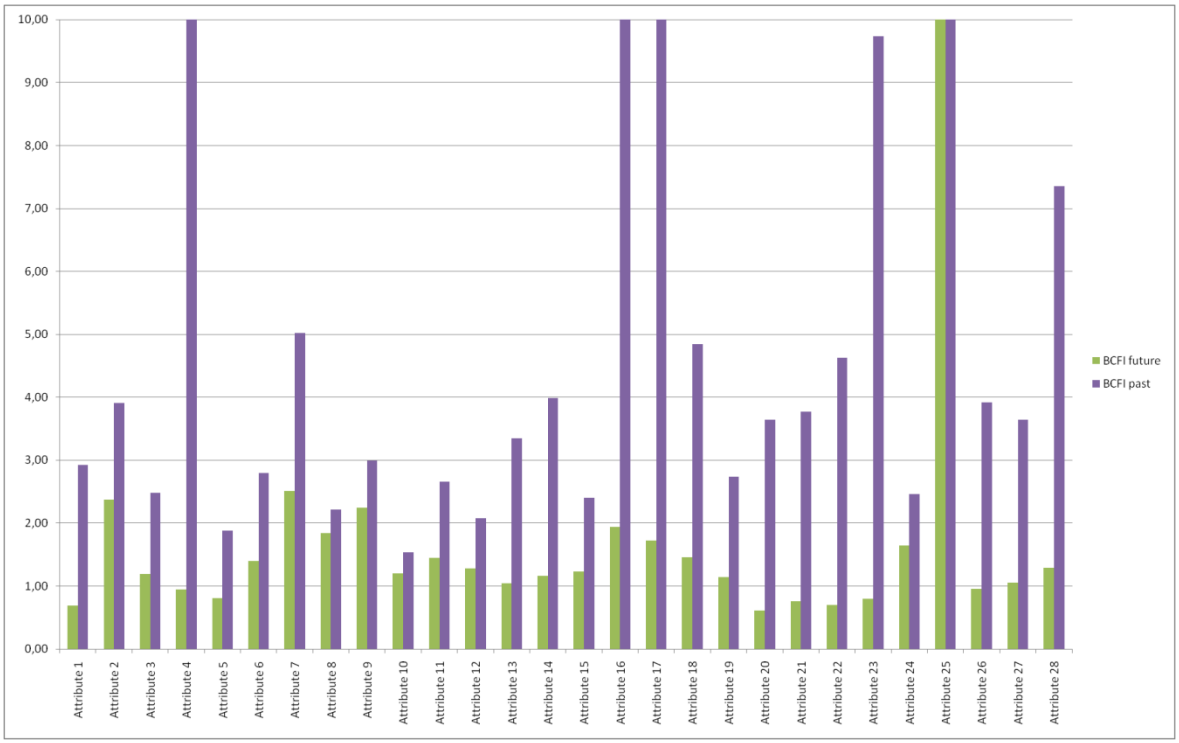

Figure 1: Future and past BCFI

From the figure it is seen that the values for attributes 1, 20 and 22 are the most critical. This coincides with previously collected data and confirms the need for development in these areas. The attributes have been identified as lacking historically, and the respondents' expectations for improvements make it the focus for future development.

The peak values in attributes 16, 17 and 25 show that these particular attributes are not considered critical. Therefore, there is no imminent need for development. The nature of these attributes suggests that with any development to other (critical) attributes, the ones in question will also be improved.

The past BCFI values show several peaks in attributes 4, 16, 17, 23 and 25. These attributes are either non-critical or otherwise there has not been a common view on them between the respondents. Previously collected data indicates that these attributes have not been in use much, which explains the ambiguity around them.

CONCLUSIONS

The study was made to find out the critical attributes for the development of idea management in the case company. The BCFI method gave valuable results based on the expectations and experiences of company employees both on manager and expert levels. It clearly showed that the company is strong in some attributes, mainly around its core competencies. The method also indicated that idea management is a necessary, albeit ambiguous function, and requires the company clearly defined rules and connections to its processes.

The BCFI method was found to be most effective when the indices were separately handled for the future and past development. In both indices, the critical values correspond with previously collected data well and provide valuable information that will help the case company to develop its business with the studied function of idea management.

A CASE STUDY ON CHINESE FAILURE IN ERP IMPLEMENTATION

Dr. Farshad Salimi, www.reprocess.co
farshad@reprocess.co

ABSTRACT

This article is a single-case study on ERP implementation processes at a Chinese enterprise. The enterprise, Ω, implemented the second generation of ERP system supplied by SAP R3 to supersede its earlier own custom-designed first generation ERP system. We selected five Key Critical Success Factors (KCSFs) of; top management support, business process re-engineering (BPR), change management, project management, and company context for analysis of second generation ERP SAP R3 implementation at Ω. The primary reason for change over from first generation to second generation ERP SAP R3 was business expansion and modernization. Ω failed to customize SAP R3 to its business processes. There were variety of reasons for this failure with amongst others, users' resistance, company culture, complex business processes, error in input to database, lack of understanding of business processes by SAP consultants and understanding of SAP functions by key users.

Keywords: Change management, Project Management, Business Process Re-engineering (BPR), Culture.

INTRODUCTION

Ω is one of China's largest microscope enterprises, claiming to be the fifth brand in the world. The enterprise was established in 1983 in Xiamen, and now it has six subsidiary companies all over the world: Hong Kong, U.S., Canada, Germany, Spain, and U.K., with over 2500 employees. Ω at China, Xiamen is the production HQ and the manufacturing center and technology development centers. Chengdu, Guiyang, and Sanming production plants produce different components of the microscope. Since most of its sales are for overseas, Hong Kong is the international marketing and sale center. Ω Enterprise founded by purchasing Xiamen Optical Instrument Factory, a state-owned company, and taking over all its employees. Ω has built international reputation from its Hong Kong based investments, international business and its state-owned legacy. Due to its state-owned background, government has influence on Ω business affairs.

Ω specializes in manufacturing of both conventional microscope and digital microscopes. The main product, i.e. digital microscope, is used for education, lab research, industry measurement, and medical application. On this perspective, Ω is also a high-tech company. It possesses a Research & Development center, which integrates sub-divisions of optics, mechanics, chemical, industry design, electronic, software, and it has over 100 professional engineers and technicians. The Ω technology high-tech know-how is a key success factor in

ERP implementation efforts.

The ERP Implementation at Ω

Motivation behind ERP Implementation at Ω

Begin 1999, **Ω** planned to implement ERP in the period when most Chinese firms were eager to change from business expansion to modern high-tech business. Ω aimed at developing technology innovation and expansion in both domestic and global market share. A number of problems aroused from the firm expansion. For this reason, Ω searched for effective and advanced management tools to support its business processes to resolve the problems:

-Since the headquarters for; the marketing and sale center, manufacturing center, and technology and development center are at different locations and far from each other, the real-time and reliable communication and cooperation has been the most urgent problem.

-The product serial numbers outdated and malfunctioned because of rapid new development and products updates. For instance, the same type of digital microscope, customized for different companies, and ordered by different serial numbers enhanced the problems in resource management.

-One complete set of digital microscope comprise of hardware and software, which each also contains several components. Different departments had their own ways to mark them, i.e. the same part of the product has more than one tag number. This was the cause of some communication problem.

-The information flow has been phase-by-phase and slow.

-The database for daily activity had functional limitation because of data expansion.

-In addition to State publicity, ERP implementation trend influenced the Ω top management decision on ERP implementation.

These problems were present in Ω prior to ERP SAP R3 implementation, while the top management had its own reasoning for ERP adoption.

The first generation own custom-designed ERP implementation

In this section, the analysis for the first generation of ERP system is based on the process model developed by Ross (1998). In an ERP implementation model, Ross (1998) links the process stages to organizational performance. The following section presents how the custom-designed ERP system developed and performed at Ω.

- Design Stage

According to Ross (1998), the decisions timeline has to be determined; including changing business processes or ERP customization period, and period for determination of process

standardization domain must be specificed. Ω decided to design and implement the ERP system by itself, and for this reason it selected some experienced programmers to learn how to design the ERP system. On one hand, the custom-designed ERP system focused in solving the most urgent problems and potential problems what considered by CEO as most critical to firm operation. On the other hand, the software programmers involved in design of ERP system were not ERP experts, and they had limited knowledge on ERP functions.

- Implementation Stage

At this stage, firm starts with ERP implementation, and some problems emerge because of the new system. It will take time to take the problems and then, the effects come out (Ross, 1998). In this case, the ERP system was designed to solve the existing problems and Ω was less flexible users towards this ERP system. Initially, the ERP system was a small module, aiming to solve the serial number for different products. There were limited number of users and departments involved. The system was implemented smoothly because of 1. Training, 2. Phase by phase implementation, and 3. Users' acceptance.

This ERP system was based on following three modules: 1) Planning: Planning includes MRP (Material Resource Planning) simulation, purchase orders application, short resource checking. It was mainly to provide the general resource schedule for the next manufacturing set. 2) Manufacturing: This involved receiving orders from Hong Kong, and arranging the manufacturing orders to sub-manufacturer. In this function, ERP acted as a link among the headquarters (Xiamen), the sale center (Hong Kong) and sub-manufacturing company (Chengdu, Guiyang, Sangming), and 3) Resource management: Resource management included tracing of purchase orders, and adjusting the resource order in case there was any priority order.

- Stabilization Stage

Firms take benefits from the ERP system, if it performs its functional expectations in implementation stage (Ross, 1998).

Ω entered stabilization stage at the end of 2000 at which some of the above mentioned problems were resolved. For instance, the disorderly product serial numbers were organized, and this enabled the product parts to have unified identification codes.

The basic access to the resource database allowed the subsidiaries to have a real time input and output for all resources, which had facilitated the resource management. In general, the improvement in communication, coordination and cooperation based on the three modules (planning, manufacture, and resource management) formed effective supply chain for Ω; and Ω had a better performance than before.

- Continuous Improvement Stage

After the stabilization stage, the change in business environment must force companies to roll out change management throughout the organization. The ERP system also has to be improved according to these changes, with the development of new functions (Ross, 1998). Since 2002,Ω launched its focus on the digital microscope instead of the conventional microscope. The transfer of the products led to the ERP updates, which increased the requirement for an increase in database capacity for recording more microscope categories and parts. This included different types and parts of hardware and different versions of software. However, problems were that the new products, digital microscopes, developed more problems, especially after integration of hardware and software. This required more efficient and sufficient information exchange throughout the entire value chain. In this aspect, ERP system played a critical role in information collection and information sharing. With the ERP support, Ω aimed to develop more businesses at domestic and global markets.

- Transformation Stage

At this stage, firms use ERP system to perform process reengineering and to increase their business margin; however, firms have seldom reached this stage (Ross, 1998).

The firm expansion brought various changes to both organizational structure and business activities. There was more demand on the customer specific requirement. The firm had to put more product attributes for custom-designed product. In a Digital Lab, Japanese prefer the monitor of the students' microscope by; while the western focus is on the real time communication between teacher and students. ERP had to reflect broad customers' requirements, and assign tasks to each department to fulfill these requirements. The custom-designed ERP failed to support these complicated process requirements, and the system appeared to regenerate more problems gradually. By taking all the factors into account, the reasons for ERP change-over can be explained as follows:

The function and module of first generation ERP system was difficult to develop and expand to other functions and descriptions.

The ERP system was designed and developed by in-house Ω programmers. They had no or less knowledge of ERP systems and less capability to forecast the changes in business processes, and to understand marketing focus, and management structure. The design of the system was all based on the situation at that time, and there was less flexibility for further development. In addition, at technical level, there were unexpected bugs in the first ERP generation, and Ω had no experience how to trouble shoot the bugs.

Ω had developed with progressive changes in its organizational structure, management model and manufacturing processes. Thus, secondly, first ERP generation did no longer fit to organizational business processes. The system was difficult to modernize and it was no longer suitable for the enterprise.

The system had fatal limitations, which slowed down the ERP system developing in parallel

with organizational changes. Finally, the gap between the system and actual business processes became a barrier to Ω further business development in the market. Despite all, the first generation of ERP system was successful in achieving its objectives for the lifetime of product.. It improved the resource management at Ω, and it synchronized the flow of resources among different business units. The large boost in Ω revenue owed to this ERP application. However, considering the ERP shortcomings and opportunity costs, Ω decided to supersede the first ERP generation system by a professional ERP system.

The second generation off-the-shelf ERP SAP R3 implementation

Ω chose SAP R3 for their new business processes. Since 2005, the ERP experts worked at Ω on ERP implementation project. The ERP SAP R3 implementation process took the following implementation phases;

- Chartering Phase

In 2004, the CEO decided to to replace the out of date inhouse ERP with a new ERP SAP R3 system. Ω made a comparison among different ERP vendors, such as Yongyou, Oracle, and finally he chose SAP R3. SAP was recognized as the most advanced and flexible ERP system for Ω application. After the final decision on SAP R3 implementation, SAP consultant started with their business process study at Ω. At this phase, Ω held several meetings to introduce the business processes and firm database to SAP consultants

- Project Phase

Ω outsourced ERP SAP R3 implementation project to SAP. In order to provide the critical process operations of different department, Ω built a SAP team consisting of the key users in each department. SAP held several trainings for these users involved in the ERP SAP R3 system.

In begin 2007, the ERP SAP was pilot tested for about two months atΩ. The basic results were in accordance to the expectations, and SAP rolled out SAP R3 implementation in entire organization.

- Shakedown Phase

At this phase, Ω worked on the adaptation to ERP SAP R3 system, and it adjusted the ERP SAP R3 system to its live business processes. There are temporary problems like 'reduced productivity' and 'business disruption' in the beginning of this phase (Markus & Tanis, 2000). Ω faced the same situation with unpredicted problems emerging and causing business disruptions. There were some system bugs which were not discovered during the test stage. For instance, since the design of the system omitted the function 'software serial number management', this function was realized manually, or by the old ERP system. For this reason, the new ERP SAP R3 system operated in parallel with its predecessor.

- Onward and Upward Phase

At this phase, ERP SAP R3 system had to be stable and profitable. Ω did not reach this phase, and ERP SAP implementation required a great deal of improvements.

The implementation of SAP R3 moved to its third phase. The problems which the first generation faced had been considered in the design of the new ERP system. There were more modules in the new system to fit the more complex business operations. Ω emphasized on upgrade of ERP system to meet the requirements for a dynamic business environment. However, more difficulties became more visible, and the new ERP system seemed difficult to adapt to, and some of the functions were not flexible enough. There was a gap between the new ERP system business processes and the live business processes at Ω. Ω became a little bit anxious since the system did not function to users' expectations, and the problems were hard to overcome.

ERP SAP R3 Implementation Critical Success Factors Model

Ω encountered many problems in ERP SAP R3 implementation process. We analyzed the ERP implementation process on the basis of five KCSFs at Ω.

-Top Management Support

The implementation of ERP system involves the entire firm involvement, and it can't be successful without the top management understanding, support and participation (Davenport, 1998; Holland, 1999; Esteves & Pastor, 1999; Z.X. Chen, 2001; Yang W. S. & Yan H. H., 2001). The support from the top management is significant for the success of ERP implementation.

In details, the executive support could be *involvement* and *participation* (Jarvernppa & Ives, 1990): Involvement is a subjective and psychological concept, reflecting the cognition and attitude towards the information system. Low involvement illustrates that the executive considers the information system as a common technical project. As Davenport (1998) argues, only the top management possesses the capability to solve the conflicts between the business activities and technology.
The participation is the concept of activity, which refers to the investment on the projects, including time, money, concentration and so on (Jarvenppa & Ives, 1991). The executive support should be at strategic level, not only considering the budget, but also organizational innovation, management and culture, aiming to remove the resistance to ERP system.

At Ω, the executive had highly involved and participated in the ERP implementation. Initially, Ω budgeted 10 million yuan available to ERP SAP R3 implementation project required capital. Secondly, Ω required its staff to cooperate with ERP implementation SAP team, which assured the supports from "soft" factor. Thirdly, the executive played an important role in selection of the ERP supplier, the build-up of ERP project team, and negotiations with ERP consultants.

It was obvious that top management gave importance to the ERP SAP R3 implementation project. However, the problem was the top management sometimes took over the project management role, making decisions for the ERP implementation process. Some of these decisions pushed the ERP system into predicament.

-Business Process Reengineering (BPR) versus Customization of ERP System

As for information system, ERP is a tool which supports the firm to conduct change management; as for management method, ERP is a change management strategy (Esteves (2002). It is generally considered that BPR is essential for the success of ERP implementation (Davenport, 1998; Holland et al., 1999; Zhang et al, 2002; Guo & Tang, 2001). The *best practices* that ERP system advocates may misfit the organizational structure, operational procedures, management model, and infrastructure of the legacy system (Soh et al., 2000; Shang & Seddon, 2000). Therefore, firms have to minimize these misfits by balancing the BPR and ERP customization. According to Soh et al. (2000), the greater the organization changes, the better for ERP implementation is anticipated.

In ERP implementation process, the customization of ERP software is common for the enterprise. According to organization configuration; it is impossible to adjust ERP system completely to the previous organizational and business operation characteristics. On one hand, refining the ERP software is not an easy job, and it can trouble the maintenance in future; On the other hand, ERP is an advanced management concept, which the *best practices* has already been designed embodied in the ERP software (Soh et al., 2000). Adjustments on the system will be difficult to realize the potential benefits from ERP (Al-Mudimigh et al., 2001).

ERP is considered to be the new technology which can bring fundamental innovation on organizational and change management. Chen & Ye (2002) even regards ERP itself as a kind of BPR.

Similarly to Soh et al.'s (2000) point of view, Shang & Seddon (2000) created a matrix with four strategies to achieve fit in an ERP according to two dimensions: 'preparedness to change the enterprise application software' and preparedness to change organizational processes.

Shang & Seddon considers that system exploration create most value for the company among these four strategies; next are software modification & enhancement and process modification & enhancement.

Prior to ERP implementation,Ω business process was complex and inefficient. Because of widespread office locations in HK, Chengdu, Guiyang and Sanming, the communications between these centers were an issue.Ω expected that ERP SAP R3 system could resolve these problems.

Ω implemented the first ERP generation based on the strategy of *software modification & enhancement*, because there was no change in organizational business processes prior to the implementation. The system design and implementation were all aiming to solve the existing problems. The problems did not completely settle down by ERP implementation since the SAP R3 system could not improve the business processes. The failure to improve the Ω business processes was the main reason for the ERP failure.

SAP provided the second generation of ERP for Ω with the design concept based on the western business and management model. The Chinese enterprises have strong characteristics of their own, especially with the Chinese culture and state-owned background. The traditional management model and organization structure of Chinese enterprise differed from that of in West. in addition, Ω had its own company culture different from other Chinese enterprises.

A review of Ω business processes showed that customization was a complex process at Ω. The external SAP ERP implementation team did not understand the chaotic business processes and a mass of data from different subsidiaries. This led to some obvious bugs. One of the bugs was that the ERP system did not contain the price module for Digital Lab products (one of the most saleable products), so, Hong Kong could not check the price through ERP system. They requested the price from colleagues in Xiamen. This was a small error and easy to refine at the design stage. It decreased the efficiency of the whole supply chain and added trouble to entire business operations. That was the reason for manual operation of second generation ERP SAP R3 system.

Ω learnt that ERP system was not a tool for to settle with all the management problems or to solve the organizational process problems automatically.

Ω did not create the business process work responsibility for each department clearly, and it did not unify materials serial numbers and standards prior to ERP implementation. As a result, ERP SAP R3 system did not manage to support the materials efficiently. The serial number for each product part was not assigned in a systematic order. The initial input data to ERP SAP R3 system had no uniform or consistent system. This caused the ERP SAP R3 system to lose its key and basic function in resource management.

-Change Management

Change management focus is on how to deal with users' resistance. One of the important reasons for ERP failure is change management, since many problems in the ERP implementation arise from users' resistance (Kelly et al. (1999) and Sumner (1999)). Any resistance from individuals or functional groups can endanger the success of ERP implementation. Change management, with in particular, the management of users' resistance has been a real challenge to ERP implementation process.

The emotion for changes amongst the key users was the key critical failure factor in implementation of second generation of ERP SAP R3 at Ω. The reason was because some of the users had participated in the design and implementation of the first generation ERP

system; while the second generation ERP system was all designed and implemented by SAP. The emotional resistance was to the extent that key users were reluctant to contribute to the ERP SAP R3 team and ERP R3 implementation process.

This was despite their familiarity with Ω's ERP environment and their potential critical roles in success of SAP implementation.

The new ERP SAP R3 system was more complete. It contained more functional modules than the previous Ω own custom-designed ERP system. However, users were used to the simple operation of the old system. Users found the new system hard to operate. The reasons for users' inadequacy were inadequate training and narrow focus on certain ERP areas.

With implementation of new ERP SAP R3 system, there were more changes in the business processes at Ω. This demanded new relationships, interface and situations in enterprise. The work responsibility became ambiguous, especially for cooperation between teams and individuals. Users felt unstable because of the technical and management changes they encountered. Ω did not invest enough on smoothening of the changes during the ERP implementation.

-Project Management

ERP implementation is a considerable investment. It is a lengthy information-based project, involving the overall operations within an enterprise.

An ERP project has to draw up detailed requirements, target planning, and formal implementation schedule (Somers & Nelson, 2001; Chen & Ye, 2002). ERP is viewed as a process oriented IT tool, which the specific target or business vision has to transfer into the measurable mission or tasks (Al-Mashari et al., 2003). Without the definite business target, the ERP implementation may become a software installation project, and the implementation team would lose their direction, finally the system would be useless. It is essential that the project manager possesses experienced IT background, familiarity of the business process and organizational environment, as well as excellent communication skills. Moreover, most important thing is that the manager has to be empowered (Scott & Vesssey (2002) and Somers (2001)).

At Ω, the first generation ERP implementation team was familiar with business processes and organization infrastructure. Though, they lacked formal ERP implementation requirements, target analysis, and step-by-step implantation plan. The project was more like problem solving rather than a management tool. Consequently, the first generation ERP system developed many limitations over the years, and it no longer fit the business processes at Ω.

The implementation team for second generation of ERP also encountered a great deal of problems understanding complicated business processes and organizational structure. Ω

held extensive meetings and brainstorming sessions for SAP implementation team to understand the firm business structure and business processes.

Despite all efforts, the post ERP implementation system still developed a big bug. Overall, there was a huge gap in understanding Ω business processes and operation of the ERP SAP R3 at Ω.

-Company Context

Ω is a middle size company with several subsidiaries at different locations. Ω devoted a large budget to ERP SAP R3 implementation process.
The Chinese culture had an impact on ERP SAP R3 implementation process, especially at Ω, which had a state-owned background. The management at Ω was heavily hierarchical, and seldom empowered by middle or low level management. ERP systems which derive from western culture require empowerment and information sharing (Davison, 2002). At Ω, CEO made all the decisions, ranging from the business strategy to authorization of daily expenses at Ω. Every decision in the ERP system had to go through authorization of the CEO. Chinese culture follows 'rule of man', and the decision making is based on the experiences rather than the information system.

ERP system requires each activity to follow the designed practice, which means the business process activities rely on the regulations. Identification of regulation and unification of the standards in each department were significant processes to ERP SAP R3 implementation at Ω.

As a state-owned enterprise, Ω was influenced by politics (Liusong, 2001). Many Chinese firms adopted ERP system because the ERP system was considered to advance their management and technology tools. To catch up with high technology and modern management, Ω decided to implement ERP SAP R3 system without careful business analysis and acknowledgement of detailed requirements for implementation.

A typical Chinese characteristic advocates that the organization should be stable and harmonized. The users may reject the information system which breaks the previous internal relationships within the organization. They work hard and efficiently; but they are indifferent, and they avoid troubles, by shifting the responsibility to keep their job secure. For this reason, change management could have played a critical role in success of ERP implementation process at Ω.

Prior and post implementation of ERP process was with a lot of changes and staff brain drain, with software department in particular. Ω invested to a great deal in training the new users. Due to complex business processes and databases, critical users at each department experienced how the businesses worked in their domains. These critical users were not always the managers. The ERP SAP R3 implementation most of all needed the support of these critical users. With departure of these critical users, the difficulties with ERP SAP R3

implementation and post implementation process enhanced to the failure of implementation objectives.

CONCLUSION

Strong support from top management had positive impacts on ERP implementation process whereas weak BPR, resistance by key users, hierarchical autocratic culture and SAP R/3 misfit were among reasons for partial ERP customization and implementation failure at Ω. In this paper, we aimed to identify the KCSFs of two ERP implementation processes in a Chinese enterprise. We selected five KCSFs for analysis: top management support, BPR, change management, project management, and company context.

We drew up the following conclusions on the five KCSFs of ERP implementation:
Top management support had positive impacts in ERP implementation. However, the traditional Chinese management concept with hierarchical management, could lead the top management support to an autocratic control.

BPR was one of the most important factors in an ERP implementation at Ω. We learnt that the balance between BPR and customization of ERP software will have to be carefully considered prior to ERP implementation and in the course of ERP adoption.
Change management was the most important KCSF in ERP implementation at Ω. In China, the level of enterprise IT integration has been relatively lower in comparison to IT integration in Western countries. The user resistance has been higher towards both IT integration and ERP adoption.

Project management role was undermined at Ω because of the strong power of top management. The ERP project was little empowered by middle and low level management. As a result, it lowered the motivation for participation and ERP application.

Company context influenced ERP implementation process at different levels. The Chinese culture with a hierarchical management model and with characteristics of Chinese users had negative impacts on an ERP project at Ω.

Based on the analysis of the ERP implementation KCSFs of at Ω, we also concluded that Ω had to facilitate the information flow throughout the supply chain across Ω to improve the resource management and order management. The ERP implementation had to focus on solving the issues of resource management and order management. The implementation process had to be well planned and each step had to take the firm actual business processes into account.

ABSTRACT

Lots of research work is focused on innovation. The theory is based on concepts as: innovation, innovative individuals or organizations, innovation potential / capacity, innovation capability. The practice is centered on innovation assessment or audit, and innovation management. In the process of designing the company strategy, it is critically important that top management becomes familiar with the competitive advantage of their company in the area of innovativeness – as the innovation capability has a leverage effect: if applied, the competitive advantage is considerably amplified.

Based on the authors recent research work on innovation potential of the small and medium size firms, the paper aims at applying the DISTEH method for assessing the firm's innovation potential. This method was successfully applied in the case of a Romanian firm active in the media industry. The results prove to be useful for the company managers who are making decisions to enhance its innovation potential and, therefore, competitiveness.

The implications are of high importance for practitioners (entrepreneurs and managers) as well as for the researchers and academics interested in developing tools to assess the firm's innovation potential.

Keywords: innovation, innovation potential assessment, DISTEH method, Romania

INTRODUCTION

Innovation potential may be assessed either at macroeconomic or microeconomic levels. As example, the MERIT Centre (Maastricht Economic and social Research and training centre on Innovation and Technology) is publishing studies on innovation in the European Union Member States (MERIT, 2008). However, most of the research and literature is focused on the company as the innovation generator.

Any company has a potential to be creative and innovate. According to Goffin and Mitchell (2005), the innovation drivers are: changes in the clients' needs, changes in the business environment, growing competition, and new technologies.

Innovation is a complex process (Rüggeberg, 2008); its theory is based on concepts as: innovation, innovative individuals or organizations, innovation potential / capacity, innovation capability. Innovation was defined by prestigious scholars (Kuhn, 1985; Wolfe, 1994; Drucker, 2000; Wolpert, 2002) – to name just a few.

The practice is currently centered on innovation assessment or audit, and innovation management. The process of innovation assessment is known as innovation audit as well, mainly in the German school (Eckelmann, 2002; Herstatt et al., 2007). In the process of designing the company strategy, it is critically important that top management becomes familiar with the competitive advantage of their company in the area of innovativeness – as the innovation capability has a leverage effect: if applied, the competitive advantage is considerably amplified. Such companies are well-known for their excellence in innovation (Warschat, 2005) or innovation excellence (Nilsson et al., 2010). The innovation capability, intimately linked with the entrepreneurial capabilities (Alvarez and Barney, 2000), is assessed in order to provide strategic tools for companies' managers.

The focus of this paper is to test the use of the DISTEH method (Scarlat, 1980, 2000, 2005c) for assessing the firm's innovation potential – in the framework of a more comprehensive model for assessing, analyzing and continuously improving the firm's innovation capability (Alexe, 2010). Assessing the innovation potential is just a stage of this complex process.

Based on the authors' recent research work on innovation potential of the small and medium size firms (Scarlat and Alexe, 2010), the paper present the results of applying the DISTEH method for assessing the innovation potential of a Romanian small business. The strengths of the method are highlighted – as it has previously applied to investigate innovative technologies as well as technology prediction (Scarlat 2004, 2006). The method was successfully applied in the case of a Romanian firm active in media industry and – according to the – seven groups of innovation factors were analyzed (conceptual – firm's philosophy on strategy, company culture, organization, personnel, technology, learning capability, economic and financial performance) comprising 95 criteria as a total.

The results of the experiment prove to be useful for the firm's managers who have made decisions to enhance its innovation potential and, therefore, the firm's competitiveness. The implications are of high importance for practitioners (entrepreneurs and managers) as well as for the researchers and academics interested in developing tools to assess the firm's innovation potential.

The remaining of this paper is structured as follows: Assessment of the firm's innovation potential; DISTEH method, Case study: The Company IMG, Conclusions.

ASSESSMENT OF THE FIRM'S INNOVATION POTENTIAL

In March 2011, Google search for "innovation potential" has generously offered approx. 5,000,000 items in 0.22 seconds and for "innovation capability" displayed in 0.25 seconds only 2.600.000 items!

In order to avoid any confusions, for the needs of this study, it is agreed that the concept of 'innovation capability' is larger than 'innovation potential': as described by Alexe (2010), the model for assessing and continuously improving the firm's innovation capability is a ten-stage process – in which the assessment of the firm's innovation potential is one of the stages only (Table 1). The model is an adaptation of the methodology of the Fraunhofer Institut (2007) to improve innovation capability while the method to assess the firm's innovation potential is largely inspired by the methods developed by Eckelmann (2002) and Arthur D. Little (2002). The main features of this process are summarized in Table 1.

Table 1: Model for assessing and continuously improving the firm's innovation capability.

No.	Stages	Content briefly	Participants
1.	Planning stage	Stages, activities, timing, outcomes Participants	Top management
2.	Define the company profile	Data collection, questionnaire-based Design the company innovation profile	Management
3.	Assess the managers' and employees' attitude towards innovation	Surveys questionnaire-based: - addressed to managers - addressed to employees	Management Employees (partly)
4.	Assess the company's innovation potential	Analyze the innovation factors and criteria Calculation of the scores of the innovation potential – by factors and overall Analysis of the disagreements and conflicts Benchmarking	Management Employees (partly)
5.	Feedback to the company management	Presentation of the results of the innovation potential assessment: scores of the innovation potential – by factors and overall; disagreements and conflicts; position – relative to the competition	Management
6.	Design the innovation balanced scorecard	Design a comprehensive set of indicators – to monitor the innovation process	Management
7.	Analyze possible solutions to improve the innovation capability	Explore and identify possible solutions Decide on the best solutions – according to the firm's strategy Decide on the intervention areas and methods	Top management
8.	Action planning	Design the set of measures / solutions to improve the innovation capability Planning of the associated actions	Top management
9.	Implementation of the action plan	Implement the plan (measures / solutions)	Project teams
10.	Progress evaluation	Re-calculation of the scores of the innovation potential – by factors and	Managers Employees (partly)

	overall Assess the efficiency of the solutions (effects noticed after 6 months at least) Resume the process and continue →

The authors have tested and improved the above model and methodology as well as the method to assess the firm's innovation potential (Alexe, 2009; Scarlat and Alexe, 2010; Alexe et al., 2010; Scarlat et al., 2010).

The focus of this paper is on the fourth stage – assessing the company's innovation potential, (Table 2) assuming that:

(i) this stage is just a component of the larger process of improving the firm's innovation capability – which assumes that the company innovates needs-based, innovation is part of its strategy; there is an innovation culture in place; the company continuously implements and learns out if its innovation actions (Lercher, 2008);

(ii) the factors and criteria presented in Table 2 are the result of thorough analysis aiming at identifying the significant elements that define the innovation potential.

Table 2: Innovation potential assessment – factors and criteria (Alexe, 2010).

No.	Factors	No. of criteria	Examples of criteria
1.	Strategy philosophy	15	Environment strategic analysis Forecast exercises Vision Mission statement does include innovation Innovation strategy New products marketing strategy Resources allocated for innovation …
2.	Company culture	12	Innovation culture Openness (outward) Conflict resolution Leadership style Risk orientation Attitude regarding the mistakes made …

4.	Personnel	15	Training Promotion Change in organization Creative employees Financial motivation Non-financial motivation Focus on creative individuals

			…
5.	Technology	12	Technology know-how Patents Focus on technology change Methods to assess innovative ideas IT and dedicated software Benchmarking …
6.	Learning capability	16	Knowledge access Best practice Lessons learnt Involving clients in the learning process Involving suppliers in the learning process Sharing knowledge with others Relationships with consulting firms Relationships with R&D, HE institutions …
7.	Economic and financial performance	9	System to measure innovation activity System to register innovative ideas Indicators to measure innovation Innovation budget …
Total number of criteria		95	-

To note that each criterion implies actually a question or a set of questions; some examples follow:

(i) the "Environment strategic analysis" criterion should read as "Is the company running environment strategy-type analyses (on regular basis)?"

(ii) the "Knowledge access" criterion should read as "Do the company's employees have access to the company's knowledge database? Is there a system in place to disseminate the knowledge among employees?"

(iii) the "Indicators to measure innovation" criterion should read as "Does the company have a system of indicators to measure innovation and innovative activities, in place?" and so on.

The system is open in that sense that new criteria might be added if necessary; this might happen if a certain criterion generates more questions. For example: the criterion (ii) above.

Each factor is assessed criterion by criterion, as a percentage, independently, according to the IPAM (Innovation Potential Assessment Method) complex multi-interviewing procedure (Alexe, 2010). The results are summarized using an assessment fiche: Table 3 displays – as example – the matrix of a such fiche, used in the case of "Economic and financial performance" innovation factor.

Table 3: Innovation factors assessment fiche – "Economic and financial performance" factor: Calculation of the innovation potential score.

No.	**Innovation criteria**	**Evaluation scale, p [%]**				
		0	25	50	75	100
		No evidence	A few evidences	Partial evidences	Clear evidences	Complete evidences
		'Never happens'	'Sometimes happens'	'Balanced'	'Usually happens'	'Always happens'
1.	System to measure innovation activity					
2.	System to register innovative ideas					
3.	Indicators to measure innovation					
…						
9.	Innovation budget					
	Total number of answers	i = 1	i = 2	i = 3	i = 4	i = 5
		n_1	n_2	n_3	n_4	n_5
Score of the innovation potential				$S(F_7)$		

F_7 is the innovation factor number 7 (per Table 2).
$S(F_7)$ is the score of the innovation potential associated to the firm's "Economic and financial performance" – calculated as follows:

$$S(F_7) = (\Sigma_i n_i p_i) / (\Sigma_i n_i) \quad (1)$$

where:

$i = 1, 2, \ldots, 5$
n_i = number of answers associated to each percentage
p_i = percentage (i) i.e. 0%, 25%, ..., 100%
Σ_i = summation symbol, by i, from 1 to 5

A legitimate question (why the number of criteria is different – it varies from factor to factor) is addressed by using comparable measurement systems (as percentage). Consequently, the number of criteria is neither a limitation nor a limit; the design is open, new criteria might be added if considered necessary. However, deleting criteria is a huge mistake because disregarding a certain criterion (then a specific element related to innovation) is going to alter (lower) the score of the innovation potential.

A significant strength of the IPAM is the analysis of the divergences or even conflicts identified among opinions expressed by the interviewees (Table 4).

Table 4: Innovation factors assessment fiche – "Economic and financial performance" factor: Analysis of the conflicts in opinions (an example).

No.	Innovation criteria	Evaluation scale, p [%]				
		0	25	50	75	100
		No evidence	A few evidences	Partial evidences	Clear evidences	Complete evidences
		'Never happens'	'Sometimes happens'	'Balanced'	'Usually happens'	'Always happens'
1.	System to measure innovation activity	● ▲			♦	□
2.	System to register innovative ideas	● □ ▲ ♦				
3.	Indicators to measure innovation				▲	□ ● ♦
…						
9.	Innovation budget	▲	●	♦ □		
	Legend	● = respondent A; □ = respondent B; ▲ = respondent C; ♦ = respondent D; ...				

In principle, different cases are possible:

- strong disagreement (on the "system to measure innovation activity");
- strong agreement that the "system to register innovative ideas" is a weakness; here is a lot of room to improve the innovation potential;
- agreement that the "indicators to measure innovation" is a strength, an innovation advance;
- relatively limited disagreement (on the "innovation budget").

Each case or situation is managed by specific means; it should be underlined that the *innovation consultant plays a key-role.*

After assessing all factors, the firm's innovation potential is measured by the overall score of innovation potential S(IP):

$$S(IP) = \Sigma_j S(F_j) / 7 \qquad (2)$$

where:

$j = 1, 2, \ldots, 7$ (the total number of innovation factors considered)
F_j = innovation factor j
$S(F_j)$ = score of the innovation potential associated to the factor F_j
Σ_j = summation symbol, by j, from 1 to 7

The major critique addressed to this method is that the score itself – regardless how high or low is – does not offer decision support or image of the innovation potential of the company. For example: a company reporting a score like S(IP) = 49% is it good? Is it worse than another company with 55% innovation potential score? How innovative is our company overall?

DISTEH DECISION MODEL AND METHOD

It is extremely important for the company decision makers to have practical and operational tools to assess, analyze and rank their products according to their performance – compared with similar products of their competitors, which is, basically, to apply multi-criteria decision making models. The Neumann and Morgenstern's Utility Theory is probably the most

extensively used method to make multi-criteria decisions; since then (1944) lots of improvements were reported. Romanian school of industrial management made notable efforts in the area of developing new models to rank the industrial products according to their performance – compared with similar products of the competition.

Originally the DISTEH method was developed as decision model to assess the products' technical performance – as displaying some advantages compared to other decision methods (Scarlat 1980, 1981, 1987, 2000). The method was developed as a tool to assess the level of technical performance of products (goods or services) and technologies, within laboratories of Industrial Management Department from University "Politehnica" of Bucharest, Romania. The method was originally named "DISTEH" (Costake and Scarlat 1981, 18). The influence of time factor is considered first time by Costake and Scarlat (1985: 226, 233). DISTEH method was tested in a number of practical training, consulting and research circumstances and continuously improved; it is actually a multi-criteria decision-making model (Scarlat 2005c), and some of its major applications are addressed to products' competitiveness analysis (Scarlat 2004, 2005b, c), marketing pricing strategies (Scarlat 2004, 2005b), technology analysis (Scarlat 2004, 2005a) or technology prediction (Scarlat 2006). The flexibility of the method is tested in this case in a different area: assessing the innovation potential – considered a multi-criteria decision situation.

The basic DISTEH model: Absolute ranking

Assuming that any given decision option A_i (i = 1 to m; m = number of the available decision options) is characterized by a set of characteristics (criteria for assessing the innovation potential, in this case) C_j (j = 1 to n; n = number of criteria), one can define the performance matrix:

$$C = [c_{ij}] \tag{3}$$

where: c_{ij} is that value of the criterion C_j in the case of the option A_i.

In this case, the decision options correspond to the firms for which the innovation potential assessment is conducted. Then an important aspect is highlighted: *the assessment does have sense only in a larger context (the industry in which the targeted company is active). This also means that data about the firms active in this industry should be available and a consistent database should be developed. All these elements characterize a mature, well developed business environment.*

It is also understood that – for each company (i): a key-performance indicator (p_i) and the time of assessment (t_i) are known as well.

The purpose is to determine a unique value associated to each firm A_i ; this value is expected to describe the firm's innovation potential.
One can define an ideal firm (I) – in terms of its innovation potential, real or virtual – having the best criteria c_{Ij}, as follows:

$$c_{Ij} = max_i\,(c_{ij}) \quad \text{when criterion } C_j \text{ is to be as high as possible} \tag{4}$$
$$c_{Ij} = min_i\,(c_{ij}) \quad \text{when criterion } C_j \text{ is to be as low as possible} \tag{4'}$$

Note that (I) describes, generally, a virtual company. Its coordinates may vary in time but – if the analysis horizon is relatively short – the position of (I) is considered as time-stable (Scarlat 2000, 372).

The key-idea is that each company (i), either real or virtual, can be represented as a point in n-dimensional space. The closer the point is to (I), the better the firm – in terms of its innovation potential. Thus, it makes sense to define, for each company, *the innovation potential distance (ex technical distance) between the targeted firm and the ideal one,* as:

$$\overline{IP_i} = \sqrt{\sum_{j=1}^{n}\left(b_j \frac{c_{ij} - c_{Ij}}{c_{Ij}}\right)^2} \qquad (5)$$

where: b_j is associated with the importance of the criterion C_j; and b_j weights the criterion C_j ($0 < b_j < 1$).

The firms are ranked starting from the best one as innovation potential (minimum $\overline{IP}_i$). Note that the innovation potential distance is zero in the case of the ideal firm as innovation potential ($\overline{IP}_I = 0$). Bigger the $\overline{IP}_i$ value, lower the innovation potential of the company A_i and most probably its overall performance. In other words, for any given firm A_i (i = 1 to m), one might calculate a unique value associated to that firm $\overline{IP}_i$, value that allows the ranking of all the companies considered (starting with the best on the top).

Note that if only one company is assessed then the analysis makes sense as well because the ideal might be defined, by different techniques (e.g. benchmarking-type).

DISTEH model: Relative ranking

The DISTEH method can also apply when the decision maker needs to select not the absolutely best firm but the *relatively best firm*, in a similar manner (Scarlat 2000, 372-373). The formula is slightly different (6): only "D" ("Desired") replaces "I" ("Ideal").

$$\overline{IP_{Di}} = \sqrt{\sum_{j=1}^{n}\left(b_j \frac{c_{ij} - c_{Dj}}{c_{Dj}}\right)^2} \qquad (6)$$

The "desired" firm does not have necessarily the best features. *The coordinates of the D point/firm are decided usually by the customer, not by the decision maker.*

Self-calculation of the weight coefficients

When necessary and/or required, all decision-making methods consider the weight coefficients (b_j). And almost all methods estimate b_j values subjectively. Only when those values are the result of well-conducted (marketing) surveys, the decision making process is fair. Most methods assess the weight coefficients (b_j), subjectively. A much simpler approach is used by DISTEH method: each of the weight coefficients b_j is calculated based

on dependency reported by each of the $P(C_j)$ linear regression curves (Scarlat 1987, 285, 287):

$$m_j = \frac{m\sum_{i=1}^{m} c_{ij} p_i - \sum_{i=1}^{m} c_{ij} \sum_{i=1}^{m} p_i}{m\sum_{i=1}^{m} c_{ij}^2 - \left(\sum_{i=1}^{m} c_{ij}\right)^2} \tag{7}$$

and

$$b_j = \left| \frac{m_j}{\sum_{j=1}^{n} m_j} \right| \tag{8}$$

where:

$P = [p_i]$ is the vector of firm performance
$C_j = [c_{ij}]$ is the vector of values of the criterion C_j (j = 1 to n) for all the firms (i = 1 to m).
The signum of m_j has its own significance: "+" identifies "high features" (4) and "-" points "low features" (4').

Identifying the *Critical Characteristic*

The *Critical Characteristic (CC)* defines that criterion, which worsens the firm's innovation potential (makes the corresponding value $\overline{IP}_i$ too high). CC could be easily identified - as corresponding to:

$$\max_j \left\{ \left(b_j \frac{c_{ij} - c_{Ij}}{c_{Ij}} \right)^2 \right\} \tag{9}$$

respectively

$$\max_j \left\{ \left(b_j \frac{c_{ij} - c_{Dj}}{c_{Dj}} \right)^2 \right\} \tag{9'}$$

Once identified, CC must be improved: "Improving the CC" would be the major task for the consulting team working with the target company top management and R&D department. The improving process is continuous: when CC completes its "improving potential", the next-in-line criterion follows.

Usually, the ranking depends on the weights. However, there are cases – both in theory and practice – when the ranking of two options remains unchanged, for all the possible values of their respective weights ($0 \le b_j \le 1$) or, at least, for large variation intervals. Such analysis is presented in (Scarlat 1981).

To conclude, the DISTEH method is a useful tool to assess the firms' innovation potential and rank them accordingly, objectively. Based on the same model, the firm's overall

innovation capability can be improved by setting research priorities – corresponding to the most sensitive criteria.

CASE STUDY: THE COMPANY IMG. RESULTS AND DISCUSSION

The applicability of the DISTEH method for assessing the innovation potential of companies was tested in the case of a Romanian company active in media industry (IMG) which was already analyzed in terms of its innovation capability, and its innovation potential was already assessed by a 'control' method (IPAM) – as previously described by formulas (1) and (2).

It is worthy to mention that both methods were developed by the authors (IPAM by Alexe and DISTEH by Scarlat), first as a dedicated method, second as a multi-purpose decision tool. Just anecdotally: while IPAM is an image of incremental innovation, the use of DISTEH for assessing the innovation potential corresponds to a disruptive innovation.

Under same hypotheses (assuming that the factors and criteria presented in Table 2 are the result of thorough analysis aiming at identifying the significant elements that define the innovation potential; and based on the same results of the analysis – same consequences per each criterion) the comparative results are depicted in Table 5. The assessment of the firm's innovation potential was a part of the more comprehensive analysis of the firm's innovation capability which was conducted in 2010-2011.

Table 5: Model for assessing and continuously improving the firm's innovation capability.

No.	Innovation factors	IPAM [%]	DISTEH	
			Absolute[1]	Relative[2]
1.	Strategy philosophy	58.88 (V)[3]	0.0587 (V)	0.0445 (V)
2.	Company culture	63.88 (VII)	0.0516 (VII)	0.0516 (IV)
3.	Organization	59.37 (VI)	0.0580 (VI)	0.0295 (VII)
4.	Personnel	40.00 (II)	0.0857 (II)	0.0857 (II)
5.	Technology	45.19 (III)	0.0783 (III)	0.0426 (VI)
6.	Learning capability	54.16 (IV)	0.0655 (IV)	0.0655 (III)
7.	Econo-finance performance	18.51 (I)	0.1164 (I)	0.1164 (I)
Overall score for innovation potential		**48.57**	**0.2019**	**0.1803**

[1] To the ideal [100%; 100%; 100%; 100%; 100%; 100%; 100%]

[2] Relative to a desirable profile of innovation potential [90%; 100%; 80%; 100%; 75%; 100%; 100%]

[3] The priority ranks are given in brackets (parenthesis)

Both methods offer the same results – in terms of priority ranking: both point at "economic and financial performance" as the factor that damage the firm's innovation potential the most (only 18.51% innovation potential / 0.1164 maximum distance from the ideal point of innovation potential). And the "company culture" is the most advanced innovation factor for the company IMG.

The results in both methods are non-dimensional. However, it should be noted that DISTEH values are distances to the ideal point of innovation potential: lower the value, shorter the distance, better – see formula (5).

Both methods allow watching the dynamics of the innovation potential (how the score evolves in time – calculated periodically).

Results are presented in case of non-weighted criteria and factors. The results are not changing significantly in the case of considering weighted criteria and/or factors. However, there are twofold advantages of the DISTEH method in this respect:

- it allows the objective self-calculation of the weights;
- it allows direct correlation between firm's innovation criteria, factors, and potential – on one hand – and firm's key-performance indicators.

The latter is actually a direction of further research.

The higher potential of the DISTEH method is evident when DISTEH is relatively calculated (6). The relative point is the desired level of innovation potential factors, to be reached in the future. Those target levels (which might differ from 100%) are established by benchmarking methods, using adequate database. In the case of the company IMG analysis, a top competitor was surveyed and its levels of innovation potential factors assessed accordingly. The results are changing in that sense of priority setting: some of the innovation potential factors are unchanged as priority (I and II) while others are changing; the IMG's "strategy philosophy" keeps its rank (V) just by accident.

The implications for the IMG top management are of substantial importance: as priorities are changing, the actions are different – following to the ranking determined by calculating the relative technical distance. And so are the associated cost, and the expected efficiency of the efforts to improve the IMG's innovation capability. Currently, this process is in full progress.

IPAM has the advantage of simplicity and directness. DISTEH is more sophisticated as the calculus is little bit more complex. The trade-off is that DISTEH has a higher potential offering more information for the firm's decision makers.

CONCLUSIONS

The firm's innovation potential assessment is a necessary exercise – part of the firm's process to improve its innovation capability, and – supposedly – its competitiveness and overall performance.

Assuming that the analysis of the innovation factors and inventory of the innovation criteria is fairly conducted, the need for improving the firms' innovation capability could be satisfied using IPAM and DISTEH methods for assessing the firm's innovation potential.

The use of the DISTEH model and method for assessing the innovation potential was validated – its outcomes resonating to the IPAM results.

Both methods offer reliable and coherent results, and both could be used for examining companies' dynamics in terms of innovation potential. However, IPAM is more intuitive (as percentage is calculated), more direct and simple that the more complex DISTEH, although the latter has a higher potential offering more information for the firm's decision makers.

In any case, there are critical prerequisites: quality consulting services, quality databases – by industry and own firm, which allow benchmarking studies, dynamics analyses and alike as reliable background for sound strategic decisions.

When the target is specifically set by benchmarking techniques or other reasons-based, then the assessment of the innovation potential, and the actions to improve the company's innovation capability must be conducted by use of DISTEH and calculating the relative technical distance of the innovation potential.

The IMG case study (assessment of the innovation potential of a Romanian company active in the media industry) reveals important implications for firms' top management: choosing the appropriate method (as DISTEH associated to benchmarking techniques to calculate the relative technical distance) impacts the firm's priorities, actions, and – consequently – the associated cost, and the expected efficiency of the firm's efforts to improve its innovation capability.

The results of the experiment prove to be useful for the firm's managers who have made decisions to enhance its innovation potential, innovation capability and, therefore, the firm's competitiveness. The implications are of high importance for practitioners (entrepreneurs and managers) as well as for the researchers and academics interested in developing tools to assess the firm's innovation potential, continuously.

ABSTRACT

The ability of companies to meet consumer expectations depends deeply on their ability to innovate and deliver new products at competitive prices. Especially in the low and medium technology industries there is still a gap in the area of innovativeness studies. This research was designed to determine the key innovativeness factors for the Taiwanese food industry and uses a questionnaire to collect data about its innovativeness. The Data Envelopment Analysis (DEA) shows which products/brands, among our sample group, are the most innovative and which are the least. Strategies how to improve the innovative ability are then proposed by assessing the differences between the best and the worst companies, also, taking the size of a company into consideration. Our study contributes by finding a set of factors of innovative ability for the Taiwanese food industry, determining outstanding examples from the researched industry that can be used as a benchmarks, and finally, it proposes innovativeness improvement strategies to the food industry in Taiwan, considering the size of the company.

Keywords: innovativeness, food industry, DEA, Taiwan

INTRODUCTION

Nowadays, innovation is one of the key drivers for company's competitiveness and success, in any industry (OECD, 2005; O'Regan et al., 2006). It is a popular topic for research especially in the high-technology and IT industries that are heavily dependent on Research and Development activities (Armbruster et al., 2008). No wonder that a common thinking is that innovation equals to R&D activities, however this is not a case, especially in less technology-oriented industries – low and medium technology industries (LMT industries). There is also less focus in the innovation literature on the Small and Medium Enterprises' (SMEs) innovativeness ability, as they rarely can afford the expensive R&D activities. However, in latest years it was acknowledged that SMEs also have potential to innovate (OECD, 2005), therefore this article will compare the findings for small, medium and large food industry companies in Taiwan.

Nonetheless, an important question is how to asses innovativeness ability (or innovativeness, both terms used interchangeably in this paper) of a company? Therefore, the measurement of innovation results or innovativeness of companies, products, or just certain innovation projects is the focus of our paper, especially for the food industry Taiwan.

The study chooses Taiwan as the research base, because of the strong innovation culture that exists in this country due to its high development and mature high-technology sector. The researcher believes the results can be useful for application in other countries with similar development level, or used as a benchmark by developing countries.

LITERATURE REVIEW

Innovation and Innovativeness

Firstly it is important to understand what innovation is and what opportunities it brings to businesses, as it is agreed that it is critical for achieving the competitive advantage (Hsieh et al., 2009). According to Schumpeter (1934) innovation is considered to be a complex phenomenon, which includes technical (new products and production methods) and non-technical aspects (new markets and forms of organization).

Then, Myers and Marquis' (1969) definition describes innovation as follows: '*Innovation' is not a single action but a total process of interrelated sub processes. It is not just the conception of a new idea, nor the invention of a new device, not the development of a new market. The process is all of these things acting in an integrated fashion*. This definition combines all kinds of innovations into one broad term and therefore can be used in researches aiming at innovation measurements.

In the 21st century, more studies broadened the concept of innovation to all other business fields, including Low and Medium Technology Industries (LMT) and also Small and Medium Enterprises (SMEs), that was earlier rather neglected by innovation researchers (OECD, 2005). "Oslo Manual - Guidelines for Collecting and Interpreting Innovation Data" published by the OECD (the Organization of Economic Co-operation and Development) and European Commission defines four basic kinds of innovations: Product, Process, Organizational, and Marketing Innovation (OECD, 2005).

On the other hand, according to Garcia and Calantone (2002) innovativeness is the most frequently used measure for a degree of innovation's "newness", and so a highly innovative product or process would be one of a high degree of newness. However, product innovativeness is not equal to firm's innovativeness, and it is the second that we find more interesting, as it can help to evaluate companies' positions within the industry. Ettile et al. (1984) defined organizational innovativeness as the tendency for the firm to innovate or develop new products, while Rogers (1995) called it also a tendency to adopt innovations. In these both cases we can see that the newness of product does not influence the innovativeness of the organization. Still, there is many innovation strategies that companies can choose from and the problem is how then these companies can be compared.

Food Industry

The study can only focus on a certain industries since innovation processes differ greatly from industry to industry in development, rate of technological change, linkages and access to knowledge, as well as organizational structures and institutional factors (Malerba, 2005; OECD, 2005). Prior researches usually focus on high-technology industries (3C, biotechnology,

pharmaceutical industries), and only few in agriculture or food industries (Fortuin et al., 2007). Some of these are: Pannekoek, Van Kooten, Kemp and Omta (2005) - innovation projects in greenhouse horticulture, Batterink, Wubben and Omta (2006) - agrifood industry, and Fortuin et al. (2007) - innovation projects in food industry.

Food industry is a LMT industry, and more recent studies are starting to research innovation among LMT firms (Heidenreich, 2009; Robertson et al., 2009) acknowledging their important role in building global innovativeness. Generally, the innovation ability of the LMT firms may be underestimated since they buy their technological expertise, formally or informally, from outside, rather than develop it inside the organizations (Hirsch-Kreinsen et al., 2006).

In each country, food industry is one that provides basic, daily products to the national market. In our research, we want to use a comprehensive but simple definition of food industry, proposed by the UK's Food Standard Agency (2009): *the whole food industry – from farming and food production, packaging and distribution, to retail and catering*. It is comprehensive, however focuses on the companies, in which food products, or for which food handling, is crucial and influences the way these businesses run.

Innovativeness Factors for Taiwanese Food Industry

We gathered and organized in five dimensions the factors having an influence on the Taiwanese food: Product, Process, Organizational, Marketing, and Eco-Innovation (see Table 1).

Table 1: Innovation dimensions and factors for Taiwanese food industry.

Product	**Process**	**Organizational**	**Marketing**	**Eco-Innovation**
1. product superiority, 2. market potential, 3. competitive pressure, 4. project--company fit, 5. project resources	1. technological skills and know-how, 2. R&D activities	1. strategy and innovation culture, 2. communication and cooperation, 3. business groups, 4. new managerial methods	1. advertising and promotion	1. Eco-innovation

The first dimension is 'Product Innovation' and it consists of 5 factors. They are: product superiority (is the product being superior to competing products; is it the first in the market; does it have higher quality than competitors; does it offer new applications to customers; etc.), market potential (the monetary value of the existing or potential market; is the market growing; do the potential customers have a great need for this product; will the customers definitely use the product; will it contribute to the competitive advantage of the firm), competitive pressure (is the market highly competitive; number of active competitors; price competition wars), project-company fit (the nature of the production process, distribution system and/or type of sales force; customers and competitors and their newness to the firm), project resources (company's financial and production resources; management and engineering skills adequateness for the project; marketing research skills; sales and distribution resources adequateness for the project) (Fortuin et al., 2007).

The second dimension 'Process Innovation' includes two factors: technological skills and know-how, as well as R&D activities. Both those factors have been drawn in directly from the 3rd edition of the Oslo Manual. Technological skills and know-how concern about the technological skills of the workforce of the company, technological resources, as well as the way company acquires external knowledge in connection to development and implementation of new innovations. Then, R&D activities include two aspects, one being the basic research, the second one being the new product or process development and testing (OECD, 2005).

Even though some studies were mentioning the non-technological aspects of innovation much earlier, it was the beginning of the 21st century when academic world fully acknowledged and appreciated the importance of organizational innovations (OECD, 2005). Examples of other studies using organizational innovation in their researches are: Greenan, 2003; Rejeb et al., 2008; Armbruster et al., 2008. The 'Organizational Innovation' dimension includes following factors: Strategy and innovation culture - one of the key factors influencing product innovation management (Cormican and O'Sullivan, 2004) that should specify market niches as targets for the company's focus and formalize the necessary structures for implementation; Communication and cooperation (good communication within the team, management commitment, clear performance requirements, understanding the project problems by the employees, etc.) (Fortuin et al., 2007); New managerial methods (organisational changes implemented in response to a new managerial strategy that represent the first implementation of a new organisational method) (OECD, 2005); Business groups (relationships that the companies establish with other organizations, or within the company, to facilitate their capabilities through synergy effect). In Taiwan, the business groups are called 'Jituanqiye' (集團企業), and are specific kind of business models distinct from traditional enterprises. They consist of legally independent companies that are however controlled by only one owner. These independent companies have to meet their own independent objectives as well as the whole business group's goals. The group factors influencing company's innovation include group affiliation, diversification, inside ownership and family ties (Hsieh et al., 2009),

The OECD also included the marketing into their innovation definition arguing that nowadays firms allocate large amounts of resources into market research and development on new marketing channels, including targeting new markets or market segments as well as coming up with new advertising/promotion ways (OECD, 2005). This paper use one factor called 'Advertising and promotion' to represent this dimension, based on the marketing innovations concepts used in the Oslo Manual and the Fortuin et al. study (OECD, 2005; Fortuin et al., 2007). The marketing innovations' goal is to better address customer needs, open up new market, or position firm's product on the market in a new way, with the objective of increasing the firm's sales, which can be achieved by better communication with the customer, which is done by the advertising and promotional activities.

The final innovation dimension incorporated into this paper is called 'Eco-Innovation'. It was not included in neither the Oslo Manual, nor the Fortuin et al. (2007) study, however the literature review of articles from last few years revealed that environmental issues are growing in importance in every area and every industry and should not be left out, especially that there is still huge room for innovations to create more environmentally

friendly products. Especially when food products are considered, the eco factors are often perceived as safety and healthy factors by customers, and therefore there is a pressure from consumers onto the industries to innovate their product and processes in the 'green' way. Rennings (2000) argues that eco-innovation should be included in the common understanding of the concept of innovation. Some of his arguments are: the demand for drastic reductions of environmental burdens, innovation is expected to offset burdens and costs induced by the environmental regulations, new types of vehicles, renewable energy systems or corresponding infrastructure often need at least a decade for invention, adaptation and diffusion, long-term sustainability goals cannot be met by progress in environmental technology and must be supplemented by corresponding lifestyles and institutional changes, environmentally-friendly processes or products are already a part of everyday life in majority of firms so managing eco-innovation is increasingly important issue for them, and finally it is crucial to define key determinants and success factors of innovation processes for sustainability. We use the definition of 'eco-innovation' propsoed by Klemmer et al. (1999): *Eco-innovations are all measures of relevant actors (firms, politicians, unions, associations, churches, private households) which:*
1. develop new ideas, behavior, products and processes, apply or introduce them and
2. which contribute to a reduction of environmental burdens or to ecologically specified sustainability targets.

This paper uses just one combined factor names same as the dimension eco-innovation that combines four eco-innovation concepts together, these concepts are: Land and water resources management (part of the agriculture sustainability practices) (Wall and Smit, 2005), Environmental technologies (Rennings, 2000; Freeman, 1996), Green Supply Chain Management (reducing material intensity, reducing energy intensity, reducing dispersion of toxic substances, enhancing recyclability, maximizing use of renewables, extending product durability, 'green' certification, organic products) (European Environment Agency, 2006; Desimone and Popoff, 1997), Pollution management (air pollutions, noise pollutions, and recyclability of materials and products) (Fortuin et al., 2007; Desimone and Popoff, 1997; European Environment Agency, 2006).

RESEARCH METHODOLOGY

This study follows the steps of prior innovation studies, which have already been well established in the literature, and uses a questionnaire survey for data collection. Most importantly, this research chose to use the questionnaire as the main data collection tool in accordance with the Fortuin et al. (2007) research.

Based on the literature review, we incorporated the five innovation dimensions as five parts of the questionnaire, and adding the company's data as the last part of the survey. Basically the questionnaire used 7 points Likert's scale questions and statements (from 1 as 'strongly disagree', to 7 as 'strongly agree.'), similarly to other studies, such as the Fortuin et al. (2007) survey. Only few open-ended questions were used, asking for short, numerical answer about the company's chosen most successful product/product line/brand, and a few multiple-choice questions for numerical data, that asked about percentage data (e.g. % of the annual budget reserved for new product development). These kinds of questions were designed to assess numerical data about the company, for example asking about number of employees

working on new product development projects.

The distribution of the questionnaire had place in between 20th and 26th March 2010, by sending out the forms via e-mail to various Taiwanese food industry companies. In total 91 filled questionnaires came back in between 20th March and 30th April 2010. After the preliminary screening of the questionnaires forms and combining samples for the same food product line/brand, 46 usable samples were viable for the data analysis. According to Ramanathan (2003), the sample size for a DEA analysis need to be at least 2 or 3 times larger than the sum of the number of inputs and outputs, which is the case of this study (see Table 1). We determined 13 of such factors, which mean the sample size of 46 is representative enough to draw conclusions.

Data Envelopment Analysis

Since one of the main objectives of this study is to observe the innovativeness of the food industry in Taiwan and create the industry's benchmark and way to compare companies' innovative ability, Data Envelopment Analysis (DEA) is used in this research for the data analysis.

DEA is a method used to evaluate the efficiency among a number of organizations (or some kind of independent units) (Anderson, 1996). It is an extreme point method that compares these units, in this case food companies in Taiwan, with the “best” ones, or in our case the most innovative ones. In the literature, these units are usually called decision making units (DMUs), but for simplicity and clarity, this study refers to them as 'products', 'product lines', 'product categories' or 'brands.' The fact that the efficiencies estimated in DEA are relative to the best performing companies is what makes DEA different from other analysis tools, which usually are concerned with finding the theoretical optimum. The best-performing unit is assigned with an efficiency score of unity '1' or 100%, and performance of other companies, then, varies between 0 and 100% relative to this best performance (Ramanathan, 2003). In the case of this research, the comparison between different companies' products can be made because all of them are a part of the same environment - the Taiwanese food industry. DEA was already used in innovativeness studies, however mostly they have focused on technological innovations, such as Guan et al. (2006) and Diaz-Balteiro et al. (2006).

The innovativeness is an effect of certain inputs and can be captured as a certain output. According to Hussain and Jones (2009), an input *is any resource used by a unit to produce its outputs (products or services)*, including resources that are not a product *but are an attribute of the environment in which the units operate*. Inputs can be controlled or uncontrolled by the unit. An uncontrollable input is one *over which the unit's management does not have control and hence cannot alter its level of use or production*. Whereas outputs *are the products (goods, services or other outcome) which result from the processing and consumption of inputs (resources)*. They can be *physical goods or services or a measure of how effectively a unit has achieved its goals.* Therefore, this study uses the previously determined factors (see Table 1) as inputs, with only one exception, product superiority factor, being used as an output. It is one of the strengths of DEA that the number of inputs and outputs is not restricted, there only needs to be at least one input and one output determined to perform the analysis.

Having the DEA results, the ranking of the Taiwanese food industry innovativeness, we can assess the innovativeness situation among Taiwanese food industry firms and help the non-perfect companies to improve to the level of the fully efficient (innovative) companies. The basic measurement concept of the DEA is the ratio of total outputs to total inputs:

Efficiency = Output / Input

The specialist software The Frontier Analyst® software (developed by the Banxia Frontier Analyst Professional) is the one used in this research to perform the calculation and comparison between the product lines/categories. It requires specifying if the inputs are controllable or not, and we have only set up two factors, market potential and competitive pressure, as uncontrollable factors. These two inputs variables are depending on the company's competitive environment and market, and therefore it is only logical to set them as uncontrollable inputs. Also, we have chosen to use the Mac Out optimization mode in the analysis, which is output maximization mode. It is the DEA mode adopted in which the analysis tries to maximize the outputs produced for a fixed amount of inputs (Hussain and Jones, 2009), since in our study the high level of innovativeness is an output, therefore we rather find out the good benchmark of how to reach the high innovation ability than focus on the minimization strategies for its input variables (resources). Finally, in the analysis we used the BCC ratio model, that is *used when a variable returns to scale relationship is assumed between inputs and outputs* (Banxia Software Ltd., 2010). If the increases are not proportional, it means there is no linear relationship between inputs and outputs. In such case, the BCC ratio model is suggested to be used.

RESULTS

This study has received 91 questionnaire responses, combined into 46 samples, from 18 different food industry companies. In some cases, there was more than one sample (product line/brand) representing a company. An example can be a big retail chain store company, that provided the study with total of three samples, one as for the retail service, one for their own branded coffee product line and one for their private labeled food. Table 2 below, summarizes the samples source.

Table 2: Samples sources.

Company	**Products/Services (code, numbers of responses for each sample)**	**Number of samples ***	**No. of responses****
Winery	ice-creams (A, 3), cookies (B, 2), wine egg (C, 4), wine (D, 1), sake (E, 1), wine 1 (F, 1), wine 2 (G, 1), beer (H, 1), Chinese style wine (I, 1), strong wine (J, 1), vodka (K, 1), whiskey (L, 1), beer 1 (M, 1), healthy food (N, 1), frozen wine egg (O, 1);	15	21
Honey Farm	honey (P, 1), honey wine (R, 1), propolis (S, 1);	3	3
Convenience stores chain	convenience store (T, 8), coffee (U, 1), private brand (V, 1)	3	10
Noodles company	fried flavored noodles (W, 1), instant noodles (X, 6), vegetarian instant noodles (Y, 4), instant noodles 1 (Z, 3), instant noodles 2 (BA, 1), snacks (BB, 2), flavored noodles (BC, 1), instant noodles 3 (BF, 3), functional drink (BG, 2)	9	23
Juice company	fruit juice (BD, 1), vegetable juice (BE, 1)	2	2

Food company A	food products (BH, 1)	1	1
Food processing company	aquatic products (BI, 1)	1	1
Fishery company	frozen sea food (BJ, 1)	1	1
Steak house restaurant	Steaks (BK, 1)	1	1
Supermarket	supermarket (BL, 1)	1	1
Functional food and tea	functional food (BM, 1)	1	1
Food company B	long preserved food (BN, 1)	1	1
Seafood company	sea food (BO, 1)	1	1
Food company C	instant noodles 4 (BP, 1)	1	1
Food company D	breakfast product (BR, 1)	1	1
Natural Healthy food	natural healthy food (BS, 1)	1	1
Food packaging	food packaging (BT, 1)	1	1
Beverages company	beverages (BU, 1)	1	1
Dairy products company	milk (BV, 1)	1	1
TOTAL	46	46	73

*Note: Sample is a sum of responses for a certain product line/brand in a company.
**Note: Responses are number of questionnaires received for each sample. Some product categories got more than one response, therefore the number of responses may be higher than number of samples.

To summarize the respondents characteristics, we can say the sample group used in this study is quite diversified, which is an advantage in the case of this research, as it can represent the innovative ability of different kind of companies in the Taiwanese food industry, especially considering their different sizes. Also the respondents' experience background is quite varied, and it is not only R&D and product development background as in traditional innovation studies, which should allow us to observe the innovation in companies not only through the technological dimension, and see if the innovativeness culture of the company clearly throughout the whole organization. The definition of food industry that was chosen in this study was actually a guideline for choosing the sample group, and in the end companies that did not match the definition were excluded from the analysis. In summary, we think the sample group represents the Taiwanese food industry well with its diversity in specializations, size and market experience, which allows us to draw conclusions about the benchmark for the industry in Taiwan.

DEA Results

The general results are firstly presented as a list of the samples and their efficiency. However, one needs to remember that 'efficiency' in the DEA means getting the optimal level of outputs with the optimal level of inputs, in comparison to other peers used in the analysis, so in our case it means that the higher product superiority and product novelty, that represents the innovativeness of the company, the better efficiency can be achieved by the company (Max Out mode). Among our sample group, only 5 samples were determined as inefficient (efficiency below 100%), and the overall results are presented below in Table 3.

Table 3: Sample group efficiency scores.

Sample code*	**Efficiency**
A, C, D, E, F, G, H, I, J, K, L, M, N, O, P, R, S, U, W, X, Y, BA, BC, BD, BE, BG, BH, BI, BJ, BK, BL, BM, BN, BO, BP, BR, BS, BT	100%
BF	99.23%
V	99.07%
BB	92.84%
Z	91.22%
T	90.53%
BV	87.83%
B	87.70%
BU	84.20%

*Note: For the analysis convenience, the samples were coded with the roman alphabet symbols from A to Z, and then BA to BV.

Therefore, only 17.39% of the studied sample was found inefficient. Generally it is true that the Taiwanese food industry is quite innovative, but it also means that the level of innovativeness among the industry is homogenous. Therefore, in peer comparison (as in DEA), most of the sampled products/brands were determined to be as innovative as the others in the sample group, hence the high 100% efficiency results.

Even though 38 of the analysis units were defined as 100% efficient, Frontier Analyst® gives us a tool to choose the best examples among this group. By checking the Reference Set Frequency, the researcher can see how many times a certain efficient unit (product/brand) appeared in the inefficient unit's reference set. Generally, the higher the frequency, the more the efficient unit is an example of good performance, and that is why it was chosen as peer more often for comparison (Hussain and Jones, 2009). In our analysis the highest set frequency was achieved by following samples: I (Chinese style wine, middle sized company), BL (retail supermarket, large company), and BG (functional drink, middle sized company) 5 times, U (coffee, large company) and BD (fruit juice, middle sized company) 4 times, BS (natural healthy food, small sized company), BM (functional food, middle sized company), BI (aquatic products, small sized company) 3 times.

The Frontier Analyst® also calculates the “potential improvements” for each unit. It is presented as the percentage change in each input variable (or output variable) that is necessary for the unit to become 100% efficient. It can have positive or negative value, indicating if the inputs or outputs are too big or too small, to reach the optimal level. The potential improvement is calculated based on the actual score and the target score (value of input or output that should be achievable by the sample, and which would assure it the 100% efficiency) set for each sample. For example, if the suggested improvement is -2.83% for input I1, it means that to reach 100% efficiency score for sample BF, the scores for factor I1 should be decreased by 2.83%. The potential improvements with the highest value are put in bold. Below the results for the most inefficient cases are presented. But first we presents the codes for each of the factors used in the analysis and presentation of the results below: O1 (Product Superiority, the only output in our analysis), I1 Market Potential, I2 Competitive Pressure, I3 Project-Company Fit, I4 Project Resources, I5 Technological Skills and Know How, I6 R&D Activities, I7 Strategy and Innovative Culture, I8 Communication and Cooperation, I9 Business Groups, I10 New Managerial Methods, I11 Advertising and Promotion, I12 Eco-Innovation (also, see Table 1).

1. Instant noodles 3 (BF) - efficiency 99.23%. DEA suggested potential improvements: O1 0.77%, I1 -2.83%, I5 -0.76%, I8 -1.38%, **I10 -6.18%**, **I11 -13.99%**. In this case the focus should be put on improving the New Managerial Methods (I10) and Advertising and Promotion (I11). It can be observed that all improvements are negative, which means that now, the company puts too much efforts in those factors to improve their snacks (BB) innovativeness, and could achieve same output level (a level similar to other companies in the industry, which are here defined as 100% efficient) with lower levels of input factors, so with less effort.

2. Convenience store's private brand (V) - efficiency 99.07% Suggested potential improvements: O1 0.94%, I1 -11.50%, **I3 -18.69%**, **I4 -22.96%,** I5 -8.41%, I8 -10.9%, **I9 -25.69%,** I10 -11.66%, I11 -11.86%. Similar as above, the company puts too much effort in certain areas, such as: Project-Company Fit (I3), Project Resources (I4) and Business Groups (I9).

3. The snacks (BB) - efficiency 92.84%. Suggested potential improvements: O1 7.71%, I1 -4.33%, I4 -3.88%, **I8 -13.07%**, **I9 -19.9%, I11 -10.76%**. In this case, again, the company puts too much of its resources into Communication and Cooperation (I8), Business Groups (I9) and Advertising and Promotion (I11).

4. Instant noodles 1 (Z) - efficiency 91.22%. Suggested potential improvements: O1 9.63%, I1 -9.25%, I3 -6.35%, **I8 -14.23%**, I9 -8.52%, I10 -6.08%, **I11 -15.94%**, **I12 -11.78%**. As in samples above, the noodle company puts too much effort in Communication and Cooperation (I8), Advertising and Promotion (I11) and Eco-Innovation (I12).

5. Convenience store, retail (T) - efficiency 90.53%. Suggested potential improvements: O1 10.46%, **I1 -12.26%,** I3 -11.87%, **I4 -15.96%**, I8 -1.87%, I9 -9.26%, I11 -1.41%, **I11 -14.74%**. Again, the convenience store put too much effort in following factors: Project Resources (I4), Advertising and Promotion (I11), and also Market Potential (I1).

6. Milk (BV) - efficiency 87.83%. Suggested potential improvements: **O1 13.85%**, **I3 -13.65%**, I5 -0.69%, **I6 -15.14%**, I7 -1.0%, I8 -1.61%, **I9 -15.14%**, I10 -5.72%, I11 -6.16%. In this case, the output factor, Product Superiority, has to be especially increased, suggesting maybe the product's innovativeness is not strong enough. Other than that too much effort is put into following areas: Project-Company Fit (I3), R&D Activities (I6) , and Business Groups (I9).

7. Cookies (B) - efficiency 87.70%. Suggested potential improvements: **O1 14.02%**, I2 -7.42%, **I4 -20.52%**, I7 -6.50%, **I9 -25.05%**, I10 -1.01%, I11 -4.59% Similarly as above, the output level is too low and should be increased (Product Superiority). Other than that, too much effort is used in Project Resources (I4) and Business Groups (I9) factors.

8. Beverages (BU) - efficiency 84.20%. Suggested potential improvements: **O1 18.76%**, I2 -3.65%, I4 -6.73%, I5 -8.20%, **I6 -22.35%**, **I8 -30.55%**, **I10 -22.80%**, I11 -15.96%. In the least efficient case, the output levels should also be increased, and the efforts used in R&D Activities (I6), Communication and Cooperation (I8), and New Managerial Methods

(I10) should be decreased.

Generally there are two ways for the inefficient companies to improve their innovativeness. The first one, is to keep the current high input levels (high effort in the certain innovativeness factors) and at the same time trying to increase the output (through better implementation of the inputs). Or, the second option is to decrease the efforts where the DEA analysis suggested to (negative potential improvements). In that case, however, the management needs to be careful, not to lower the input levels too much, and still ensure the same output level.

Improvement Strategies

The interest in SMEs among the academics is growing, as is the number of small firms all around the world, and also in Taiwan (Taiwan SME, 2010). We use the United States division of the companies according to their size, according to which, the SOHO (small office/ home office) size is up to 10 people, the small company is one with up to 100 employees, and a medium sized company with up to 500 employees (U.S. Census Bureau, 2010).

Below we present the most innovative and the least innovative companies according to their size. The most innovative companies, are those who were used as peer references in the analysis (see reference set analysis results above) and the least innovative one are those who received efficiency scores lower than 100%. Small sized companies were not found either among the most or the least innovative groups.

1. Large companies (employees number, % efficiency): BL Supermarket (5000, 100%), U Convenience store's coffee (1500, 100%), V Convenience store's private brand (1500, 99.07%), T Convenience store retail (1500, 90.53%), BV Milk (2000, 87.83%).
2. Medium companies (employees number, % efficiency): I Chinese style wine (196, 100%), BG Functional food (395, 100%), BD Fruit juice (400, 100%), BF Instant noodles 3 (395, 99.23%), BB Snacks (395, 92.84%), Z Instant noodles 1 (395, 91.22%), B Cookies (196, 87.70%), BU Beverages (300, 84.20%).

Based on the company size and comparison of the DEA analysis results some improvement strategies for better innovativeness are proposed:

a) Small companies (up to 100 employees) - all of the small food companies participating in the study were found to be 100% efficient in their innovativeness. It proves that small size does not have to be an obstacle in innovating, and that it is worth researching the way small companies innovate. All of the samples among this group got high overall scores in the questionnaire for the inputs and outputs, which can be understood that they both input a lot of effort and resources into innovativeness, treating innovation as important part of their business strategy, but also they are implementing it efficiently, so they can reach relatively higher output levels. However, none of the small companies was identified as the best example among the efficient group by the DEA analysis, which still leaves room for improvements. Small companies were found to be most innovative in the organizational, marketing and eco-innovation dimension, as compared to medium and large firms, they usually does not have enough financial resources for pursuing the more technological

innovations.

It is worth noticing that especially eco-innovations might be a good opportunity for small food companies, as the philosophy of the organic production is to produce in small scale, for local needs only. Therefore what before was a weakness, now can become an advantage for the small sized firms. However, it is very important to market eco-products effectively, and therefore the marketing innovations also should play an important role in company's strategy. It is advised that small companies use integrated marketing tools, especially those that can be accessed with low budget, such as the Internet marketing tools (e.g. using social networking, micro-blogging, website, etc.), but also reach to the local consumers and build relationships with them by joining local and regional events.

b) Medium companies (101-500 employees) - the biggest part of the sample group was represented by medium sized food companies, and so there were fully efficient and inefficient companies found among this group. Those companies are generally focusing on national markets, usually having regional product lines as well. Their biggest challenge is facing the competition of big corporations who are usually more technically developed and have more resources for product and process innovations. In a way, the medium company's problems are the problems of both large companies (eg. managing implementation of new organizational innovations might be as difficult among 500 people as 1000 people) and small companies (eg. lack of financial resources for buying new patents, technologies, investing in in-house R&D, etc.). We could see in the results of inefficient companies, that the factors in need of improvements are spread throughout all dimensions. Therefore, the study suggests that medium food companies should focus on one kind of innovation dimension or factor and put direct their effort in that area first, instead of spreading it among all five dimensions, because it results in too high inputs level, whereas the output is not significantly increased. Also, it was found that different samples from the same company can have different innovativeness ability. For example, the sample B (Cookies) which is one of the inefficient samples, is produced by the same company that the sample I (Chinese style wine), which is the best example among all 100% efficient samples. Therefore, we suggest the companies identify which product categories within their organizations are the innovativeness leader and identify what are the reasons for it, and learn from their own managers or departments that are the most innovative.

In the results for medium inefficient companies, the biggest improvement suggestions were made for Communication and Cooperation (I8), Advertisement and Promotion (I11), New Managerial Methods (I10), Business Groups (I9) and Product Superiority (O1). Except of the Product Superiority, which is our output variable, all suggested potential improvement were negative in value, meaning the inefficient companies overemphasize those areas. It is worth to observe, that all those factors, except Product Superiority, are from Organizational and Marketing dimensions. It seems that due to the high competition that the medium sized companies face in the industry, they tend to overinvest in these areas.

c) Large companies (501 or more employees) - there were 7 samples representing this group in our study, representing convenience chain stores, supermarket chain stores, and instant noodles company. Three samples among this group got efficiency score lower than 100%. It was found that all the large companies generally has no problems with Process and Eco-

innovation dimension's factors, as well as the Green Supply Chain Management factor, of the eco-innovation dimension, as their input all got high scores in those areas. It is that the large size of the company goes usually together with material resources that play an important role in the product and process innovations. However, it can be observed that the inefficient representatives of the large companies tend to put too much effort/resources in the Product dimensions factors (especially Project-Company Fit, and Project Resources). As for the Eco-Innovation, it seems that there is a lot of social pressure, backed up with newly rising government policies, that the large corporations become more sustainable and 'go green'. Also, large companies need to be more careful in managing the safety of their supplies, as it can affect the safety of their final products, which in food industry is critical. The bigger the company, the easier it is to have a safety break in the supply chain. Implementing GSCM, as a part of Eco-innovation, is also often perceived by the consumer as safety facilitator.
Furthermore, a big challenge for large food companies is an efficient implementation of organizational innovations, which can bring cost-savings in large firms, because of the bigger scale of administrative and organizational processes and procedures. The results showed that Business Groups factors got too much efforts in case of both the medium and large companies. Even though joining a business group may be a goof leverage for the company, it might not always be the most efficient thing to do.

CONCLUSIONS

There has been no detailed research information about innovation and innovative ability of the food industry. Even though many researchers conducted studies in order to find innovative factors and key success factors for innovativeness in high-technology industry, they could not be directly translated into the food industry, which is a part of LMT industry. Therefore, collecting and organizing innovativeness dimensions and factors suitable for the food industry is the biggest contribution of this research.

On the other hand, the practical contributions of this study for the Taiwanese food industry would be: (1) Developing an assessment method for innovativeness of food industry companies that provides relevant, reliable and valid management information for the food industry in Taiwan, (2) Creating a benchmark for the food industry in Taiwan that can help to understand the innovative ability of the industry in Taiwan and also determine the space for improvements, (3) Proposing improvement strategies that can be used by companies that would find themselves below the benchmarked level, and (4) Developing special improvement strategies considering the size of the company, especially taking in consideration SMEs.

Even though the study focuses on the Taiwanese food industry, we believe that chosen innovativeness factors might be applicable in other researches, which are dealing with other LMT industries, or with countries other than Taiwan (e.g. researches about other Asian countries, or researches with global scope).

To sum up, the size of the company is important in designing and implementing the strategies for building and improving innovativeness of the firm to gain a competitive advantage in the marketplace. However, whatever the size of the company, it surely can be very innovative, as innovation is no more just a privilege of large enterprises. Also, it is worth

to observe the trends in eco-innovation dimensions in the future, as this dimension is relatively new and still growing in importance, and most probably its advantages will be fully seen in the future.

ABSTRACT

This paper describes the study conducted by pilot study and following expert interviews to find out the factors of well-being at work and how those factors can be represented in the work system model. In addition this paper expands the original work system model adding the micro and macro level to the model to fully meet the requirements of the well-being at work.

Keywords: well-being at work, work system model, expert interviews,

INTRODUCTION

The population is aging in Europe and in other continents. This causes a variety of challenges in to working lives (e.g. Lutz et al., 2008; The demographic future of Europe – from challenge to opportunity, 2006). The ageing of the population is also one of the reasons why the well-being at work has been much discussed in recent years.

The Finnish institute of occupational health defines well-being at work as “safe, healthy, and productive work in a well-led organisation by competent workers and work communities who see their job as meaningful and rewarding, and see work as a factor that supports their life management” (Anttonen and Räsänen, 2008). Briefly and simply “well-being at work means employees’ capacity to manage and cope their work tasks.” It is influenced by several factors, such as the worker’s physical, mental and social condition as well as factors related to work society and work environment. Many other factors influence well-being at work too, for example remuneration, private and family life and life situation in general (Research on Well-Being at Work in Finland – Focusing in Occupational Health and Safety, 2005). Several studies have been shown that issues related to well-being at work interest employers, not least because these studies have indicated that well-being at work increases productivity (e.g. Ingelgård and Norrgren, 2001; Marjala and Haapasalo, 2008; Sparks et al., 2001). In addition the costs of absenteeism can be enormous (Danna and Griffin, 1999). Considering the well-being at work, understanding about the entirety could be more transparent, if the work itself is divided into smaller parts.

The work system model considers all the elements of work that affect the worker and outcomes systematically. The model includes five elements interacting with each other when performing certain part of work. These elements are: 1) a person who performs 2) his tasks using 3) tools (technology) needed 4) in his working environment and 5) work organisation. If a change occurs in some element of the work system, many changes may occur in other work system elements (Carayon, 2009). Balancing the elements of the work system in a way that satisfies the employee and enhances the quality and effectiveness is very complex (Carayon and Smith, 2000; Smith and Sanfort, 1989; Väyrynen, 2010).

OBJECTIVES

There are numerous definitions for well-being at work. Also a lot of research literature exists on well-being at work and its effects on productivity issues. There has been some discussion on how productivity can be improved by balancing work systems (e.g. Carayon and Smith, 2000; Kleiner and Hendrick, 2008). Nonetheless quite a little research exists regarding on how well-being at work could be improved by focusing and balancing work systems and thereby improving productivity. Often well-being at work is seen as a by-product outcome of a well-designed work system (e.g. Carayon, 2009).

In this study, the authors try to discuss how well-being at work can be the very part of the balanced work system model itself, and not merely an outcome. This is executed by allocating the empirical findings of the factors of the well-being at work into work system elements and by pondering their significance on the basis of literature. The above-mentioned can be condensed into three more specific research questions:

RQ1: What is the essence of well-being at work according to interviewed experts?
RQ2: Is it possible to represent the factors of well-being at work in the work system model?
RQ3: What parts of the work system model seem to affect the most to the well-being at work?

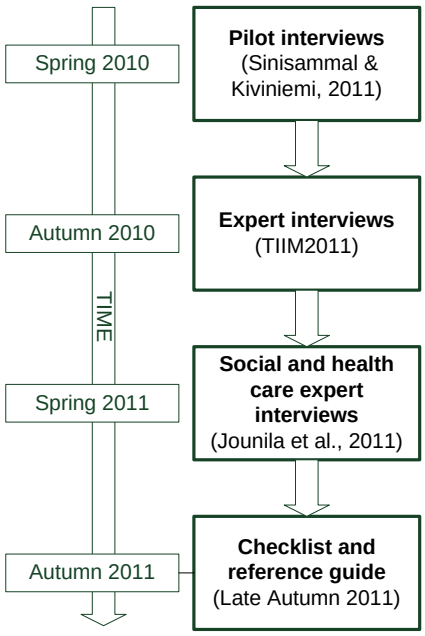

Figure 1: The timeline of the project from where the empirical material of this study was gathered.

This study is one part of a Finnish development project that aims to develop well-being at work in the municipality sector and it utilises empirical material which was gathered in that project (Figure 1). The project stakeholders include employees and management from two municipalities and private organisations and representatives from labour and employers' organisation. The project is still continuing and ends in the autumn of 2011.

METHODOLOGY

The main questions of the study were so extensive and focused at the same time that it was difficult to approach directly. Before committing to a full-scale research and expert interviews a small scale pilot study and pilot interviews were conducted as a test and rehearsal phase. As Teijlingen et al. (2000) for instance consider pilot study a crucial step in the research process. The goal of a pilot study is to identify, if not all, as many as possible flaws and weaknesses of the study protocol, equipment, methods etc. before actual research gets started.

Since the researchers already had preliminary, experience-based understanding of well-being at work, interviewing experts was regarded as an adequate method in order to achieve deeper and broader understanding about the issue (e.g. Hirsjärvi and Hurme, 2010).

The starting point of the pilot study and the pilot interviews was to design the questions to meet the definitions of well-being at work. After several discussions, fifteen questions were formulated. The questions covered topics e.g. occupational health and safety, communication, participation, the role of management and individual worker, and the effect of organisational values.

Twenty participants were selected based on their professional and representative experiences from different areas related to well-being at work. Informants included physicians, labour union representatives, occupational safety professionals, teachers and workers' safety representatives. Six experts participated in one focus group discussion (e.g. Langford & McDonagh 2003; Edmunds, 1999), other participants were interviewed individually. Five of the interviews were carried out by phone, one by videophone and the rest in a face-to-face setting. The interviews were documented by typing the answers in situ using a laptop computer.

After the pilot study, the next stage of the expert interviews was formed. This part of the study was composed of unstructured, open interviews for seven experts in the field of well-being at work at national level. The experts represent professionals at educational, consulting and university sectors. During the interviews, the experts utilised mind map - method for expressing their knowledge on the subject. The method is simple, easy to use and applicable to different kinds of situations. Mind maps are an efficient and quick way to accumulate data on the subject matter and its' factors and relations. The analysis yields a concrete and illustrative picture of the different factors. The method can be used alone, in pairs and small groups. As a method of group work it gives and amasses several different personal view points of the subject matter, adds to group cohesion and commitment as well encourages the processing of personal matters (Buzan, 2000; Farradi et al., 2002).

An open coding approach was utilised to summarise and synthesise the mind map data. First the researchers grouped the terms given by the experts under the five elements of the work system model. At the same time, the researchers removed the overlapping and totally the same terms from the lists. Secondly the terms that did not fit under these five elements were aggregated into their own group to wait for the conclusions of the research group. Because all these procedures this study is qualitative and interpretative in nature.

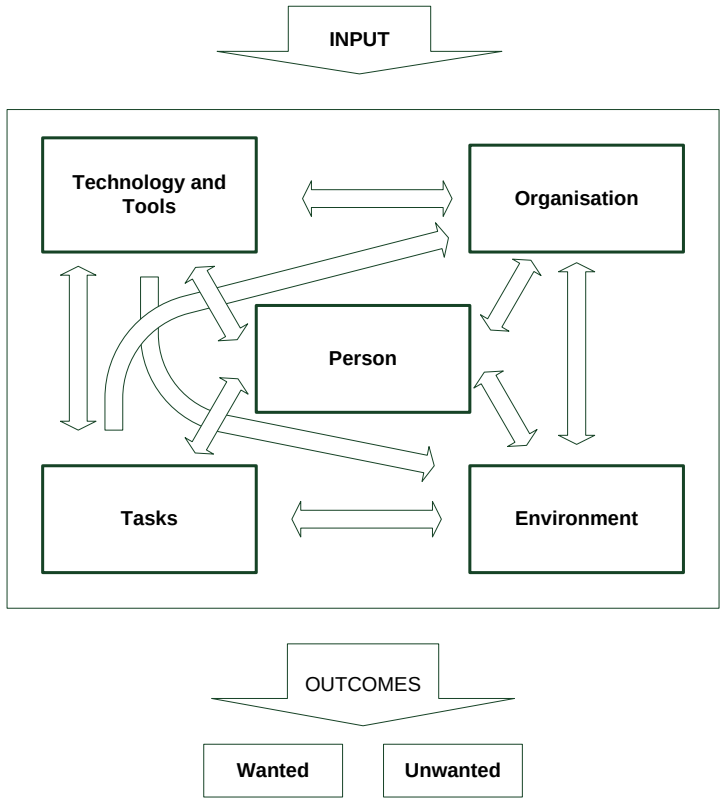

Figure 2: The balanced work system model aims to achieve the best relations of factors when pursuing wanted outcomes. (Väyrynen, 2010 modified and enhanced from Smith & Sainfort, 1989).

One of the research questions was that is it possible to represent the factors of well-being at work in the work system model. As mentioned earlier, the work system model provides a way to describe the elements of work that affect worker and outcomes of the model. The work system model includes five elements: the person (employee), tools and technologies, tasks, a physical environment and organisation (Figure 2). These five elements of the work system model interact with each other (Carayon, 2009). The balanced work system model aims to achieve the best relations of the factors by optimising the interaction of the employee, technology and tools, organisation, (work) environment and tasks. Productivity and well-being are the main positive outcomes when errors, accidents, sicknesses and discomfort are unwanted outcomes (Väyrynen, 2010).

RESULTS AND DISCUSSION

The pilot study and pilot interviews made it possible for the researchers to define and compose the content, the structure and used the methods of the next phase of the study. Followed expert interviews became more refined and more accurate to meet the requirements of the chosen research questions.

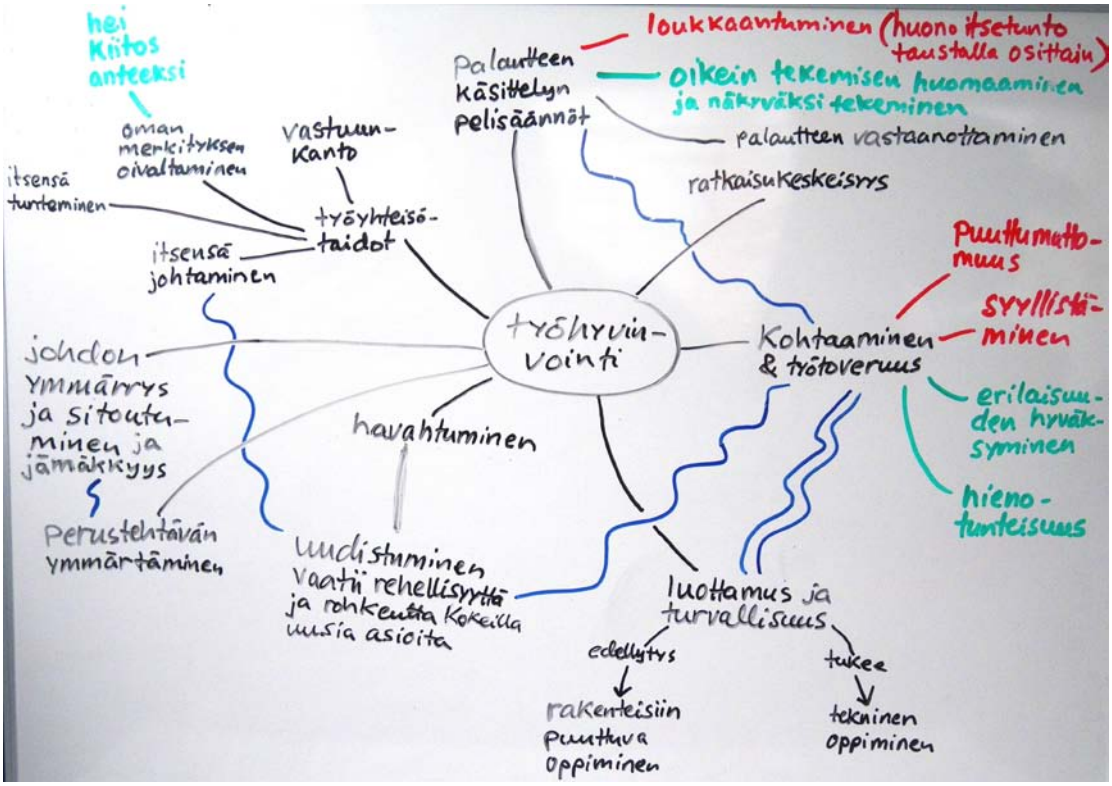

Figure 3: One raw mind map (out of seven) results from one expert interview.

After the expert interviews, researches had seven different (raw) mind maps formulated during the interview phase of the study. Mind maps represented the visions of the interviewees considering the main factors of well-being at work and all the cause and effect relationships between those factors as well (Figure 3).

Those raw mind maps were constructed and drawn again using somewhat similar terminology where applicable to find comparison between the mind maps. It was also necessary to see the cause and effect relationships between the factors affecting the well-being at work (Figure 4).

When researchers had gathered all the factors of the well-being at work collected from the expert interviews it was time to find out the common elements of those results. When expert interviews were carried out, researchers didn't instruct the interviewees to approach the question from the work system model point of view. All those different elements and terms used by the interviewed experts needed to be gathered together under the common topics, topics that eventually fit in the work system model.

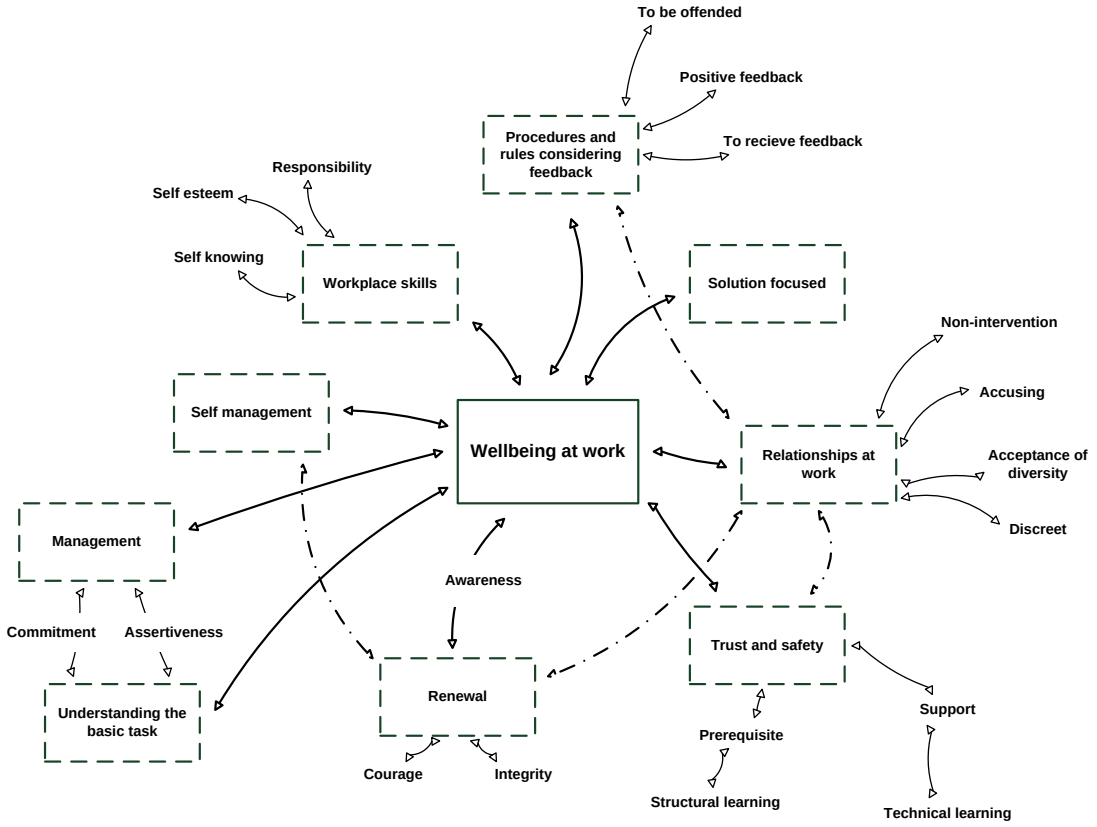

Figure 4: One out of seven mind map results from one expert interview.

The work system model represents the employee in the collaborative system with work environment, organisation and technology and tools used in to do the task itself (Figure 2). The work system model encompasses the psychosocial, cognitive and physical aspects of work that can create psychosocial, cognitive and/or physical loads on the individual. All those factors affect greatly into well-being at work. Therefore one of the main research questions of this study was to find out if the work system model can be used as the framework to describe well-being at work or does the model need more definitions or elements in it. In addition we pursued to find out what particular elements of the work system model are more definitive in comparison with others when considering the well-being at work.

Preliminary hypothesis was that the work system model can be effectively used to describe most of the factors of the well-being at work, but the model is not accurate enough to describe all the factors of the well-being at work.

One of the main goals of the study was to find the most influential parts of the work system model that affect directly or indirectly into well-being at work. We situated the factors of well-being at work gathered from the interviewed experts into the work system model. That symbiosis is shown in Figure 5.

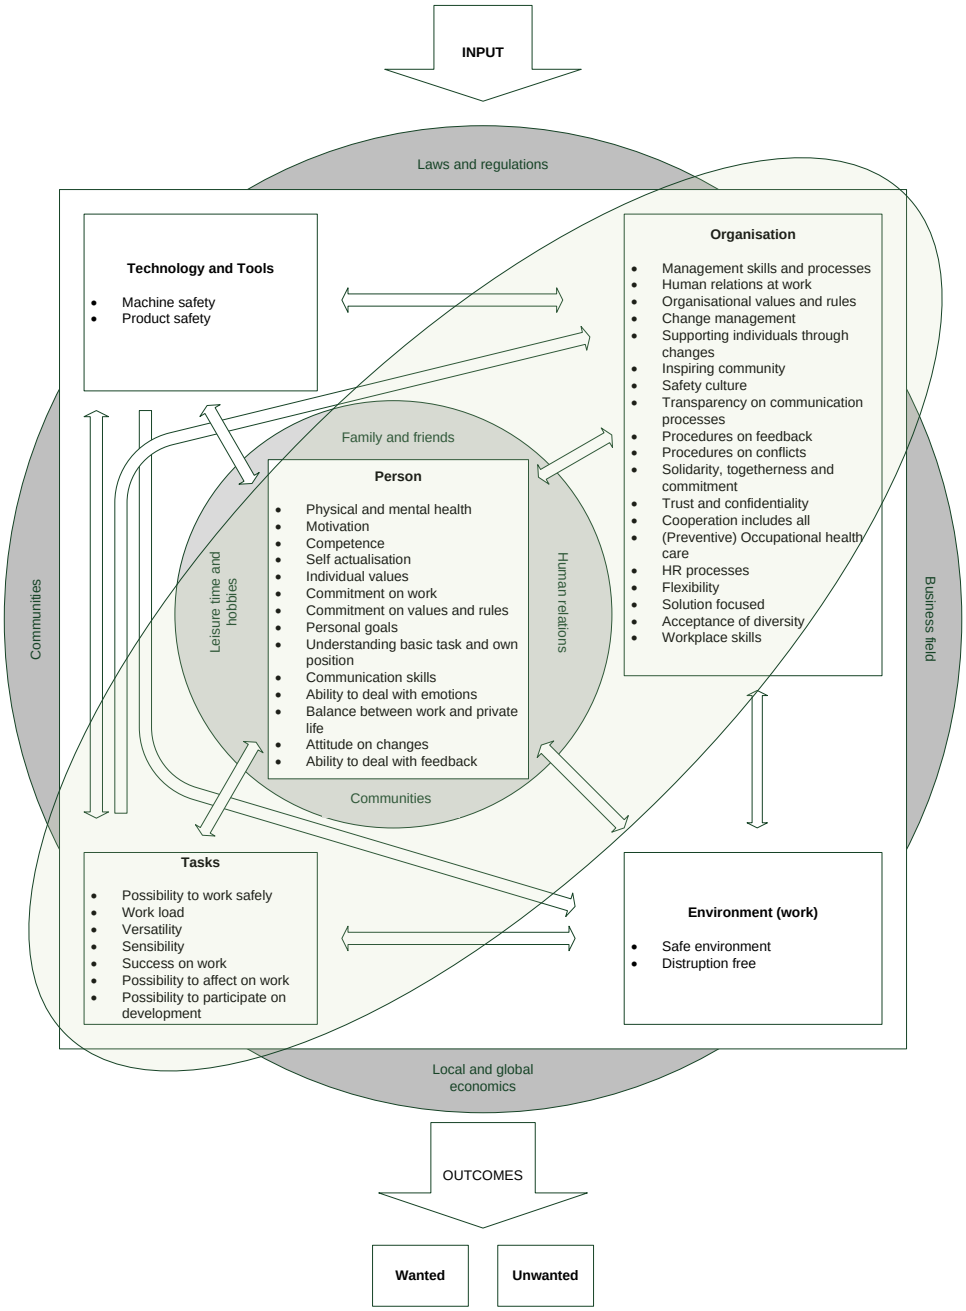

Figure 5: The factors of well-being at work in the balanced work system model after the expert interview phase of the study.

It was quickly discovered that subsections of the work system model that affected most to the well-being at work were “organisation” and “person” i.e. the worker itself. “Tasks” subsection got some effective factors that influence to the well-being at work, but “technology and tools” and “environment (work)” subsections were seen somewhat insignificant when discussing the effective variables toward well-being at work.

The organisation subsection is the major influencer considering the well-being at work. It includes the management itself and both management skills and management processes of the organisation have a major effect on the work related well-being altogether. It can be

seen that organisation subsection includes all those variables that create procedures, framework and even boundaries to the human relation interactions of all kind happening in the organisations. It has an effect on the management and procedures needed in communication between employer and the employee and it also greatly have an effect on the conducts between the employees.

The person subsection proved to be the second important influencer considering the well-being at work. It naturally includes all the physiological, psychological and cognitive variables of the person to affect all kind of well-being not just at work related. There was also motivation and competence based variables as well as commitment, self-actualisation and self-development to be found. The main notion on to the basic work system model was that there were more variables affecting the person than could fit in the original model. Therefore micro level had to be added to the model, micro level that affect to the person greatly, but is not part of the work system model.

The work related tasks the person (employee) is going to perform could also affect the well-being at work. The physical and mental loads are the major influencers but those form only the base level. The versatility and the sensibility of the work tasks can have huge input toward possibility to affect ones' work and eventually participating in development processes. All of which have positive influence toward well-being at work.

The conducted study indicates that the work system model itself is insufficient for representing all the factors considering the well-being at work. We had to consider both macro and micro levels that affect various factors in the system. Macro level includes all the "external" factors that affect into the work system itself such as laws and regulations, local and global economics and interaction in the business field, that are not included in the work system model as such even those variables take effect into well-being at work. On the other hand micro level represents the factors that affect into the employee itself considering the well-being at work. Those external factors include the social network such as family and friends and free time activities and hobbies that can greatly affect into well-being at work and thus productivity.

Other notable preliminary notion is that the interviewed experts emphasized the meaning of organisational practices and habits influencing the well-being at work together with personal factors expense of the meaning of technology, tools and work environment.

At the moment, the factors of the work system model include too many variables affect the well-being at work, too many to construct well-aimed and valid checklist or reference guide to follow when pursuing the better well-being at work. The study will continue when the next round of interviews is carried out. Those interviews are targeted to the experts working in social and health care business. That round of study aims to find the essence and the most influential factors in the work system model to affect the well-being at work based on the now existing work in progress model constructed and detailed in this study. After the next round of interviews and iterations a reference guide and/or check list considering the well-being at work can be build.

ACKNOWLEDGEMENTS

This study was made possible as a result of the financial supports of the Finnish work environment fund and the Finnish funding agency for technology and innovation's Finnish workplace development programme. The theoretical contributions, valuable suggestions and comments on this paper from Prof. Seppo Väyrynen are gratefully acknowledged. In addition the authors want to thank all the interviewees for their participation.

DISTRIBUTED LEADERSHIP FOR NETWORKED TEAM PERFORMANCE

Aelita Skaržauskienė, Mykolas Romeris University, Lithuania
aelita@mruni.lt

ABCTRACT

Purpose *– This paper analyses the role of* ***distributed leadership in networked teams****. The team-based formal or informal networked or virtual (online) collaboration requires a different kind of leadership from that in positional hierarchies. Such leadership may be more flexible and sophisticated, capable of encompassing ambiguity and rapid change. Leaders in networked teams need to be partially invisible, delegating power and distributing task. Distributed leadership responses to complex situations and fosters team performance, facilitated through group interaction and decision-making, active distribution of specific tasks.*

Design/methodology/approach *– This paper makes an attempt to relate distributed leadership with the networked team performance. The paper follows a qualitative and quantitative research approach: case study and Insights Team Effectiveness Profile. Drawing on qualitative and quantitative evidence the paper analysis the complex process of the institutionalization of self-managing team approach through distributed leadership and networking in Department of Translators (A) in European Commisssion (EC) in Luxemburg.*

Findings *– Based on the analysis and synthesis of the scientific literature a conceptual model of relationship between distributed leadership and networked self-managing team was developed. The theoretical model was supported by empirical evidence from real public service organization in EC perspective. The analyses of research results revealed that distributed leadership was associated with higher networked team performance. Distributed leadership could be promoted as being well suited to public service organizations because of their multiple goals, less pronounced managerial authority and presence of powerful professional groups.*

Keywords: Networked team, Distributed leadership, Interactions, Collective Intelligence, Virtual team, Self-managing team, Team performance

INTRODUCTION

Today's organizational landscape is populated with work teams. Highly motivated and successful self-managing teams are the benchmark of successful organizations. The use and development of work teams, continues to be a prominent issue in different kinds of organization. This paper analyses the role of **distributed leadership in networked self-managing teams**. The team-based formal or informal networked (online) collaboration requires a different kind of leadership from that in positional hierarchies. Such leadership may be more flexible and sophisticated, capable of encompassing ambiguity and rapid

change. Recent developments in the field demonstrate that leadership and management is more complex, nuanced, and subtle than previously portrayed. Leaders in networked teams need to be partially invisible, delegating power and distributing task. Distributed leadership responses to complex situations and fosters team performance, facilitated through group interaction and decision-making, active distribution of specific tasks. In this context it is critical to understand the role of distributed leadership and particularly what are the key competencies to be developed in order to deal with the fluidity and complexity of the world.. This has led to look at leadership in a new light – and in particular to focus on how requirements of leaders have changed, what companies are doing to enable leaders to develop the required capabilities and what has been the impact.

The dominant organization priorities that were emerging as a result of the global economy are: *cost reduction*, *new technologies, networked and virtual organization etc.* These conditions require flexibility, collaboration, innovation and the courage to embrace uncertainty and ambiguity. Such extreme challenges require radical solutions and the transformation of leadership development. Innovation has been studied in a variety of contexts, in relation to technology, commerce, social systems, economic development, and policy construction. "We define innovation as the successful implementation of creative ideas within an organization. In this view, creativity by individuals and teams is a starting point for innovation; the first is necessary but not sufficient condition for the second" (Goyal. Akhilesh, 2007). In this paper we try to present distributed leadership in networked teams as an innovative management practice in public service organizations for addressing complexity, uncertainty and changes. Public organizations change the focus the ineffective bureaucratic models to more flexible communities of professional workers such as online communities, virtual self-managing teams, networked organizations etc.

Defining distributed leadership

J. Schumpeter (1950) believed that leaders are the people who make things to happen in the economy by transforming innovative ideas into practical opportunities. Much has been said of leadership throughout the last years. Different authors emphasize the importance of different factors, highlight different aspects, and use different terms for defining the role of the leader in the organization. The field of leadership – in theory and in practice – has been a fast-growing part of management knowledge since the beginning of the 20th century. In most conceptions of management and organization, leadership has a given and central place in enforcing principles, motivating employees and communicating future goals and visions. Leadership is assumed to make a special, significant and positive contribution to processes in most organizations, and leadership studies in academic field try to identify practices related to successful leadership. The field of leadership studies has traditionally been leader-centered, i.e. focused on the individual leaders and their traits, abilities and actions (Goyal, Akhilesh, 2007). Research on leader-follower exchanges shows that leader behavior which provides follower support (in terms of task-relevant direction or emotional relief) leads to enhanced follower motivation and commitment, transformational effects on followers are possible (Fletcher, 2004). Contemporary organizations emphasize the emergence of the relational, collectivist and non-authoritarian nature of leadership practices — opposing against unreflective mainstream perspectives that sustain heroic, individualist and authoritarian leadership norms (Crevani, Lindgren, Packendorff, 2010).

The concept of shared governance in the organization and management naturally aligns with distributed leadership defined by J.P. Spillane (2007) as „frequently used as a synonym for democratic leadership, shared leadership, collaborative leadership". The literatures contain several conceptualizations of such kind of leadership, such as *shared leadership*, *collaborative leadership* and *distributed leadership* (Bradford, Cohen, 1998). Current issues and future developments are discussed, with special emphasis given to the need for more research on distributed leadership. The idea of viewing leadership as spread throughout an organization is important but not new; it has been expressed for several years. In some situations, leadership is preferably a collaborative and collective responsibility where the responsibilities, competencies and decision-making need to be distributed onto several individuals rather than one (Collinson, 2007).

Distributed leadership as self-managing process

Conceptualizing leadership as a role that can be distributed among individuals within a team depending on the expertise required, is a critical theoretical transition given several important trends in modern organizations (Crevani, Lindgren, Packendorff, 2010). Specifically, organizations have seen an increased use of team, more problems that are rapidly emerging and complex, and an increase in the importance of innovation and adaptability. The benefit of utilizing distributed leadership with regard to these organizational developments is evidenced in a number of studies (Mumford, 2009). The findings of several compelling empirical studies point to a substantial benefit of distributed leadership to R&D project teams, and project teams in general. Two recent studies on research and development teams highlight the benefit of having multiple leaders. J. Hauschildt (2001) evaluated 133 new innovations within engineering industry and the effects that having multiple "champions", or leaders, taking on different elements of a leadership role, would have on the technical and financial success of the projects. As more leaders were involved in the development process, gains in performance increased by a factor of 30% to 50%.

Another important factor is that the distributed or collective leadership process is information-based. The distribution of information between members in the team or network and the exchange of that information is the foundation from which distributed leadership emerges (Mumford, 2009). Specifically, for the diverse skills and expertise of individuals to be effectively utilized, it is necessary for critical information regarding the problem to enter the network and be distributed among appropriate network channels. Effective information exchange is a driving force behind the self-managing among team members, information is the medium by which the leadership role is shared among a collective (Mumford, 2009).

Distributed leadership could be defined as "the distribution of leadership functions among the team, which is a group of people with formal leadership roles" (Hulpia, Devos, 2010). The definition of distributed leadership that will be used in this paper is that it is a dynamic leadership process in which a defined leader, or set of leaders, selectively utilize skills and expertise within a self-managing team, effectively distributing elements of the leadership role as the situation or problem at hand requires (Mumford, 2009).

In addition to defining the distributed leadership process, the goal in the present effort is to draw attention to the multi-level nature of this phenomenon, and to highlight the impact of distributed leadership on team performance.

The problem is that contemporary literature on leadership focuses on formulating new basic perspectives in leadership or new assumptions on how to do leadership research rather than on formulating new possible practical arrangements. It is not enough to say that leadership can successfully be shared between two or more co-leaders, or that it is about interaction between leaders and followers. „If we want to take leadership research beyond the leader-centered tradition, we must also challenge our deeply rooted tendency to make the abstract notion of „leadership" concrete in the work of individual managers" (Crevani, Lindgren, Packendorff, 2010).

Benefits of distributed leadership in teams

The social interaction of team members is an important factor contributing to successful distributed leadership (Spillane, Diamond, 2007). Most theories of organizational learning stress the importance of collective knowledge as a source of organizational capability. Organization and management researchers have extended the cognitive analysis to the team and organizational levels. Their analysis suggests that groups and organizations develop collective mental models (Senge, 1990) and interpretive schemes which affect group decision-making and action. Collective cognition differs from individual cognition because it encompasses a social dimension (Goyal, Akhilesh, 2007).

W.B. Arthur (1996) stated that in post-capitalist economies, wealth flows not to those who control financial capital, but to those who can acquire and direct intellectual capital. According to T.A. Stewart (1997) "Information and Knowledge are the thermonuclear competitive weapons of our time. Knowledge is more important than natural resources, big factories, fat bankrolls". At group or collective level cognitive ability called intelligence is a factor underlying creativity and innovation. In recent years, there has been a surge of research activity into **collective intelligence**. Massachusetts Institute of Technology, one of the most reputed academic institutions of USA has established a centre called the "MIT Center for Collective Intelligence" for understanding and taking advantage of the phenomenon of collective intelligence. Some of the notable outputs of collective intelligence, according to them, include Google, Wikipedia, and Innocentive (Goyal, Akhilesh, 2007).

Research indicated a positive relation between team members participation in **collective decision-making processes** and their organizational commitment. The effect of participative decision-making on organizational commitment varies in significance depending on a variety of conditions. These include the areas over which members have influence, administrative openness to such influence, normative acceptance of such opportunities, the organization of the participatory process, whether team members really have influence, and the results of the decision-making process (Hulpia, Devos, 2010). An open communication, which is defined by a work climate where people feel comfortable sharing ideas and information with other organizational members, strengthens organizational commitment. Similarly, E.

Mathieu (1990) claimed that good communication within the organization enhances the work environment and increases organizational commitment.

Over the last couple of decades, research on **emotions and affect in organizations** has become a popular area of study. The majority of research supports the idea that an individual's affect can have a significant influence on many aspects of their performance, such as creativity, decision making, and pro-social behaviors, among others (Barsade, Gibson, 2007) An interesting research question could be how affect might influence distributed leadership processes. Some progress has been made in evaluating the role of affective climate in organizations. Climate is a set of shared attitudes or expectations that a team has with regard to a specific context (e.g., climate for creativity, climate for safety) and thus, affective climate refers to a team's **creativity (**Pirola-Merlo, Härtel, Mann, Hirst, 2002). Affective climate has been included in the proposed framework of distributed leadership because research indicates that there is a relationship between affect and relational exchanges, feedback, contribution, conflict, and support networks (Mumford, 2009). This is a critical foundation for building long-term trust and engagement.

The final key distributed leadership component is **team performance parameters**. Some researchers have argued eloquently that distributed leadership can lead to improved effectiveness. R.F. Elmore (2000) claimed that since "instructional improvement requires that people with multiple sources of expertise work in concert around a common problem; this distributed expertise leads to distributed leadership". Distributed leadership in networked teams (NT) is quickly expanding research subject, but empirical findings based on a substantive sample of real NT remain limited at this time. NT (or virtual) are teams whose members do not share a common workspace all of the time, and must therefore interact and collaborate using networking, communication and collaboration tools such as email, videoconferencing, networks etc. In this vein, distributed leadership is similar to the way in which messages are transferred in the human neurological system. Networks are structured like neurons within the brain. These connections are not flat, but rather a 3D, layered system of linkages. Neurons serve specific roles, but there is also emergent meaning when impulses follow certain paths. Similarly, there is meaning in the way information flows through specific patterns of team members (Mumford, 2009).

Given this reasoning, the empirical case study of leadership focuses on leadership practices as constructed in interactions. This paper explores application of networking technologies for building the self-managing team praxis in public service organization.

Case study: Distributed leadership in networked self-managing teams

Details of Preparatory Work. In the month of June 2008 the French consultancy company DEMOS received background information concerning self-managing team project in Department of Translators (A) at European Commission (EC). In August, a first meeting was organized with the Head of Unit, the Training Unit of EC, DEMOS and an academic researchers group. We agreed on having a closer encounter with the team and the reality of its working conditions before actually determining the final programme. In that respect we had interviews with 4 staff members, in different functions. The information gathered in these meeting inspired the framework of the self-managing team project. We decided to

develop a double track programme: a combination of content/work-related issues, some learning points about the self-managing team as well as it's functioning and building of a networked team for developing distributed leadership approach (s-projects using Synnet technology).

Self-managing teams (,,empowered teams") are self-sufficient groups of people working together with specific goals. They have the corporate authority, experience, responsibility and skills to enact their own decisions for the organization, to maximize the use of everyone's talents. Self-management is "a leadership decision that invites initiative and not followership"(...). The major challenges organizations face in changing from a traditional environment to a high-involvement environment include developing the teams and fostering a culture of support. Teams go through several stages of increasing involvement on their way to self-management. This journey could be never-ending from a learning and renewal perspective. Comprehensive training is also critical to developing effective self-managing work teams. Not only must employees learn to work effectively in teams and develop skills in problem solving and decision making, they also must learn basic management skills so they can manage their own processes. Additionally, people must be cross-trained in every team member's job.

Comprehensive training is critical to developing effective self-managing work teams. The training for these teams must be more interactive than for other types of teams. Not only must employees learn to work effectively in teams and develop skills in problem solving and decision making, they also must learn basic management skills so they can manage their own processes. Additionally, people should be cross-trained in every team member's job. The major challenges organizations face in changing from a traditional environment to a self-managing and include developing the teams and fostering high-involvement environment. Teams go through several stages of increasing involvement on their way to self-management. This period could take between two and five years, and is never-ending from a learning and renewal perspective.

The commitments made by participants following the project was focused on self-managing and establishing new leadership style – distributed leadership:

- open up communication within the team, bringing out the contribution to improvement of each of its members,
- provide development for the whole team, including training in group problem solving, mapping of ideas, and ways to give and receive feedback,
- provide team members with insight required to facilitate an environment of honesty, trust and emotional safety,
- develop levels of personal insight,
- take the fear and resistance out of change,
- align values and direction across the organization through broad discussion of issues,
- monitor action plans to ensure completion to the satisfaction of the team.

Details of the Project

The content of the planned programme was fully covered, although the sequence of some activities had to be adjusted according to the flow of the programme and the needs of the

participants. The presentation and discussion on internal procedures took more time than expected, but every minute of it was well spent.

The building up of distributed leadership was implemented through s- projects (using Synnet technology). The technology Synnet is interactive virtual technology for building networked organizations based on the increasingly popular “wisdom of crowds“ idea. The new method helps to organize the collective decision making process. The system creates possibilities for participants to present their ideas anonymous in the virtual space. For others, it allows anonymous evaluation on a certain scale. The system generates the feedback about best offered ideas. This allows to form an objective overview of the ideas of a group, the virtual “brainstorming”. Teamwork organized in the virtual space is a lot more mobile and problems that arise are solved much faster. The s-projects outcome were two action plans: one for increasing the common sense of purpose, mission and the sense of belonging, and another - for integrating new team members in the team life.

Some participants were heavily opposed to attend this teambuilding programme, because they were not informed about the objectives of it. Some of them meant, the teambuilding must be an event, not online projects, but after the changed the mind after successful discussion about objectives of this teambuilding.

Evaluation of the Project

The objectives of the project were achieved. We used a flexible time table and methodology in order not to put pressure on the participants; the atmosphere during the whole event was respectful and constructive. There were moments of great concentration and involvement. Reviewing in a final round at the end of the programme, participants were very positive, pleased with the result, both the content and the atmosphere. Of course a critical comment should always be there: one participant expressed his doubt about the value of this kind of teambuilding programme. Many participants were enthusiastic. For some brand new team members, it was an extra-ordinary way of being introduced in their new team, getting acquainted with the content and the colleagues. The team members better realize that defining their identity as a team is not a given, but something to be achieved. The unit, not being a ‘real team’, can easily loose its sense of common purpose and belonging.

Project outcomes:

- A significantly enhanced understanding of how emotional baggage holds the individual team members and others back.
- An understanding of the power they have to impact upon the lives of others and the well-being of the team.
- Recognizing the link between personal empowerment and accountability.
- A clear understanding of the benefits to them of working as part of a forward moving and cohesive team.
- The skills for more effective communication within the team and beyond.
- Powerful skills for problem solving within the team.

Follow-Up

The next challenge for the unit is to start working in self managing teams. Every team will plan to distribute tasks itself among its members. Using s-projects approach the team will plan and guard the process on its own, solve daily problems, without always having to consult the manager or supporting services. Mutual perceptions and lack of understanding can easily affect a respectful relationship. Further building up the level of trust within the unit by giving personal feedback on the way the workflow should be organized .This feedback should be part of an ongoing process trying to improve continuously the collaboration in order to meet the mutual expectations at all levels and enhance performance. It was literally said in the review of the event that this activity should be organized on a regular base, like annually. This kind of follow up will definitely increase the impact, because it becomes a process of permanent improvement, rather than a one shot operation.

Evaluation of team performance. Empirical evidence

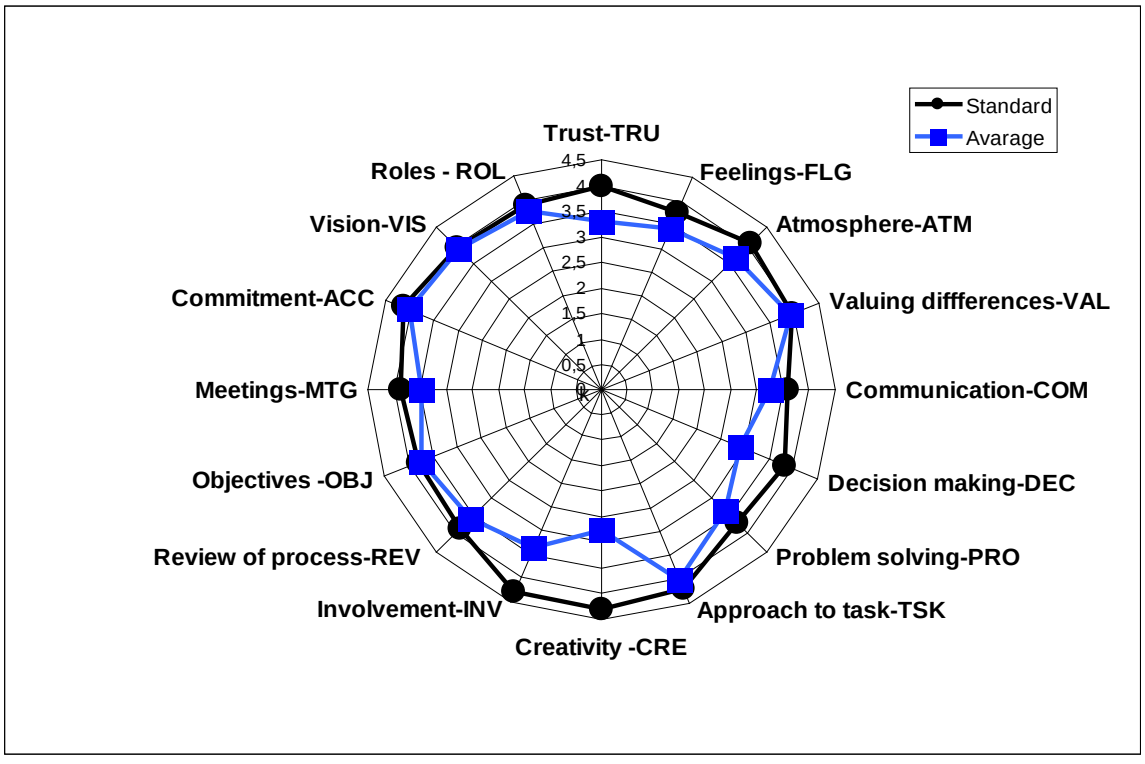
For evaluation of team performance Insigths Team Effectiveness Diagnostic was used to measure how team A is performing against critical success factors both at the beginning and over a period of time – at the end of the project (9 month period). “Insigths” is a global learning and development company working in partnership with leading organzations across the world (www.insights.com). This innovative evaluation acts as a great pre or post assessment as well as a snapshot diagnostic for teams that are struggling to be effective. The research results were used to support the establishment of performance improvement plans and benchmark team team culture performance against other teams. Each team member completed a 42-question evaluator on how they perceive the team's effectiveness in each of the 16 key areas. Team members (38 members) evaluated the team against 16 critical success factors. These sixteen elements are evenly spread around the Insights wheel. Team performance parameters are particularly critical in the distributed leadership process given that they are proposed to be behavioral indicators of a capacity for distributed leadership, antecedents to team processes, and a gateway to team performance capabilities and outcomes. The variables included within team performance parameters cover a wide range but fall into three general groups: capacity for problem-solving, team orientation, and team structuring and maintenance (Mumford, 2009).

The evaluation of team performance at the beginning of the project demonstrated significant differences (Figure 1) from the standard team performance and team A effectiviness. Size effect value should be interpreted as follows (Field, 2005): small size effect (r bellow 0.3), average size effect (between 0.3 and 0.5) and big size effect (more than 0.5). The team in department was highly centralized and bureaucratic, with a lot of formalization and standardization. The biggest negative differences exist in *Creativity* (-1,53), *Decision making* (-0,94), *Involvement* (-0,94), Trust (-0,66), as avarage could be described differences in *Feelings, Atmosphere, Communication, Problem solving, Meetings.* There are no statistically significant differences in *Valuing differences Approach to task, Review of process, Objectives.*

Figure 1: Critical success factors and its evaluation before the project.

Critical success factors	Standard	Avarage	Deviation before the project
Trust - TRU	**3,97**	**3,31**	**-0,66***
Feelings - FLG	**3,76**	**3,40**	**-0,36***
Atmosphere - ATM	**4,03**	**3,63**	**-0,40***
Valuing differences - VAL	3,96	3,92	-0,04
Communication - COM	**3,58**	**3,25**	**-0,33***
Decision making - DEC	**3,83**	**2,89**	**-0,94***
Problem solving - PRO	**3,67**	**3,35**	**-0,32***
Approach to task - TSK	4,22	4,00	-0,22
Creativity - CRE	**4,29**	**2,76**	**-1,53***
Involvement - INV	**4,29**	**3,35**	**-0,94***
Review of process - REV	3,83	3,54	-0,29
Objectives - OBJ	3,81	3,75	-0,06
Meetings - MTG	**3,87**	**3,48**	**-0,39***
Commitment - ACC	**4,16**	**3.60**	**-0,56***
Vision - VIS	3,94	3,89	-0,05
Roles - ROL	3,90	3,78	-0,12

Note: * Statistically significant difference



Observing interactions and practices one may choose to concentrate on what certain interactions 'do' as they are performed, but also to follow how interactions develop during a period of time. The evaluation of team A performance at the end of the project (in 9 month) demonstrated significant improvement of team work (Figure 2). The biggest negative differences exist again in *Creativity* (-0,75), *Involvement* (-0,73), *Trust* (-0,47), as avarage could be described differences in *Feelings, Meetings,* but all other 11 critical success factors demonstrated no statistically significant differences.

Figure 2: Critical success factors and its evaluation after the project

Critical success factors	Standard	Avarage	Deviation at the end of the project (in 9 month)
Trust - TRU	**3,97**	**3,5**	**-0,47***
Feelings - FLG	**3,76**	**3,4**	**-0,36***

Commitment - ACC	4,16	4,00	-0,16
Vision - VIS	3,94	3,9	-0,04
Roles - ROL	3,9	3,86	-0,04

Note: * Statistically significant difference

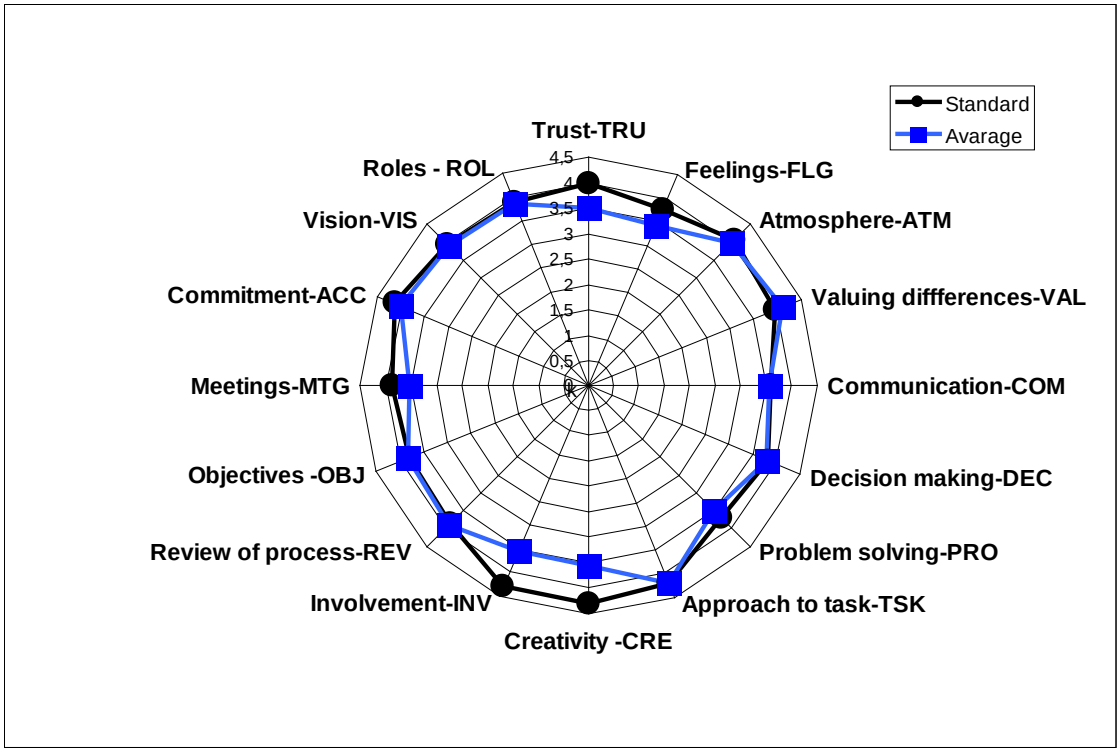

Figure 3: Critical success factors and its improvement over the project period.

Critical success factors	Standard	Avarage at the end of the project	Avarage before The project	Improvement over 9 month period
Trust - TRU	3,97	3,50	3,31	0,19
Feelings - FLG	3,76	3,40	3,40	0,00
Atmosphere - ATM	**4,03**	**3,99**	**3,63**	**0,36***
Valuing diffferences - VAL	3,96	4,10	3,92	0,18
Communication - COM	**3,58**	**3,55**	**3,25**	**0,30***
Decision making - DEC	**3,83**	**3,78**	**2,89**	**0,89***
Problem solving - PRO	3,67	3,50	3,35	0,15
Approach to task - TSK	4,22	4,21	4,00	0,21
Creativity - CRE	**4,29**	**3,54**	**2,76**	**0,78***
Involvement - INV	4,29	3,56	3,35	0,21
Review of process - REV	**3,83**	**3,89**	**3,54**	**0,35***
Objectives - OBJ	3,81	3,83	3,75	0,08
Meetings - MTG	3,87	3,52	3,48	0,04
Commitment - ACC	**4,16**	**4,00**	**3,60**	**0,40***
Vision - VIS	3,94	3,90	3,89	0,01
Roles - ROL	3,90	3,86	3,78	0,08

Note: * Statistically significant difference

The research results demonstrated significant team performance improvement in *Decision making* (0,89), *Creativity* (0,86) and average improvement in *Commitment* (0,40), *Atmosphere* (0,36), *Review of process* (0,35), *Communication* (0,30) (see Figure 3). The project activities influenced all critical success factors expect of *Feelings,* as we can see form the Insights wheel the team work is after project more balanced (Figure 2).

CONCLUSIONS

1. The team-based networked organizations requires a different kind of leadership from that in positional hierarchies. Such leadership may be more flexible and sophisticated, capable of encompassing ambiguity and rapid change. In self-managing teams leadership is preferably a collaborative and collective responsibility where the responsibilities, competencies and decision-making need to be distributed onto several individuals rather than one.

2. In this paper a perspective within leadership research is suggested that has an analytical focus on distributed leadership as it is practiced in daily interaction, rather than on individual leaders. In the face of unrelenting commercial pressure, it has become essential to maintain a strong focus on people and relationships across the organization. It is only through collaboration that solutions are found and that the commitment can be built to successfully execute. The suggested perspective opens new understandings of how leadership activities emerge in social interaction.

3. In sum, distributed leadership has significant and beneficial implications for team performance and organizational processes. It creates a more efficient use of expertise and also increases the effectiveness of teamwork by distributing elements of the leadership role to those that are best suited to take them on. The research results demonstrated significant team performance improvement in decision making, commitment and communication, creativity and atmosphere in the team. The networking activities influenced all critical success factors of team effectiveness, facilitated through group interaction and decision-making, active distribution of specific tasks.

4. The implementation of distributed leadership in public service organizations is difficult and long process, that is, the very context where policy-makers expect distributed leadership to make the most impact. Moving beyond our specific case, we argue that distributed leadership, and leadership more generally, cannot be divorced from its institutional context and that the relative influence of divergent institutional forces depends upon the immediate organizational environment. However, teams and organizations can create conditions to foster and facilitate the process, encourage leaders and team members to approach leadership as a distributed effort. A team or organization could develop their distributed leadership capabilities using new technologies: building online communities, adapting virtual communication tools and creating networked projects.

5. Distributed leadership through efficient responses in which expertise is effectively and fast utilized, would be highly valuable. Flexibility that networked teams provide could help integrate a culturally diverse and multi-generational workforce. This, together with increased competitive and financial pressure, means that the trend toward networked teaming and distributed leadership could prepare organization for the extreme challenges. Organizations need to recognize the unique implications of Climate, Process, Focus and Flow in the virtual environment and invest the time and effort to generate real results. Effective networking could be organization's unique competitive advantage.

THE ANTECEDENTS AND CONSEQUENCES OF TEAM REFLEXIVITY AND INNOVATIVE WORK BEHAVIORS OF NPD TEAMS: MULTILEVEL OF CONTINGENCY VARIABLES

Dr. Les Tien-Shang Lee, University of Kun Shan, Taiwan
llee321@mail.ksu.edu.tw

ABSTRACT

This study regards team's ability for being reflexive is crucial to transform the members' knowledge and skills as well as teams' project orientation into innovative products. This study also considers innovative work behaviors as the crucial factor that determines NPD success.

This study also proposes that members' innovative behaviors are determined project management skills, existing knowledge, and project orientation that NPD teams had.

Moreover, this study proposes that there are four moderators involved in this study. First, the relationships between project management skills, existing knowledge, and project orientation on innovative work behaviors have different magnitudes in different conditions. Second, the effects of antecedents of team reflexivity will be moderated by task familiarity. Third, the positive effects of team reflexivity and innovative work behaviors on new product success are strengthened when the NPD teams perceived that their management treated them fairly. Fourth, the task conflict also serves as the moderator between innovative work behaviors and team reflexivity on the NPD outcomes.

This study developed 18 propositions with a comprehensive research model for NPD success. Since the development of this model is still on the exploratory stage, it is suggested that further empirical validations are required to identify the robustness of this proposed research. It is expected that the results of this study can serve as a benchmark for academicians to further investigate this research issue. The study results will also be very useful for practitioners to design appropriate mechanism for the management of NPD team.

Keywords: project management skills, innovative work behaviors, team reflexivity, regulatory focus, task familiarity.

INTRODUCTION

Research Background

New product success has been an important issue in new product development (NPD) research. Previous study indicate that the average success rate of NPD in USA was 59%, whereas 100 ideas lead to 15.2 successful new products. Recent study reports that the success rate in Hong Kong is 44.91%, and 100 ideas only lead to 2.15 successful new products. These facts attract more attentions from academicians and practitioners to investigate how to increase the success rate of NPD. One of the key determinants of new product success is product innovation. This study defines innovation as uniqueness (Cooper & Kleinschmidt, 1987) or newness (Jordan & Segelod, 2006) of the product. Therefore, developing new product which offers uniqueness or newness is the ultimate way for company to make their product success in the marketplace.

Currently, organizations are increasingly relying on teams to innovate and respond to the rapidly changing marketplace (e.g., West, 2002). In other words, an organization needs to maintain and strengthen their NPD teams if they are going to innovate. This study regards team's ability for being reflexive (West, 1996, 2002) is crucial to transform the members' knowledge and skills into innovative products. This study asserts that team reflexivity determined by members' project management skills (Hoegl and Parboteeah, 2006). The skills are necessary for flexible planning and ongoing controlling of the task process, which is of particular importance in the case of innovative projects, since it has high degree of task-related uncertainty and complexity. Moreover, NPD teams will have capability to be reflexive when they have adequate knowledge on certain issues related with the newly developed product. Refer to Brockman and Morgan (2006), members' knowledge is critical to determine the quality of reflexivity that team's has. When the members' have adequate level of knowledge and project skills, team's reflection could generate innovative ideas. Furthermore, this study proposes that project orientation also determine the level of team reflexivity, either customer- or competitor-related orientation (e.g., Kohli and Jaworski, 1990; Homburg et al., 2007).

In addition, this study considers innovative work behaviors as determinants of NPD success. This study argues that NPD team members' intentional introduction or application of new ideas, products, processes, and procedures to their team (West and Farr, 1989, 1990b; Yuan and Woodman, 2010) also will facilitate the success of NPD. Despite proposing ideas from themselves, innovative work behaviors also includes the ability to adopt others' ideas that are new to one's organization or work unit (Woodman et al., 1993). Similar to the antecedents of team reflexivity, this study proposes that members' innovative behaviors are determined project management skills, existing knowledge, and project orientation that NPD teams had.

Finally, this study proposes that there are four moderators involved in this study. First, this study asserts that the relationships between project management skills, existing knowledge, and project orientation on innovative work behaviors have different magnitudes in different conditions. This study argues that regulatory focus (Higgins, 1997) could serve as the moderator. Specifically, this study argues that the relationships will be strengthened when the

NPD team members are promotion-oriented than prevention oriented due to the concern for more accomplishments and aspirations, and thus they will be more creative in problem-solving processes (e.g., Brockner and Higgins, 2001; Friedman and Forster, 2001). Second, this study proposes that the effects of antecedents of team reflexivity will be moderated by task familiarity. This study argues that the positive effects of project management skills, existing knowledge, and project orientation on team reflexivity will be strengthened when the NPD team members are familiar toward their current tasks. Third, this study proposes that the positive effects of team reflexivity and innovative work behaviors on new product success are strengthened when the NPD teams perceived that their management treated them fairly. The greater perceived procedural justice, the more likely they are to trust the organization; this will interact with outcome favorability - work behaviors, such as developing innovative products. Fourth, this study proposes that task conflict also serves as the moderator between innovative work behaviors and team reflexivity on the NPD outcomes. Task conflict fosters learning and the development of new and sometimes highly creative insights, leading the group to become more effective and innovative (Jehn, 1995). By experiencing task conflict, NPD team members will have greater team reflexivity and innovative work behaviors by the deep and deliberate processing of task-relevant information, during which the development of new and creative insights will be fostered leading the team to become more effective. On the other hand, relationship conflict has only a detrimental role on team performance.

LITERATURE REVIEW

Theoretical Background

Project Management Skills

Project management skills refer to team members' abilities to plan and control projects. This includes abilities to structure the team task and to plan the workflow (Gladstein, 1984). To be effective, teams must organize themselves in a way that allows all team members to work simultaneously without gaps and overlaps. Project management skills are necessary for flexible planning and ongoing controlling of the task process, which is of particular importance in the case of innovative projects, given their high degree of task-related uncertainty and complexity. This study follow the Hoegl and Parboteeah's (2006) argument that a team's project management skills are positively related to team reflexivity, as a high level of task structuring and coordination offers the basis for, and likely prompts the awareness of, its current work status relative to given quality, budget, and schedule expectations. As such, teams that have the skills to properly structure and control their task processes will likely demonstrate higher levels of team reflexivity, scanning internal and external environments for feedback based on proper information regarding current task status, routinely re-evaluate chosen task strategies and are prepared to alter them if the situation calls for such action.

Existing Knowledge

Existing knowledge similar with organizational memory proposed by Moorman and Miner (1997) which defined as collective basis, behavioral routines, or psychological artifacts that vary in their content, level, dispersion, and accessibility (Brockman and Morgan, 2006). It has been recognized as an essential component of organizational learning (Slater and Narver 1995); the depth and breadth of an existing knowledge base determines how easily new information is incorporated. Because NPD is considered an organizational learning process (Leonard-Barton 1992), research on the role of existing knowledge in NPD is relevant. According to Moorman and Miner (1997), the link between existing knowledge and new product innovativeness and found an insignificant relationship between the two variables. However, this study assumed that organizational memory which refers to collective basis or behavioral routines in the organizations play determinant role of product innovativeness. Moreover, it assumed that these behaviors will determine the level of team reflexivity in the new product development project.

Project Orientation

According to Homburg, Grozdanovic, and Klarmann (2007), responsiveness is typically a main facet of market orientation. They further proposed that there are two different kinds of responsiveness: "customer-related responsiveness as the extent to which an organization responds quickly to customer-related changes, and… competitor-related responsiveness as the extent to which an organization responds quickly to competitor-related changes" (Homburg et al., 2007, p. 19). Based on that, this study will adopt this perspective and operationalizes project orientation as customer-related and competitor-related responsiveness. This study asserts that timely responses to customer-related changes and competitor-related changes have several beneficial consequences for NPD teams.

Team Reflexivity

Group members face obstacles as they try to coordinate effort, strengthen interpersonal relationships, and integrate ideas. Groups need considerable management to identify frustrations and develop and implement solutions. West (1996, 2000, 2002) has labeled this group management as team reflexivity and defined it as the extent to which team members collectively reflect on and adapt their team's objectives, strategies, and processes. Teams monitor and become aware of how they work together and develop and implement improvement plans. Reflexivity would also seem to require a degree of entitativity, which is the extent to which group members believe themselves to be one unit (Lickel, Hamilton, and Sherman, 2001). Reflexivity is expected to help teams know their actual workings and develop new understandings and methods that respond to emerging conditions and challenges (Carter and West, 1998). Reflexivity is especially useful for groups working on challenging tasks and operating in complex environments. The major implication is that to the extent that teams engage in reflexivity are able to continue to perform effectively (Frese and Zapf, 1994; Johnson, Johnson, Stanne, and Garibaldi, 1990), and can keep groups focused and efficient.

According to West (1996, 2000, 2002), there are three central elements to the concept of reflexivity—reflection, planning, and action or adaptation. Reflection consists of attention, awareness, monitoring, and evaluation of the object of reflection. Planning is one of the potential consequences of the indeterminacy of reflection, since during this indeterminacy, courses of action can be contemplated, intentions formed, plans developed (in more or less detail), and the potential for carrying them out is built up. High reflexivity exists when team planning is characterized by greater detail, inclusiveness of potential problems, hierarchical ordering of plans, and long as well as short range planning. The more detailed the implementation plans, the greater the likelihood that they will manifest in innovation (Frese and Zapf, 1994; Gollwitzer, 1996). Indeed the work of Gollwitzer and colleagues suggests that innovation will be implemented almost only when the team has articulated implementation intentions. This is because planning creates a conceptual readiness for, and guides team members' attention towards, relevant opportunities for action and means to implement the innovation. Action refers to goal-directed behaviors relevant to achieving the desired changes in team objective, strategies, processes, organizations, or environments identified by the team. In a variety of studies links between reflexivity and team innovation and effectiveness have been demonstrated (Carter and West, 1998; West, Patterson, and Dawson, 1999; Borrill et al., 2000). This study uses these dimensions - reflection, planning, and action or adaptation – to represents the team reflexivity which will influence the product innovativeness of NPD teams resulted as well as the new product performance.

Innovative Work Behaviors

Drawing on West and Farr (1989, 1990b), Yuan and Woodman (2010) define innovative behavior as an employee's intentional introduction or application of new ideas, products, processes, and procedures to his or her work role, work unit, or organization. Examples of such behavior include searching out new technologies, suggesting new ways to achieve objectives, applying new work methods, and investigating and securing resources to implement new ideas. In keeping with Kanter (1988), Janssen (2000), and Scott and Bruce (1994), this study asserts that innovative behavior as complex behavior consisting of activities pertaining to both the generation/introduction of new ideas (either by oneself or adopted from others) and the realization or implementation of new ideas. One related construct in the literature is creative behavior, which refers to behavior pertaining to the generation of ideas that are both novel and useful (Amabile, 1988; Oldham and Cummings, 1996). Creative behavior can be considered as one type of innovative behavior because innovative behavior includes not only generating novel ideas by oneself but also adopting others' ideas that are new to one's organization or work unit (Woodman et al., 1993). Also, creative behavior concerns new idea generation, whereas innovative behavior includes both the generation and implementation of new ideas (Shalley et al. 2004; Zhou, 2003).

This study asserts that members of NPD teams have innovative work behaviors as the rational decisions of innovative acts to support the functioning of the team.

Outcomes

At the firm level, this study operationalizes based on financial and market performance. Previous studies mostly employ financial performance as the consequence of the adoption of NPD (e.g., Jordan and Segelod, 2006; Weerawardena and O'Cass, 2004). Another consequence is performance related to market measurements. NPD programs can create better customer satisfaction and enhance their business image, and thus it might improve business reputation. Good reputations provide the rationale for a cross-sectional relationship between reputation and financial performance. Specifically, good reputation may enable the organization to charge premium prices, attract better applicants, enhance their access to capital markets, and attract investors. Based on that, this study operationalizes organizational performance based on managers' perceptions of their firms' financial and market performance.

Regulatory Focus

Higgins (1997, 1998) developed the regulatory focus theory, which describes important differences in the processes through which people approach pleasure and avoid pain. Self-regulation refers to the process by which people seek to align themselves (i.e., their behaviors and self-conceptions) with appropriate goals or standards (Brockner and Higgins, 2001). Specifically, Higgins (1997) proposed that people have two basic self-regulation systems. One regulates the achievement of rewards and focuses individuals on promotion goals, while the other regulates the avoidance of punishments and focuses individuals on prevention goals. Promotion goals represent the "ideal self" and include hopes, wishes, and aspirations, whereas prevention goals represent the "ought self" and include duties, obligations, and responsibilities.

Regulatory focus theory can be thought of as one of the most comprehensive motivation theories, since its constructs seem to comprise a primary element of human motivation. Previously, motivation has been examined by focusing on individual differences in approach-related versus avoidance-related emotions (e.g., Gray, 1982; Sutton and Davidson, 1997). In contrast to the approach-avoidance literature (e.g., Gray, 1982), regulatory focus theory suggests that there are different pathways to achieve different desired end states (Higgins, 1997). Since export behavior focuses on bringing about desired end states, this theory is particularly appropriate for analyzing the different possible outcomes of export behaviors. This study expects that managers' or owners' regulatory focus, through the manipulation of work context, can affect the situational factors of the regulatory focus, priming followers' promotion or prevention focus and shaping their motivations.

Task Familiarity

The concept of familiarity in organizational teams has been defined as "the knowledge that members of a team have about the unique aspects of their work" (Goodman and Garber 1988), such as knowledge about the task itself and about other members on the team (Littlepage et al. 1997). As members of a team work together over time, they become familiar with the task domain and with each other, and they develop a common knowledge base through which team

interaction and location of expert sources in the team can occur (Alavi and Leidner 2001). This study focuses on task familiarity rather than team familiarity, since it deals with the innovation outcomes, whether it is radical or incremental innovation.

Procedural Fairness

Based on organizational justice theory (Greenberg, 1987), procedural justice refers to the perceived fairness of the processes used to determine the outcomes received (Colquitt et al., 2001). The basic premise is that fair treatment determines individuals' reactions to decisions and is thus central to their behavior (Lind and Tyler, 1988). It emphasizes structural elements such as process control as major determinants of fairness perceptions (Greenberg, 1987). Procedural justice researchers argue that organizational members are concerned about the fairness of the procedures that govern or affect organizational members, because procedural fairness signals a member's positive or valued position within the organization or group (Lind and Tyler, 1988, Tyler and Lind, 1992).

In the context of NPD teams, Li et al. (2007) define perceived procedural justice as "a project member's perceptions of the fairness of rules and processes used by top management to make decisions regarding the development of new products" (p. 201). Fair in the context of NPD such that procedures and criteria used to screen, create, appraise, and test new product are unbiased, representative, transparent, correctable, and ethical (Luo, 2008). In summary, this study asserts that procedural justice is NPD teams' perception toward how fair the rules and processes being set up by the management regarding the development of new product.

Team Conflict

Team conflict refers to a process resulting from the tension between team members because of real or perceived differences (e.g., De Dreu, Harinck, and Van Vianen, 1999; De Dreu and Weingart, 2003). Because team members contribute to the team through social inputs and task inputs (e.g., Forsyth, 1983), conflict in teams is concerned with relationship and task issues (e.g., Amason and Schweiger, 1997; Jehn, 1997). Examples of relationship conflict are conflicts about personal taste, political preferences, values, or interpersonal style. Examples of task conflict are conflicts about the distribution of resources, about procedures and policies, and about judgments and interpretation of facts. Task conflict increases group members' tendency to scrutinize task issues and to engage in deep and deliberate processing of task-relevant information (Amason, 1996; Amason and Schweiger, 1997; Jehn, 1995, 1997), while relationship conflict tends to result in a focus of members on each other rather than on the assigned task (De Dreu and Weingart, 2003). This fosters learning and the development of new and sometimes highly creative insights leading the group to become more effective.

Research Propositions

The Determinants of Innovative Work Behaviors

This study argues that being innovative in the workplace, such as in the context of NPD teams, need to have basic requirements. Project management skills refer to team members' abilities to plan and control projects, and its necessary for flexible planning and ongoing controlling of the task process, which is of particular importance in the case of innovative projects, given their high degree of task-related uncertainty and complexity. With these skills, it can be expected that NPD team members are expected to be innovative by introducing several planning and how to implement those planning. Furthermore, Narver and Slater (1990) proposed that existing knowledge is an essential component of organizational learning (Slater and Narver 1995); the depth and breadth of an existing knowledge base determines how easily new information is incorporated. In other words, when the NPD team members have sufficient existing knowledge related with current assignments, it can be expected that they will have greater innovative work behaviors.

In addition, this study argues that project orientation positively contributes to innovative work behaviors. As described previously, NPD teams might have customer- or competitor-related responsiveness (Homburg et al., 2007). Either one, responsiveness of the NPD team members toward customer- or competitor-related changes will increase the innovative work behaviors from the members. Following the social-political perspective in understanding innovation (Yuan and Woodman, 2010), this study also argues that being innovative is a prerequisite to impress others. Individuals' reality is, at least partially, socially constructed. Individual behaviors have both technical and symbolic functions. Regardless of whether the introduction of new ideas or procedures will help to improve efficiency or performance, the act of engaging in innovative behaviors is a signal; it conveys information about an actor to the social context. Other people's potential perceptions or impressions are important determinants of individual behavior because such impressions influence others' reactions to the actor and therefore the possibility for the actor to get necessary resources and social support to achieve goals. In a product design firm, Sutton and Hargadon (1996) found that design engineers used brainstorming sessions as "prestige" or "status auctions"—that is, as opportunities to impress their peers and establish favorable social images. Thus, when NPD teams have customer- or competitor-related responsiveness, the members will tend to introduce innovative ideas in order to impress each other. Therefore, the following two propositions are developed.

Proposition P_1: Innovative work behaviors are positively influenced by (a) project management skills and (b) existing knowledge of NPD team members.

Proposition P_2: Project orientation is positively influence the level of NPD team members' innovative work behaviors.

The Determinants of Team Reflexivity

This study asserts that having reflection needs some knowledge from team members, such as technical knowledge or behavioral routines (Brockman & Morgan, 2006), as materials to be processed further in the reflection process. Moreover, this study asserts that a team's project management skills are positively related to team reflexivity (Hoegl and Parboteeah, 2006). A team that has the skills to properly structure and control their task processes will likely demonstrate higher levels of team reflexivity, routinely re-evaluate chosen task strategies and are prepared to alter them if the situation calls for such action. Because reflexivity involves each team member to present their accounts of the situation, they are less likely to be judgmental about ideas of NPD and more likely to find the best solution to problems. The information sharing within the team and across the team is likely happen when all team members are better informed about problems they are facing and ways to solve them in NPD (Hoegl & Parboteaah, 2006). According to, the constant self-reflection fosters the ongoing collection and sharing of information that is so critical to project success.

As an aspect of corporate culture, project orientation places the highest priority on creating and maintaining superior customer value profitably, and provides firm-wide norms and beliefs that guide organizational behaviors (Narver and Slater, 1990). It consists of two behavioral components: customer orientation and competitor orientation. Customer orientation echoes the classic tenet of "stay close to the customer" and "put the customer at the top of the organizational chart" and therefore is the most essential part of a market orientation. Consequently, the NPD team needs to be more reflexive on any changes related with their customers. On the other hand, competitor orientation focuses on the strengths and weaknesses of its competitors. To response on any actions being taken by its competitors, NPD team also need to be reflexive in order to overcome the thgreats posed by the competitors. In summary, Day and Wensley (1988) propose that customer and competitor orientations are two distinct approaches that lead to competitive advantage. A customer orientation, with its detailed analyses of customer needs and wants, helps a firm satisfy its customers better, and thus is more likely to lead to a differentiation advantage. In contrast, a competitor orientation may lead to a cost advantage because competitor-oriented businesses tend to watch costs closely, so they may quickly match the marketing initiatives of competitors. These advantages could be reach when the NPD teams are being reflexive toward their current tasks. Therefore, based on the above literatures, this study proposed the following two propositions:

Proposition P_3: Team reflexivity is positively influenced by (a) project management skills and (b) existing knowledge of NPD team members.

Proposition P_4: Project orientation is positively influence the level of NPD team's reflexivity.

The Effect of Team Reflexivity

Team reflexivity allows NPD teams to continuously assess current situations and accurately understand objectives, making the teams effective and focused under dynamic market and

technological changes (Hoegl and Parboteeah, 2006). As a result, NPD teams have better problem solving abilities by solving the "right" problems in the right order, ultimately developing innovative products. Thus, it can be expected that NPD team members able to introduce and implement innovative work behaviors when their team is more reflexive. Furthermore, team reflexivity positively relates to higher levels of innovation and greater product performance (e.g., Carter and West, 1998; Tjosvold et al., 2004). Reflexive teams are also likely to make better use of team members' expertise, thus achieving better project success due to greater awareness of their fellow team members' expertise and skills. This comprehensive knowledge of team strength and weakness is likely to lead to better innovation as expertise is distributed in the most appropriate way. Moreover, each team member needs to present their accounts of the situation to be reflexive; consequently, they are less likely to be judgmental about others' ideas and more likely to find the best solution and develop innovative products. Therefore, the following propositions are:

Proposition P_5: Team reflexivity has a positive influence on the level of innovative work behaviors among NPD team members.

Proposition P_6: Team reflexivity has a positive influence on the level of product innovation and product performance.

The Effect of Innovative Work Behaviors

One major reason people innovate in the workplace is to bring performance gains (Yuan and Woodman, 2010). New technologies are introduced and new work methods are applied because these are "better" than the existing ones and are expected to bring performance improvement and efficiency gains. Such a belief in performance gains reflects the dominant efficiency-oriented perspective in the innovation literature, according to which the goal of technical efficiency guides innovation adoption and diffusion. Expected performance outcomes are positive when employees believe that their innovative behaviors will bring performance improvement or efficiency gains for their work roles or work units, particularly in NPD teams (Yuan and Woodman, 2010). They also suggested that innovative work behaviors lead to greater job satisfaction due to their personal orientation to be effective and efficient has been accommodated by the organization. Therefore, the following two propositions are developed.

Proposition P_7: Innovative work behaviors of NPD team members lead to greater job satisfaction.

Proposition P_8: Innovative work behaviors of NPD team members have a positive influence on the success of NPD.

The Effect of Individual Outcomes and NPD Success

According to affective events theory (AET - Weiss and Cropanzano, 1996), job satisfaction is a pleasurable or positive emotional state resulting from an individual's appraisal of their job, and

is the result of the employee perceptions of how well their job provides those things which they view as important. Moreover, satisfied employees have a favorable evaluation of their job, based on their observations and emotional experiences (Lum et al., 1998). As a result, these employees tend to perform favorable outcomes (Luthans, 1989). In the context of NPD, this study assumes that satisfied NPD team members will perform more innovative which then increase the performance of the product. As a result, the organizational performance also will be increased due to NPD team members' positive attitudes toward their organization.

Prior studies in NPD context never empirically discuss the influence of NPD success directly to organizational performance. As described by Weerawardena and O'Cass (2004) that innovative product is applying ideas that are new to the firm to create added value, either directly for the enterprise or indirectly for the customers. Moreover, product can be called innovative when there are new product advantage and product newness offered to the customers (Jordan and Segelod, 2006). As a result, it can be expected that NPD success directly influence to organizational performance through the increase of financial and market performance. Based on that, the following three propositions are developed:

Proposition P_9: The greater job satisfaction that NPD team members had, the higher NPD success will be.

Proposition P_{10}: Job satisfaction among NPD team members will contribute positively toward the organizational performance.

Proposition P_{11}: The innovativeness of the product and market performance will positively influence the organizational performance.

The Moderating Effect of Regulatory Focus

According to Higgins (1997), individuals have two basic self-regulation systems. One regulates the achievement of rewards and focuses individuals on promotion goals, while the other regulates the avoidance of punishments and focuses individuals on prevention goals. In the context of NPD teams, members who operate primarily within the promotion focus are more concerned with accomplishments and aspirations, use approach as a goal attainment strategy, are more creative in problem-solving processes, and show more willingness to take risks (e.g., Brockner and Higgins, 2001; Friedman and Forster, 2001). Moreover, Kark and Van Dijk (2007) indicate that the purpose of the promotion focus is to pursue development and change and to explore the advantage of creative and novel behaviors. Consequently, these members will have greater willingness to perform innovative work behaviors when they have greater promotion focus.

In contrast, members who operate primarily within the prevention focus are more concerned with duties and obligations, are likely to be sensitive to the presence or absence of punishments, and use avoidance as a goal attainment strategy (e.g., Crowe and Higgins, 1997; Friedman and Forster, 2001). Further, the purpose of the prevention focus is to assure one's

safety and security, to maintain routines, and to preserve the status quo. This study argues that members with prevention focus have less willingness to perform innovative work behaviors due to their avoidance attitude. Therefore, the following proposition is developed:

Proposition P_{12}: Regulatory focus will moderate the positive effects of (a) project management skills, (b) existing knowledge, and (c) project orientation on innovative work behaviors such that these positive effects will strengthen when the members has promotion than prevention focus.

The Moderating Effect of Task Familiarity

Previous studies seem to intuitively propose that familiarity with the task improves team performance; however, the empirical evidences are not so clear. Summarizing the mixed results in the familiarity literature, Harrison and colleagues conjectured that the effects of familiarity on team performance may differ depending on the nature of the task itself. Similarly, Argote and colleagues also concluded that the task matters when studying the effects of familiarity. Their experimental study shows that team performance increased with task experience and decreased with task complexity; performance on simpler tasks improved more strongly with task experience than on more complex tasks. This study argues that the positive effects of project management skills, existing knowledge, and project orientation on team reflexivity will be strengthened when the NPD team members are familiar toward their current tasks. Based on the above discussion, the following proposition is developed:

Proposition P_{13}: Task familiarity will moderate the positive effects of (a) project management skills, (b) existing knowledge, and (c) project orientation on team reflexivity such that these positive effects will be strengthened when the NPD members are more familiar with their current tasks.

The Moderating Effect of Procedural Justice

In addition, this study posits that the positive effects of team reflexivity and innovative work behaviors on new product success are strengthened when the NPD teams perceived that their management treated them fairly. The exchange theory posits that individuals will give back commensurately what they perceive to have received from the other party, through greater trust and accountability. Greater perceived procedural justice contributes to how individuals' inference about how much they need to trust the organization (Lind and Tyler, 1988). The greater perceived procedural justice, the more likely they are to trust the organization; this will interact with outcome favorability - work behaviors, such as developing innovative products. In other words, NPD teams make inferences about their perceptions of procedural fairness as a signal that the organization is trustworthy; and thus, teams respond positively by delivering favorable outcomes. Similarly, greater perceived procedural justice increase team members' inferences about how much they should hold the organization accountable for the outcomes that they receive. In other words, when NPD teams perceive that the procedures are unfair, they believe that the organization's accountability is high; and as a result, they will lower their initiatives and activities to deliver favorable outcomes. Consequently, it can be expected that

the positive effects of team reflexivity and innovative work behaviors on NPD success will be strengthened when the NPD team members perceived greater procedural justice. Based on these discussions, the following proposition is developed:

Proposition P_{14}: When project members perceive a higher level of perceived procedural justice, the positive effects of (a) team reflexivity and (b) innovative work behaviors on new product success is strengthened.

The Moderating Effect of Team Conflict

The previous discussion does not indicate under what conditions that the positive effect of team reflexivity and innovative work behaviors contribute more or less toward NPD success. Jehn (1995, 1997) noted that task conflict can be beneficial to task performance when working on nonroutine tasks, which are typically complex tasks without standard solutions, therefore requiring some consideration by the NPD team. Task conflict increases team members' tendency to elaborate task issues and to engage in extensive knowledge exchange regarding task-relevant information (Amason, 1996; Amason and Schweiger, 1997; Jehn, 1995, 1997). This fosters learning and the development of new and sometimes highly creative insights, leading the group to become more effective and innovative (Jehn, 1995). By experiencing task conflict, NPD team members will have greater team reflexivity and innovative work behaviors by the deep and deliberate processing of task-relevant information, during which the development of new and creative insights will be fostered leading the team to become more effective. Moreover, Simons and Peterson (2000) noted that groups who experience task conflict tend to make better decisions because such conflict encourages greater cognitive understanding of the issue being considered. As a result, it can be expected that when an NPD team has more team reflexivity and innovative work behaviors and at the same time experiences task conflict, the success of a newly developed product will increase.
In contrast, relationship conflict has only a detrimental role on team performance. The previous results have indicated that relationship conflict generally decreases satisfaction and interferes with task performance (e.g., Jehn, 1995, 1997; Amason, 1996). According to De Dreu and Weingart (2003), relationship conflict limits the information processing ability of an NPD team because each member spends his/her time and energy focusing on others rather than the assigned task. Consequently, it is expected that the positive effect of team reflexivity and innovative work behaviors on new product success will be weakened when the team members engage in relationship conflict. Based on this, the following two propositions are developed:

Proposition P_{15}: Task conflicts will moderate the positive effects of (a) team reflexivity and (b) innovative work behaviors such that these positive effects on new product success will strengthen when the members experience more rather than less task conflict.

Proposition P_{16}: Relationship conflicts will moderate the positive effects of (a) team reflexivity and (b) innovative work behaviors such that these positive effects on new product success will weaken when the members experience more rather than less relationship conflict.

CONCLUSION AND SUGGESTIONS

The primary aim of the current study, accordingly, is to emphasize the antecedents and consequences of innovative work behaviors and team reflexivity on NPD outcomes. This study regards team's ability for being reflexive is crucial to transform the members' knowledge and skills as well as teams' project orientation into innovative products. This study also considers innovative work behaviors as the crucial factor that determines NPD success. Similar to the antecedents of team reflexivity, this study proposes that members' innovative behaviors are determined project management skills, existing knowledge, and project orientation that NPD teams had.

Moreover, this study proposes that there are four moderators involved in this study. First, this study asserts that the relationships between project management skills, existing knowledge, and project orientation on innovative work behaviors have different magnitudes in different conditions. Second, this study proposes that the effects of antecedents of team reflexivity will be moderated by task familiarity. Third, this study proposes that the positive effects of team reflexivity and innovative work behaviors on new product success are strengthened when the NPD teams perceived that their management treated them fairly. Fourth, this study proposes that task conflict also serves as the moderator between innovative work behaviors and team reflexivity on the NPD outcomes.

Based on the above literature review, 18 propositions are developed that subject to further empirical validation. A preliminary research model is developed and shown in Figure 1.

Since the antecedents, moderators, and consequential variables of NPD team strain have not been comprehensively evaluated, it is expected that the results of this study can serve as a benchmark for academicians to further investigate this research issue. The study results will also be very useful for practitioners to design appropriate mechanism for the management of NPD team.

Based on the above research model, four contributions are expected to be delivered by this study:

1. This study has aimed to develop comprehensive sources of NPD team reflexivity and innovative work behaviors by proposing that project management skills, existing knowledge, and project orientation are the determinants. Further validations can enhance understanding on the role of these antecedents on NPD team operations.
2. This study has aimed to extend the concept of innovative work behaviors as the phenomenon inside NPD teams that will contribute to members', teams, and organizational outcomes. This study further argues that members will have innovative work behaviors when the team has sufficient time to reflect their current assignment. Thus, further validation on these research issues can provide valuable information for NPD management and for further academic validation.

3. Based on the suggestions of previous literature, this study proposed that regulatory focus, the familiarity level of NPD team toward the tasks assigned, their perception toward procedures being set up the management, and team conflict will serve as moderating variables. Further empirical validations could provide important references to human resources managers to develop the effective NPD teams to achieve better new product performance by integrating the consideration of these variables.
4. Previous scholars has proposed that a mixed study approach, which combined qualitative approach and quantitative approach in a research setting can largely improve the validity and generalizability of the study (e.g., Shah and Corley, 2006).

ABSTRACT

In this paper, we aim to develop a best-fitting neural network model which can be employed to detect various severity levels of CKD based on the two different sets of influence factors as the inputs for model learning and developing. Firstly, the influence factors of CKD which most physicians employ in the computational formula are used as the inputs to three preselected fundament neural network models to detect (classify) various levels of chronic kidney disease. Secondly, the potential key influence factors of CKD which are identified by reviewing the CKD relevant literatures as well as conducting expert interviews are used as the inputs to three models as well. Three fundamental neural network models selected for detection and comparison include back-propagation network (BPN), generalized feedforward neural networks (GRNN), and modular neural network (MNN). Furthermore, three hybrid neural network models which are modeled by embedding genetic algorithm (GA) into each respective fundamental neural factor are employed for conducting CKD detection and comparison. The comparison among network models are based the CKD detection performance measured by the computation accuracy, sensitivity, and specificity in model training and testing.

The results of model experiment show that almost all models employed in experiment may gain near 100% accuracy in CKD detection in the training stage regardless of which sets of influence factors used in model training. However, if the model testing is further conducted, it is found that the network models with the inputs of influence factors of CKD used by physicians employed in the computational formula always shows better detection performance in all three aspects of measures. The BPN gain the highest 94.75% accuracy measures in the testing stage among three fundamental neural network models while GFNN gain only 86.63% in accuracy measure which is the lowest performance in three models. Through further observations from experiment results, it is found the hybrid network model of GFNN plus GA embedded may significantly enhance detection performance in all three measures from its fundamental model in the testing although the the detection performance are degraded in BPN and MNN.

We conclude that BPN might be the best-fitting factor Among three fundamental neural network models employed in detecting CKD while the models with GA embedded in BPN and GFNN respectively might be the best-fitting hybrid models for CKD detection.

Keywords: Chronic Kidney Disease, Disease Detection, Risk Estimation, Artificial Neural Networks, Genetic Algorithms.

INTRODUCTION

As people's life level become more and more modernized and life span become longer in our society, chronic kidney disease (CKD) becomes more common which may result in developing different levels of ill-function and damage of patient kidneys. Once a person gets CKD, he/she will suffer from the disease which may decrease his/her working ability as well as live quality. It is also very likely to develop other chronic diseases like high blood pressure, anemia (low blood count), weak bones and cause poor nutritional health and nerve damage. In the meantime, kidney disease increases patient risk of contracting heart and blood relevant diseases. Chronic kidney disease may be caused by other chronic disease such as diabetes, high blood pressure and other disorders. High CKD risk groups include those who have diabetes, hypertension, and family history of kidney disease. Early detection and treatment can often keep chronic kidney disease from getting worse. When kidney disease progresses, it may eventually lead to kidney failure which even requires dialysis or even proceeds to kidney transplant to maintain patient life.

According to the statistical data announced by the Department of Health of Taiwan's government in 2010 (DOH, 2010), the mortality caused by kidney disease has been ranked in the 10th place in all causes of death in Taiwan and thousands of others are at increased risk. The mortality caused from kidney disease is estimated as 12.5 in every 100,000 peoples. As a result, it costs as high as 35 percent of health insurance budget to treat the chronic kidney disease (CKD) patients with the age over 65 years old and end stage kidney disease patient in all ages. It occupies a huge amount of expenditures in national insurance budget.

Regarding to the measurement of serious levels of CKD, presently glomerular filtration rate (GFR) is the most commonly measuring indicators used in health institutions to estimate kidney health function. The physician in the health institution can calculate GFR from patient's blood creatinine, age, race, gender and other factors depending upon the type of formal-recognized computation formulas (Firman, 2009; NKF, 2002; Levey, 2005) is employed. The GFR may indicate how health of a patent's kidney and can be also taken to determine whether a people has kidney disease. The physician may also depend upon this indicator to determine the stage of kidney disease of a patient and help him to set a treatment plan for the patient (Firman, 2009; Levey et al., 2005).

The objectives of this paper aims to develop decision models by applying artificial neural networks and fuzzy expert system in artificial intelligence which attempts to provide physicians an alternative method to detect chronic kidney diseases and estimate the risk levels of a patient in early CKD stage. This study of this paper was cooperatively carried out with a district teaching hospital in New Taipei City located in the northern district of Taiwan.

In the first stage of this paper, we aim to develop a best-fitting neural network model which can be employed to identify various levels of CKD based on two different sets of influence factors as the inputs for model learning and developing. To reach this develop objective, firstly the set of influence factors of CKD which most physicians employ in the computational formula to diagnose CDK are determined for being used as the inputs to three preselected fundament neural network models. Next, another set of potential key influence factors of CKD which are identified by reviewing the CKD relevant literatures as well as conducting expert interviews are used as the inputs to three models as well. Three fundamental neural network models selected for detection and comparison include back-propagation network (BPN), generalized feedforward neural networks (GRNN), and modular neural network (MNN). Furthermore, three hybrid neural network models which are developed by embedding genetic algorithm (GA) into each respective fundamental neural factor Are employed for conducting CKD detection and comparison. The comparison among network models is based on the CKD detection performance measured by the measurement of factor Accuracy, sensitivity, and specificity respectively in model training and testing. The input data for the training, testing, and experiment of ANN models is collected from the people's health examination which is periodically carried out by collaborative hospital.

METHODS AND LITERATURES REVIEW

In this section, firstly the different methods of measuring CKD followed by two sets of influence factors used as the inputs for network modeling are reviewed. Next, the investigation of the criteria of CKD classification (i.e., detection) and risk evaluation of CKD is conducted. The three different neural network models employed for detection and comparison in this paper are surveyed and briefly introduced as well**.**

The Review of the Methods of Measuring Chronic Kidney Disease

The GFR is a most-commonly method used to measure kidney health function. It refers to the water filterability of glomerular of people's kidney. The normal value of measurement ought to be between 90 and 120 ml/min/1.73m^2. There are three common computation methods of GFR, which are (1) Removing rate of 24-hour urine creatinine (i.e., Creatinine Clearance Rate, Ccr) ; (2) Cockcroft-Gault formula (i.e., known as C-G formula) ; (3) Modification of Diet in Renal Disease formula (i.e., known as MDRD) (Firman, 2009). The CKD is categorized into five stages by making using of GFR to measure kidney function. Although the course of the change from stage one to five may usually last for years, it sometimes may enter into fifth stage pretty soon resulted in the necessity of dialysis or

kidney transplant (NKF, 2002; Levey et al., 2005).

Again, according to the guideline developed by the National Kidney Foundation's Kidney Disease Outcomes Quality Initiative (KDOQI) (NKF, 2002), an independent not-for-profit foundation governed by an international Board of Directors in 2002 providing a new conceptual framework for a diagnosis of CKD independent of cause and developing a classification scheme of kidney disease severity based on the level of glomerular filtration rate (GFR). The new system represented a significant conceptual change, since kidney disease historically had been categorized mainly by cause. The diagnosis of CKD relies on markers of kidney damage and/or a reduction in GFR. Stages 1 and 2 define conditions of kidney damage in the presence of a GFR of at least 90 ml/min/1.73 m2 or 60 to 89 ml/min/1.73 m2, respectively, and stages 3 to 5 define conditions of moderately and severely reduced GFR irrespective of markers of kidney damage. The summarized of this guideline is shown in Table 1. The common definition of CKD has facilitated comparisons between studies. Thus, this new diagnostic classification of CKD has likely been one of the most profound conceptual developments in the history of nephrology. Nevertheless, there are limitations to this classification system, which is by its nature simple and necessarily arbitrary in terms of specifying the thresholds for definition and different stages. When the classification system was developed in 2002 (NKF, 2002; Levey et al., 2005), the evidence base used for the development of this guideline was much smaller than the CKD evidence base today. Therefore, this guideline is constantly revised from then on by Kidney Disease Outcomes Quality Initiative (KDOQI) with the modification and endorsement by Kidney Disease: Improving Global Outcomes (KDIGO). The currently available methods to estimate GFR and ascertain kidney damage are evolving (Levey et al., 2005).

Table 1: Classification of CKD as Defined by KDOQI and Modified and Endorsed by KDIGO.

Stage	**Description**	**Classification by Severity By GFR (ml/min/1.73m^2)**
1	Kidney damage with normal or GFR increasing	GFR >=90
2	Kidney damage with mild decreasing in GFR	GFR of 60-89
3	Moderate with decreasing in GFR	GFR of 30-59
4	Severe with decreasing in GFR	GFR of 15-29
5	Kidney failure	GFR <= 15 (or dialysis)

One of most recognized versions of the classification and risk evaluation of CKD was released by National Kidney Foundation (NKF) of US written by Firman in 2009 (Firman, 2009). Its severity classification and risk evaluation criteria are shown in Table 2 and 3, respectively. It is properly the most referable guideline regarding the classification and risk evaluation of CKD.

Table 2: Classification and Risk Evaluation of Chronic Kidney Disease.

Stage	**Description†**	**GFR *(ml per minute per 1.73 m^2)***	**Action plans**
-	At increased risk for chronic kidney disease	> 60 (with risk factors for chronic kidney disease)	Screening, reduction of risk factors for chronic kidney disease
1	Kidney damage with normal or elevated GFR	$\geq$ 90	Diagnosis and treatment, treatment of comorbid conditions, interventions to slow disease progression, reduction of risk factors for cardiovascular disease
2	Kidney damage with mildly decreased GFR	60 to 89	Estimation of disease progression
3	Moderately decreased GFR	30 to 59	Evaluation and treatment of disease complications
4	Severely decreased GFR	15 to 29	Preparation for kidney replacement therapy (dialysis, transplantation)
5	Kidney failure	< 15 (or dialysis)	Kidney replacement therapy if uremia is present

Table 3: Risk Factors for Chronic Kidney Disease and Definitions.

Type	Definition	Examples
Susceptibility factors	Factors that increase susceptibility to kidney damage	Older age, family history of chronic kidney disease, reduction in kidney mass, low birth weight, U.S. racial or ethnic minority status, low income or educational level
Initiation factors	Factors that directly initiate kidney damage	Diabetes mellitus, high blood pressure, autoimmune diseases, systemic infections, urinary tract infections, urinary stones, obstruction of lower urinary tract, drug toxicity
Progression factors	Factors that cause worsening kidney damage and faster decline in kidney function after kidney damage has started	Higher level of proteinuria, higher blood pressure level, poor glycemic control in diabetes, smoking
End-stage factors	Factors that increase morbidity and mortality in kidney failure	Lower dialysis dose (Kt/V)*, temporary vascular access, anemia, low serum albumin level, late referral for dialysis

*-In Kt/V (accepted nomenclature for dialysis dose), "K" represents urea clearance, "t" represents time, and "V" represents volume of distribution for urea.

In Taiwan, the Taiwan Society of Nephrology (TSN) also presented the self-detecting method of kidney for the public. The MDRD formula (Levey et al., 2000; Levey et al., 2005), which is recognized as a more accurate with mostly adopted method by kidney physicians to estimate glomerular filtration rate (GFR) from serum creatinine, is adopted for the use in diagnosis. Therefore, in this paper of study we also take MDRD to calculate the GFR. The method of calculation formula is shown in formula 1. The input data for the GFR calculation of each individual patient case in health examination are provided by the collaborative hospital of this research. We also use the calculated results as the desired (targeted) value to train our neural network models in experiment.

$$\mathrm{GFR} = 186 \times \mathrm{Creatinine}^{-1.154} \times \mathrm{age}^{-0.203} \left(\frac{\mathrm{ml}}{\frac{\mathrm{min}}{1}} . 73\mathrm{m}^2 \right) \ldots\ldots(1)$$

Note: For female the result should be multiplied by a factor of 0.742。

Snyder and Pendergraph (2005) indicated that the MDRD was suitable to be used to the group of diabetes mellitus, older age (age above 51), patient with kidney replacement

therapy (dialysis, transplantation). It also takes less number of factors than other two popular methods, which are Creatinine Clearance Rate computation and Cockcroft-Gault formula. It becomes easier and simple but still maintains the result effectiveness for calculating GFR. Hence, this paper adopts MDRD to conduct the calculation of GFR directly from the data collection of creatinine, age, and sex. The three factors, which are 'creatinine', 'age', and 'sex', considered in MDRD calculation also majorly compose the first set of input influence factors for modeling neural network models.

Artificial Neural Network

An artificial neural network (ANN), usually called neural network (NN), is a mathematical model or computational model that is inspired by the structure and/or functional aspects of biological neural networks. Kriesel (2011) indicates neural networks are a bio-inspired mechanism of data processing that enables computers to learn technically similar to human-being brain. The generic structure of ANN is shown in Figure 1 (Nagnevitsky, 2005). A neural network consists of an interconnected group of artificial neurons, and it processes information using a connectionist approach to computation. In most cases an ANN is an adaptive system that changes its structure based on external (input) or internal information that flows through the network during the learning phase. Modern neural networks are non-linear statistical data modeling tools. They are usually used to model complex relationships between inputs and outputs or to find patterns in data (http://en.wikipedia.org/wiki/Artificial_neural_network). It is properly the most prestigious and adoptable model in all application models in the field of artificial intelligence.

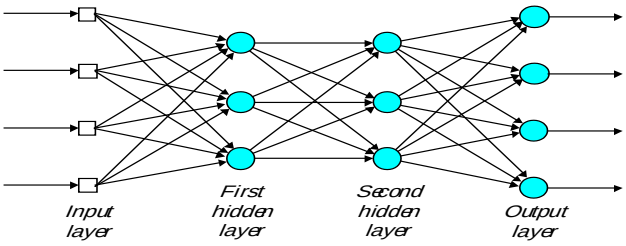

Figure 1: A Generic Structure of ANN.

There are many types of neural network models derived from the generic structure of ANN. Three fundamental neural network models employed for the experiment in this paper are briefly introduced in next sections

Back-Propagation Neural Network

The back-propagation neural network is aslo known as a "feed-forward back-propagation network". It is a supervising learning multi-layer perceptron (MLP) neural network model (Negnevitsky, 2005). A training set of input patterns is presented to the network. The network computes its output pattern, and if there is an error - or in other words a difference between actual and desired output patterns - the weights are adjusted to reduce this error. Since the real uniqueness or 'intelligence' of the network exists in the values of the weights between neurons, we need a method of adjusting the weights to solve a particular problem. It learns by example, that is, we must provide a learning set (or called as training set) that consists of some input examples and the known-correct output (desired output) for each case. So, we use these input-output examples to show the network what type of behavior is expected, and the back-propagation learning algorithm allows the network to adapt. Hence, this neural network is called as back-propagation neural network (BPNN). A three-layer architecture of BPNN is illustrated in Figure 2 (Negnevitsky, 2005).

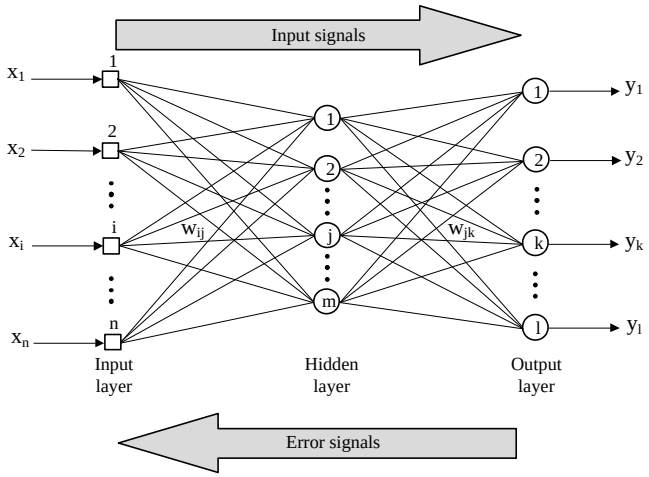

Figure 2: Three-layer Back Propagation Neural Network.

This model is properly the most popular and applicable model in artificial neural network used in academic research and the development practical decision support applications in terms of forecasting, classification, regression, data mining, and so on.

Generalized Feedforward Neural Network

The feedforward neural network was the first and arguably most simple type of artificial neural network devised. In this network the information moves in only forward direction which is simply from the input neuron data goes through the hidden neuron and to the output nourons. There are no cycles or loops in the network where the data flow from input

to output units is strictly feedforward. The data processing can extend over multiple layers of neurons, but no feedback connections are present. Its generalization model, which is konwn as generalized feedforward neural networks (GFNN). It has the same architecture as back-propagation neural network and also adopts the same learning methods to train the network. The differences are that GFNN adopts generalized distributed-flow neurons in its hidden layers and take perceptron as its inhibitory neuron. Arulampalam and Bouzerdoum (2000) mentioned that the GFNN architecture used as the basic computing unit is a generalized shunting neuron (GSN) model which includes as special cases the perceptron and the shunting inhibitory neuron. GSNs were capable of forming complex, nonlinear decision boundaries. This allows the GFNN architecture to easily learn some complex pattern classification problems. Arulampalam and Bouzerdoum (2003) applied GFNNs to several benchmark classification problems, and their performance was compared to the performances of multilayer perceptrons such as a back-propagation neural network. Experimental results show that a single GSN can outperform multilayer perceptron networks. An exemplified architecture of GFNN is illustrated as Figure 3.

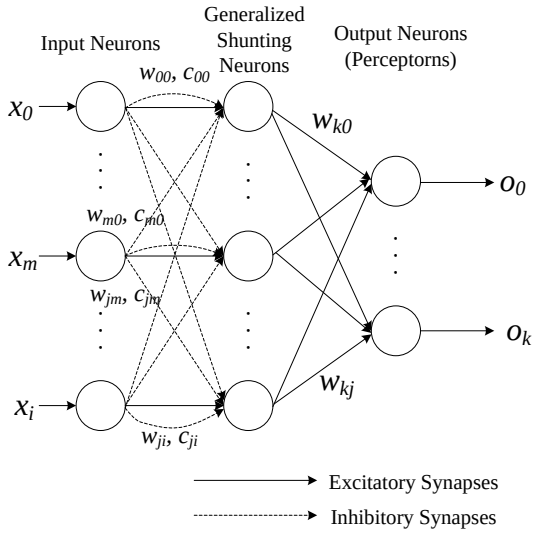

Figure 3: The Generic Architecture of Generalized Feedforward Neural Networks.

Modular Neural Network

The modular neural network (MNN) was initially presented by Jacobs, et al. in 1991 (Jacobs et al. 1991). The architecture of this network is shown in Figure 4. It is characterized by a series of independent neural networks moderated by some intermediary. Each independent neural network serves as a module like an expert and operates on separate inputs to accomplish some subtask of the task the network hopes to perform. The intermediary takes the outputs of each module and processes them to produce the output of the network as a whole (Azam, 2000). The intermediary only accepts the modules' outputs—it does not

respond to, nor otherwise signal, the modules. As well, the modules do not interact with each other. One of the major benefits of a modular neural network is the ability to reduce a large, unwieldy neural network to smaller, more manageable components. There are some tasks it appears are for practical purposes intractable for a single neural network as its size increases.

The following are benefits of using a modular neural network over a single all-encompassing neural network.

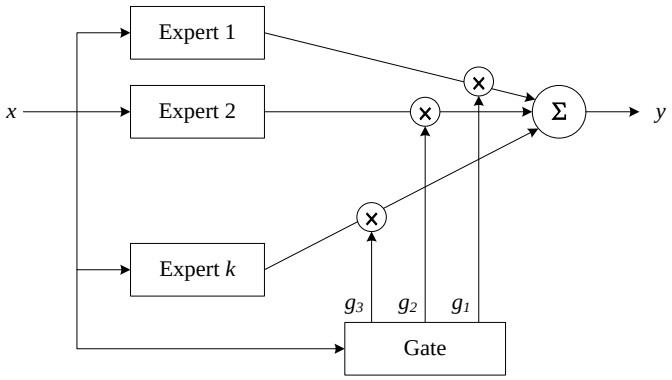

Figure 4: The Generic Architecture of Modular Neural Networks.

RESEARCH MATERIALS AND METHODS

Based on the literature reviews and expert interviews, this research takes three neural network models, back propagation neural network, feedforward neural network, and modular neural network, respectively to generate the detection model for chronic kidney disease. The input data set for neural networks training and testing are collected from the population data of health examination provided by collaborative hospital. The key influence factors input for the each factor Are determined and verified from professional kidney experts and physicians. The set of influence factors derived from GFR computation formulas such as MDRD is shown in Table 4 and another set of key influence factors selected and determined in this paper as the inputs of Neural Networks is shown in Table 5, respectively. The classification performance of two sets input for model training and testing are compared in model experiment.

Table 4: The Influence Factors Derived from Formula Computation for GFR.

Factors	Description	Mean	Maximum	Minimum
Sex	0→Female;1→Male	---	---	---
Age	Integer	77.38	93	67
Creatinine	Real	0.88	4.28	0.37
Weight	Real	60.719	98	32
GFR Levels	0→Negative;1, 2, 3,4,5→Positive measured in levels	---	---	---

Table 5: The Influence Factors Investigated Determined by This Paper.

Factors	Description	Mean	Max.	Min.
Creatinine	Real	0.88	4.28	0.37
Glucose (GLU)	Real	109.63	271	82
Systolic Pressure (SP)	Real	135.78	195	88
Protein in Urine (UP) or called proteinuria	0→Negative 1→Trace; 2→+ 3→++; 4→+++	---	---	---
Hematuria		---	---	---
Blood Urea Nitrogen (BUN)	Real	15.80	80.1	5.4
GFR-Level	0→Negative;1, 2, 3,4,5→Positive measured in levels	---	---	---

The Learning Data and Preprocessing

The input learning data set for neural networks are collected and sampled from the cases of the elderly people with age over 65 years old of health examination provided by collaborative hospital in past few years. The areas of sampled data cover the hospital neighboring cities and counties located in northern part of Taiwan. There are 1161 heath examination case records are sampled. Before they are input for training and testing network models, a data preprocessing is processed to remove duplicate, correct the error, inconsistency and missing fields, numerification of class field in each case record.

By this process, we can ensure the accuracy, completeness and integrity of the input data. After data preprocessing, only 945 sampled cases are left as the use of learning data set. Meanwhile, initially there are 21 fields contained in each source of case record. Only 6 fields specified in Table 5 are selected and maintained for each case.

Model Learning and Experiments

We take NBuilder of neural solution, a well-known neural network modeling tool, to train and test our neural network model through a series of simulations in experiment. In consideration of the tool restriction for building the hybrid model of neural network and genetic algorithm which is also studied in this research, we only take the most accurate 430 cases from 945 sampled cases left after preprocessing in learning process. By this selection, we can ensure there are equal numbers of cases used in the leaning process of each factor Building. As it is shown in Table 6, among 430 cases, 300 cases are selected for training, 100 records are used for testing, and 30 cases for cross verification. The desired output of diagnosis is identified by the professional physicians of chronic kidney disease from the collaborative hospital with the aid of MDRD calculation formula.

Table 6: Data Distribution for Model Training, Testing, and Cross Verification.

Sampled Data	**Record #**	**Desired Output #**
Training Data	300	101 Negative
		199 positive in various levels
Testing Data	100	34 negative
		66 positive
Cross Verification	30	10 negative
		20 positive

EXPERIMENTS AND COMPARISONS OF NEURAL NETWORK MODELS

The experiment for a specific network model can be viewed as a series of modeling and simulation through leaning process. We attempt to pursue a best model through the selection of different combination of modeling parameters for conducting learning in different network models. The parameters combination shown in different model experiments have been filtered from a series of learning process.

The Experiment of Back-propagation Neural Network

Table 7 shows the parameters set for the experiment of back-propagation neural network.

Table 7: Parameters Selected for Back-propagation Neural Network.

Parameters	**Value Setting**
# of Hiding Layers	1、2、3
# of Neurons in Hiding Layer	5、8、12
Learning Rules	Step、Momentum、ConjugateGradient、LevenbergMarquar、Quickprop、DeltaBarDelta
Transformation Functions	TanhAxon、SigmoidAxon、LinearTanhAxon、LinearSigmoidAxon、SoftMaxAxon、BiasAxon、LinearAxon、Axon
Weight Update Methods	Batch
Criterion for Termination	MSE_{min}:0.0001; $Epochs_{max}$:3000

In this paper, we also take the hybrid models of combining each neural network factor And genetic algorithm (GA) in experiment and comparison. The model parameters selected for genetic algorithm are shown in Table 8. GA will be taken to combine with back-propagation neural network, feedforward neural network, and modular neural network, respectively in model experiment and comparison as well.

Table 8: The Parameters Selected for Genetic Algorithm.

Network Parameters	**Value Setting**
Method of Selection	Roulette
Method of Crossover	One Point
Rate of Crossover	0.9
Rate of Mutation	0.01
Termination Criterion	MSE_{min}:0.0001 $Epochs_{max}$:100 Population: 20 Generations：50

Through a series of simulation by taking the different sets of parameter combination selected from Table 7, we gain that the best model of backpropagation neural network in terms of their respective network parameters with respect to two models, which are the factor By adopting the key factors used in computation formula (called as Factor A hereafter) and the factor By adopting the key factors selected in this paper (called as Factor B

hereafter), respectively, are listed in Table 9. The classification accuracy, sensitivity, and specificity with respect to factor A and B, respectively is shown in Table 10.

Table 9: The Best Models with Backpropagation Network Parameters Setting.

Network Parameters	**By Adopting the Key Factors Used in Computation Formula (Factor A)**	**By Adopting the Key Factors Selected in This Paper (Factor B)**
Learning Rule	LevenbergMarquar	LevenbergMarquar
Transformation Functions	TanhAxon	SigmoidAxon
# of Hiding Layer	2	2
# of Neurons in Hiding Layer	5	8
Criterion for Termination	MSE_{min}:0.0001 $Epochs_{max}$:3000	MSEmin:0.0001 Epochsmax:3000
Methods for Weight Update	Batch	Batch

Table 10: The Experiment Results from Backpropagation Neural Network Models.

BPN	**Factor A**		**Factor B**	
Pure BPN	Training	Test	Training	Test
Accuracy of Classification	100%	94.75%	100%	72.42%
Sensitivity	100%	97.06%	100%	70.59%
Specificity	100%	92.42%	100%	74.24%
BPN+GA	**Test**		**Test**	
Accuracy of Classification	91.71%		77.68%	
Sensitivity	97.06%		81.82%	
Specificity	86.36%		73.53%	

In Table 10, “accuracy” is used to measure the classification accuracy with the proportion of the sum of the number of true positives and the number of the true negatives which are correctly identified. “Sensitivity” is used to measure the proportion of actual positives which are correctly identified as such (e.g. the percentage of sick people who are correctly identified as having the condition). “Specificity” is used to measure the proportion of negatives which are correctly identified (e.g. the percentage of healthy people who are correctly identified as not having the condition). These two measures are closely related to the concepts of type I and Type II. From the results shown in Table 10, our experiment may gain very good results with BPN in model training stage but it shows a significant drop

measured in model testing stage both with BPN and BPN plus GA. By the results shown in Table 10, BPN may obtain better results in accuracy measure, but GPN plus GA gain better result in sensitivity measure. The result also shows the model with the adoption of the key factors used in computation formula gains better results in all three indicators measures. These results tell us that a hybrid model with the combination of BPN and GA does not improve the model performance in accuracy measure but it is helpful to improve sensitivity measure.

The Experiment of Generalized Feedforward Neural Network

Table 11 shows the parameters set for the experiment of generalized feedforward neural network (GFNN). The classification accuracy, sensitivity, and specificity with respect to factor A and B, respectively is shown in Table 12. As the results shown in Table 12, pure GFNN obtain a perfect classification percentage in three measures including accuracy, sensitivity, and specificity in training stage, but GFNN plus GA apparently may gain better results in testing. However, they also show the results gained from GFNN are not so good in all three measures as those gained from BPN and BPN plus GA, respectively.

Table 11: The Best Models with Generalized Feedforward Neural Network Parameters Setting

Network Parameters	**Factor A**	**Factor B**
Learning Rule	LevenbergMarquar	LevenbergMarquar
Transformation Functions	SigmoidAxon	TanhAxon
# of Hiding Layer	2	2
# of Neurons in Hiding Layer	8	8
Criterion for Termination	MSE_{min}:0.0001 $Epochs_{max}$:3000	MSE_{min}:0.0001 $Epochs_{max}$:3000
Methods for Weight Update	Batch	Batch

Table 12: The Experiment Results from Generalized Feedforward Neural Network Models

GFNN	**Factor A**		**Factor B**	
Pure GFNN	**Training**	**Test**	**Training**	**Test**
Accuracy of Classification	100%	86.63%	100%	71.03%
Sensitivity	100%	82.35%	100%	61.76%
Specificity	100%	90.91%	100%	80.30%
GFNN+GA	**Test**		**Test**	
Accuracy of Classification	91.09%		78.39%	
Sensitivity	88.24%		76.47%	
Specificity	93.94%		80.30%	

The Experiment of Modular Neural Network

Table 13 shows the parameters set for the experiment of modular neural network (MNN). The classification accuracy, sensitivity, and specificity with respect to factor A and B, respectively is shown in Table 14. As the results shown in Table 13, pure MNN same as prior two models which may obtain a perfect classification percentage in three measures in training stage, but MNN plus GA apparently may gain worse results in testing stage which are different from the results shown in prior two models.

Table 13: The Best Models with Modular Neural Network Parameters Setting.

Network Parameters	**Factor A**	**Factor B**
Learning Rule	LevenbergMarquar	LevenbergMarquar
Transformation Functions	SigmoidAxon	SigmoidAxon
# of Hiding Layer	2	2
# of Neurons in Hiding Layer	4	8
Criterion for Termination	MSE_{min}:0.0001 $Epochs_{max}$:3000	MSE_{min}:0.0001 $Epochs_{max}$:3000
Methods for Weight Update	Batch	Batch

Table 14: The Experiment Results from Modular Neural Network Models.

MNN	**Factor A**		**Factor B**	
Pure MNN	**Training**	**Test**	**Training**	**Test**
Accuracy of Classification	100%	93.23%	100%	70.99%
Sensitivity	100%	97.06%	100%	64.71%
Specificity	100%	89.39%	100%	77.27%
MNN+GA	**Test**		**Test**	
Accuracy of Classification	88.82%		78.34%	
Sensitivity	89.39%		79.41%	
Specificity	88.24%		77.27%	

CONCLUSIONS

The performances of three neural network models developed for comparison in this paper in terms of detection (i.e., classification) accuracy measure are summarized and shown in Table 15 and 16, respectively. Table 15 shows the detection accuracy in three pure (i.e., fundamental) neural network models while Table 16 shows the detection accuracy with GA embedded in three respective models. We found BPNN may obtain best accuracy regardless of in factor A or in factor B which are measured with 94.75% and 72.42% accuracy, respectively in model testing. However, factor A, which is the test by adopting the key factors used in computation formula, may gain much better performance than factor B, which is the test by adopting the key factors selected in this paper. The same result is gained with the GA embedded in each fundamental model in experiment. As the results observed from Table 16, both BPN plus GA and GFNN plus GA gain close results in accuracy measure which is much better than MNN plus GA.

Table 15: Detection Accuracy in Three Pure Neural Network Models.

Network Models	**By Adopting the Key Factors Used in Computation Formula (Factor A)**	**By Adopting the Key Factors Selected in This Paper (Factor B)**
BPN	94.75%	72.42%
GFNN	86.63%	71.03%
MNN	93.23%	70.99%

Table 16: Detection Accuracy in Three Pure Neural Network Models Plus GA.

Network Models	**Factor A**	**Factor B**
BPN+GA	91.71%	77.68%
GFNN+GA	91.09%	78.39%
MNN+GA	88.82%	78.34%

By further observation from the results of model experiment shown in section 4, it is found that almost all models employed in experiment may gain near 100% accuracy in CKD detection in the training stage regardless of which sets of influence factors used in model training. However, if further model testing is conducted, it is found that the network models with the inputs of influence factors of CKD used by physicians employed in the computational formula always shows better detection performance in all three aspects of measure including accuracy, sensitivity, or specificity measures. The BPN gain the highest 94.75% (shown in Table 10 and 15) accuracy measure in the testing stage among three fundamental neural network models while GFNN gains only 86.63% (shown in Table 12 and 16) in accuracy measure which is the lowest performance in three models. Through further observations from experiment results, it is found the hybrid network model of GFNN plus GA embedded may significantly enhance detection performance in all three measures from its fundamental model in the testing although the reversed enhancement are shown in BPN and MNN. Again, by the experiment figures shown in section 4, although pure neural network models plus GA shows degraded performance improvement for factor A in testing stage in terms of three measures in accuracy, sensitivity, and specificity but it shows significant improvement for factor B. As a result, we conclude a hybrid model indeed may improve detection performance. This result may conclude that GA provides no benefit in the yield of better detection performance with the adoption of the key factors used in computation formula as the inputs to all models in testing.

Above all, we conclude that BPN might be the best-fitting factor Among three fundamental neural network models employed in detecting CKD while the models with GA embedded in BPN and GFNN respectively might be best-fitting hybrid models for CKD detection but only GFNN plus GA can gain enhancement in detection performance in both sets of influence factors as inputs. These conclusions should be further verified and compared with other models selected for experiment in later studies before they can be assured.

We believe that the neural network models respectively developed for CKD detection and risk level estimation in this paper may equip medical staff with the ability to make precise diagnosis and treatment to the patient. Meanwhile, public users may take advantage of these system instruments to conduct self-detection of the risk level of causing CKD in order to take necessary precaution in advance to avoid any risk of causing CKD or prevent their condition from getting worse.

ABSTRACT

The purpose of this case study is to create a competitive operative management system to enable efficiency and quality performance in a mid-sized electronic manufacturing company, and the product and service creation process for the globally competitive electrical markets.

Sense and Respond, a multi-criteria decision making method is used as a tool in this study, in order to define the most critical development areas in the business process redesign and quality, especially COPQ (Cost of Poor Quality) point of view.

A qualitative research method with multi-criteria decision making process has been created and utilized in order to collect data through in-depth expert interviews. The performance measurement and improvement system developed has been implemented into practice in the case company.

Keywords: performance management, multi-criteria decision making, competitiveness, quality, electronics manufacturing industry, production, product and service creation.

INTRODUCTION

The purpose of this study is to find the most critical areas of the quality development needing improvement. Quality in this study is considered as a companywide examination, all main processes and main functions are covered.

The Case organization had recognized a need for an investigation of the process re-engineering concerning customer closeness and COPQ (Cost of Poor Quality) issues. Another matter that organization had considered was the role of the functions in relation to the key processes and also how well the current key processes correspond to the current way of action.

The research theory is based on the method introduced by Takala and Rautiainen and later Ranta and Takala, providing a tool to measure and indicate the most critical development areas. The method measures responder's expectations and experiences of quality and process related issues. Difference between expectations and experiences together with the deviation of the answers determines the so called critical factors index. The critical factor index calculation is utilized by the methods presented later in this study. The critical factor index indicates the most critical areas that need further development and respectively

indicates also areas that have enough actions. A questionnaire has also a part where the direction of the development is measured and this information is taken into account in a statistical calculation. Also the direction of the development of individual aspects is taken into account (Rautiainen, Takala, 2003; Ranta, Takala, 2007).

The data regarding the current situation of quality and process was collected through interviews with the case-company's employees. People of the organization that took part in the questionnaire, have been chosen on the principle that they represent either management function or expert function. The case-company, ABB Oy, Distribution Automation Finland (ABB/DA/FI), is a company which provides numerical protection relays for international markets wordwide.

The results of the research identify critical development areas of the organization. The results are not unambiguous and require interpretation. The results of the study have been considered through the experience of responders, the view points between different groups of responders and also the answers between different groups.

CUSTOMER SATISFACTION AND QUALITY STRATEGIES FOR THE ELECTRONIC MANUFACTURING BUSINESS

Numerical Protection Relay are considered as Intelligent Electronic Device (IED), which consists of electronics parts, such as analog and digital input and output device, large scale of different communication modules and intelligent software. An IED is placed in an operational usage part of a larger electrical distribution network or power systems in order to measure and control operations in a way that all abnormal situations are controlled according to pre-programmed parameters and intelligent software control (ABB, 2011).

ABB's Relion® product family consists of several product series, which cover a wide range of protection, control, measurement and supervision of power systems (ABB, 2011).

Quality is one of the key stones in the Electronic Manufacturing Business. The competitive advantage of a company depends on the quality of the manufactured IEDs, design of electronics and software of the IED, and the interface between other parts of the electric power network or power system devices (ABB, 2011). The Certified Quality Handbook categorized quality in Management and Leadership, The Quality System, Product and Process Design, Product and Process Control, Continuous Improvements and Quantitative Methods and Tools (Kubiak and Benbow, 2008). Quality is a diverged concept in a general point of view. Sometimes a simple question of "what is quality" is presented. Nowadays customer satisfaction is one of the paradigms that drive company actions. The research results indicate that quality conformance has a significant impact on the customer satisfaction (Maiga, 2004). Based on this, quality would be defined as follows: Quality is defined through customer's satisfaction. Kumar (S C Chen) & al represent in their article that a better customer satisfaction and business profit can be achieved by the high level product design, effective manufacturing and high level of service quality (Kumar et al 2009, 3). Gordon writes in his article as follow: "*Product delivery is the culmination of all of the business processes, and output is a measure of system capability*"(Gordon, 2008, 2). This has

to be taken into account during optimizing of all processes instead of falling for sub-optimization.

Quality Tools serve many kinds of purposes. The case company has recently focused on the 4Q and 5S quality tools. 4Q is a problem solution tool, which brings a systematic way of actions in quality improvement. 4Q is an ABB internal quality tool which is quite close to the Deming PDCA –circle. The 4Q method consists of a four step circle: Measure, Analyze, Improve and Sustain (Praveen 2006). 5S is a systematic quality tool that consists of five stages following each other: 1. Sorting 2. Simplifying 3. Self-discipline 4. Sweeping and 5. Standardizing. The case company has a whole organization wide systematic implementation of the 5 S tool (Becker, 2001).

Total Quality Management is considered here as a company wide way of actions in all level of organizational actions. Definition for the Quality management according to the Enterprise Performance Management (2009): *"A management system that seeks the efficient achievement of the stakeholder expectations by focusing the efforts of every member of the organization on customer satisfaction and by using quality techniques in each of the sub - systems of the organization"* (EPM, 377).

Total Quality Management has two functional levels, a strategic and an operational level, and a third tactical level between. Based on "A Grounded Theory Research Study of Strategic Dynamics of Total Quality Management" (Leonard and McAdam, 2002; Leonard and McAdam, 2003), it can be founded on the above mentioned strategic drivers model for Total Quality Management, which is presented in Figure 1.

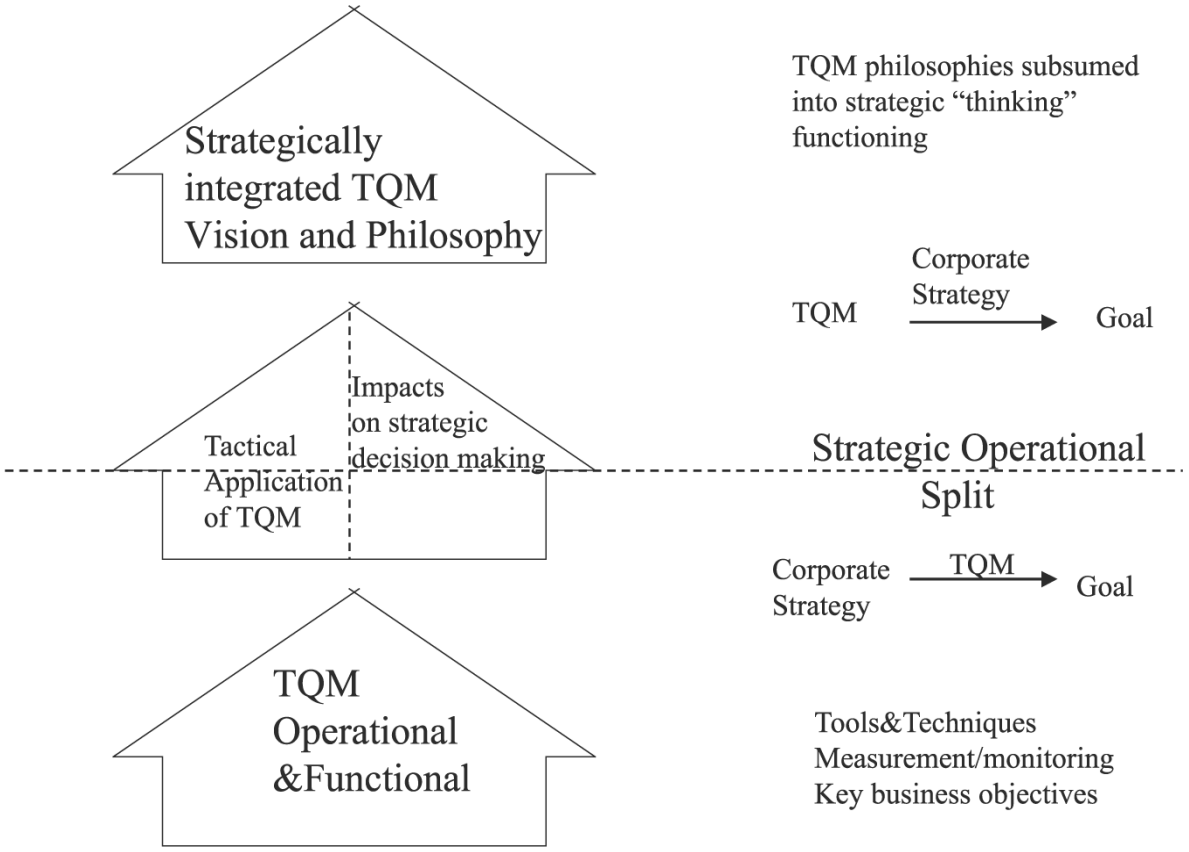

Figure 1: Strategic driver model for Total Quality Management (Leonard, McAdam, 2003).

Total Quality Management is basically a wholeness of how organization has organized its operations at the strategic level, for example a guideline of a matrix organization, where all the core actions of the company management are defined. Leonard and McAdam have defined a term “An Evaluative framework for TQM dynamics”, where the effect and dynamics of TQM in the organization are analyzed (Leonard and McAdam, 2003). Quality Management practices have a positive influence on the customer satisfaction, removing barriers between the individuals and departments, ensuring the company to achieve better productivity and business performance (Terziovski, 2006, 9). Markku Tinnila considers in his article the difference between Quality Management and Business Process Redesign. He argues that they both tend to improve efficiency and quality. Quality management improves through the TQM activities that company has, while Business Process Redesign covers also the definition of new ways of actions that have not been taken into account before (Tinnilla 1995, 4).

Business Process Redesign (BPR) is performed in order to achieve considerable improvements in the performance (Kallio et all 2002, 1). BPR has to be performed in an integrative and holistic way. Important aspects are processes, technology, organization structure, relationship and culture. The BPR definition is not unambiguous. There are different aspects of BPR. Some authors prefer more the customer aspect focusing on activities to provide adding value for the customer, while others prefer more process and measures of the activities varying according to the business area and the specific situation of a company. (Al-Mashari et all 2001, 1-3; Hustic 2009, 1-2). Tinnila emphasizes the importance of Information Technology (IT) as an enabler of the strategic planning and observation of the potential of BPR. The notion of functional departments and processes similarities is seen as an obstacle in the BPR performing (Tinnila 1995, 1).

When considering BPB activities, the company has to define, which particular part of the business process needs renewal and further more, what method should be used. It is quite common that the company has to resort to some external consultation (facilitator) during the BPR activities. The methods used during the consultation are based on experience or wisdom of best practices of the consultation partner (Mansar et all 2007). According to the article of Tom Dolan, benchmarking is the most common tool in the process improvement. Among other popular methods are cause and effect, analyze, change management, control charts and decision making. Besides the suitable methods, the company has to identify the main problem and how it effects matters such as customer satisfaction, employee involvement and financial returns. More significant issues in BPR are a visible top management support, effective and working cross functional team with enough wide representation of different parts of the organization and effective communication in all levels of the organization (Dolan et all 2003, 1-4).

When considering BPR in order to increase the company competitiveness, BPR has to be directed towards the strategic position. According to Si *et al.* (2008), quality, customer focus and know-how are the three most important factors of the competitive priorities of manufacturing strategy. (Si et al 2008, 4). According to the authors, there are four fundamental processes: technical, innovation, enabling and social, on which the company has to focus during business process re-engineering or redesign (Tinnilla 1995, 2).

Process organization is considered in this study as a business process, a companywide way of actions. The process in this case is defined as follows: Activity process is a group of logical operations and recourses to perform these actions in order to create results of the activities (Laamanen 2001).

Customer closeness is considered as well one of the key success factors during improving quality. Especially this has to be taken into account when a new expedient has to been found in order to find a way of action to improve ability to create added value for the customer. When considering the similarity between TQM, Six Sigma and Lean, one common denominator is customer satisfaction. All of these viewpoints tend to increase customer satisfaction by minimizing waste and resources (Andersson et al, 2006, 2-4).

BUILDING THE METHOD

The research method is mostly a case study in order to focus in one case company, but it also has the features of empirical, weak market test and constructive methods. Empirical material based on the questionnaire performed in the case company. The weak market test features represented by the question of how the implemented research methods suit to define the efficiency and quality performance for a company in a mid- sized electronic manufacturing business. A constructive method in this study represents the performed research method "Sense and Respond multi-criteria decision making". The method used is performed in the same format as in earlier study in the literature, and this study does not contain any new application of the above mentioned research method.

The research theory is based on a method introduced by Rautiainen and Takala, which is a tool to measure the quality of service. Based on the calculated percentage values compared with competitors and direction of development, it measures expectations and experiences of the organization performance. The gap between the expectations and experiences, the direction of development and importance are calculated. Importance index measures the importance and pressure to improve (Rautiainen, Takala, 2003; Ranta, Takala, 2007).

The tools contain several indexes calculated from the results of the questionnaire. These tools are used to gain a more overall interpretation of the results. The research method includes averages and standard deviations calculation for all the measured attributes of the expectations and experiences. Standard deviations help to evaluate the validity and reliability of the results. Percentual figures are calculated from direction of the development and compared with competitors. Ranta and Takala have developed the Critical Factor Index (CFI). This index takes also the standard deviation of the expectations into account. The factors in the devisor are Importance index, which are the average of importance divided by ten, Gap index which measures the gap between the expectations and experiences and the Direction of development index (Rautiainen, Takala, 2003; Ranta, Takala, 2007).

$$CFI = \frac{\text{standard deviation of expectation} * \text{standard deviation of experience}}{\text{Importance index} * \text{Gap index} * \text{Direction of development index}}$$

Figure 2: CFI, Critical Factor Index (Rautiainen, Takala, 2003).

The first step of the used research method was to create a questionnaire that gathers the responder's opinions. Each attribute was evaluated in four different ways: expectation, experience, compared with competitors and direction of development compared with time scale of 1 year and 2 years ago. To ensure that the reliability and validity was high, the questionnaire was short, clear and easy to answer. The more comfortable the questionnaire is to answer, the more reliable and valid the answer is. Rautiainen & Takala used a simple numerical estimation scale ranging from 1 to 10. The wide scale ranging from 1…10 makes it easy to find differences between the attributes. Figure 3 introduces how the information was gathered (Rautiainen, Takala, 2003).

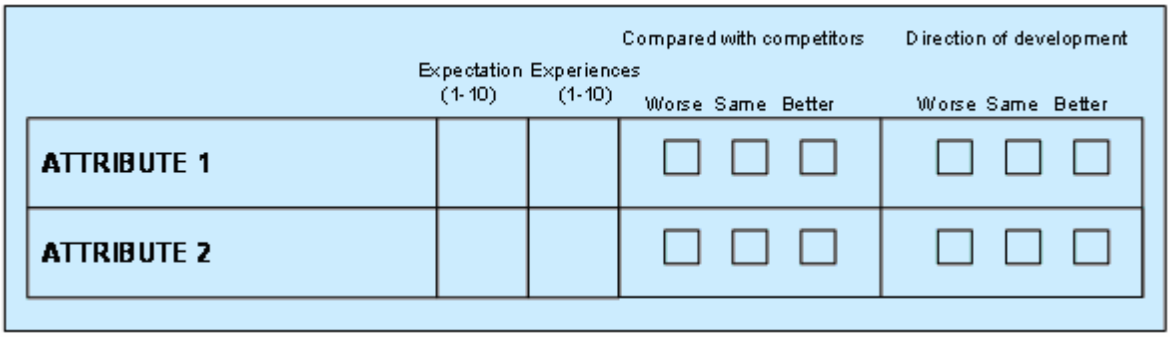

Figure 3: Questionnaire (Rautiainen, Takala, 2003).

The Attributes were categorized under four main categories: Process Capability with nine attributes, Product Capability with six attributes, Personnel Capability with five attributes, and Measures KPI's current status with nine attributes, all together 29 attributes. The four main categories mentioned represent the research area of the study. The questionnaire was executed via email by using an Excel form especially created for this purpose.

RESULTS

The questionnaire was directed to the experts and management for the following functions: Management, Operations, R&D department, Product and Portfolio Management, Sales & Marketing, Customer Support and Other Management. The questionnaire was delivered to 48 persons and 24 answers were received. The questionnaire was delivered by email. Answers' reliability would be increased by a personnel interview instead by sending it by email and this has to be considered in future for similar questionnaire. The answers are divided in to subgroup as follows (answers got / answers sent): Management 4/7, Operations 4 / 7, R&D 5 / 11, Product Portfolio Management 3 / 6, Sales&Marketing 2 / 8, Customer Support 4 / 8 and Other Management 2 / 8. Due to the partly low scope of the answers, Sales&Marketing and Other Management departments are left out of the department specific study. The scope of the rest department is also low, so only an indicative conclusion can be done whereas group all (24 / 48) has enough scope and statistical conclusions to be reliable.

95 % confidential level has calculated from all results according Table 1.

Proc#1	Experiences	5,86	< P(n) <	7,32		Expectations	8,59	< P(n) <	9,41

KPI#9	Experiences	7,40	< P(n) <	8,42		Expectations	6,47	< P(n) <	8,34

Table 1: 95 % confidential level for all the answers.

Experiences variation min value is 1,80 and max value is 1,87 while Expectation variation min value is 0,30 and max value is1,87 which are calculated according to Student's t-distribution.

All together the questionnaire consists of 29 questions categorized in four groups: Nine questions about the process, six questions about the product, five questions about the personnel, and nine questions about Key performance Indicators (KPI). The period of the question direction of the development and compared with competitor was considered in a time scale of two years; one year and two years ago. Time scale defining was based on the quite rapidly changing situations and the turbulent electronics manufacturing business.

Compared with competitors section, only our own personnel were asked, and therefore, it represents only an estimation of the customers' way of thinking. Due this limitation, the study sets more value on other parameters.

Table 2 shows the preliminary results analyzed by the methods introduced in this study.

	Avarage of the Expectations (1-10)	Standard deviation of the Expectations	Avarage of the Experiences (1-10)	Standard deviation of the Experiences	(2)Direction of development index

Table 2: Experience figures.

The following represents some findings about above preliminary analysis. Critical values of the experiences indicated in red color hit on the following groups: Process two, Product one and one in Personnel group. Respectively the experiences on a good level are indicated in yellow: two in Product and the rest four yellow signs are in the KPI group. The conclusion of this is that the experience of KPI is seen to be on a good level. The process group needs some improvements and the group Product needs to be considered with further analysis because it has both red and yellow sign values.

Some more consideration are done according to the results in Table 3, where the left part of the Table 3 represents an Average of the Experience and the right side represents the result of Critical Factor Index (CFI). The results are represented from sub-groups Management, Operations, R&D, Product Portfolio Management, Customer Support and group All.

	Average of the Experiences							Critial Factor Index CFI

Table 3: Average of experience and the Critical Factor Index.

The left part of the Table 3 represents the results of an Average of the Experience. Most of the red areas are on the process group with four red sign items and the personnel group with three red sign items. According to this finding, a conclusion can be made that Process and Personnel groups need corrective actions. The yellow sign of the groups Product and KPI indicates that respondents' experiments are on a good level.

The CFI values in the right side of the Table 3 are more disassembled. Dissection results of the lowest part of the Table 3 (KPI-values), it can be done at least to findings. First, the CFI results at the right and lower part of the Table 3 are quite opposite to the experiences at the left and lower part of the Table 3 where experiences results were in a good level meanwhile the CFI values include a lot of red values. Secondly, the upper part of CFI indicates also some red attributes, but also some yellow signs which represents a good result. The results have to be analyzed more analytically.

KPI#5	0,89	0,90	0,95
KPI#6	0,70	0,89	1,47
KPI#7	0,68	0,88	1,94
KPI#8	0,94	0,80	1,67
KPI#9	0,50	0,74	6,89

Table 5: Direction of development index, Importance Index and Critical Factors Index (CFI).

The direction of the experience development index has only two values where the index indicates the worse development direction (Process #8 and Personnel #3), all other indicate to remain on the same level or to improve. The Importance Index indicates that Prod #3 with value 0,99 and KPI#2 with value 0,97 has more importance than other.

Finally the most potential development areas can be nominated according to the indication by CFI: Product group on one, item Prod#3 and KPI group four items: KPI#2, KPI#3, KPI#4. KPI#5.

The nominated most critical items are represented also on Figure 4 with red color and the respectively items in good situation are with yellow –color.

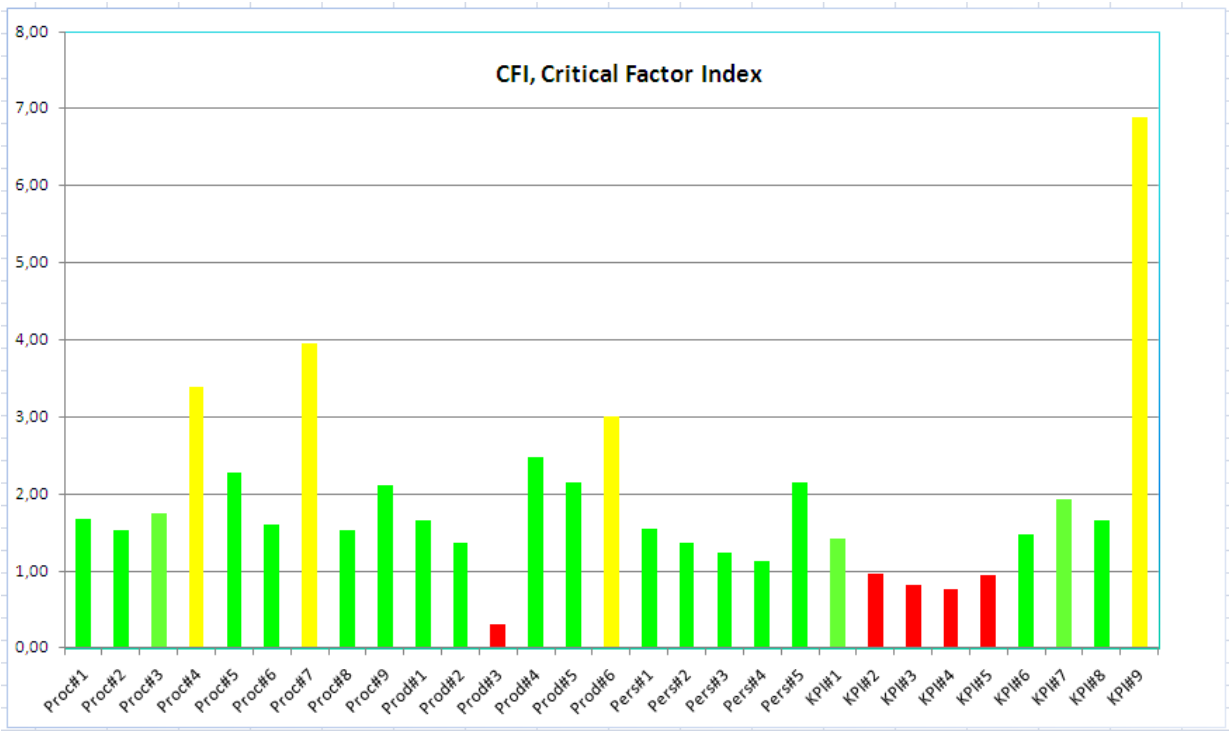

Figure 4: Results of Critical Factors Index.

UTILIZATION AND EVALUATION OF THE RESULTS

The evaluation of the weak market test question is how the method describes the development areas as expected. As mentioned, the study has some limitation on how much value can be set on the customers' way of thinking. Due to this limitation, more value has been set on the average of the experience, the direction of the development index and finally, in the CFI index.

The empirical material has partly low scope, especially with Sales & Marketing (two of eight responders) and Other Management (two of eight responders). Due to this limitation, only the results from Management, Operations, R&D, Product Portfolio Management and Customer Support departments are used in the analysis.

The Sense and Respond method has been basically used as in earlier studies. This study contains more comparison between the questionnaire groups and also between the departments. Also the answers received from the questionnaire have been tested by Student's t-distribution and 95 % confidential level has been calculated.

The differences between the different groups of organization on average of the experience and Critical Factor Index were large. One reason for the gap might be that different functions of the company are working independently. Actually the results from the business process re-engineering workshops performed in the company support thinking of this kind of way (the workshops are not presented in this study).

The used Sense and Response research method identified the most important attributes which indicated low CFI values. Concerning the CFI and average of experience as most important result of the study, the study indicates the most critical development areas as written above based on information of Table 5 and Figure 4.

The major managerial implication of the study has been to specify the guidelines of the process redesign activities in the case company. Also the implemented study provided important information about essential themes, such as quality and customer closeness.

CONCLUSIONS

The focus of the questionnaire was very large and it gave a general view of the organization's status regarding its capability in general. The case organization had recognized a need for to investigate quality improvement actions. A fundamental way to perform the actions was an idea to improve performance by doing process redesign activities. The theoretical review at the beginning of the study gave fundamental information about Quality, Quality Tools, Total Quality Management, Business Process Redesign, Process Organization and Customer Closeness. Together, the empirical part of the study is based on the research on the Sense and Respond method.The theoretical review on the necessary areas gives a source of information for the case organization to go further with the business process redesign activities. The practical importance of the study delivers important information for Process Redesign in order to streamline the processes. Secondly the company has also set a target to increase registration and follow up of the COPQ expenses.

A further study is to investigate and perform Business Process Redesign activities based on these study and separately performed process workshops. After the Business Process Redesign activities have been taken into effect, it is recommendable to perform a Sense and Respond follow-up study. During the follow-up study it would be possible to take the improvements presented in this study into account.

AGENT-BASED MODELING OF THE SOFTWARE INDUSTRY STRUCTURE IN JAPAN: PRELIMINARY CONSIDERATION OF INFLUENCE OF OFFSHORING IN CHINA

Dr. Yasuo Kadono*, Tokyo University of Technology, Japan
kadono@media.teu.ac.jp, *corresponding author

ABSTRACT

This study aims at the preliminary assessment of the future software industry structure in Japan from the viewpoint of the influence of offshoring in China based on surveys on software engineering capabilities of Japanese IT vendors with the Japanese Ministry of Economy, Trade and Industry. Through the agent-based simulation model mainly focusing on customer's price preference and communication quality with customers, Japanese vendors can possibly lose their share of the market if Japanese customers prefer the lower prices offered by offshore vendors. The results suggest that Japanese vendors should improve their communication skill to realize the customer's requirements for the quality of enterprise software while avoiding the cost competition with the Chinese vendors and considering the customer's price preference. Otherwise, some Japanese vendors within the current multi-layered software industry culture will not survive in the drastically changing Japanese market.

Keywords: software industry, agent-based modeling, innovation

INTRODUCTION

The information service industry in Japan is a 10.5 trillion yen market, which includes 7.6 trillion yen in software development and programming. In 2009, orders for software totaled 6.4 trillion yen and accounted for 60.3% of the entire information service industry, while the market for software products was only 1.2 trillion yen (Ministry of Economy, Trade and Industry, Japan, 2010).

However, software vendors in Japan are facing drastic changes in their business environment due to technology innovations and new entrants from emerging countries, such as China, India, and others, despite domestic Japanese software industry has been showing low growth. Also, the issues in the IT industry in Japan, such as the multilayer subcontractors and the business model depending on custom-made applications for domestic market orientation, have been pointed out over times (Cusumano, M., 2004; Kadono, Y., 2007). The multilayer subcontractors industry structure implies the posibility of the growth accelleration of software development offshoring in China and other countries.

In fact, the offshore software development market has experienced high growth: 63.6 billion yen in 2005, 103.5 billion yen in 2007 and an expected 199.5 billion yen in 2010. In 2007, 36.8% of Japanese software development firms developed software offshore to reduce costs and to complement Japan's 80% deficit of domestic human resources. In 2005, the offshore development in China was 53 billion yen, accounting for 83.5% of the entire offshore

development for Japan (Kondo, 2009; Ministry of General Affairs, Japan, 2007).

Compared to Japan's 10.5 trillion yen market, the information service industry in China is still lower at 9.3 trillion yen, but has been growing by more than 20% annually since 2002. The export of software from China was 3.6 billion dollars (approximately 396 billion yen) in 2005 and has been growing by over 30% annually since 2002 (Kondo, 2009; Ministry of General Affairs, Japan, 2007). Therefore, new entrants from China entering into the Japan market are becoming a threat to Japanese domestic software vendors (Porter, 1980).

OBJECTIVES AND METHOD

The focus of this study is an assessment of the market shares in Japan of Japanese and Chinese software vendors and the conditions for sustaining the competitive advantage of Japanese vendors in the similar situations to the current software industry in Japan based on a survey on software engineering excellence (SEE) in 2005, 2006 and 2007 with the Japanese Ministry of Economy, Trade and Industry. In the survey, we collected data of software engineering and competitive environment from 233 IT vendors in Japan totally (Kadono et al. 2006). The assessment is conducted through an agent-based simulation that is an extension of the Sugarscape model (Epstein and Axtell, 1996; Kadono et al., 2002; Yamakage, 2007) under the condition that the price preference of Japanese software customers is changing.
In this paper, we assume Japanese and Chinese vendors to be agents and set parameters such as communication levels, service levels, switching cost and price preferences. Also, we assume that Japanese vendor can outsource projects only to another Japanese vendor under certain conditions.

Then, we model the following two scenarios considering the above situations:
- customers prefer the communication level and the price level simultaneously, and
- customers prefer the price level over the communication level, which directly influences the quality of the software.

SIMULATION MODEL

Agents and parameters

In this paper we assume the agents are Japanese vendors, Chinese vendors, and customers. The following parameters are set based on the current situations of the Japanese enterprise software service industry (Kadono, Tsubaki, Tsuruho, 2006; Kadono, 2007; Kadono, Tsubaki, Tsuruho, 2009; Kadono, Imanishi, 2011).

- Japanese and Chinese vendors
  - Number of vendors: Japanese vendors are in the majority in the current Japanese market.
  - Improvement of communication level: Chinese vendors have increasingly improved their communication levels to meet the requirements of Japanese customers.
  - Improvement of price level: Japanese and Chinese vendors reduce their prices to

meet the requirements of Japanese customers.
  - Switching cost: Chinese vendors need to pay more initial cost for new customers.
  - Outsourcing scope of Japanese vendors: Japanese vendor can outsource their projects only to another Japanese vendor, although Chinese vendors cannot outsource their projects to the other vendors.

- Customers
  - Number of customers: sufficient software customers exist in the current Japanese market.
  - Desirable communication level: Japanese customers take into account the communication level of Japanese vendors.
  - Preference of low price: Japanese customers also take into account the price.

Algorithm

In this agent-based simulation, the agents of Japanese and Chinese vendors and customers are distributed randomly on a 50x50 matrix, as shown in Figure 1. The mobile direction of each vendor agent is randomly set. Each vendor agent moves one cell per time step based on the following algorithm until either the Japanese or the Chinese vendors monopolize the market or until the time reaches the certain limit steps.

Step 1: A vendor agent moves by one cell randomly.
Step 2: The vendor successfully makes a contract if encountering a customer whose requirements of communication level and price meet the vendor's offering.
Step 3: If the Japanese vendor make a contract, it can outsource the project to another Japanese vendor within accessible distance from the Japanese prime contractor.
Step 4: The vendor improves its communication level depending on the parameter of improvement of the communication level. Also, the vendor reduces the price depending on the parameter of improvement of the price level if the vendor cannot get the customer to agree to a contract.
Step 5: The market share is updated depending on the contracts completed by the Japanese and Chinese vendors.

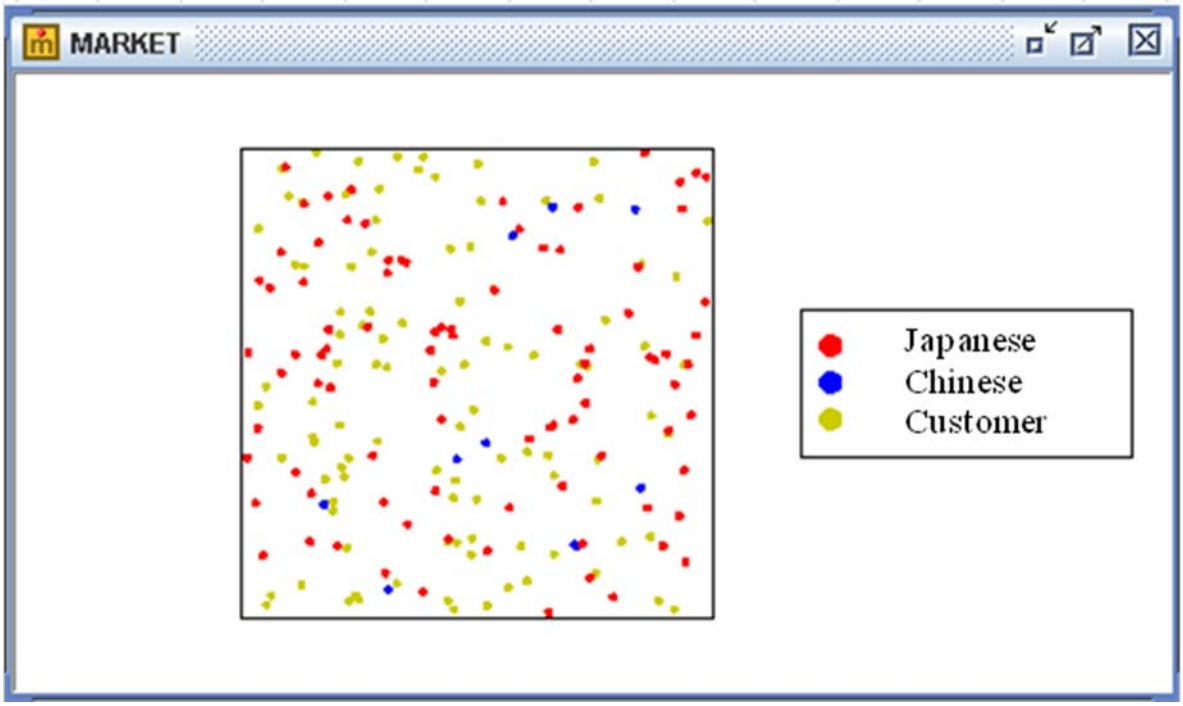

Figure 1: Market in the agent-based modeling
Japanese vendors (read circles), Chinese vendors (blue circles), and customers (yellow circles) on the market (50x50 matrix).

Simulation conditions and parameters

We assume the following two conditions regarding the communication levels and the prices of software development:

1. Customers seek the communication level and the price simultaneously, i.e.,
   A customer contracts with a vendor if the communication level of the vendor >= the communication level the customer requires + the switching cost, and if the price level of the vendor >= the price level the customer requires + the switching cost.
2. Customers prefer the price level to the communication level, i.e.,
   A customer contracts with a vendor if the price level of the vendor >= the price level the customer requires + (the communication level the customer requires – the communication level of the vendor) * (2 – the price preference of the customer) + the switching cost. The price preference of the customer is defined as more than 0.1 and less than 0.9.

In terms of the simulation parameters of the Japanese and Chinese vendors, based on the current industry situations, we assume the number of agents, communication level, price level, switching cost, price reduction and communication level improvement are as shown in Table 1. Also, we assume the number of customers is 100 and the preference of price is 0.8. And, the outsourcing scope of Japanese vendors is 3, while the outsourcing scope of Chinese vendors is not applicable (NA).

Table 1: Basic parameters.

	Japanese vendor	Chinese vendor
Number of vendors	90	10
Communication level	10	7
Price level	7	10
Switching cost	0.1	0.2
Price reduction (%)	0.02	0.04
Communication level improvement (%)	0.005	0.005
Number of potential customers	100	100
Customer's preference of price	0.8	0.8
Outsourcing scope	3	NA

RESULTS

First, we investigated the following two cases using basic parameters in Table1.

Case 1: the simulation with condition 1 (customers seek the communication level and the price simultaneously). The results are shown in Figure 2.

Case 2: the simulation with conditions 1 and 2 (customers prefer the price level over the communication level). The results are shown in Figure 3.

In Figures 2 and 3, the horizontal axis indicates one-tenth of the number of simulation steps and the vertical axis indicates the share of the market by the Japanese and the Chinese software vendors.

In Case 1, the Japanese vendors keep a more competitive situation than do the Chinese vendors until the end.

In Case 2, the share of the Chinese vendors remains 7% until the 1,650th step, begins to increase at the 1,650th step and the 2,100th step, then overcomes the Japanese vendors, and finally dominates the market. This means that Japanese vendors possibly lose their market share if the Japanese customers increasingly prefer the lower price.

These results suggest that Japanese vendors should improve their communication skill to realize the customer’s requirements while avoiding the cost competition with the Chinese vendors considering customer’s price preference. Otherwise, some Japanese vendors will not survive in the Japanese market.

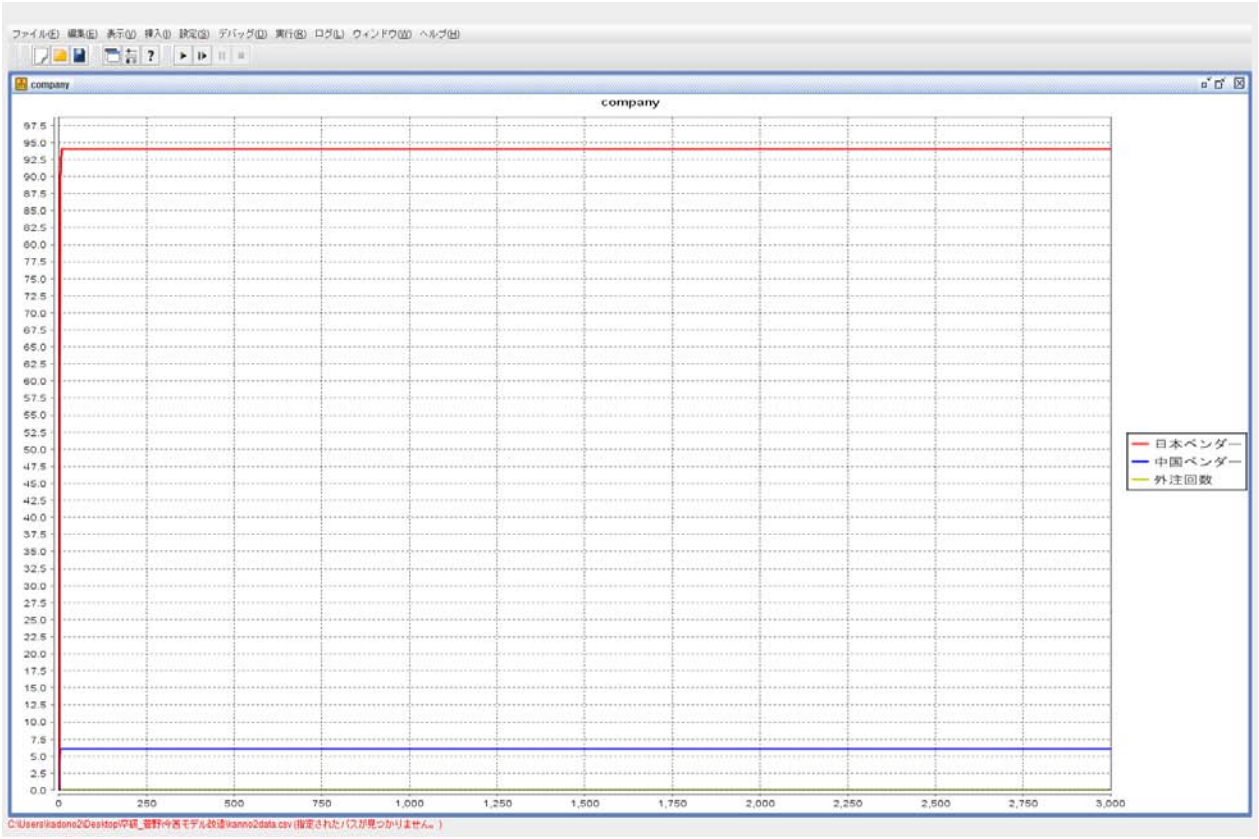

Figure 2: Result of Case 1 with parameters in Table 1.
Vertical axis: share of market of Japanese vendors (red line) and Chinese vendors (blue line).
Horizontal axis: simulation steps*1/10.

Figure 3: Result of Case 2 with parameters in Table 1.

Second, we performed the preliminary analyses in Case 2 with different parameters from those in Table 1, such as the number of Chinese vendors, the Japanese price level, scope of outsourcing from Japanese vendors to Japanese vendors.

For example, even if the number of Chinese vendors is 2 and the number of Japanese vendors is 100, Chinese vendors result in overcoming the Japanese vendors if Japanese price level is 5 (Figure 4). On the other hand, if Japanese vendors improve their price level up to 8, Japanese market reject one Chinese vendor and Japanese vendors dominate the market (APPENDIX: Figure 5).

Figure 4: Result of Case 2 with parameters: Chinese vendor = 2 and Japanese price level = 5.

Another case is shown in Figure 6 (APPENDIX), where both of Japanese and Chinese price levels are 8 and the Japanese outsourcing scope is 9. In the case we can observe that Chinese vendors are revitalized after decreasing its share of market until around the 100th step.

Furthermore, we can observe several phenomena with various combinations of vendor's parameters in Table 1, such as number of vendors, communication level, improvement of communication level, price level, improvement of price level, switching cost, outsourcing scope not only for Japanese vendors but also for Chinese vendors. Regarding the parameters of customers, we can further consider the number of customers, desirable communication level of customers, preference of price, and other parameters.

CONCLUSIONS AND DISCUSSION

This study constructed a simplified agent-based simulation model to preliminary estimate the tradeoff between the communication skill and the price of Japanese and Chinese

software vendors. Based on the results of the agent-based simulation, Japanese vendors could lose their share of the market if the Japanese customers increasingly prefer the lower price. Consequently, to survive intense global competition, Japanese vendors must enhance their communication skill to improve their software outcome and simultaneously enhance the cost competition with Chinese vendors.

In this paper, our focus was assessing the influence of future offshore development on the Japanese enterprise software service industry, particularly in relation to Chinese software vendors. However, the software vendors in Japan are facing drastic changes in their business environment due to technology innovations and new participants from emerging countries, including China, into the low-growth Japanese domestic software industry. In order for the software industry in Japan to meet these challenges, an important step is also to evaluate the significance of the software engineering capabilities for achieving medium- and long-term success.

Therefore, we designed surveys on software engineering excellence (Barney, 2007; Bollen, 1989; Carnegie Mellon University; Fujimoto, 2003; Matsumoto, 2005; Ministry of Economy, Trade and Industry, Japan, 2010) and administered them in 2005, 2006 and 2007 with the Ministry of Economy, Trade and Industry, Japan (METI) (Kadono et al. 2006). By surveying the previous papers on the types of Japanese software vendors (Kadono et al. 2009), we found that the software maker-turned-vendors tend to significantly expand business with well-resourced R&D, while the user-turned-vendors seem to depend heavily on the demand of the parent companies. Therefore, some of user-turned-vendors are thought to gain inimitable capabilities. In contrast, many of the independent vendors serve as non-principal contractors that supply people without specific strengths as temporary staffing in a multi-layer industry structure. However, some of the independent vendors with inimitable assets are thought to be the role models of software vendors in Japan. Based on these results, for future study, we suggest considering the relationship between the types of Japanese software vendors and the key factors to the success of offshore software development.

Also, in order to model the current and future structures of the software industry in Japan, we developed another agent-based simulation model that was an extension of the Sugarscape model (Epstein and Axtell, 1996; Kadono et al., 2002; Yamakage, 2007). The model consisted of software vendors with variations in their scale, innovation adoption and outsourcing ratio. In the model, we assumed that the market would follow the innovation cycle of technology for mainframe computers, client servers, Web applications, cloud computing services, and so on, and that the larger software vendors would tend to invest more in the technology innovation and outsource more jobs to the smaller software vendors in a multi-layer industry structure (Kadono, Terano, Ohkuma, 2010).

For the investigation, we set the following three scenarios. In each scenario, we continue to pursue the conditions and parameters of availability through the agent-based simulation model.

- Survival by size and skill: the big software vendors grow increasingly due to their resourceful staffs and skills based on the scale merit and the scope merit, whereas the small/medium-sized software vendors do not survive without catching up with the rapid

technology innovation. As a result, the software industry structure in Japan will consist of a smaller number of players with clear characterizations of their scale or special skills.

- Reciprocal relationships: all types of the current players survive by outsourcing the jobs from the big (medium-sized) software vendors to the medium-sized (small) software vendors in the current multi-layer software industry structure. Particularly, the small software vendors will not survive without outsourcing from the big (medium-sized) vendors.
- Reverse phenomena: some medium-sized technology-oriented vendors outpace big software vendors who tend not to invest as much in technology innovation.

Based on the above scenarios, we suggested that future studies be conducted on the following: interactive behaviors among software vendors, e.g., a project-based alliance and a merger and acquisition (M&A); influences of offshore developments and new participants on the Japanese software industry.

Finally, to expand this paper, we would integrate findings in the above papers regarding the types of Japanese software vendors and the Japanese software industry structure into this paper, and assess the future Japanese software industry structure in relation to China, India, the U.S. and the rest of the world.

AN EMPIRICAL STUDY OF THE RELATIONSHIP BETWEEN INTELLECTUAL CAPITAL AND THE PERFORMANCE OF A MANUFACTURING FIRM

Narongsak Comepa, Kasetsart University, Thailand

Kongkiti Phusavat, Ph.D., Kasetsart University, Thailand

ABSTRACT

Introduction—*The competitiveness of a country's manufacturing sector is critical to its long-term economic prosperity and growth. The manufacturing sector creates a sustainable economic in country. A strong manufacturing sector also encourages a country's intellectual capital and innovativeness, underwriting research and development, pushing the technological envelope, and driving the growth in demand for highly skilled workers and scientists.*

Many manufacturing firms in Thailand's stock market do not have good research and development; there are 24 big market capitals manufacturing firms in Thailand SET100, and only 11 of them have expenditure in research and development. As we know, one of the outputs of research and development is intangible assets.

In current economic knowledge, an intangible asset is considered the key factor to increase manufacturing competitiveness performance. Many manufacturing firms in Thailand support world-class manufacturing systems located in Thailand—such as Toyota, Honda, Seagate, and more. Therefore, Thailand manufacturing firms should understand principle of intangible assets (Intellectual capital) for measurement and how to manage it.

Purpose—*The purposes of this research are as follows–*
1. Review the definition and classification of intellectual capital.
2. Apply intellectual capital measurement tools in manufacturing firms.
3. Study the interactive effect between intellectual capital and the manufacturing firm's performance.
4. Investigate empirically the effects of human capital, structural capital, and innovation capital on the manufacturing firms' performance.

Design/methodology/approach—*Data was used from Thailand's list of manufacturing companies and Value Added Intellectual Coefficient (VAICe) as the efficiency measure of human capital, structural capital, innovation capital, capital employed, and intellectual capital. The author applied correlation to examine the relationship between intellectual capital and manufacturing firms' performance. The author constructs multiregression models to examine the relationship between sub capital of intellectual capital (human capital, structural capital, innovation capital, and capital employed) and manufacturing firms' performance (return on equity, return on assets, growth in revenues, and employee productivity).*

Findings—*Intellectual capital positively and significantly affects a manufacturing firm's performance. The study proves that there are interactive effects between the sub capital of intellectual capital and the manufacturing firm's performance, as demonstrated below.*
Sub capital effect on manufacturing firm's performance
1. *Innovation capital is positively associated with growth revenue.*
2. *Human capital is positively associated with return on asset and employee productivity.*
3. *Capital employed is positively associated with return on equity and return on assets.*

Key words: Intellectual capital, Intangible assets, Human capital, Innovation capital, Structural capital, Manufacturing firm, Firms' performance.

INTRODUCTION

A manufacturing sector is very important for developing country because the manufacturing sector creates a sustainable economic ecosystem, increase foreign investment and enhances a country's balance payments. The strong manufacturing sector also encourages a country's intellectual capital and innovativeness. Customer requirement and technology are pushing more research and development in product and process. And high global competitiveness in knowledge economy is also driving a manufacturing firm need to develop more highly knowledge worker, engineer and scientist to support their research and development.

One of the research and development output is intangible assets such as intellectual property, patent etc. And this output is not generated only from tangible asset. There are also generated from intangible assets such as worker's skill, experience, firm's policy, IT system, firm's strategy and etc.

A performance of manufacturing firm also generate from tangible and intangible assets of the firm. The issue is not happened if the intangible asset is easily to measure. So the main problem is how to measure intangible assets in a manufacturing firm. And there are any relationship between intangible asset and a firm's performance.

Currently we call intellectual capital (IC) instead of intangible asset. Understand in IC is the first thing that we must do but until now a definition of IC is not defined. Not only the definition is not valid, the relationship between a firm's performances and IC is not valid also. Why we want to know the relationship between IC and a firm's performance? Because if IC is increase but your firm performance is decrease it's mean you may go to the wrong measurement way. IC increase and also a firm's performance increase, it make sense to keep monitor and improve a firm's IC.

This research paper aims to define the classification of the Intellectual capital, how to apply the measurement tool and proved a relationship between IC and manufacturing firms' performance. The main part of this article are consist of
1. Definition and classification of Intellectual capital.
2. VAIC^{TM} definition and how to calculate each sub-capital of Intellectual capital.

3. Research model and hypotheses.
4. Regression analysis and result.

DEFINITION AND CLASSIFICATION OF INTELLECTUAL CAPITAL (IC)

Definition of Intellectual capital

Definition of Intellectual capital is not a conclusion and the main message that we find from many researchers are "Intellectual capital is the intangible value generated from human (Knowledge, motivation etc.) and resources (Equipment, i.e. Computer, IT etc.), and contribute to the firm's value added". Stewart (1997) define Intellectual capital as the sum of everything everybody in the company that gives it a competitive edge in the market place. Edvinsson and Sullivan (1996) define Intellectual capital as knowledge that can be converted into value. Brooking (1997) define Intellectual capital as the term given to combined intangible assets which enable the company to function.

Edvinsson and Malone (1997) define Intellectual capital as those that have no physical existence but are still of value to the company.

Brennan and Connell (2000) define Intellectual capital as knowledge-based equity of a company. Harrison and Sullivan (2000) define Intellectual capital as knowledge that can be converted into profit. A broad definition of intellectual capital states that it is the difference between the company's market value and its book value. Knowledge based resources that contribute to the sustained competitive advantage of the firm from intellectual capital Pablos (2003). Andriesssen and Stem (2004) define Intellectual capital as all intangible resources that are available to an organization, that gives a relative advantage, and which in combinations are able to produce future benefits. Yound (2004) define Intellectual capital as the sum of all knowledge that an organization is able to leverage in the process of conducting business to gain competitive advantage. Roose (2005) define Intellectual capital as all non-monetary and non-physical resources that are fully or partly controlled by the organization and that contribute to the organization's value creation.

Classification of Intellectual capital

The capital in Intellectual capital is very important. Classification of Intellectual capital is provided and it helps the researcher to understand the definition of Intellectual capital. Practitioners also know which capital should be more focused on to increase the intellectual capital in company. And they know well where the strategy begins.

Edvinsson and Malone (1997): Intellectual capital consists of structural capital and human capital.

Definition of each capital

Human Capital is defined as the collective capabilities of employees to solve customer problems. This capital includes the collective experience, skills, and general know-how of all of the company's employees.

Structural capital consists of customer capital and organizational capital. Organizational capital consists of innovation capital and process capital.

Definition of each capital

Structural capital includes customer and organizational capital that relates to the external and the internal focus of structural capital.

Customer capital is defined as the combined value of the relationships with customers, suppliers, industry associations and markets.

Organizational capital includes the organization philosophy and systems for leveraging the organization’s capability.

Innovation capital is that which creates success in the future and includes intellectual assets and intellectual property.

Process capital includes the techniques, procedures, and programs that implement and enhance the delivery of goods and services.

Sveiby (1997): Intangible assets or IC consist of External structure, Internal structure and Individual competence.

The definition of each component

Internal structure consists of a wide range of patents, concepts, models, and computer and administrative systems.

External structure consists of relationships with customers and suppliers, brand names, trademarks and reputation, or "image".

Individual competence is people's capacity to act in various situations. It includes skill, education, experience, values and social skills.

Brooking (1997): Intellectual capital consist of Market assets, Human-centered assets, Intellectual property assets and Infrastructure assets.

The definition of each asset

Market assets are the potential an organization has due to market-related intangible. Examples include various brands, customers and their loyalty, repeat business, backlog, distribution channels, various contacts and agreements such as licensing, franchise.

Human-centered assets comprise the collective expertise, creative and problem solving capability, leadership, entrepreneurial and managerial skills embodies by the employees of the organization.

Intellectual property assets include know-how, trade secrets, copy-right, patent and various design rights. They also include trade and service marks.

Infrastructure assets are those technologies, methodologies and processes which enable the organization to function. Examples include corporate culture, methodologies for assessing risk, methods of managing a sales force, financial structure, data base and communication systems.

Bontis (1999): Intellectual capital consists of Human capital, Structural capital and Relational capital.

The definition of each capital,

Human capital is defined as the combined knowledge, skill, innovativeness, and ability of the company's individual employees to meet the task at hand. It also includes the company's values, culture, and philosophy.

Structural capital deals with the mechanisms and structures of the organization that can help support employees in their quest for optimum intellectual performance and therefore overall business performance.

Relational capital is knowledge of market channels, customer and supplier relationships, as well as a sound understanding of government or industry association impacts.

Chen, Zhu and Xie (2004): Intellectual capital consists of Human capital, Structural capital, Innovation capital and Customer capital.

The definition of each capital

Human capital is defined as employees' knowledge, skill, capability, and attitudes in relation to fostering performances which customers are willing to pay for and which the company's profit comes from.

Structural capital deals with the mechanism and structure of an enterprise that can help support employees in their quest for optimum intellectual performance, and the overall business performance achievement.

Innovation capital is the competence of organizing and implementing R&D, unremittingly bringing forth the new technology and the new product to meet the demands of customers.

Customer capital is the value embedded in the marketing channels and relationships that an enterprise develops by conducting business.

In the new economic era, innovation is becoming a key factor for a company to keep its long-term competitive excellence. Economic growth in developed countries has been driven by innovation rather than by investment. Then Chen, Zhu and Xie (2004) agree to separate Innovation capital from Structural capital.

In this research, Intellectual capital consists of Human capital, Structural capital and Innovation capital. The model of research and hypothesis are provided in part_3.

VAIC^{TM} DEFINITION AND CALCULATION METHOD OF EACH SUB-CAPITAL OF INTELLECTUAL CAPITAL

Value Added Intellectual Coefficient (VAICe) is widely applied in the Intellectual capital research and it was devised by the Austrian Intellectual Capital Research Center (AICRS) under Pulic (2000b). VAIC^{TM} uses the data from financial statements and using value added to measure performance. It measures how much and how efficiently intellectual capital and capital employed create value based on the relationship to the three major components. They are capital employed (CE), human capital (HU) and structural capital (ST).

In this research, Innovation capital is one of indicator in VAIC^{TM} and the R&D expenditure is used for calculating the VA efficiency of Innovation capital (Nazari and Herremans, 2007).

VAIC^{TM} Calculation method

Calculation formula: VAIC = VAHU + STVA + VACA + InCE

Component calculation

VACA is indicator of VA efficiency of capital employed = VA ÷ CE
VAHU is indicator of VA efficiency of human capital = VA ÷ HU
STVA is indicator of VA efficiency of structural capital = SC ÷ VA
InCE is indicator of VA efficiency of innovation capital = R&D ÷ VA

Where

VA = Net sales revenue - Cost of good sold - Depreciation (Riahi-Belkaoui (2003))

CE = Physical capital + Financial assets
= Total assets - Intangible assets (Pulic (2000a, b) and Firer and Williams (2003))

HU = Total expenditure on employees (Pulic (2000a, b) and Firer and Williams (2003))

SC = VA - HU (Pulic (2000a, b) and Firer and Williams (2003))

R&D = Total R&D expenditure (Bosworth and Rogers, 2001)

Many researchers had applied VAIC method to measure IC in firm and studied how IC related to a firm's performance. Chen, Cheng and Hwang (2005) conclude that IC has a positive impact on market to book value and financial performance of Taiwan listed company. And the R&D expenditure may capture additional information on Structural capital and has a positive effect on firm value and profitability also. Chan (2009) conclude no significant related between IC and a firm performance of Hong Kong listed company. Only a moderate positive association has been found between VAICe and profitability.

RESEARCH MODEL AND HYPOTHESES.

Research model

The purpose of the model is to define,
1. The relationship between Intellectual capital and manufacturing firm performance.
2. The effect of each sub-capital to the manufacturing performance.

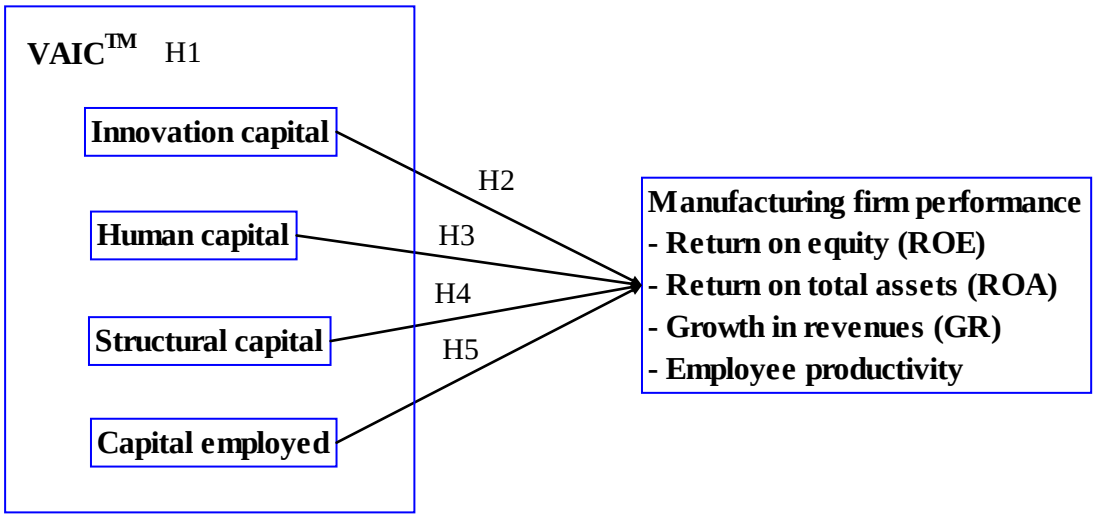

Figure I. Framework of research hypotheses

Manufacturing performance definition and hypotheses
Company performance: Considered in term of value added.
Financial performance. The four financial performance variables are defined as follows:

. Return on equity (ROE) = pre - tax income ÷ average stockholders' equity.

ROE represents returns to shareholders of common stocks, and is generally considered an important financial indicator for investors.

. Return on total assets (ROA) = pre - tax income ÷ average total assets.

ROA reflects firms' efficiency in utilizing total assets, holding constant firms' financing policy.

. Growth in revenues (GR) = (current year's revenues ÷ last year's revenues) - 1) × 100%.

GR measures the changes in firms' revenues. Increases in revenues usually signal firms' opportunities for growth.

. Employee productivity (EP) = pre - tax income ÷ number of employees.

EP is a measure for the net value added per employee, reflecting employees' productivity.

Hypotheses on Research model

Intellectual capital effect to manufacturing performance
H1a. VAIC^{TM} positive associated with ROE
H1b. VAIC^{TM} positive associated with ROA
H1c. VAIC^{TM} positive associated with GR
H1d. VAIC^{TM} positive associated with EP

Sub-capital effect to manufacturing performance
H2a. Innovation capital positive associated with ROE
H2b. Innovation capital positive associated with ROA
H2c. Innovation capital positive associated with GR
H2d. Innovation capital positive associated with EP
H3a. Human capital positive associated with ROE
H3b. Human capital positive associated with ROA
H3c. Human capital positive associated with GR
H3d. Human capital positive associated with EP
H4a. Structural capital positive associated with ROE
H4b. Structural capital positive associated with ROA
H4c. Structural capital positive associated with GR
H4d. Structural capital positive associated with EP

H5a. Capital employed positive associated with ROE
H5b. Capital employed positive associated with ROA
H5c. Capital employed positive associated with GR
H5d. Capital employed positive associated with EP

Sample selection and method

Manufacturing companies were selected from Thailand listed companies in SET100 (Big market capital).There are 24 manufacturing companies from a total of 100 companies. Others are service and finance companies.11 companies from 24 companies which can be used because they have R&D expenditure shown in the annual report. These companies consist of 3 automobile part manufacturing firms, 2 electronic component manufacturing firms, 2 consumer product manufacturing firms and 4 construction component manufacturers.

From 44 firm-point observations due to lack of the R&D expenditure in year 2008. Because the Stock exchanges of Thailand announce the new format of annual report and effective in year 2008. Then R&D expenditure is not shown in annual report since year 2008.

The data from annual report is used to calculate the VAIC^{TM} and data is used during year 2004 - 2007.

VAICe offers the constructs for the measurement of IC and the independent variables for regression analysis.

The dependent variables are manufacturing performance; Return on equity (ROE), Return on total assets (ROA), Growth in revenues (GR) and Employee productivity (EP).

Data sources

The data for this paper is mainly collected from primary sources. Data is available in the listed company's annual report which is published by the Stock Exchanges of Thailand. The data for the paper was collected from the SEC website (see www.sec.or.th) directly.

Independent variables	Dependent variables
VAIC	Return on equity (ROE)
Human capital	Return on total assets (ROA)
Structural capital	Growth in revenues (GR)
Innovation capital	Employee productivity (EP)
Capital employed	

Table I: Descriptive for Independent and Dependent variables.

Apply the statistic tool to investigate the hypotheses,

1. Test correlation between VAIC and Firm's performance to investigate H1a, H1b, H1c and H1d.

2. Test correlation between Independent variables.

3. Apply multi regression to investigate H2a, H3a, H4a and H5a.

$$ROE_{it} = \alpha_0 + \alpha_1 VACA_{it} + \alpha_2 InCE_{it} + \alpha_3 VAHU_{it} + \alpha_4 STVA_{it} + \varepsilon_{it} \quad (1)$$

4. Apply multi regression to investigate H2b, H3b, H4b and H5b.

$$ROA_{it} = \alpha_0 + \alpha_1 VACA_{it} + \alpha_2 InCE_{it} + \alpha_3 VAHU_{it} + \alpha_4 STVA_{it} + \varepsilon_{it} \quad (2)$$

5. Apply multi regression to investigate H2c, H3c, H4c and H5c.

$$GR_{it} = \alpha_0 + \alpha_1 VACA_{it} + \alpha_2 InCE_{it} + \alpha_3 VAHU_{it} + \alpha_4 STVA_{it} + \varepsilon_{it} \quad (3)$$

6. Apply multi regression to investigate H2d, H3d, H4d and H5d.

$$EP_{it} = \alpha_0 + \alpha_1 VACA_{it} + \alpha_2 InCE_{it} + \alpha_3 VAHU_{it} + \alpha_4 STVA_{it} + \varepsilon_{it} \quad (4)$$

VAIC™ and VAICe calculation result

Calculation value added; VA = Net sales revenue - Cost of good sold - Depreciation

Component calculation

VACA is indicator of VA efficiency of capital employed = VA ÷ CE
VAHU is indicator of VA efficiency of human capital = VA ÷ HU
STVA is indicator of VA efficiency of structural capital = SC ÷ VA
InCE is indicator of VA efficiency of innovation capital = R&D ÷ VA

VAIC™ Calculation method

Calculation formula: VAIC = VAHU + STVA + VACA + InCE

Company	Year	Value added (VA) = Net sale - Cost of good sold - Depreciation		
		Net sale revenue	Cost of good sold & Depreciation	VA

Table V: Descriptive for VAIC^{TM} ,VAICe and firm's performance.

EMPIRICAL RESULTS

To apply statistical tool by following each hypotheses test, results show;

1. Test correlation between VAIC and Firm's performance to investigate H1a, H1b, H1c and H1d.

	VAIC	ROE	ROA	GR
ROE	0.395			
	0.008			
ROA	0.311	0.791		
	0.040	0.000		
GR	0.302	0.325	0.159	
	0.046	0.032	0.303	
EP	0.875	0.299	0.282	0.251
	0.000	0.049	0.064	0.101

Cell Contents: Pearson correlation
P-value

Table VI: Correlation table between VAIC and Dependent variables
P-Value < 0.01 Strong correlation. (99% Confidence interval)
P-Value < 0.05 Correlation. (95% Confidence interval)

Intellectual capital effect to manufacturing performance

H1a. VAIC^{TM} positive associated with ROE	Yes, strong positive correlation.
H1b. VAIC^{TM} positive associated with ROA	Yes, positive correlation.
H1c. VAIC^{TM} positive associated with GR	Yes, positive correlation.
H1d. VAIC^{TM} positive associated with EP	Yes, strong positive correlation.

VAIC is positively affected to all manufacturing firm's performance. Firm can use VAIC as a measurement tool to measure the intellectual capital in the organization. Benchmarking also can applied both internal and external. Value of VAIC is positively related to the firm's performance and they can improve the VAIC value to increase their firm's performance. This result show IC trend and a firm's performance trend go with the same direction.

2. Test correlation between Independent variables.

	VAHU	STVA
STVA	0.693	
	0.000	
InCE	-0.359	-0.609
	0.017	**0.000**

Cell Contents: Pearson correlation
P-value

Table VII: Correlation table between Independent variables
P-Value < 0.01 Strong correlation. (99% Confidence interval)
P-Value < 0.05 Correlation. (95% Confidence interval)

Relationship between sub-capitals

H2. Structural capital associated with Innovation capital	Yes, strong correlation.
H3. Structural capital associated with Human capital	Yes, strong correlation.
H4. Human capital associated with Innovation capital	Yes, correlation.

Base on the theory of multi regression analysis, independent variables must verified the correlation before apply in the regression model. From the result, structural capital, human capital and innovation capital are correlated. So the model should have only one sub-capital in each model by the way the study is applied multi regression model to see the relationship of each capital to the firm's performance. Researcher do not use the model for predict the new value so all independent variables can be use in model and see the coefficient and P-value for judgment the relationship.

3. Apply multi regression to investigate H2a, H3a, H4a and H5a.

$$ROE_{it} = \alpha_0 + \alpha_1 VACA_{it} + \alpha_2 InCE_{it} + \alpha_3 VAHU_{it} + \alpha_4 STVA_{it} + \varepsilon_{it} \quad (1)$$

Independent variable	Coefficient	t-statistic	P-value
Constant	-0.0488	-0.44	0.663
VACA	**1.3112**	5.29	**0.000**
VAHU	0.0095	1.88	0.068
STVA	0.1010	0.62	0.536
InCE	-0.0619	-0.28	0.780
Notes: Adjusted R^2 = 45.9%; F-value = 10.12 (P-value < 0.0001)			

Table VIII: Regression result of ROE and Independent variables.

P-Value < 0.01 Strong associated. (99% Confidence interval)
P-Value < 0.05 Associated. (95% Confidence interval)

H2a. Innovation capital positive associated with ROE No.
H3a. Human capital positive associated with ROE No.
H4a. Structural capital positive associated with ROE No.
H5a. Capital employed positive associated with ROE Yes, strong associated.

Innovation, human and structural capital are not positively affected to ROE. Capital employed (VACA) is positively affected to ROE. Increase value of VACA is also increasing ROE. Base on calculation formula of VACA, VACA = VA ÷ (Total assets – Intangible assets), firm should be increase VA and Intangible assets to increase VACA value. By the way the intangible assets are the one of innovation capital outcome. Firm should monitor on the R&D expenditure and see the outcome in term of intangible assets increasing.

4. Apply multi regression to investigate H2b, H3b, H4b and H5b.

$$ROA_{it} = \alpha_0 + \alpha_1 VACA_{it} + \alpha_2 InCE_{it} + \alpha_3 VAHU_{it} + \alpha_4 STVA_{it} + \varepsilon_{it} \quad (2)$$

Independent variable	**Coefficient**	**t-statistic**	**P-value**
Constant	0.0936	2.30	0.027
VACA	**0.5873**	6.47	**0.000**
VAHU	**0.0061**	3.30	**0.002**
STVA	-0.1246	-2.10	0.042
InCE	-0.1387	-1.73	0.092
Notes: Adjusted R^2 = 54.1%; F-value = 13.68 (P-value < 0.0001)			

Table IX: Regression result of ROA and Independent variables.

P-Value < 0.01 Strong associated. (99% Confidence interval)
P-Value < 0.05 Associated. (95% Confidence interval)

H2b. Innovation capital positive associated with ROA No.
H3b. Human capital positive associated with ROA Yes, strong associated.
H4b. Structural capital positive associated with ROA No.
H5b. Capital employed positive associated with ROA Yes, strong associated.

Innovation and structural capital are not positively affected to ROA. Human capital (VAHU) and Capital employed (VACA) are positively affected to ROA. Increase value of VACA and VAHU are also increasing ROA. Base on calculation formula of VACA, VACA = VA ÷ (Total assets – Intangible assets) and VAHU, VAHU = VA ÷ Total expenditure on employees. Firm should be increase VA and Intangible assets to increase VACA and VAHU value. Increasing of intangible assets is the key factor of increasing both ROA and ROE. Base on VAHU formula, Firm should

not reduce the expenditure on employee because morale and motivation of employees are reduced.

5. Apply multi regression to investigate H2c, H3c, H4c and H5c.

$$GR_{it} = \alpha_0 + \alpha_1 VACA_{it} + \alpha_2 InCE_{it} + \alpha_3 VAHU_{it} + \alpha_4 STVA_{it} + \varepsilon_{it} \quad (3)$$

Independent variable	**Coefficient**	**t-statistic**	**P-value**
Constant	-0.1314	-0.88	0.385
VACA	-0.3359	-1.01	0.320
VAHU	0.0079	1.17	0.251
STVA	0.3612	1.66	0.106
InCE	**0.8719**	2.95	**0.005**
Notes: Adjusted R^2 = 19.0%; F-value = 3.52 (P-value < 0.05)			

Table X: Regression result of GR and Independent variables.

P-Value < 0.01 Strong associated. (99% Confidence interval)
P-Value < 0.05 Associated. (95% Confidence interval)

H2c. Innovation capital positive associated with GR	Yes, strong associated.
H3c. Human capital positive associated with GR	No.
H4c. Structural capital positive associated with GR	No.
H5c. Capital employed positive associated with GR	No.

Human, structural capital and capital employed are not positively affected to GR. Innovation capital (InCE) is positively affected to GR. Increase value of InCE is also increasing GR. Base on calculation formula of InCE, InCE = R&D expenditure ÷ VA. Firm should be increase on R&D expenditure to increase InCE and the outcome of the R&D should be positively affected to intangible assets. By the way growth in revenues is also relate to the VA value because the VA is from calculation formula; VA = Net sale revenue – Cost of good sold – Depreciation. Sale revenue growth means Net sale revenue increasing.

6. Apply multi regression to investigate H2d, H3d, H4d and H5d.

$$EP_{it} = \alpha_0 + \alpha_1 VACA_{it} + \alpha_2 lnCE_{it} + \alpha_3 VAHU_{it} + \alpha_4 STVA_{it} + \varepsilon_{it} \quad (4)$$

Independent variable	Coefficient	t-statistic	P-value
Constant	2.942	1.27	0.212
VACA	-4.994	-0.97	0.339
VAHU	**1.221**	11.52	**0.000**
STVA	-9.243	-2.74	0.009
InCE	-0.872	-0.19	0.850
Notes: Adjusted R^2 = 80.4%; F-value = 45.18 (P-value < 0.0001)			

Table XI: Regression result of EP and Independent variables.

P-Value < 0.01 Strong associated. (99% Confidence interval)
P-Value < 0.05 Associated. (95% Confidence interval)

H2d. Innovation capital positive associated with EP	No.
H3d. Human capital positive associated with EP	Yes, strong associated.
H4d. Structural capital positive associated with EP	No.
H5d. Capital employed positive associated with EP	No.

Human capital (VAHU) is only one sub-capital which positively affected to EP. Increase value of VAHU is also increase EP. Base on calculation formula of VAHU, VAHU = VA ÷ Total expenditure on employees. Firm should be increase VA to increase VAHU value. To maintain morale and motivation, firm should not reduce on the expenditure of employees. The conclusion section is provided summary of all relationship and strategic of increasing the intellectual capital in manufacturing firm.

CONCLUSION

In the new economics knowledge, the productivity of manufacturing is not only from labor intensive but also the knowledge of workers. They are the significantly contribution of the manufacturing firm value added. This paper uses the measurement tool in term of value added to define how the intangible assets also known in the name of intellectual capital contribute to the manufacturing firm's performance. The conclusion the author found from the empirical model and the measurement tool is that "Intellectual capital has a very strong positive effect on the manufacturing firm performance". And as the author goes deep down to details of each sub-capital, the innovation capital has positive effect to the growth in revenue. The growth in revenue is concern with the customer. R&D is more focused on what the customer want, need or goes beyond the customer expectations. What we call quality is one part of innovation capital.

The results of this paper show capital employed affects to the return on equity and return on total assets. The human capital also affects the employee productivity and the return on total assets. Manufacturing firms should be more focused on the human capital development and prepare the high performance equipments to increase productivity. This paper proved that intellectual capital measurement tool can be applied to the manufacturing firm.

The measurement method can be adopted in manufacturing firm to benchmark internally and externally in the industry and set strategies to improve each sub-capital and increase the intellectual capital for sustaining a competitive edge.

Result summary

VAIC positively affects to ROE, ROA, GR and EP.
VACA (Capital employed) positively affects to ROE and ROA.
VAHU (Human capital) positively affects to ROA and EP.
InCE (Innovation capital) positively affects to GR.

To focus on the result, author selects a research which has similar dependent and independent variables to compare results with this paper. A conclusion of positively relationships between dependent and independent is shown in Table XII.

Researchers	**Independent variables**	**Dependent variable**	**Comparable result**	**Different result**
Chen, Cheng and Hwang (2005)	VAIC VACA VAHU STVA R&D	ROE ROA GR EP	VAIC and ROE, ROA, GR, EP VACA and ROE, ROA VAHU and ROA, EP InCE (R&D) and GR	VACA and GR, EP VAHU and ROE, GR, EP InCE and GR VAHU and EP
Kamath (2008)	VACA VAHU SCVA	ROA	VACA and ROA VAHU and ROA	-
Chan (2009)	VAIC VACA VAHU STVA	ROE ROA	VAIC and ROE, ROA VACA and ROE, ROA	VAHU and ROA

Table XII: Result comparison with prior research.

Based on the finding of this paper and compare to the prior research, it can be proved that intellectual capital or intangible assets strongly affect to manufacturing firm's performance.

Manufacturing firm can applied VAIC to measure intellectual capital in the organization. Benchmarking also can be use both internal and external organization for improvement and enhance the firm's performance.

CASE STUDY: PERFORMANCE MEASUREMENT IN A WALES BASED CONSTRUCTION COMPANY – OPCO.

Yadam Sai Hrushikesh Reddy, OPCO, Cardiff- U.K
YReddy@opco-construction.co.uk

Nick Kelly*, OPCO, Cardiff- U.K
NKelly@opco-construction.co.uk, *corresponding author

ABSTRACT

There are a vast amount of studies on performance measurement in general, for manufacturing and service sectors. However, very few studies were reported on performance measurement of business processes in a construction industry. This paper describes how a Wales based Construction Company are working towards the design and implementation of a unique performance measurement model for measuring business processes. This model will help to improve overall organisational performance, and in order to achieve this goal we focused mainly on four elements namely People, Communication, Process and Technology. By carefully implementing Statistical Process Control Technique (to check process performance) and Mobile Computing Technology (to capture primary and secondary data, which in later stages feed into statistical process control model to generate individual process or overall organisational performance).

This model can be applicable to not only within the construction industry, but for any organisation determined in achieving productivity by practicing quality methods through strategic change management, which is described in the paper.

Keywords: Performance Measurement System, Business Process Management, Statistical Process Control, Mobile Computing System, Construction Industry

INTRODUCTION

Designing performance measurement system to measure business processes is very complex, challenging and yet very important for any organisation to increase its overall efficiency. There is vast amount of literature available on performance measurement of business processes for non – construction industry [21]. However, this aspect is unexplored in construction industry because of its complex nature [10, 39]. Hayes [28] stated *"construction sector is facing same problems that the manufacturing sector faced in 1980's".*

Research back ground:

Performance measurement system is an interesting research topic for both organisations and academicians [10]. Most of the organisations measure performance based on traditional methods [15, 19] like analysing financial reports etc. Many researchers [10, 19, 28, 35] find this approach wrong because financial reports depicts organisational performance of only past and does not help in measuring present and predicting future performance. [22, 28] Many researchers [8, 11, 12, 16, 18, 26] criticised the financial

performance measurement model and felt the need to improve efficient model which can increase quality and flexibility by reducing lead time and wasteful costs [19, 34]. Since then both business practitioners and researchers are trying to design a perfect model [8, 10, 19]. The ability to measure the performance of operations is very critical for the construction industry, as majority (core) of its business purely depends on operational activities.

Usually many companies implement performance measurement strategy only for the lower management levels [25, 40] and expect change throughout the organisation. Recent literature points out [3, 12, 16, 28, 33, 42], that the common reason for failures in implementing performance measurement system are mainly due to top management's resistance to support the strategic change process. Performance measurement is not a quick fix tool; its main purpose is to monitor long term plans by measuring business processes regularly [2, 6, 25, 36] (not only core processes but also supporting processes) and to deliver validated information for the management to support decision making [39, 6, 19]. Enough caution should be taken [4, 12, 16, 32] during design and implementation phase, because it is very important to choose what to measure (KPI's), how to measure (data collection and process analysis) and when to measure (time intervals).

Yadam's research developed a casual relationship between performance measurement system (of business processes), statistical process control and mobile computing system. If design is implemented and used appropriately, there are high chances of achieving competitive edge by increasing the efficiency of an organisation at all levels.

Hence the main aim of this research is to design a robust PMS (performance measurement system) model for the construction industry to achieve efficiency. Next section provides updated literature review to support the PMS model followed by research methodology. Finally, paper includes a discussion of the model, conclusion and recommendations for both practitioners and researchers.

Company Background:

Formed in July 2001 OPCO is a UK based multi disciplinary contractor that specialises in the designing and construction of high value buildings for national and international clients. OPCO has developed an enviable reputation for delivering quality high rise residential, commercial buildings, industrial, process engineering facilities, public sector works and leisure complexes by having strong site, commercial and design management providing assurance to clients that their projects will be delivered within agreed project timelines and budgets with high quality standards and safety.

Opco's aim is to be distinctive. This means being different from its competitors - and, in key respect, better than its competitors. It is very important to give clients reason for choosing OPCO in the first place, and the reason to keep them coming back. Delivering on time, within budget and right level of quality is not enough to achieve competitive edge. These goals are important, but every contractor in this industry aspires for them. In order to be distinctive, and better, OPCO deeply concentrates on four key areas of its business, namely people, communication, process and technology.

A crucial part of Opco's distinctiveness is the implementation of Deming's 14 points into its corporate culture right from the start which are also Opco's 14 visions and working hard to continuously improve its business processes and systems to withstand the internal and external uncertainties. This always helped opco to increase its quality and productivity by reducing non value added activities in the business to a great extent.

LITERATURE – BACKGROUND

This chapter gives an overview of current literature on Performance Measurement systems ***[PMS]*** (to measure business processes), Mobile Computing System ***[MCS]*** (for data capture) and Statistical Process Control ***[SPC]*** (for analysing data, previously captured through MCS).

Performance Measurement System [PMS]:

It is very important for organisations to analyse how their performance is measured and how they communicate performance strategy with their market audience [14], for example: stake holders, employees and customers. Mostly organisations measure performance based on traditional methods [15, 19] like analysing return on investment (ROI), profit per unit produced and financial reports. Many researchers [28, 10, 19, 35] feel, this approach is totally wrong and misleading because financial reports only shows information happened in past but does not help in measuring present and predicting future performance. The main disadvantage according to ghalayini & noble cited in [14], is that *"Traditional performance systems based on financial reports encourages short term thinking; lack strategic focus and fail to provide data on quality, responsiveness and flexibility; encourages local optimisation; do not encourage continuous development; reports organisational performance not current performance".* [28, 22] Many researchers [8, 26] criticised the financial performance measurement model and felt the need to improve an efficient model, which can increasing quality and flexibility by reducing lead time and wasteful costs [34, 19]. Since then both business practitioners and researchers are trying to design a perfect model [8, 10, 19]. The ability to measure the performance of operations is very critical for the construction industry, as majority (core) of its business purely depends on operational activities.

A success of design and implementation of an efficient performance measurement system depends on various factors [17] like:

1) *Qualitative*: based on human judgement
2) *Quantitative*: based on physical measures
3) *Attribute*: when a characteristic such as defect is measured as either present or not.
4) *Variable*: When measured on continuous scale.

Performance Measurement Models:

Balanced Scorecard [BSC]:

This is a very popular [28] and widely used performance measurement system. This model has four elements (Procedural framework) namely people, process, finance & training [17].

The objectives and measures of the scorecard are derived from an organisation's vision and strategy. This model incorporates four main measurement categories each of which with a wider range of potential sub-measures. It includes various lagging and leading indicators, but the only drawback is that it does not show any relationship between the measures. It is very important to establish relationship between indicators because it will help the management to analyse data in different dimensions and take productive decisions.

Performance Prism:

Performance prism is an improved version [28] of balanced scorecard model. This model deals with concerns of stakeholders like investors, suppliers, customers, employees and so on. According to [14], "It consists of five sections,

1) Stakeholder Satisfaction: who are our key stakeholders and what are their needs?
2) Strategies: what strategies must we put in place to meet these various needs?
3) Processes: what critical processes must be built or re-designed to execute these strategies?
4) Capabilities: what capabilities do we need to operate and further develop (processes)?
5) Stakeholder Contribution: what contribution do we expect from our stakeholders if we are to develop, maintain and enhance these capabilities?"

Performance Metrics:

A good performance measurement system depends on its performance metrics [14]. It is very important to design metrics as they are the links (build relationship) between various perspectives that an organisation decide to implement. This relationship between the performance management system and the metrics used do not relate to the strategic goals of the organisation. Ghalayini & Noble cited in [14] states that *"The danger of measuring the wrong things right when the sole purpose of an exercise is to design performance metrics, which might not necessarily, related to strategy".* This can usually occur when a large number of performance metrics is present in an organisation where "everything is measured but little that matters", 1996 state that this is not only necessary but it is performed at a great expense to the organisation, in terms of the efforts made to capture and manage the necessary data.

Performance Measurement in construction:

Today's construction industry still relies on traditional methods to measure performance. The major problem in construction industry is the amount of resources wasted due to its complex nature. Nudurupati [28] stated "The main weakness for construction industry is the logistics, material and information flow. Approximately 40% - 50% wasted due to different actors with their own time plans, 50% due to non production activities on site and 80% on purchase order rush. In order to overcome this problem Construction best practise programme [CBPP] launched 12 headline KPI's [28, 14]. These are meant to measure the business performance efficiently. The 12 KPI's are as follows

Table 1: Construction best practise programme - 12 headline KPI's [28, 14]

01 – Defects	07 - Predictability of design
02 – Safety	08 - Cost of design
03 – Productivity	09 - Customer satisfaction – product
04 – Profitability	10 - Customer satisfaction – services
05 – Construction cost	11 - Predictability of construction cost
06 – Construction time	12 - Predictability of construction time.

But Nudurupati [28] and few more researchers criticised the above named KPI's, "are lagging factors and they do not provide opportunity for change and do not predict future performance".

Mobile Computing System [MCS]:

According to Chen and Kamara [5], "In the recent years, construction information management has greatly benefited from advances in information and communications technology through increasing the speed of information flow, enhancing the efficiency and effectiveness of information communication and reducing the cost of information transfer". As we know the construction industry is very complex in nature, it is very important to manage communication efficiently. Ineffective communications can lead to negligence of important issues that require a quick response, which may result in on site decision being deferred [5].

Many researchers focused and developed various tools like electronic document management systems, knowledge management systems and web-based project management systems to [5], "reduces construction time, capital cost of construction, reduction in operation and maintenance cost, reduction in defects, reduction in accidents, reduction in waste, increase in productivity and increase in predictability". Yet the potential of mobile computing Technology in construction industry is not fully exploited and adopted broadly.

The main barriers for using mobile computing technology in construction industry are as follows,

1) Hardware: Screen Size, Resolution, Processing Capabilities and Input Methods.
2) Nature: Complex Industry.
3) High Setup Cost: Software, Equipment And Employee Training Cost are High.

Statistical Process Control [SPC]:

According to Grant & Leavenworth cite in [32] stated that "statistical process control is a statistical method for analysing certain product characteristics to determine the likelihood that improvement can be made in the process to reduce variability and achieve higher quality". The additional benefit is that it can be used to provide feedback to the process and develop wherever necessary.

SPC is a statistical based analysis method that is used to analyze process data and it is hoped, assist the process or control engineer in making improvement to the process. A statistical analysis of quality measurement should reveal any assignable cause variation.

Following are the statistical tools required for successful implementation and maintenance [Rienzo]:

- **Flow Diagrams:** To understand process.
- **Control Charts:** To monitor the process performance.
- **Scattered Diagram:** To check process behaviour.
- **Histogram and Pareto Charts:** To monitor defect frequency rate.
- **Cause and Effect Diagram:** To understand the relation between business components.

RESEARCH METHODOLOGY

Research Objective:

Yadam's research developed a casual relationship between performance measure (of business processes through) statistical process control and mobile computing Technology. If design is implemented and used appropriately, there are high chances of achieving competitive edge. Hence the object of this paper is to design a robust PMS model for the construction industry. Finally paper includes a discussion of the model conclusion and future recommendations for practitioners and the researchers.

Research Strategy:

According to the literature and information gathered, ***Action Research*** seems more relevant to this research. Many scholars defined action research in different ways [30]. According to Stefan & Goran [36] "Action Research means a research practice and a business practice integrating to achieve a common goal". During this process, the researcher has to make sure his research objectives are matching with the organisation objectives (goals or outcomes). The following diagram illustrates the process of action research in simple.

Figure 1: Action Research Method in Simple.

The above diagram explains how researcher and business practitioner come together and achieve common goals. It is very evident that, this is best practice in this research.

Data Collection:

The data for this research was gathered through various sources. This action research was conducted through

1) Interviews, Group Discussions
2) Analysis of Organisation Internal Documents.
3) Online Research.

DISCUSSION

Designing performance measurement system to measure business process in a construction industry is very difficult due to its complex nature. The modern construction industry is still using traditional performance measurement (financial). Many researchers stated that this is risky and totally wrong approach of performance measurement because financial measures only shows the performance in past, and do not help in measuring present and predicting future performance trends. The efficient performance measurement system must consider both the financial and non-financial measures.

Opco Performance Measurement Model:

The Opco's performance measurement model uses mobile computing technology at site level and web-based technology at office level to capture data. The captured data is then fed into the statistical process control tool to study the variations in the business processes and later report to top management for their decision making purpose. Following is the Opco's performance measurement model.

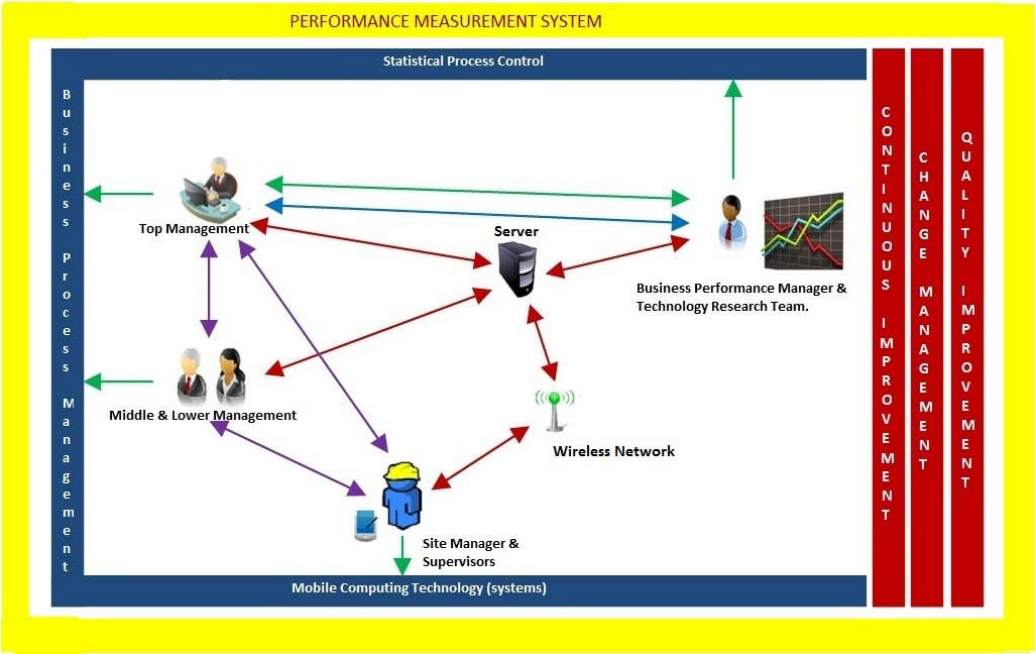

Figure 2: Opco's Performance Measurement Model.

The above performance measurement model is divided into four working phases, as follows:

1) The first phase represents data capture (red lines),
2) Second phase represents analysis of process behaviour, reporting to top management and capturing data (blue and red lines),
3) Third phase represents consultation between top management and other management levels to solve problematic areas (violet lines) and data capture (red lines),
4) The fourth phase represents reengineering of business processes (green lines) and data capture (red lines).

The following figure clearly illustrates the working process of Opco's performance measurement model.

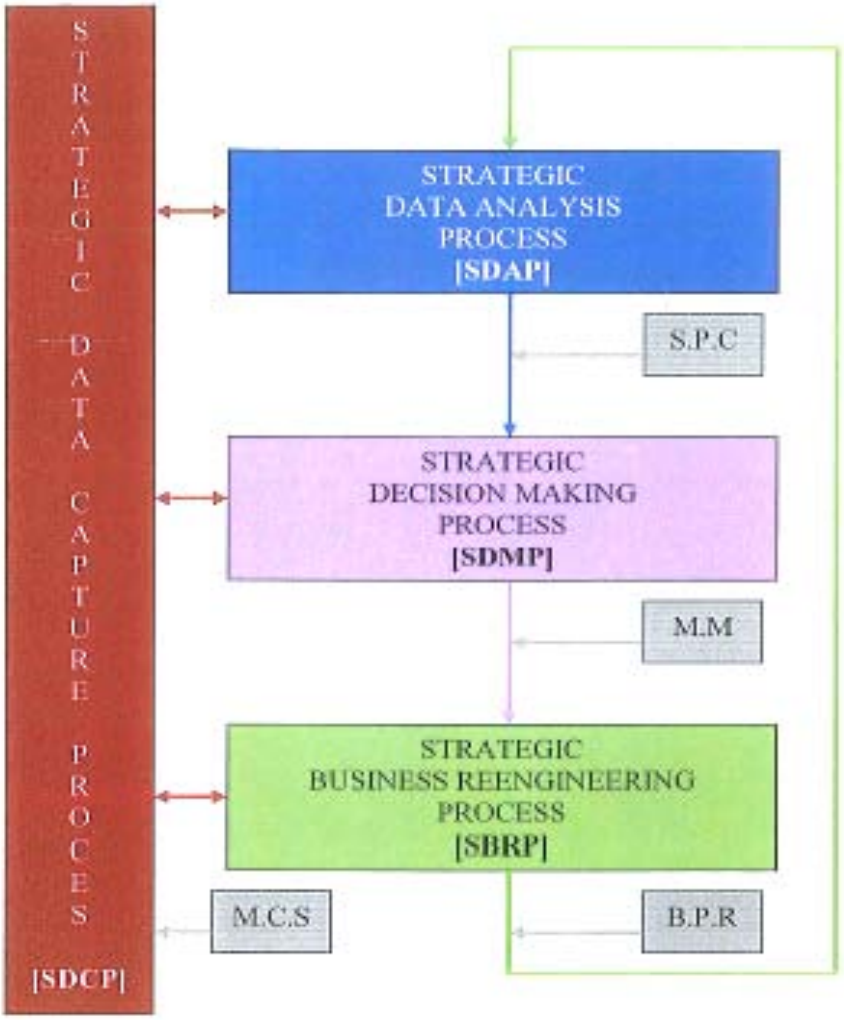

Figure 3 : Opco Performance Measurement Model – Working Process.

As we can see, every phase is a process itself and it is driven by powerful tool. The tools are as follows

1) M.C.S – Mobile Computing Technology (Systems).
2) S.P.C – Statistical Process Control.
3) M.M – Meeting Matrix.
4) B.P.R – Business Process Reengineering.

Opco Performance Measurement Model – Phase 1:

The main objective of this phase is to capture data. Capturing data is the base for this model because if the data collected is not accurate (gaps), the analysis will not be accurate. This will lead to wrong decision making and results in business failure. Firstly, a very efficient data capture strategy must be in place to monitor the data capture process across the business and secondly, it should be flexible and realistic in nature.

The major problem in this phase is to capture data accurately at site level. Many sites face the connectivity problems; this will lead to reduction in the speed of information flow (effecting the efficiency of information communication) and increasing the cost of information transfer. As we know the construction industry is very complex in nature, it is very important to manage communication efficiently. Ineffective communications can lead to negligence of important issues that requires a quick response, which may result in on site decision being deferred [5].

Following is the Opco's performance measurement model – phase 1.

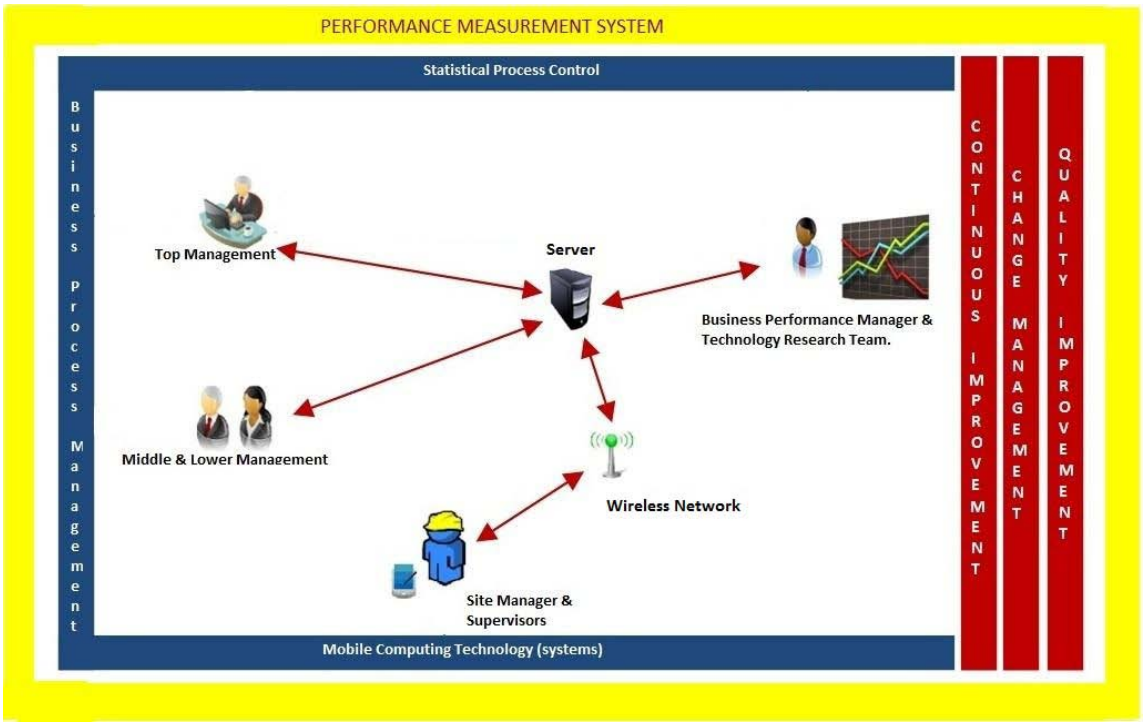

Figure 4: Opco Performance Measurement Model – Phase 1.

As we can see, everybody takes part in capturing data (red lines). The office based employees capture data and stores onto the server directly but the site based employees' captures the data using mobile computing technology and stores data onto the server. It is advised to continuously monitor data capture strategy in order to avoid information gap, which will destroy the whole measurement process.

Opco Performance Measurement Model – Phase 2:

The main objective of this phase is to analyse process behaviour, report to top management and to capture data continuously. Firstly, the performance manager analyse captured data using statistical process control tools to report (top-management) the variations (behaviour) of the processes. A statistical analysis of quality measurement should reveal any assignable cause variation.

In order to complete phase 2 operations successfully, we need statistical tools like

- Flow Diagrams: To understand process.
- Control Charts: To monitor the process performance.
- Scattered Diagram: To check process behaviour.
- Histogram and Pareto Charts: To monitor defect frequency rate.
- Cause and Effect Diagram: To understand the relation between business components.

Following is the Opco's performance measurement model – phase 2.

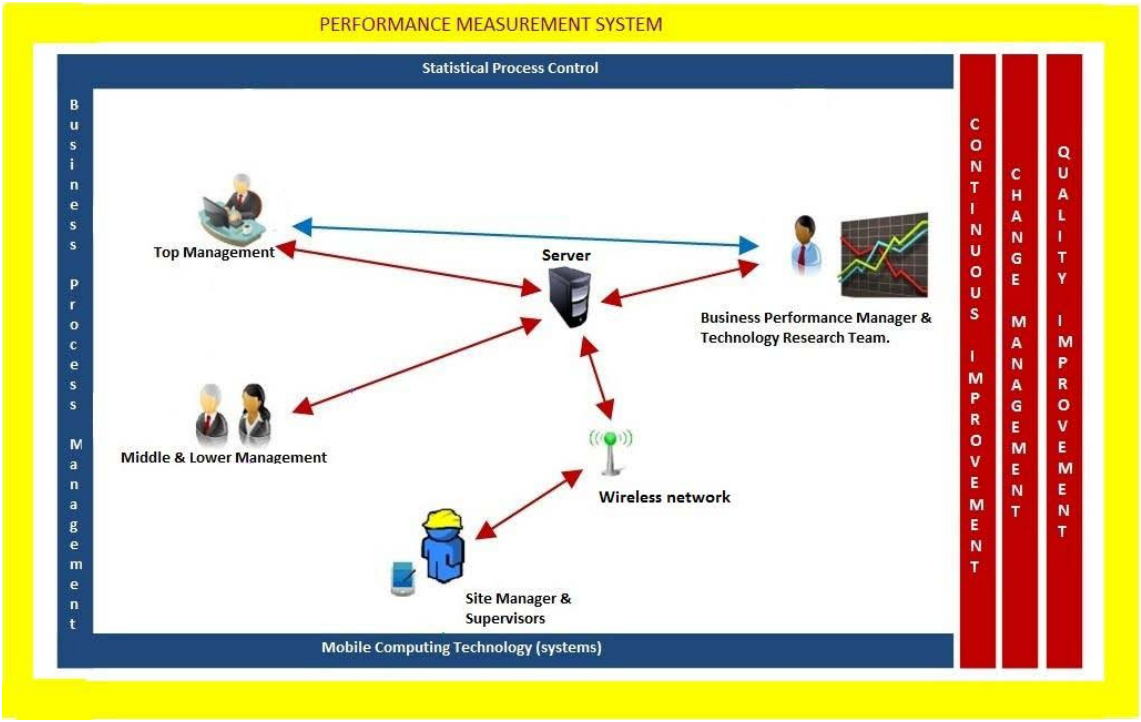

Figure 5: Opco Performance Measurement Model – Phase 2.

As we can see, this phase is divided into two parts. First part shows how the performance manager receives captured data from the server then analyse it using statistical tools and report to the top – management (blue line). Second part shows how everybody is participating in data capture strategy (red lines).

Opco Performance Measurement Model – Phase 3:

The main objective of this phase is for the top management to consult middle and lower management to discuss the problematic areas in the business processes and to capture data continuously. It is very important to have communication strategy (meeting matrix) in place; this will reduce the lead time and uncertainty by increasing the efficiency of decision making, planning and operations.

Majority of the decisions are taken during these meetings and it is advisable to make changes only if top management and the process owner mutually agree to the changes. And

the agreed changes must be reported back to the performance manager to commence process reengineering phase and change process.

Following is the Opco's performance measurement model – phase 3.

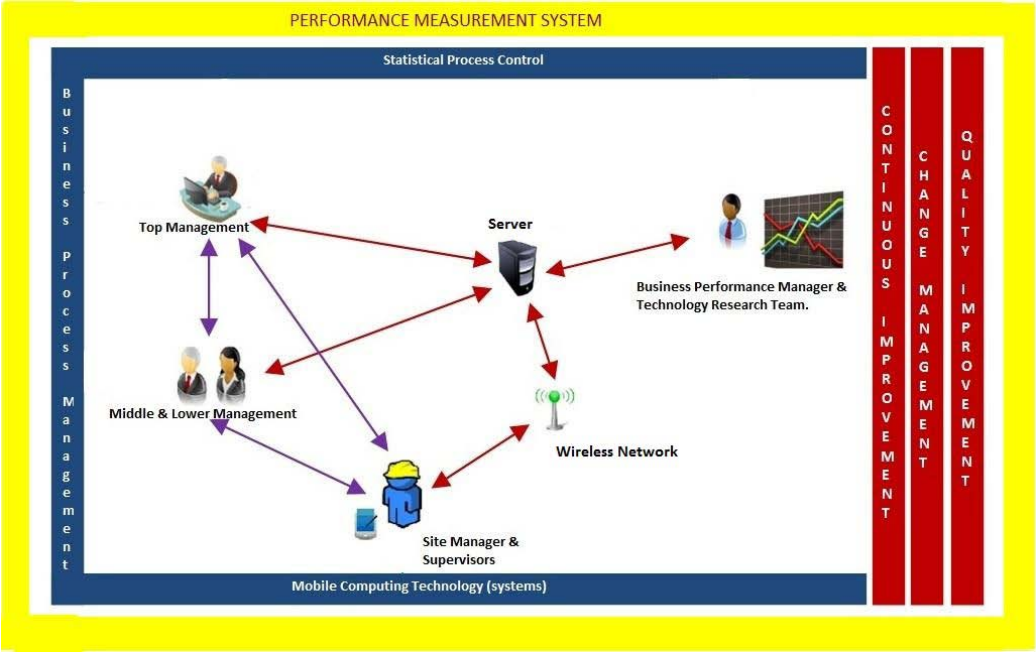

Figure 6: Opco's Performance Measurement Model – Phase 3.

As we can see, this phase is divided into two parts. First part shows how all the employees communicate across the organisation (violet line). Second part shows how everybody is participating in data capture strategy (red lines).

Opco's Performance Measurement Model – Phase 4:

The main objective of this phase is to reengineer business processes (by all) and to capture data continuously.

Following is the Opco's performance measurement model – phase 4.

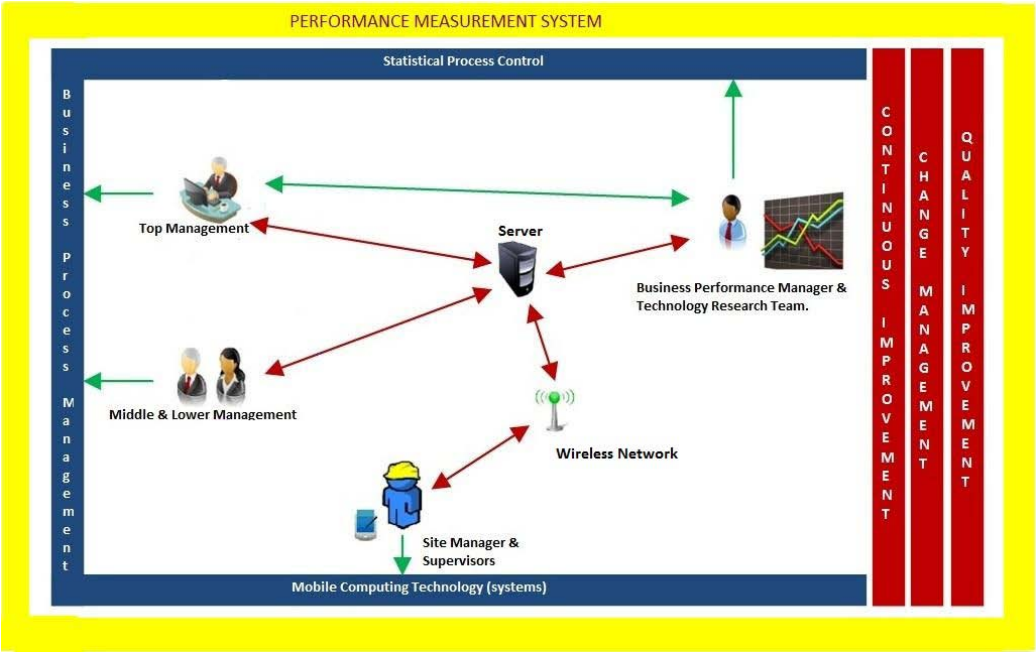

Figure 7: Opco's Performance Measurement Model – Phase 4.

As we can see, this phase is divided into two parts. First part shows how all the employees involved in change process through reengineering business processes (green line). These green lines show how everybody's working as a team to expand horizons in all directions. Second part shows how everybody is participating in data capture strategy (red lines).

Summary:

This section summarises the whole working process of Opco's performance measurement model.
Phase 1 : Capture data using web-based project management system (office level) and mobile computing technology (site level).
Phase 2 : Analysis of captured data using statistical process control tools, reporting to top-management and data capture.
Phase 3 : Top-management consults other employees regarding the performance reports, mutually agrees to the proposed changes to the processes and data cature takes place normally.
Phase 4 : Reengineering business processes across the organisation and data capture.

As you can see data capture never stops throughout the process

Table 1 : Summary of Opco's Performance Measurement Model.

CONCLUSION & RECOMMENDATIONS

The main aim of this research is to design a robust performance measurement model for the construction industry to achieve competitive edge by increasing the efficiency of an organisation at all levels.

It is very difficult to design performance measurement model to study business process behaviour in a construction industry because of its complex nature. Majority of the companies are still using traditional (financial) performance measurement models. It is very risky to make decisions based on the traditional measures because it provides past information and do not provide present performance and future forecasting. Usually companies implement performance measurement system at lower management levels, it is a must to implement it across organisation. But majority of the organisations face resistance from top management to support strategic change management.

A good performance measurement system depends on its performance metrics and it is very important to set the metrics right. The danger of measuring the wrong things right when the sole purpose of an exercise is to design performance metrics, which might not necessarily, related to strategy. This can usually occur when a large number of performance metrics is present in an organisation where “everything is measured but little that matters”.

Finally, the recommendations for both the researchers and practitioners are as follows

1) Performance Measurement System must be implemented at all levels of the organisation to maximise efficiency.

2) Performance Measurement System needs to establish relationship between various measures and promote conscious management of inevitable conflicts.

3) Performance Measurement System must facilitate continuous improvement in line with the strategic objectives of the business

4) Should try to avoid following traditional accounting based performance measures solely and to integrate it with the non-financial performance measures under one system.

5) Performance Measurement System design should consider mobile computing technology and web-based information systems capabilities to provide necessary level of data in terms of accuracy and reliability.

6) Performance Measurement System design should consider the organisational, behavioural and cultural aspects of the organisation concerned [2].

ABSTRACT

The Thai automotive industry has been ranked one of the top ten of the Thai export products for several years. Effective supply chain management has become a key strategy for the industry to stay competitive. Performance measurement has thus become a crucial issue in automotive supply chains. The purpose of the research is to gain insight into the relevant performance attributes that affect the automotive supply chains. The critical factor indexes (CFIs) are calculated in order to determine which of the performance attributes are considered to be the strength and which ones need to be specially focused, so that precautions could be made in developing the performance measurement system. Based on the CFIs, companies in Thai automotive supply chains can support their decision making under scarce resources with valid data. A set of questionnaires with different performance attributes is used comprising of two separate parts, one intended for the first tier supplier companies and the other for the automakers. Each performance attribute in the questionnaires is assessed on how important the company sees them from their perspective, how well the tasks measured by each performance attribute have been carried out in their companies, how they see themselves compared to their competitors, and how they see each performance attribute developing compared to the situation 1 to 2 years before. The results provide a guideline to the companies in Thai automotive supply chains to measure the right performance attributes for making the right decision in a competitive environment.

Keywords: Supply chain performance, performance measurement, critical factor index, Thai automotive industry

INTRODUCTION

The Thai automotive industry is important to the Thai economy. It has been ranked one of the top ten of the Thai export products. Besides Thailand is a regional hub of automotives and auto-parts manufacturing of leading automakers in the world. To have low prices as a competitive advantage factor is no longer sufficient for surviving under this high competitive economy. For instance, during the 1980s there was the cheapest car, branded “Yugo”, sold

in the United States but it went out of business because of its poor quality and the customers did not want to buy this car at any price. Thus, the company using the cost strategy required to deliver the consistent quality to customers while still retaining an attractive margin between prices received from its customers and the amount it pays its suppliers. Similarly, this principle also applies to the company's suppliers. Effective supply chain management has become a key strategy for the industry to stay competitive. Performance measurement has thus become a crucial issue in automotive supply chain. With the scarce resources in highly competitive environment, the first step to improve supply chain performance is to know which supply chain's performance attributes are critical and should be improved.

LITERATURE REVIEW

The automotive supply chain in Thailand

Nowadays Thailand is a trusted regional automotive manufacturing hub of automotive leaders around the world. There are many automakers establish in Thailand (Automotive Intelligence Unit, 2010) such as Toyota Motor Thailand Co., Ltd., Isuzu Motors Company (Thailand) Co., Ltd., Honda Automobile (Thailand) Co., Ltd., Thai-Swedish Assembly Co., Ltd., General Motors (Thailand) Co., Ltd., Thonburi Automotive Assembly Plant Co., Ltd., Tata Motors (Thailand) Co., Ltd. (with manufacturing facility established at Thonburi Automotive Assembly Plant Co. Ltd.), Nissan Motor (Thailand) Co., Ltd., Nissan Diesel (Thailand) Co., Ltd., BMW Manufacturing (Thailand) Co., Ltd., Mitsubishi Fuso Truck (Thailand) Co., Ltd., Mitsubishi Motors (Thailand) Co., Ltd., Siam Motors And Nissan Co., Ltd., Auto Alliance (Thailand) Co., Ltd., Hino Motors Manufacturing (Thailand) Co., Ltd. etc. The Thai automotive supply chain involves many different industry sectors. The supply chain of Thai automotive industry is depicted in Figure 1.

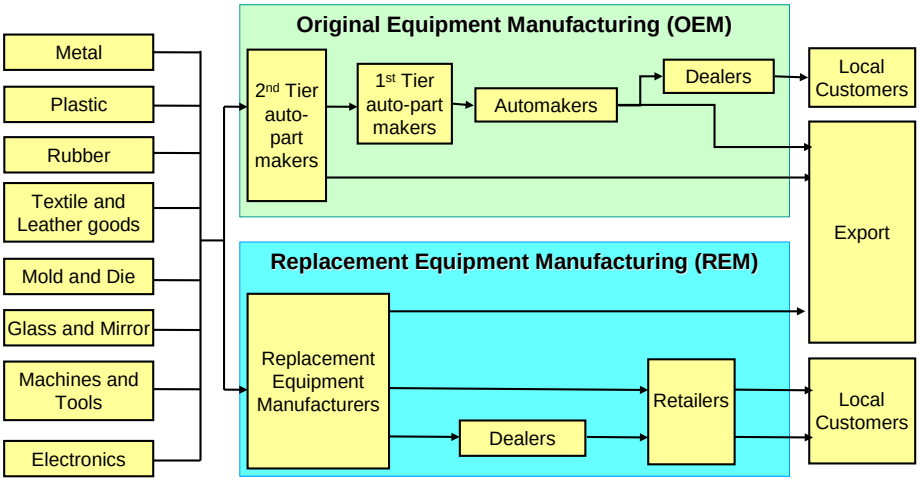

Figure 1: Thai automotive supply chain (adapted from NESDB, 2006).

As per National Economic and Social Development Board (2006), the generic Thai automotive supply chain comprises various industries from downstream to upstream (see

Figure 1). This ranges from the basic products such as metal, plastic, rubber, textile and leather goods, mold and die, electronics, etc. to the more complex products such as engine parts, body parts, lighting and electrical parts, transmission and steering parts, etc. The Thai automotive supply chain is separated into two groups, namely the Original Equipment Manufacturing (OEM) and Replacement Equipment Manufacturing (REM). This research is focused on the OEM side between first tier auto-part makers (or "first tier supplier" in this paper) and automakers.

Performance of the individual firm: Balanced scorecard

The balanced scorecard allows managers to look at the business from four important perspectives and could minimize information overload by limiting the number of measures used (Kaplan & Norton, 2005). Kaplan & Norton (2005) indicated that companies rarely suffer from having too few measures; on the contrary, they keep adding new measures whenever an employee or a consultant suggested. The balanced scorecard helped managers to focus on the handful of measures that are most critical, by forcing managers to consider all the important operational measures together, the balanced scorecard lets them see whether improvement in one area may have been achieved at the expense of another. The balanced scorecard translates a mission and strategy into a set of measures and metrics that comprises of four perspectives which link to performance measures. (Kaplan & Norton, 2005) Chareonsuk and Chansa-ngavej (2010) have studied the effect of intangible assets on the business performance of individual firm by adapting from the strategy map of balanced scorecard. They have explored the interrelationships of three elements of intangible assets: learning and growth, internal process, and external structure on the business performance of the firm.

Linkage for the firms in a supply chain: Trust

Nowadays several companies increase their competitive advantage by making the collaborative relationships with their alliance partners in the supply chain. Trust makes the supply chain relationships strong (Jones, Fawcett, Fawcett & Wallin, 2010; Robertson, 2006, p.81; Svensson, 2001). Benefits of trust to supply chains are as follows: (Jones, Fawcett, Fawcett & Wallin, 2010)

- Lower transaction costs to develop and maintain supply chain relationships by using fewer resources to develop detailed contracts; lower contract monitoring and enforcement costs; and reducing contract renewal, switching, and set up costs.
- Increased value-creation opportunities by identifying and sharing resources and knowledge to solve problems; jointly developing the product; and making process improvement
- Enhanced collaborative learning by having close collaboration allow information to flow freely among parties results in transfer of existing knowledge and generation of new knowledge.

Trust is a multidimensional concept (Jones, Fawcett, Fawcett & Wallin, 2010; Svensson, 2001) and the definitions of trust from several scholars are summarized (Jones, Fawcett, Fawcett and Wallin (2010) as per Table 1.

Table 1: Definitions of trust (Jones, Fawcett, Fawcett & Wallin, 2010).

Author(s)	Definition
Anderson and Narus (1990)	A firm's belief that another company will perform actions that will result in positive outcomes for the firm, as well as not take unexpected actions that would result in negative outcomes for the firm
Ring and Van de Ven (1992)	Confidence in the other's goodwill
Sabel (1993)	The mutual confidence that no party to an exchange will exploit the others' vulnerability
Mayer et al. (1995)	Willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party
Zaheer et al. (1998)	Expectation that an actor can be relied on to fulfill obligations, will behave in a predictable manner, and will act and negotiate fairly when the possibility of opportunism is present
Sako (1998)	Expectation held by an agent that its trading partner will behave in a mutually acceptable manner (including an expectation that neither party will exploit the other's vulnerabilities)
Dyer and Chu (2003)	One party's confidence that the other party in the exchange relationship will not exploit its vulnerabilities
Lui and Ngo (2004)	Expectation of a partner fulfilling a collaborative role in a risky situation, and (the reliability) of both the partner's intention to perform and its ability to do so
Kwon and Suh (2005)	A willingness to take risk and a willingness to rely on an exchange partner in whom one has confidence
Ireland and Webb (2007)	The decision to rely on a partner with the expectation that the partner will act according to a common agreement

Companies with supernormal returns (relational rent) are generated when partners make investment in relation-specific assets; exchange knowledge that results in joint learning; having join resources that create unique new products and services; and lower transaction costs because of effective governance mechanisms.

Fawcett et al. (2004) as cited in Jones et al (2010) developed a robust construct of trust that can be measured by categorizing trust to be five indicators as follows:

1. *Performance-to-promise*
   Trust are increase when the partners perform according to the promises they have made such as the buyers will gain more confidence in a supplier if the supplier repeatedly delivers product on time with consistent quality.
2. *Professional-relationship*
   The relationships occur from the buyer's agent and supplier's agent. The company's trustworthiness can be built if the company's agent demonstrates a consistent, credible, and positive interface with its partner's agent.
3. *Openness*
   Openness can be shown by the amount, frequency, and type of information sharing among supply chain partners. The openness can signal commitment to a relationship and increase trust because it makes visibility to the partners, then the uncertainty can be reduced.
4. *Benevolent-collaboration*
   Benevolent-collaboration can be in the form of resources planning. If supply chain partners share the saving they get, make some investments (such as in equipment, people etc.) to increase efficiency that benefit to their partner; then the supply chain partners will perceive one another as fair and can increase trust in each others.
5. *Empathy*

Supply chain partners that act with empathy will treat their partners fairly and consider their needs when making decisions. If the external environment changes such that their partner is in trouble, they may choose to alter its contract to safeguard the relationship.

RESEARCH FRAMEWORK

The purpose of the research is to gain insight into the relevant performance attributes that affect the automotive supply chains. The performance attributes were established according to each indicator for individual company. The companies in a supply chain can create more competitive advantage than individual company by making collaborative relationships with each other. Therefore, the benefits gained by two companies are more than sum of them. As mentioned in Jones, Fawcett, Fawcett and Wallin (2010), "trust" is the most essential elements to develop the strong collaborative relationships and the alliance parties in the supply chain could gain mutual benefit to achieve the competitive advantage. Hence, trust is an element that links the individual company in the supply chain and the level of trust can affect the performance of a supply chain.

According to the above reason, the individual company's elements (Chareonsuk & Chansa-ngavej, 2010), and the collaborative relationships element or "trust" (Jones, Fawcett, Fawcett & Wallin, 2010) with their indicators were used as a basis to established the elements of supply chain performance and their indicators. The elements of supply chain performance and their indicators are depicted in Table 2. The Thai automotive supply chain was used as a case study for finding the critical performance attributes of the first tier suppliers and automakers.

Table 2: The elements of supply chain performance and their indicators.

Elements of Supply Chain Performance	Supply Chain Performance Indicators
Business performance	Financial Sales Customer
External structure	Customer satisfaction Customer loyalty Brand
Internal process	Process improvement Innovation Information technology
Learning and growth	Know-how Knowledge Competency Engagement
Trust	Performance-to-promise Professional-relationship Openness Benevolent-collaboration Empathy

RESEARCH METHODOLOGY

Planning the questionnaire

The primary data for analyzing and investigating the critical performance attributes were gathered by opinion survey questionnaire. The population was limited to the companies within the automotive industry in Thailand. Two questionnaires were developed. The performance attributes in the questionnaires are based on the research performed by Chareonsuk and Chansa-ngavej (2010) and Jones et al. (2010) that were categorized under five main elements: business performance, internal structure, external structure, learning and growth, and trust. A set of questionnaires comprising of two separate parts; one intended for the first tier supplier companies, i.e. companies that produce materials and components for car manufacturers; and the other for the automaker companies, i.e. automotive assemblers. The list of the target group is gathered from the database of Automotive Intelligent Unit, Thailand Automotive Institute (TAI). The questionnaires were mailed to the top management, factory managers, sales managers, and purchasing managers of first tier suppliers and automakers in the Thai automotive supply chains.

Each performance attribute in the questionnaires is assessed on how important the company sees them from their perspective, how well the tasks measured by each performance attribute have been carried out in their companies, how they see themselves compared to their competitors and how they see each performance attribute developing compared to the situation 1 to 2 years before. The format of the questionnaire had been adapted from Ranta and Takala (2007) and shown in Figure 2. The questionnaire format can be used to collect answers that reliable and valid ones, the structure is attractive to answer and the wide numerical estimation- scale from 1 to 10 made the questionnaire to be easy to find differences between attributes (Ranta & Takala, 2007).

Performance Attribute	Scale: 1 = Low, 10 = High		Compared with competitors			Direction of development		
	Expectation (1-10)	Experiences (1-10)	Worse	Same	Better	Worse	Same	Better
Performance Attribute#1			☐	☐	☐	☐	☐	☐
Performance Attribute#2			☐	☐	☐	☐	☐	☐

Figure 2: Format of the questionnaire (adapted from Ranta and Takala 2007).

RESULTS

Data analysis

A total of 14 questionnaires from 1st tier suppliers were completed. In order to compare the views and opinions of the different interest groups, the respondents were divided into 4 groups: Top management, Factory managers, Purchasing managers and Sales/Marketing managers. The purchasing manager group was excluded from the analysis since only one respondent answered which could not be analyzed by using one respondent. Then, the averages and standard deviations of the expectations and experiences for each performance

attributes are calculated. Standard deviations help to evaluate the validity and reliability of the results. Gap index is calculated from the absolute value of the expectations and experiences. The direction of development and importance index are calculated by using the formulas shown in Figure 3.

The value of each index can be interpreted as shown in Table 2.

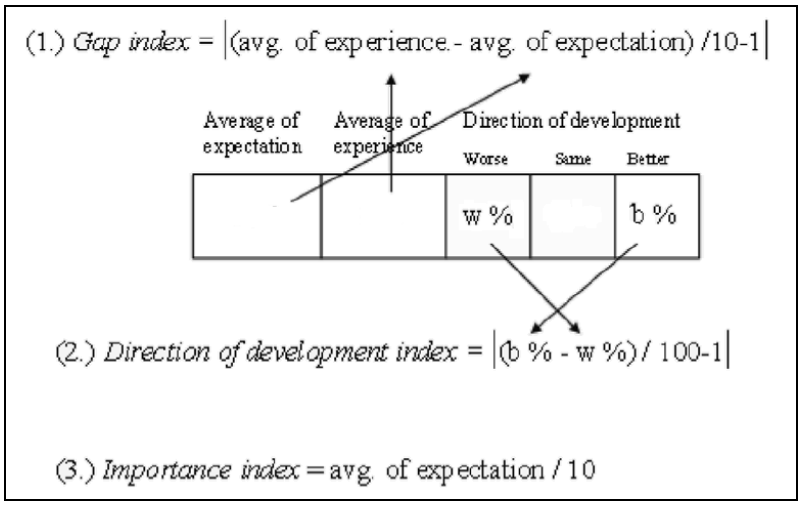

Figure 3: Calculating formulas (Ranta and Takala, 2007).

Table 2: Meaning of each indexes (Ranta and Takala, 2007).

Index	Value	Meaning
Direction of development	= 1	The performance has remained on the same level.
	< 1	The performance has been developed.
	> 1	The performance has been decreased.
Gap index	= 1	There is no gap between expectations and experiences.
	< 1	The expectations are lower than experiences.
	> 1	The experiences are lower than expectations
Importance index	Large	More important expectation of the attribute.
	Small	Less important expectation of the attribute.

The results of standard deviations and indexes are used to calculate Critical Factor Index (CFI) in order to determine whether which performance attributes are considered to be strength and which ones need to be specially focused. The equation of CFI is depicted in Figure 4. The smaller value of the CFI is more critical performance attribute.

$$\text{CFI} = \frac{\text{SD of expectation} * \text{SD of experience}}{\text{Importance index} * \text{Gap index} * \text{Direction of development index}}$$

Figure 4: Critical Factor Index (CFI) (Ranta and Takala, 2007).

Research results

The analysis was done by including all the answers and separating each group of respondents i.e. Top management, Factory manager, and Sales/Marketing manager. The

reason to separate these groups is to see the critical performance attributes from different perspectives. The top management group looks at the performance attributes in the strategic view. The factory manager group looks at the performance attributes in the operation or practical point of view. The sales/marketing manager group considers the performance attribute as a joint that is closest to the automotive customer.

Preliminary analysis – All

The preliminary result for answer collected from all 13 respondents of 1st tier suppliers is depicted in Table 3.

Table 3: Preliminary result for answer collected from all 1st tier suppliers.

Performance Attribute		*Expectations*		*Experiences*		*Compared with competitors*			*Direction of development*		
		Average	*SD*	*Average*	*SD*	*Worse %*	*Same %*	*Better %*	*Worse %*	*Same %*	*Better %*

Preliminary result indicates the high expectation on TPR3, BC1, and BC8 which are honest and truthful with customers; customer satisfaction; and overall response to customer. The performance attribute of TPR3 (honest and truthful with customers) also has high value in how the companies see that the performance attribute is being carried out in their companies (experience). The lowest importance for companies are IIT4, TBC4, and TBC5 which are completing the registration of new ideas and products at the Department of Intellectual Property; offering technical training/education to customers to help them improve performance; and sharing profits gained through collaborative efforts with their customers. The IIT4 (completing the registration of new ideas and products at Department of Intellectual Property) also has lowest value in how performance attributes are being fulfilled in the companies (experience).

All the performance attributes have the score higher in importance than the experience in their companies. This features show that all the performance attributes should be developed. However, there are a total of 88 performance attributes and the companies have the scarce resources. Therefore, they have to find and focus on the critical performance attributes determined in this paper by using CFI. The respondents see that nearly all performance attributes in their companies are better than competitors, except 7 out of 88 performance attributes that are worse than their competitors. These seven performance attributes are LKL1 (comprehensive in recruitment program by dedicating to hiring the best candidates available), LKL5 (provision of self-learning facilities for employees), LE2 (The employees generally give their all which makes the firm different from the others in the industry), LE3 (Employee involvement in business policy and strategy setting), II5 (Development of new ideas and products), IIT4 (Registration of new ideas and products at the Department of Intellectual Property), and BS3 (Market share). There is one performance attribute that is the same as their competitors, which is TBC4 (Technical training/education that offered to customers to help them improve performance). This may be because they see the TBC4 as low in important as the average of expectation is only 6.77. Normally in the Thai automotive supply chain, most of the automakers are huge multinational companies that transfer knowledge to them.

All the performance attributes at the time the respondents answer in the questionnaires are better than last two years, except LE3 (The employee involvement in business policy and strategy setting), which is worse than previous; and LKH5 (A succession training program for replacement an employee who leaved the firm) and LKL5 (Provision of self-learning facilities for employees) are remaining the same as previous two years.
In the next sections, the answers were divided into three separated groups of positions, namely Top management, Factory managers, and Sales/Marketing managers.

Preliminary analysis – Top management

The preliminary answers from top management of 1st tier suppliers are depicted in Table 4.

Table 4: Preliminary result for answer collected from Top management of 1st tier suppliers.

	Performance Attribute	*Expectations*		*Experiences*		*Compared with competitors*			*Direction of development*

The top management sees TPR3 (honest and truthful with customers) as the highest importance and the experience of this performance attribute being carried out in the companies is also high. This is the same as the result from all positions. In the top management's point of view, the lowest importance for companies are the same as results from all positions which are TBC5, IIT4, and TBC4 which are sharing profits gained through collaborative efforts with their customers; completing the registration of new ideas and products at Department of Intellectual Property; and offering technical training/education to customers to help them improve performance. The IIT4 (completing the registration of new ideas and products at Department of Intellectual Property) is also has lowest value in how performance attributes are being carried out in the companies. This is also the same as the result from all position. This may be because most of the 1st tier suppliers of the Thai automotive companies are the OEM (Original Equipment Manufacturing). Almost all of the auto parts are designed by the customers (automakers) or otherwise the collaborative design is made by involving part makers at the beginning stage of product development. There are only a few 1st tier suppliers that have their own designed products and offer for use in the automobiles. The top management sees that all performance attributes are better than last two years as depicted in the direction of development, except LKL5 (provision of self-learning facilities for employees) and LE3 (employee involvement in business policy and strategy setting) are the same as previous two years.

Preliminary analysis – Factory manager

The preliminary answers from factory managers of 1st tier suppliers are shown in Table 5.

Table 5: Preliminary result for answer collected from Factory Manager of 1st tier suppliers.

Performance Attribute		*Expectations*		*Experiences*		*Compared with competitors*			*Direction of development*

The factory managers see several performance attributes are equal important level, as the maximum value of 13 performance attributes in average expectation is 9.75. Three of them were also the highest important in the result of all positions which are TPR3, BC1, and BC8. Lowest important in the factory managers' point of view are LE1 (employees' understanding about companies' target market segments and customer profiles), LE3 (employee involvement in business policy and strategy setting), and TBC4 (offering technical training/ education to customers to help them improve performance). LE1 and LE3 are different from the result from the other positions. For the direction of development, the factory managers see all performance attributes are improved or at lease the same as last two years.

Preliminary analysis – Sales/Marketing manager

The preliminary answers from sales/marketing managers of 1st tier suppliers are depicted in Table 6.

Table 6: Preliminary result for answer collected from Sales/Marketing Manager of 1st tier suppliers.

Performance Attribute		*Expectations*		*Experiences*		*Compared with competitors*			*Direction of development*		
		Average	*SD*	*Average*	*SD*	*Worse %*	*Same %*	*Better %*	*Worse %*	*Same %*	*Better %*

There are six performance attributes that all sales/marketing managers see them as highest important with the average expectation is 10.00 combined with the zero standard deviation. This is important to indicate that these performance attributes are the keys that should be focused. These six performance attributes are TPP3 (always deliver on promises made to customers). TPR1 (companies' culture encourages sellers to treat customers with fairness and respect), TPR3 (honest and truthful with customers), TO1 (do not use any proprietary information to our customers' disadvantage), BC1 (Customer Satisfaction), and BC2 (Customer retention/loyalty). This is not that surprising in that all are related to the customers since the sales/marketing is the function in the firm that has the closest linkage to the customers. TPP3 is the only performance attribute that all sales/marketing managers see it completely carried out in the company as can be seen that the experience was scored 10.00 combined with zero standard deviation. Sales/marketing managers saw 26 performance attributes are worse than their competitors; 22 performance attributes are the same as their competitors; the direction of development of 13 performance attributes are worse than previous two years; and 27 performance attributes are the same as previous two years.

In summary, all groups indicated that TPR3 (honest and truthful with customers), BC1 (Customer Satisfaction), and BC8 (Overall response to customer) are important to them. Their answers also indicated that IIT4 (completes the registration of new ideas and products at the Department of Intellectual Property) has been less carried out in the companies and their expectations are also low compared to other performance attributes.

Critical factor index (CFI)

The CFIs were calculated by using the formulas as mentioned previously. The goal of this CFI analysis is to provide support decision making whether which performance attributes are critical and should be focused. The CFIs were calculated from all respondents as well as separately for top management, factory manager, and sales/marketing manager. The compared CFIs results from all respondents and in separated groups are depicted in Table 7 and shown in Figure 5 to Figure 8. The numbers in red indicate performance attributes that are to be seen as critical and figures in green are attributes that are considered to be strengths.

Table 7: Results of Critical Factor Index (CFI).

Figure 5: Critical Factor Index (CFI) for answer collected from all 1st tier suppliers.

Figure 5 indicates that the highest CFIs for all positions of 1st tier suppliers are TBC5 (share profits gained through collaborative efforts with customers), BF2 (Profit growth), and TBC4 (offer technical training/education to customers to help them improve performance). The performance attributes that are proposed to be critical (in red) are TPR3 (honest and truthful with customers), BC1 (Customer Satisfaction), BC8 (Overall response to customer), and LE4 (encouraged communication with all levels in organization).

CFI – Top management

The CFIs calculated from top management's answers are depicted in Figure 6. The top management CFIs are quite similar to the overall CFIs. From this figure, it can be seen that the CFIs in red are TPR3 (honest and truthful with customers), BC8 (Overall response to customer), BC1 (Customer Satisfaction), ECS7 (A pool of their customers would indicate that the customers are generally satisfied with their organization), and LE4 (encouraged communication with all levels in organization) and four of five performance attributes are also in red while calculating by using the answers from all position, only ECS7 (A pool of their customers would indicate that the customers are generally satisfied with their organization) is different.

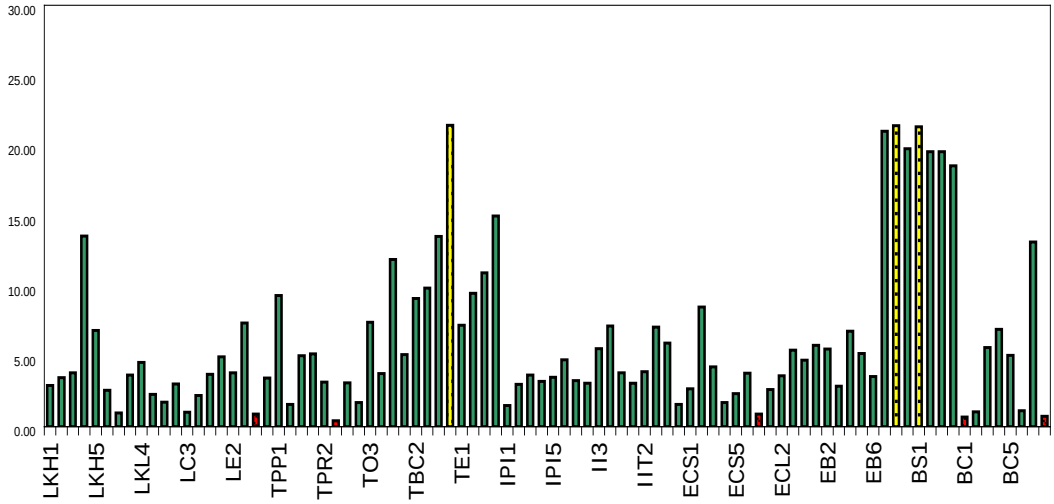

Figure 6: Critical Factor Index (CFI) for answers collected from Top management of 1st tier suppliers.

CFI – Factory manager

The CFIs calculated from factory managers' answers are depicted in Figure 7. The factory managers CFIs are quite different from the others. From the figures, the performance attributes in red are ECS4 (care about what the customer thinks or wants); BC1 (Customer Satisfaction); IIT5 (communicate with other departments to solve the problems in the organization and keep records); BF3 (Profit margin); and BS4 (Market share growth). Only BC1 is also appeared to be high score in expectation by the other positions.

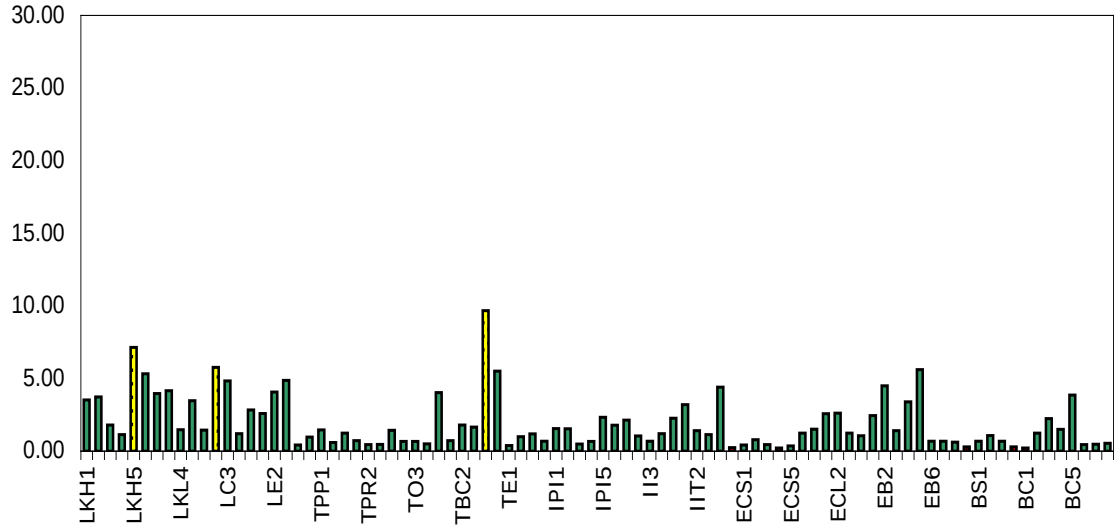

Figure 7: Critical Factor Index (CFI) for answers collected from Factory managers of 1st tier suppliers.

CFI – Sales/Marketing manager

The CFIs calculated from sales/marketing managers' answers are depicted in Figure 8. Some of the performance attributes that answers from the sales/marketing could not be calculated for CFIs since the standard deviation of expectation or experience is zero value. However, the remaining performance attributes were calculated and plot in the graph. The figures in red are TPR2 and LKH1 which are fairness and integrity accurately characterize all dealing with customers; and training for the new staff before starting job.

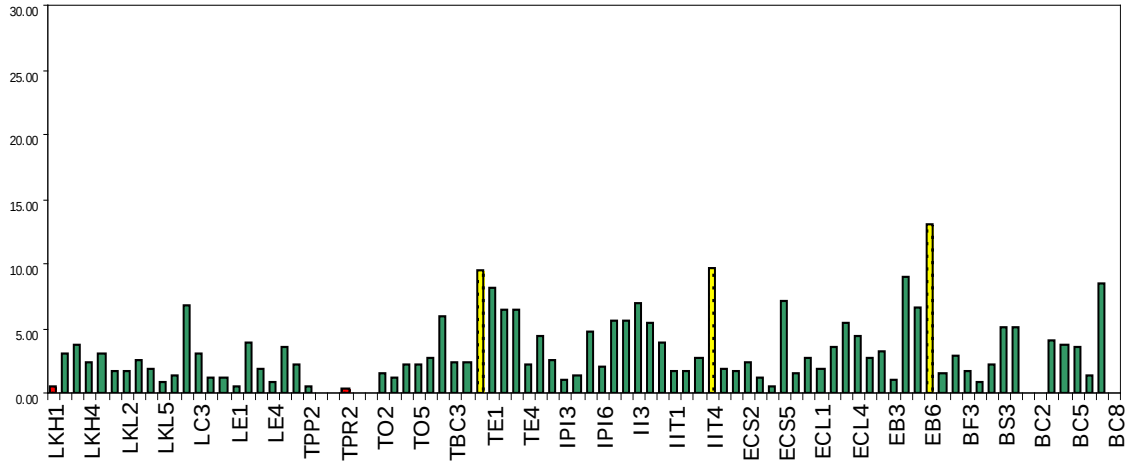

Figure 8: Critical Factor Index (CFI) for answers collected from Sales/Marketing managers of 1st tier suppliers.

DISCUSSION AND FURTHER STUDIES

The results from the analysis can be summarized in Table 8.

Table 8: Summarized Results of Critical Factor Index (CFI).

Supply chain performance		Critical performance attribute			
Elements	**Indicators**	**All**	**Top Management**	**Factory Manager**	**Sales/ Marketing Manager**
Learning and growth	Know-how (LKH)				LKH1
	Knowledge (LKL)				
	Competency (LC)				
	Engagement (LE)	LE4	LE4		
Trust	Performance-to-promise (TPP)				
	Professional-relationship (TPR)	TPR3	TPR3		TPR2
	Openness (TO)				
	Benevolent- collaboration (TB)				
	Empathy (TE)				
Internal process	Process improvement (IPI)				
	Innovation (II)				
	Information technology (IIT)			IIT5	
External structure	Customer satisfaction (ECS)		ECS7	ECS4	
	Customer loyalty (ECL)				
	Brand (EB)				
Business performance	Financial (BF)			BF3	
	Sales (BS)			BS4	
	Customer (BC)	BC1 BC8	BC1 BC8	BC1	

According to the results from all respondents, the 1st tier suppliers in the Thai automotive supply chain should focus on the engagement in learning and growth element, professional relationship in trust, and customer in business performance element. However, there are some results analyzed from different positions that appear to have some different critical performance attributes. This is understandable as different groups have different points of view. For instance, sales/marketing managers focused on the know-how in learning and growth element (LKH1: Training is required for the new staff before starting job.) because they are the contact point to the customer. Therefore they require having know-how in order to explain or answer the customers' questions about products and company. Factory managers required the information technology in the internal process element (IIT5: communication with other departments to solve the problem in the organization and keep record) because they manage the factory that produce the products where the problems that occur in the manufacturing process need to be solved quickly and always need other departments to be involved.

The results from this questionnaire process are still preliminary. The answers from the automaker companies are few and cannot be analyzed. In future researches, the answers from the automakers will be collected and analysis will be made. In the long run, the causal relationship between the supply chain performance elements focused on the critical performance attributes will be studies.

ACKNOWLEDGMENT

COMPLETENESS OF SUSTAINABILITY REPORTS: THE EXAMPLES OF POLISH AND INTERNATIONAL COMPANIES

Agnieszka Leszczynska, Maria Sklodowska Curie University, Poland
leszczynski1@poczta.wp.pl

ABSTRACT

Sustainability reporting, which integrates information on the economic, environmental, and social performance of a company into a single publication, is a new trend in corporate reporting. This article discusses research evaluating the quality and completeness of sustainability reports published by Polish and international companies. In the case of Polish organizations that have recently begun to present sustainability reports, their completeness was assessed according to the GRI guidelines. In the case of international companies, the reports published in 2005 and 2010 were compared.

Keywords: sustainability reports, corporate sustainability, reporting

CORPORATE SUSTAINABILITY AND REPORTING

Defining sustainability, corporate sustainability

The concept of sustainable development, generally used at the macroeconomic level, presupposes that it is the development that meets the needs of the present without compromising the ability of future generations to meet their own needs. As a general concept, sustainable development encompasses three interrelated and complementary fundamental approaches: economic, environmental, and that of social development. Economic sustainability is fundamental to financial success, e.g., in the long run an organization simply cannot survive if its expenditure exceeds income. Social sustainability embodies the humanitarian context and relates to issues of poverty, income inequality, disease, education, as well as access to clean water. Environmental sustainability considers the impact on the quality and quantity of natural resources, improved pollution and emissions management (Townsend, 2008). Sustainable development is the development that attempts to bridge the divide between economic growth and environmental protection, while taking into account other issues traditionally associated with development. It seeks to develop the means of supporting economic growth while supporting biodiversity, relieving poverty and without using up natural capital in the short term at the expense of long-term development. Indeed, there is a growing consensus that firms and governments in partnership should accept moral responsibility for social welfare and for promoting individuals' interest in economic transactions (Aras and Crowther, 2009).

While at the macro level there is a certain vision of what sustainable development is, at the level of organizations this concept has not been made sufficiently specific. Definitions of corporate sustainability vary on the degree to which they classify corporate sustainability as either ecological concern (Shrivastava, 1995) or as social responsibility of an organization (Carroll, 1999), or broaden the concept of corporate sustainability to integrate corporate economic activities with organizational concern about environment (van Marrewijk, 2003).

The present paper is based on the assumption that a company is sustainable if its practices contribute positively to the welfare of a society and have as small an environmental impact as possible. Sustainability therefore is currently used to refer to a company's ability to maintain and demonstrate a positive economic, environmental, social performance over the long-term.
The economic dimension refers to financial viability. It encompasses issues of competitiveness, job and market creation, and long-term profitability. Economic sustainability is increasingly understood to refer to generating added value in a wider sense rather than conventional financial accounting. The economic and financial aspects of sustainability may therefore encompass (ICC, 2002):

- reducing operating costs through the systematic management of resources,
- reducing the cost of doing business and attracting new business through rigorous business integrity policies,
- attracting a new range of investors,
- offering opportunity for inclusion in socially responsible investment indices.

The environmental dimension focuses on an organization's impact on living and non-living natural systems, including eco-systems, land, air. Environmental responsibility involves more than compliance with all applicable government regulations or even initiatives such as recycling or energy efficiency. It involves a comprehensive approach to a company's operations, products, facilities that includes eliminating waste and emissions, maximizing the efficiency and productivity of all assets and resources (Jamali, 2006).
The social dimension – centers on the impact of an organization on the social systems within which it operates. The expectations of diverse groups of internal and external stakeholders as well as interest groups comprising civil society are genuinely considered and skillfully balanced.

At the practical level, positive results achieved in all the mentioned aspects are a possible indicator of sustainable development in an organization. Thus, an organization should achieve positive financial results, at the same time implementing wide-ranging activities oriented towards the development of employees and support of a local community, as well minimizing its negative impact on the environment.

Sustainability reporting

Over the last decade, more and more organizations have moved toward monitoring their performance on environmental and social aspects. Sustainability reports become new trend in corporate reporting. Two schools can be distinguished in this area. The first school comprises those who think such reporting can usefully be based at the organizational level because the entity is what we are used to, social accounting at this level offers a challenge to financial accounting and the entity is the locus of decision-making, and probably power (Gray, 2006). The second school believes that the economic organization is the problem and that all reporting needs to be based on regions, ecological regions and local eco-system, and the boundaries between organizations must, consequently be re-drawn or even removed (Gray and Milne, 2004).It is critical to collect and analyze information on sustainability for improved resource allocation decisions. This information should then be included in internal sustainability reports to improve managerial decision-making regarding processes and

products. How companies perform on sustainability is also an important factor for external stakeholders since they are affected by organization actions.

Sustainability reporting is based on the premise that organizations are not only connected with one group of stakeholders, but are also related to other groups/stakeholders. Those groups may be interested in an organization's results and activities (plans, programmes) it undertakes in various areas. Stakeholders, and particularly investors, generally require a clear demonstration that (a) sustainability impacts are well managed, and (b) sustainability initiatives are aligned to strategy and support future performance. Organizations themselves also benefit from reporting non-financial information. It can allow them to track their progress against specific targets and help them convey information on corporate sustainability strategy internally and externally communicating all relevant efforts. If we cannot develop a consensus definition of sustainable development in organizations, we can still proceed by having a consistent tool for monitoring progress.

Literature, as well as consulting firms' offers, describes a number of methods/methodologies to assess the level of organizations' sustainable development. The most frequently named are: the World Business Council for Sustainable Development, the Global Environmental Management Initiative, the Coalition for Environmentally Responsible Economies are among the most frequently named. The common characteristics of a majority of them include (Format):

1. An explanation of how sustainability is connected to the overall operational strategy of an organization and the provision of sustainability targets. The challenge is to ensure that in mainstream reporting the sustainability information included is strategically important. Targets are important to ensure and demonstrate that sustainability issues are taken into account when making investment decisions.
2. Five key environmental indicators, which all organizations should consider reporting, they are: greenhouse gas emissions, energy usage, water use, waste and significant use of other finite resources.
3. Other key sustainability information should be given where the business or operation has material impacts. The Framework is not prescriptive in this respect to avoid the provision of irrelevant information and a "one-size-fits-all" approach.
4. To aid performance appraisal, industry benchmarks for the key performance indicators when available.
5. The up-stream and down-stream impact of the organization's products and services: the sustainability impacts of its suppliers and the use of its products or services by customers and consumers.

The most widely recognized and acknowledged is the GRI Guidelines. The GRI Guidelines are the first framework for providing guidance for disclosure about sustainability performance. More than three-quarters of the Global Fortune 250 companies follow the Guidelines. It is based on the evaluation of economic, ecological, and social performance. The GRI guidelines suggest that reports should cover the following indicators:

- vision and strategy of an organization on sustainable development, including a relevant statement by the CEO or equivalent senior manager;
- profile of the organization and the report itself, giving an overview of organization's activities and report's scope;

- organization's governance structure, including overarching policies and management systems in place to implement the vision of an organization regarding sustainable development;
- performance of an organization during the reporting period, with information grouped under indicators according to the conventional definition of sustainable development.

Some examples of indicators for three key areas of sustainability including:

- economic: wages and benefits, job creation, expenditures on research and development, investments in training, forms of human capital, traditional financial information,
- environmental: impacts of activities, products on air, water, land, biodiversity, human health,
- social: workplace health, employee retention, human rights and diversity, wages, working condition.

The GRI Guidelines offer (a) core content for reporting that is relevant to all organizations, and (b) indicator protocols that advise on definition, scope, and compilation methods to help organizations to ensure a meaningful and comparable reporting on indicators. No organizations expected to report on all the elements in the guidelines, but they are expected to expand their reporting with time. The evaluation of sustainability reports presented by organizations is based primarily on their completeness: Is the information complete and accurate enough to assess an organization's performance? As additional evaluation criteria GRI suggests:

- materiality: Does the sustainability report provide an account covering all the areas of performance that stakeholders need to judge the organization's performance?
- responsiveness: Has the organization responded coherently to stakeholder's concerns and interests?

STUDY METHOD

Scoring system

In deciding on a method for evaluating organization reports, the author looked at several potential metrics. The GRI methodology was adopted as the basis for evaluation because it is generally used and available (69 percent of the largest companies by revenue follow the GRI Sustainability Reporting Guidelines). The range of points used in evaluating sustainability reports was between 0 and 4. Points were assigned as follows:

- when a specific topic was not mentioned In the report, no points were assigned,
- brief or generic statements received 1 point,
- more detailed coverage received 2 points,
- extensive coverage received 3 points,
- 4 points was assigned to topic when coverage was full.

It should be stressed that the study did not evaluate results achieved by individual organizations, but exclusively the way (precision, reliability) in which they presented

information. The maximum score was 312 for 78 topics. The number of topics and the maximum possible score for each of them are presented in Table 1.

Table 1: Scope of the study.

Section	**Topics**	**Maximum points**
Vision and strategy	1	4
Profile, parameters	21	84
Governance	5	20
Economic performance	8	32
Environmental performance	18	72
Social performance:	25	100
Labour practices	9	36
Human rights	6	24
Society	6	24
Product responsibility	4	16

Studied reports

A web-based search was performed to collect all sustainability reports published by polish and international organizations. In total, 12 Polish reports were included in the assessment for 2010 (see Table 2). All organizations in this group were first-time reporters. The study of international organizations covered 17 companies. The reports analyzed in this group came from 2005 and 2010. 10 reports of 2005 were examined. Half of the organizations in this group did not prepare reports in the following years. 5 organizations that published their sustainability reports also in 2010 were subject to a comparative examination. In 2010, 12 additional organizations that had not earlier presented sustainability reposts were included in the study. According to the time of preparing the report, the GRI guidelines or GRI framework were used.

Table 2: List of the analyzed reports.

	2005	**2010**
International organizations	SAB Miller Cosmote Coca Cola British American Tobacco Atlas Copco BP Henkel Skoda Auto Palfinger World Steel Industry	Samusung IKEA SAB Miller Cosmote Coca Cola British American Tobacco Atlas Copco Daimler Chrysler Toyota Wal Mart Siemens Asia Development Bank Confederation of European Paper Industries HSBC Holdings US Army Hitachi Jacobs Engineering Group Sony Ericsson
Polish organizations		Telekomunikacja Polska TP Lotos Górnośląska Spółka Gazownictwa PKN Orlen Grupa Żywiec Apator Autostrada Eksploatacja Balex Metal Bank Gospodarstwa Krajowego Axel Springel Polska Polpharma

RESULTS

General results for individual areas are presented in Figure 1.

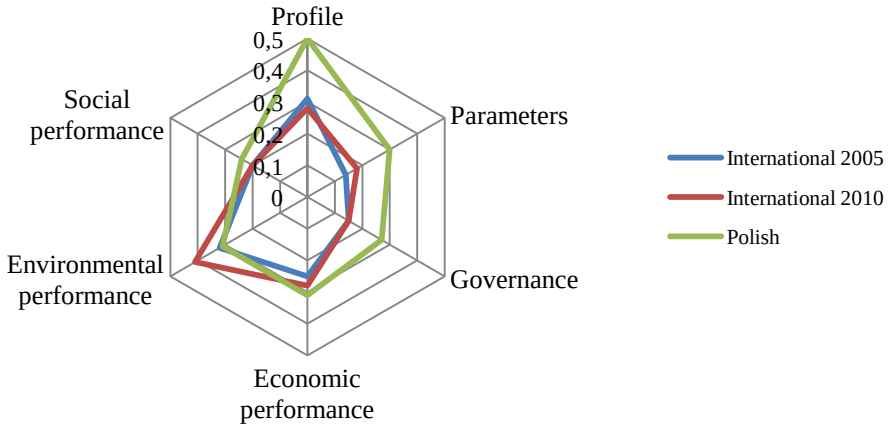

Figure 1: Average scores per group.

The greatest increase was recorded for SAB Miller, reflecting on 12 percent improvement in overall report content over 5 years. Telekomunikacja Polska, which provided the most balanced report (58 percent), should be indicated as a benchmark.

On the whole, the introductory statements did not concern sustainable development, but presented an organization's profile. The reports described the organization's major products, the countries or regions where the organization's operations are located. They referred to the scale of the reporting entity; in terms of number of employees, net sales, and volume of products or services. It should be noted that, with time, organizations presented less detailed introductory information, indicating only their branch and well-known brands. This is reflected in a significant disproportion between the Polish organizations (50%) that reported for the first time and those having reported several times (22%).

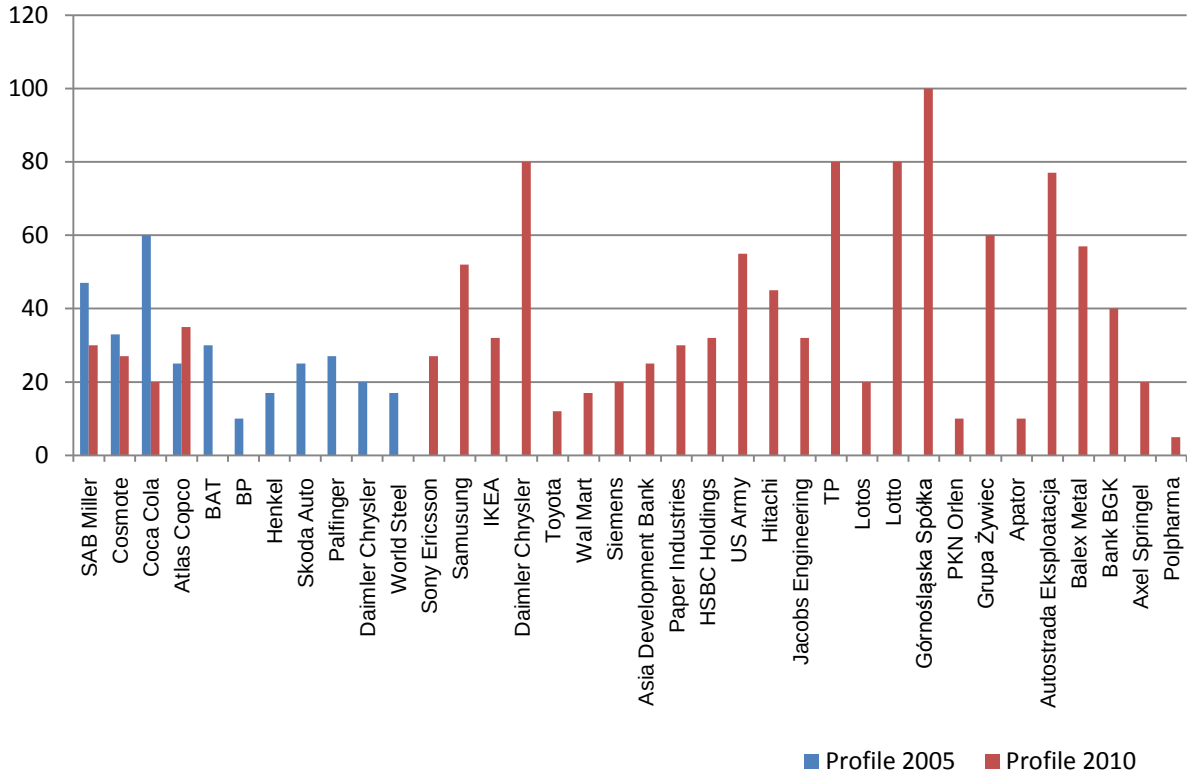

Figure 2: Results in the profile area.

In terms of the reporting parameters, the analyzed reports most frequently presented the reporting period, the reporting cycle, and the methodology used in reporting. Sporadically, the limitations of reporting and evaluation of the report completeness is also included. In the international organizations external verification of reports was performed much more frequently. The most detailed data in this area was presented by TP (70%) and Lotto (72%) – Figure 3. In the case of international organizations, in the area of parameters a 4% improvement was noted in 2010 in comparison to 2005; in both periods the increase was 13% in the studied organizations. The organizations in this group presented their mission, principles and codes of conduct in a more detailed way. The reference to the reporting entities' programs and procedures pertaining to the environmental and social performance can be found here, as well as the list of memberships in trade association.
The Polish organizations, in turn, are more focused on the power structure. The mechanisms of presenting recommendations to the management were the least defined in this area. The reports rarely included information on key issues and concerns identified as a result of stakeholder consultation or how those issues and concerns might possibly influence the organization's internal policies.

On the whole, the average score on the internal governance was 21% (2010). BGK's report scored 70 percent. The reports of Atlas Copco were one inclusive regarding relevant information in both reporting periods.

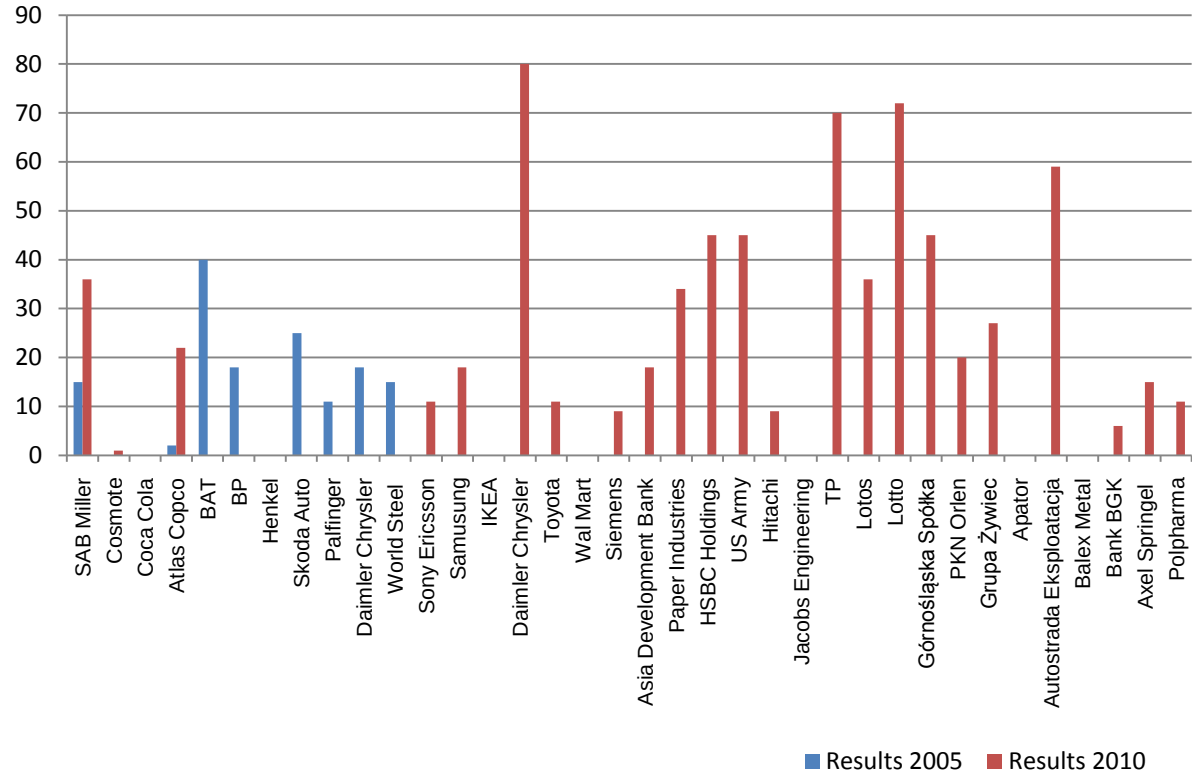

Figure 3: Results in area parameters.

Economic performance

The ways of presenting financial results of the organizations varied (Figure 4). Some of them provided detailed information (Samsung 68%, Lotos 87%), while others gave only the net sales results or referred to other financial reports (e.g. annual) (Axel Springer Polska, Jacobs Engineering). In this area, the report of the US Army is particularly noteworthy: despite the fact that data in this sector is to a great extent classified, the report presents quite detailed financial information (53%). In the economic area, the organizations most frequently focused on their income and contribution to the development of local communities, the least frequently – on the risk related to the climate change and to the organization's retirement obligation.

All reports included information about donations and charitable contributions that their organizations had made during the reporting period. In many cases, however these contributions were not referenced in financial terms or no relevant breakdown of the total amount was available. The average score was 28 percent, showing 3 percent rise from the previous assessment period.

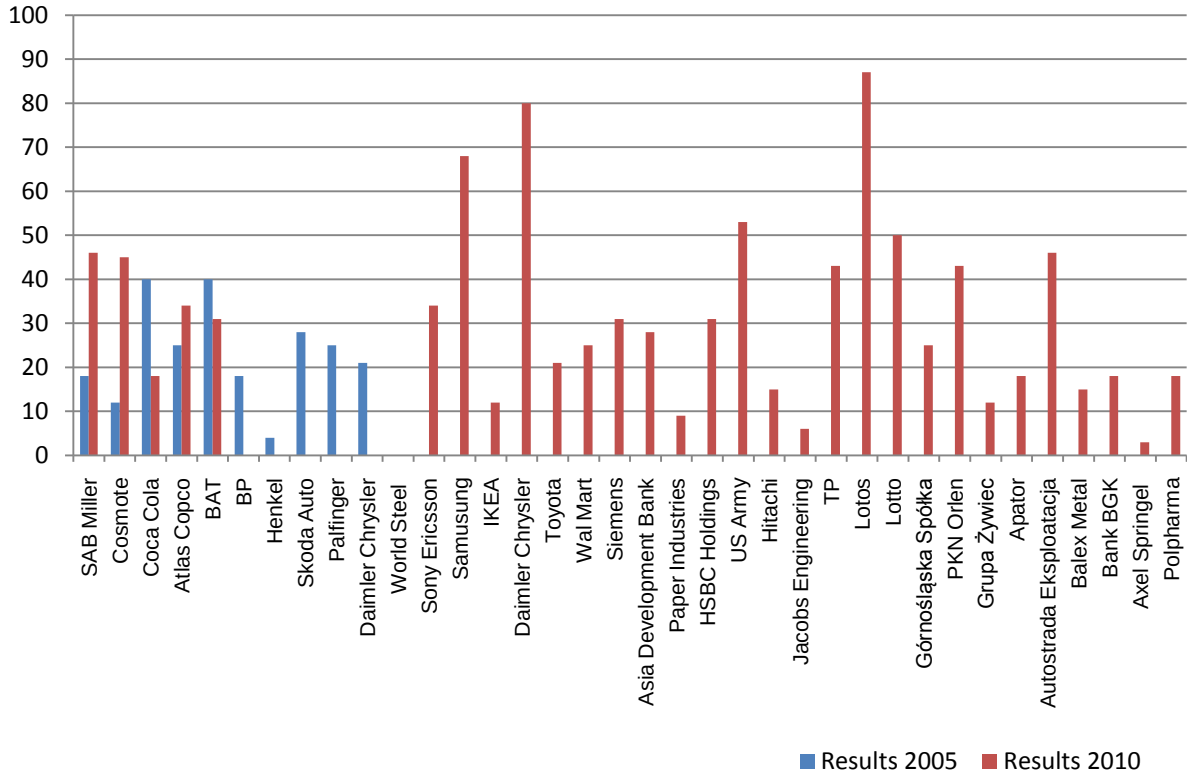

Figure 4: Evaluation of the reports in the economic sphere.

Environmental performance

The greatest gap between the Polish and international organizations concerns the environmental sphere. The average score was 31 percent for polish and 41percent for international (Figure 5). The indicators most often cited were: energy consumption, water consumption, and CO_2 emissions. The reports tend to disclose soil usage and the influence on biodiversity. All the organizations presented their activities related to environmental protection in a very detailed way. The reports presented by production enterprises, included information on developing and introducing on the environment-friendly products. The results of evaluation clearly reveal that Samsung (84%) and British American Tobacco (83%) are leading the way in environmental performance reporting. Lotos (69%) is heading the group of Polish organizations. The organizations publishing reports in 2005 and 2010 showed a significant 13% increase in reporting ecological indicators.

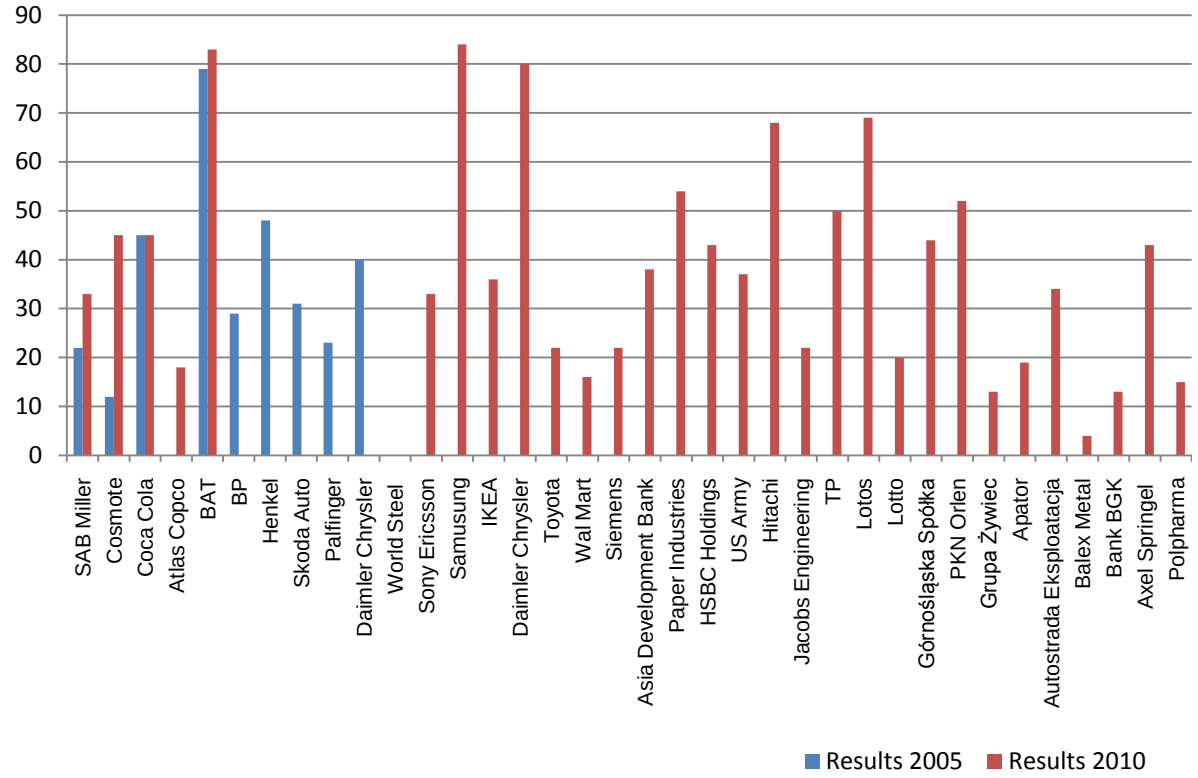

Figure 5: Evaluation of the reports in the environmental sphere.

Social performance

In the social sphere, the Polish and the international organizations obtained similar results (Figure 6). In the case of international organizations, a 12% increase in detailedness of reporting could be observed over the last 5 years. The report of the British American Tobacco and Lotos scored the highest in the social sphere. The results obtained for the sub-areas evaluated in this sphere were listed in Table 3.

Table 3: Results obtained in the social sphere sub-areas.

	Polish	**International 2005**	**International 2010**
Labor market	35	26	27
Human rights	25	14	16
Society	18	22	15
Product responsibility	19	18	23

The reports generally provided more information on internal labour practices and working environments than on broader social issues associated with their companies' business operations. In particular, most reports included analysis of the organization workforce in terms of factors such as gender, age, and the degree of education. Information on training courses was also presented. The area of human rights and society scored the lowest. In the former case, most reports include reference to freedom of association and to discrimination of employees. However, only few organizations (Coca Cola) include the human rights aspect in their reports. The results offered little discussion on their organizations' respect and protection for basic human rights or the sphere of influence of the reporting entity. In the

social area the organizations focus on the activities related to local policy: management programs, influence on local communities, and lobbing. The reports omitted information regarding bribery and corruption, anticompetitive behaviour and how companies deal with such matters. Significantly, only 3 reports of the Polish organizations indicated anticorruption activities. In the area of product responsibility, information provided by the Polish organizations scored much lower: their reports are more general and selective. Also, less attention was given to the issues such as preserving customers' health and safety during the use of products, product labelling, and consumer privacy.

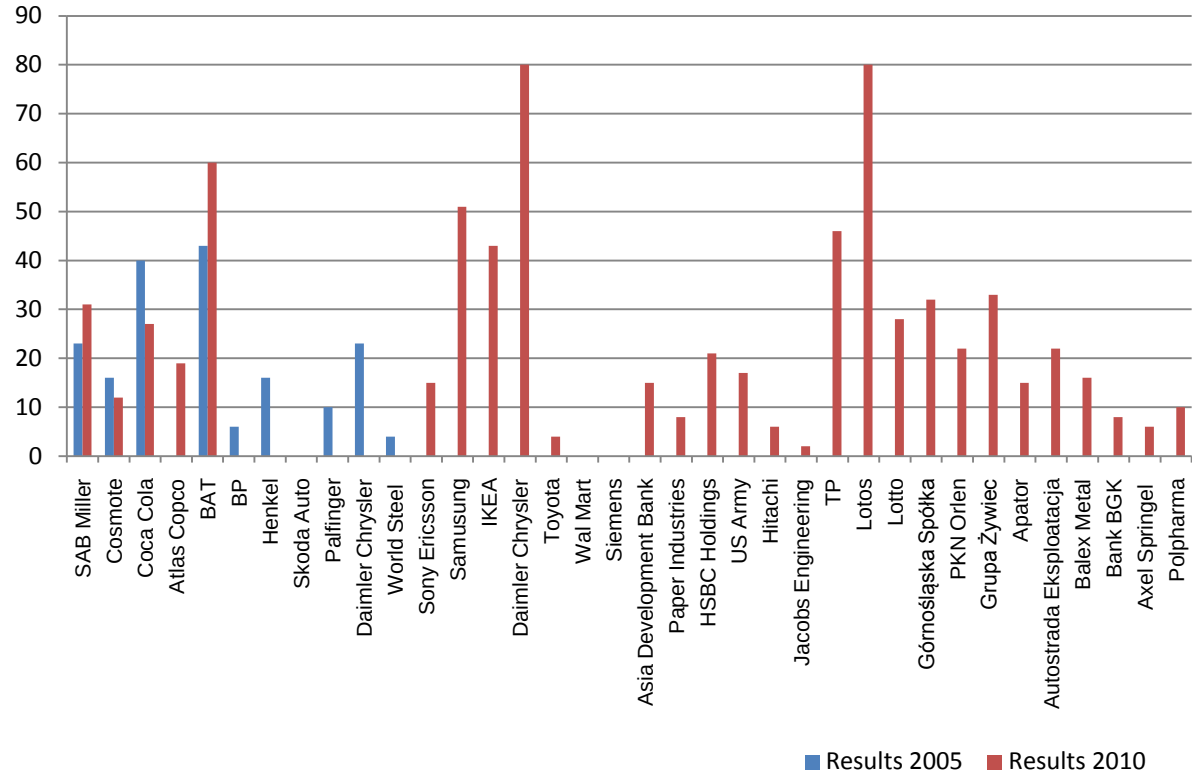

Figure 6: Evaluation of the reports in the social sphere.

Possibility of improvement

Undoubtedly, in the recent years an increase in the detailedness of the presented sustainability reports could be observed. This concerns especially the environmental sphere. However, there is still much room for improvements. In the economic sphere, the information related to the climate change is omitted. In the social sphere the least precisely reported information is that related to anticorruption policy, human rights (including children labour, forced labour), and support given by the organizations to political activity. In the case of the Polish organizations, the gaps in reporting concern social issues and product safety.

Some authors point to the need for the global architecture of standards, or normative framework, to emerge. In our opinion, the present reporting standards meet the needs of the organizations and stakeholders. The development of those standards over the recent years has made them appropriate for covering all the relevant issues.

CONCLUSION

Sustainability reporting is gaining acceptance among a growing number of organizations. The analysis of the number of reports published on the www pages showed a ca. 70% increase for international organizations over 5 years. An increase in this kind of reporting concerns also the countries where the experience of organizations with sustainability reports is much shorter. No sustainability reports of Polish organizations dating from 2005 were found, while in 2010, there are already 12 such reports. Reports are published by production enterprises (Żywiec) and by service organizations (Autostrada). We also meet reports in such untypical trades as the military or games of chance. A number of reports published by the international organizations were not integrated – financial reports, social reports and environmental reports were published separately. However, the reports by the first-timer reporters showed an integrated form.

Contrary to expectations, the Polish organizations, although they had less experience in sustainability reporting, scored higher in some of the issues. This is due to the fact that, basing on the GRI Framework, they provided exact information according to the successive points (issues) included in the Framework. International organizations adopted a holistic approach, focusing on selected aspects. They often omitted information on the profile of their activity and governance. However, the data concerning the environmental sphere and labour market was presented very precisely. The earlier indicated gaps in the social sphere result from the fact that most of the organizations operate in European Union, where human rights are clearly and fully protected by legal obligations. The ecological part of the reports should be evaluated as very good. The reports tend to highlight an improvement in their environmental results in the consecutive years. They also present extensive information on activities and campaign aiming at environmental protection.

Considering the reports prepared in 2005 and 2010, a quality improvement can be observed. An in-depth analysis of those reports showed an increase in the detailedness of reporting in the fundamental spheres, i.e. economic, environmental, and social, by 7, 13 an 12 percent, respectively. The presented study of sustainability reports indicate that there has been improvement in the comprehensiveness of the sustainability reports published by international organizations. The development of the global standards will enable organizations that have not reported so far to prepare a report. The example of the Polish organizations show that such first-time reports may be of a very high quality; the reports of some organizations can become a benchmark for others. What is more, the Polish organizations that already have experience in sustainability reporting enjoy a competitive advantage at a national level – and they can encourage other organizations to follow their example.

The potential directions of the improvement of the sustainability reports quality are related to logic, organization, editing and reliability (Figure 7). The logic of reporting requires the use of non-contradictory statements, precise determination of the scope of a report, improvement in the completeness of documents. In particular, this concerns including all information in the report, without omitting data that are unfavourable for an organization of difficult to identify. Information should be presented in as detailed and precise way as possible, and not in the form of general statements. To organize a report, it is necessary to

base on a selected method of reporting and comply with reporting standard. Editing of a report is related to using references and to the report form. In order to improve the clarity, it is recommended to group appropriate information, present it in tables, charts, and include also historical data. An improvement in the reliability of a report consists in obtaining its external confirmation. It is also important to combine environmental, financial and social report into one, integrated document and to make it available to the public. Unpublished reports loose their power of influence and serve only the internal purposes of an organization. In order for integrated reporting to be a viable and useful activity for companies, it must be underpinned by standardized financial and ESG reporting frameworks. Financial reporting standards, such as International Financial Reporting Standards (IFRS) and US Generally Accepted Accounting Principles (U.S. GAAP) and ESG reporting frameworks, principally the GRI Guidelines, will act as structural supports for potential integrated reporting frameworks.

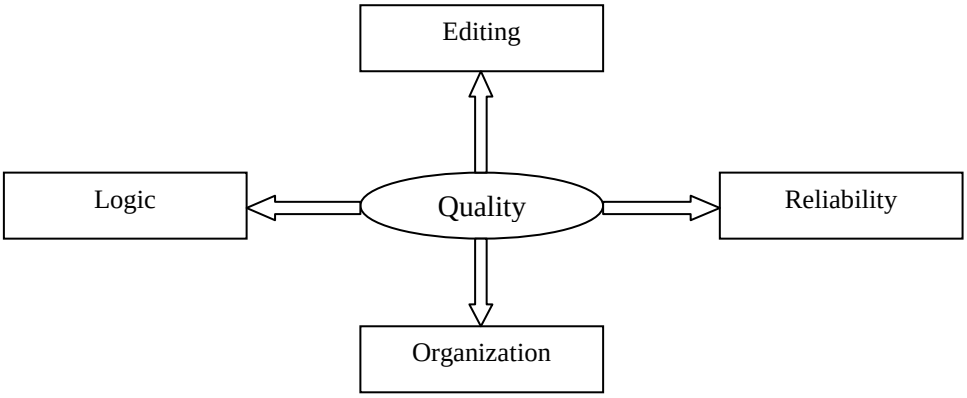

Figure 7: Directions of the sustainability reports quality improvement.

Due to an increase in the interest in sustainability reporting it is possible to predict that the sample of sustainability reports in the following years will be larger than in 2010.

ABSTRACT

Suppliers are the key source of both process and product innovation for an enterprise. The innovation of suppliers can contribute to the long-term competitiveness of the enterprise. For many enterprises, turbulence is a major factor in their business environments, and it should be considered in the development of strategies for an enterprise. In this paper we evaluate the effectiveness of supplier innovation as a strategic tool to enhance the competitiveness and viability of enterprises operating under the influence of high turbulence. Our research looks at different supplier and sourcing attributes, such as, the number of sourcing options, the supplier innovation creation and adoption capabilities, the supplier innovation speed, as well as, their interaction with market turbulence, on the ability of an enterprise to create innovative products that enhance its long-term competitiveness. Our analysis is performed utilizing data generated from agent-based simulation experiments and case-studies. Our results demonstrate the strong of influence of supplier and sourcing factors on the effectiveness of supplier innovation as a long-term competitive strategy.

Keywords: strategic management; supply-chain management; technology management; innovation management

INTRODUCTION

The development of new products and improvement of existing products, are considered to be critical to the survival of a company facing tough competition. Due to an increase in competition and rapid advancement of technology, innovation and new product development are becoming the essential strategies for the management of the companies to survive in the industry (Peterson et al., 2003). Innovation is an effective tool that an enterprise can utilize to maintain its competitive position in the market. The position of the company in the market can be influenced by the frequency of releasing new or improved products (Pisano, 1997). As a result of increased customer communications in many markets today, customers are inundated with many product choices, resulting in shorter product life cycles and rapid changes in customer

preferences. Product dynamism refers to the continuous change in the product which is characterized by speed and magnitude of technological change in the product. To cope up with competition and dynamic change in market demand many firms are adopting open innovation which involves collaboration with external entities, like customers, suppliers, universities, research organizations and competitors (Vonhippel, 1988). Many companies are switching towards open innovation models, from traditional closed innovation models, to increase their level of innovation and retain competitive position in the industry. Open innovation involves interaction of firms with several external entities such as customers and suppliers to generate new ideas to improve existing products and develop new products. The number of patents granted to the firms using open innovation models is significantly higher compared to those granted to firms utilizing only internal resources to innovate (Chesbrough, 2003).

Suppliers are a significant source of external innovation to a firm (Park and Oduntan 2010). Of all the different types of external sources of collaboration adopted for innovation of the product, suppliers innovation has the most significant impact on the performance and success of the firm (Park and Oduntan, 2010). Supplier collaboration increases the technology knowledge available to a firm, which helps it reduce the product development time by identifying the potential problems beforehand (Kessler et al., 1996). Ragatz et al. (2002) found that involvement of suppliers in innovation process result in benefits such cost reduction, improved quality and sales increase. The successful development of supplier collaboration involves shared training, mutual trust and commitment, rewards and agreed performance measures (Ragatz et al., 2002). Peterson et al. (2003) argued that the integration of suppliers into new product development activities can reduce the risk involved with technology which is at its formative stage. Companies which share the “technology road-maps” with the suppliers can help the firms to introduce first product with new technology which is considered as a competitive advantage (Peterson et al., 2003). Supplier innovation reduces potential problems during the early stages of development (Wasti et al., 1999).

Although significant benefits can be achieved through the use of supplier collaboration, for a company seeking to leverage the innovation of its supplier through collaboration, it is necessary that the correct attributes are considered in the design of supplier collaboration relationships. The objective of our research is to gain a better understanding of the factors that an enterprise must consider in its design of a supplier collaboration relationships. Results of our research will identify, for companies seeking to utilize supplier collaboration, the factors that need to be considered in selecting suppliers and the types of supplier relationships that will result in improved product development performance over the long-term.

LITERATURE REVIEW

The level of supplier integration in product development ranges from simple consultation in the design of products, to the independent development of entire modules by suppliers (Wagner 2010). Research shows that supplier involvement in new product development enhances the customer firm’s innovation performance along various dimensions. Supplier involvement in the product development reduces development cost, development time, and cost of the product to

the customer firm (Wagner 2010). Supplier involvement in innovation helps firms penetrate at a faster rate into the new markets, share risks among suppliers and increase the competency level (Wagner Hoegl). Park and Oduntan (2010) identified the following key attributes for innovative suppliers.

- Innovative suppliers are responsible for improving the attributes related to the module they innovate.
- The modules supplied by innovative supplier have unique attributes which can be perceived by the customer.
- Innovative suppliers identify the features and attributes of the module as desired by the customers and work for improving the attributes.
- Innovations in the modules supplied by innovative suppliers can influence the buying decision of the customer.

Clark and Fujimoto (1991) classified the parts related to auto industry into three types based on the extent of involvement of suppliers in their development:

- "Detailed control parts" in which development is performed entirely by the customer i.e., the auto manufacturer
- "Black-box" parts in which specifications and interface requirements are given by customer. "Supplier proprietary" parts whose development is performed entirely by the supplier (Clark et al., 1991).

Clark and Fujimoto (1991) also introduced "grey box" parts whose development is performed both by supplier and customer. Kaufman et al. (2000) proposed a typology for the classification of suppliers based on the collaboration and technical expertise of the supplier. Commodity suppliers possess lower technical expertise and collaboration is low. Collaboration specialists are detail control part manufacturers who possess lower technical expertise but higher collaboration is required. Technology specialists are proprietary parts supplier with high level of expertise and low collaboration. Problem solving suppliers are black-box part suppliers with high level of expertise and high collaboration (Kaufman et al., 2000). Fredrik et al. (2002) identified nine factors which are crucial for the success of new product development based on the case study of an auto manufacturer. Proactive role of the supplier, role of auto manufacturer as coordinator, linkage between production and development, supplier's support to other auto manufacturers are the four key factors which need to be investigated before making the decision to involve suppliers in new product development (Fredrik et al., 2002). Liker et al. (1996) identified several variables, including tier structure, degree of responsibility, inter-company communication, intellectual property agreements and supplier membership which play key role in supplier integration and the success of new product development projects.

Primo et al (2002) found that factors such as current technological capabilities and innovation level required by the customer firm are critical for analyzing the level of involvement of suppliers in the product innovation. Wagner et al. (2006) categorized the critical factors for the success of new innovation projects with the involvement of suppliers into two domains such as factors related to organizational level and management of suppliers in the project. The architecture of the product design and interaction with suppliers during innovation process

must be in coherence (Boutellier & Wagner, 2003). Modular architecture of the product allows one-to-one mapping of the functional requirements to the physical components and allows standardized interfaces between modules (Ulrcih,1995). Modular product architecture enables easy upgrade and substitution of components allowing the customer firm to divide the design and development activities to the suppliers efficiently (Schrader & Göpfert, 1997, Von Hippel, 1990). With the integral product architecture there is more than one physical component which performs a single functional requirement (Ulrcih ,1995), which makes the task of dividing the design and development of components complex because a change in one functional requirement necessitates changes in more than one physical components (Schrader & Göpfert, 1997, Von Hippel, 1990). Supplier involvement strategies depend on product architecture, design and interfaces with suppliers ranging from "none" and "white box" to "grey box" and "black box" supplier integration (Monczka et al., 2000).

Henderson and Clark (1990) distinguished the R &D capabilities of the suppliers as architectural and component knowledge. Component knowledge refers to the capability of the supplier to design and manufacture the component for the final product, but not the final product itself. Architectural knowledge refers to the ability of the supplier to integrate and coordinate the knowledge between other suppliers and customer firm. Supplier assessment based on their manufacturing, assembly and logistic expertise is vital for supplier selection in the new product development process (Monczka et al., 2000). Wasti and liker (1997) found that frequency of communication between supplier and customer during the new product development process influence the decision making process in the early stages of new product development. Birou and Fawcett (1994) found that nature of relationship between supplier and customer firm is important for success of the new product development projects. Mabert et al (1992) found that early involvement of suppliers in the innovation process reduces the development time. Gerwin and Ferrari (2004) through their investigation of several organizational structures found that success of development projects executed through collaboration relies on the various factors such as distribution skills among the partners, newness of the partnership and cooperativeness of the collaboration in the past. Hoegl and Wagner (2005) argues that the quality of working relationship between collaborative partners was dependent on mutual trust, open sharing of information and high project commitment. Wagner and Hoegl (2006) categorized the variables influencing supplier selection into "hard" and "soft" criteria categories. "Hard" criteria involve supplier potential to innovate new products for the customer, and "soft" criteria involves openness, mutual support and reliability between the supplier and the customer firms.

Although much research supports the theory that supplier innovation is beneficial to the new product development performance of a firm, there is some research that suggests supplier innovation might not have a significant positive influence on a firm's product development performance. Littler et al. (1998) through their study of UK firms in communication sector concluded that the involvement of suppliers increases the cost of product as the complexity involved in the management of collaborative projects increases. Also, Hartley et al. (1997) found that supplier involvement in the innovation process was not a significant factor. Supplier involvement was found to have a negative effect on innovation due to the differences in organizational culture. As the differentiation among the firms involved in new product

development increases, challenges to achieving common goals also increase (Susman and Ray, 1999). A major obstacle for supplier integration comes from unwillingness to share the internal design information and "not invented here" culture which prevents engineers from relinquishing product development responsibilities to suppliers (Ragatz et al., 2002). Johnson (1999) emphasizes the need for the implementation of standard procedures to involve suppliers in new product development processes.

Rapid generation of new technology creates technology turbulence in the business environment in which the firms operate. Technology turbulence reduces the life cycle of the product as new products with new technology emerge at faster rate (Tushman and Anderson 1986). Even the firms with higher market share can be squeezed out from the market if they don't acknowledge technology turbulence and take pre-emptive measures (Li and Calantone 1998). The firms should increase research and development activities and create advanced products from the new technologies to capture market and to retain competitive position (Milling et al., 2000). To cope with challenges created by the technology turbulence, the firms must continuously strive to introduce new products at faster rate to sustain competitive advantage (Pisano, 1997). Adopting supplier innovation strategy can reduce the development time of the product as the suppliers are more knowledgeable about their products which enable the manufacturer to release new products to sustain competitive advantage. By utilizing supplier innovation strategy, manufacturers can invest more resources in developing the core competency while outsourcing the innovation activities related to non-core competency. Wagner (2009) proposed the concept of downstream customer orientation of the suppliers in which suppliers acknowledge the needs of the focal firm's customers to innovate the product. Downstream customer orientation of the supplier improves the performance of the new product development (wagner 2009).

Following our review of literature we categorized the variables influencing supplier innovation into the following categories: environmental characteristics; supplier attributes; product characteristics; quality and management of relationship; and duration of partnership. The categorization of prior supplier innovation according to this typology is shown in Table 1.

Table 1: Classification of characteristics for the supplier involvement in the new product development.

Category	Variable Investigated in Prior Studies
Firm Characteristics	⅄ Willingness to accept external ideas
Nature of Enterprise Supplier Relationship	⅄ Role of the supplier (Clark) and enterprise ⅄ Supplier's responsibility ⅄ Frequency of communications (Wasti and Liker) ⅄ Nature of relationship (what aspect?) Birou and Fawcett (1994) ⅄ Newness of partnership - Gerwin and Ferrari (2004) ⅄ Distribution skills - Gerwin and Ferrari (2004) ⅄ Degree of differentiation (sushman and ray) ⅄ Coordination (Gerwin 2004 ⅄ Timing for the involvement of suppliers (wasti and liker 1997)
Supplier Characteristics	⅄ Uniqueness (Park et al. 2010) ⅄ Technical expertise ⅄ Innovativeness (wagner hoegl 2006) ⅄ Component and architectural knowledge (Henderson ⅄ Supplier support to competitors (Frederik et al ⅄ Downstream customer orientation(Wagner 2009) ⅄ Trust and reliability (wagner hoegl 2006) ⅄ Supplier Innovation rate
Business Environment	⅄ Technology Turbulence (Tushman et al 1986) ⅄ Number of suppliers (swan et al
Product Characteristics	⅄ Integral product ⅄ Modular design (Schrader & Göpfert, 1997 ⅄ Number of modules ⅄ Product Dynamism (Swan et al 2003)

In this paper we investigate the influence of supplier innovation under factors like technology turbulence, number of suppliers per product modules (nature of enterprise supplier relationship), technology assimilation capability of suppliers (supplier characteristics), firm (firm characteristics), and competitor (business environment).

PROBLEM STATEMENT

From our analysis of prior literature, with particular focus on prior research on supplier innovation modeling by Park and Oduntan (2010), we identified certain factors, such as, technology turbulence, number of suppliers per module, the rate of supplier innovation

capability, and the supplier's capability to leverage acquired technology as potential factors affecting product performance and long-term competitive performance of firms. The following research questions were proposed to investigate the significance of these factors on a firm's product innovation and long-term competitive performance.

Research Question 1 (Q1)
How do the characteristics of the business environment influence the ability of a firm to effectively leverage the innovation of its suppliers to increase its own innovation performance.

Research Question 2 (Q2)
How does the selection of a sourcing strategy, especially the use of multiple suppliers per product module, affect the ability of a firm to leverage the innovation capabilities of its supplier's in improving its long-term product development performance.

Research Question 3 (Q3)
Is the technology acquisition capability of a supplier a significant contributing factor to the new product development performance of a firm?

The following hypotheses (*H1*)was proposed to investigate *Q1*:

Hypothesis (H1): A firm utilizing a supplier collaboration strategy in a business environment with turbulence will experience higher perceived quality, market share and viability than a firm that does not utilize a supplier collaboration strategy in the similar high turbulence environment.

Hypothesis 2 (H2): A firm utilizing a supplier collaboration strategy in conjunction with a sourcing strategy utilizing with more suppliers per product module will experience higher new product performance, than a firm utilizing a supplier collaboration strategy combined with a sourcing strategy emphasizing fewer suppliers per product module.

The argument behind *H2* is that in a business environment in which technology is rapidly changing, technology investment risk can be mitigated by spreading the risk over multiple suppliers as opposed to focusing the risk on fewer suppliers.

Our final hypothesis was formulated to answer the third research question which was to determine the influence of supplier's abilities to assimilate new technology from the business environment the new product development performance of a firm.

Hypothesis 3: A firm utilizing suppliers with a higher rate of technology assimilation from its environment will have higher higher new product development performance than a firm utilizing suppliers with lower technology assimilation rates.

METHODOLOGY

Enterprise viability model (EVM) which was developed by Park and Oduntan (2010) was used to evaluate each supplier factor to determine its effect of product performance. EVM was developed using agent based modeling technique in which agents were created to represent each entity in the business environment. In each of the simulation experiment, one agent representing the focal enterprise and ten agents to represent competitors were created to simulate the business environment. All the enterprise agents were competing for the demand generated by a small sample 1000 customer agents. All the simulation experiments were designed to be of non terminating in nature. In order to investigate the long term performance of the system, non terminating simulation were used (Kelton). The experimental setup utilized by Park and Oduntan (2010), which utilized a run length of 7,200 ticks was determined to provide sufficient time for the simulation to attain a steady-state. At the end point of each run (of 7,200 ticks) data was collected for each of the response variables. Each of the viability scenarios was performed with 60 replications for each factorial point. EVM was modeled using Repast agent modeling toolkit. Various scenarios were created to generate data to test each of the hypotheses. A firm's product development performance was measured by the perceived quality of its product, its market share and viability at the end of the simulation. The viability of a system can be defined as its ability to maintain functional persistence in its environment (Truszkowski and Karlin 2000). Oduntan (2008) defined the viability as the probability of survival of the focus enterprise, where survival is measured by the firm's market share having a value greater than zero at the end of simulation. Table 2 lists all the variables and their description in the enterprise viability model

Table 2: Variables used in the EVM framework.

Variables	Description	Values
Independent Variables		
Use supplier Collaboration	Indicates whether the focal enterprise engages in supplier collaboration	True/False
Moderating Variables		
Technology turbulence	The rate of technology change in the market over a given time period	Low turbulence / Medium turbulence/ High turbulence
Number of suppliers	Number of suppliers per product module available to innovate	3/7/9/11
Number of product modules	Number of modules that product constitute	Low /medium
TechAcquisitionSuccessinaYear	Capability of the to acquire technology that was developed by the external entities in the industry	Low/medium/high
SupplierRatioofProductReleaseFrequency	Indicates the speed of innovation of the product by the suppliers	0.34/ 0.67/ 1.0/ 1.34/ 1.67
Response Variables		
Perceived quality	The customer's belief about the levels of utility for attributes of the product made by the focal company	
Market share	The market share of the focus company at the end of the simulation	
Viability	The probability of survival of the focus enterprise at the end of the simulation, where its survival is defined as it having a market share greater than zero at the end of the simulation(Od	

All the simulation experiments were subjected to the following assumptions proposed by Park and Oduntan (2010).

- The focus enterprise and the competitor enterprises were all introduced into the market at the beginning of the simulation, and began advertising to customers and developing products immediately.
- There is no restriction on competition between the focus enterprise and any of the competitor agents.
- Other than a seed amount to begin the simulation, all resources for product innovation and advertising came from sales to the customer agents.
- All resources owned by the focus enterprise or its competitor enterprises were invested either in advertising or product innovation.
- All customer agents could equally be reached by the advertising of the focus enterprise and the competitor agents.

- A customer agent had the resources to purchase a product whenever it had a demand for it.
- The customer agents did not incur any switching cost or penalty for switching from one product to another.

RESULTS AND DISCUSSION

The results of each experiment were analyzed using the following steps:

1. ANOVA tests were performed to determine the significance of the characteristics related to suppliers, product and business environment through supplier involvement in the new product development on market share and perceived quality of the focus firm.
2. Logistic regression tests were performed to determine the influence of the variables associated with product characteristics, business environment, and supplier traits through supplier involvement in the new product development on the probability of survival of the focus firm.

All ANOVA and logistics regression tests were performed using the statistical software package Minitab 16.0.

Hypothesis 1(H1): A firm utilizing a supplier collaboration strategy in a business environment with turbulence will experience higher perceived quality, market share and viability than a firm that does not utilize a supplier collaboration strategy in the similar high turbulence environment

From ANOVA results we observe that use of supplier collaboration in the innovation of the product has the highest significant (0) effect under all the three levels of technology turbulence on the market share of the focus enterprise.

Table 3: ANOVA: Influence of Supplier Collaboration on Firm Perceived quality firm under low tech turbulence.

Source of Variance	SS	DF	MS	F
Use of supplier collaboration	0.80467	1	0.80467	205.82***
Error	0.46132	118	0.00391	
Total	**1.26599**	**119**		
*** = significant at 0; ** = significant at .001, * = significant at .01, ^= significant at .05				

Table 4: ANOVA: Influence of Supplier Collaboration on Firm Perceived quality firm under medium tech turbulence.

Source of Variance	SS	DF	MS	F
Use of supplier collaboration	0.61790	1	0.61790	149.96***
Error	0.48621	118	0.00412	
Total	**1.10411**	**119**		
*** = significant at 0; ** = significant at .001, * = significant at .01, ^= significant at .05				

Table 5: ANOVA: Influence of Supplier Collaboration on Firm Perceived quality firm under high tech turbulence.

Source of Variance	SS	DF	MS	F
Use of supplier collaboration	0.77507	1	0.77507	197.37***
Error	0.46339	118	0.00393	
Total	**1.23846**	**119**		
*** = significant at 0; ** = significant at .001, * = significant at .01, ^= significant at .05				

From the above results the use of supplier collaboration has significant effect on the perceived quality of the products produced by the focus firm under all the levels of tech turbulence. Logistic regression model was formulated to assess the influence of the use of supplier collaboration on the viability of the focal firm.

Supplier collaboration is a binary variable in which the value of 1 indicates the use of supplier collaboration and 0 for using supplier collaboration. The results of fitting the logistic regression to the model *(a)* are shown below Table 6.

Table 6: Logistics Regression: Influence of Supplier Collaboration on Firm Viability under low tech turbulence.

Source of Variance	Coefficient	Standard Error	Z Value	Pr(>|z|)
Intercept	-2.9790	0.467099	-5.13	0.00***
Use of supplier collaboration	5.34233	0.754360	7.08	0.00***
*** = significant at 0; ** = significant at .01, * = significant at .05				

The results indicate that the use of supplier collaboration is highly significant to the viability of a firm. Through substitution we get the ratio of the probability of survival of the firm with the use of supplier collaboration to that of the firm without the use of supplier collaboration under low tech turbulence is *4.21* which implies that viability of the firm increases by an order of 4 with the use of supplier collaboration.

Table 7: Logistics Regression: Influence of Supplier Collaboration on Firm Viability under medium tech turbulence.

Source of Variance	Coefficient	Standard Error	Z Value	Pr(>|z|)
Intercept	-1.18958	0.305234	-3.90	0.00***
Use of supplier collaboration	5.2	1.05362	5.00	0.00***
*** = significant at 0; ** = significant at .01, * = significant at .05				

The ratio of probability of survival of the firm with the use of supplier collaboration to that of the firm without the use of supplier collaboration under medium tech turbulence is *4.2*.

Table 7: Logistics Regression: Influence of Supplier Collaboration on Firm Viability under high tech turbulence.

Source of Variance	Coefficient	Standard Error	Z Value	Pr(>|z|)
Intercept	-1.38629	0.322749	-4.30	0.00***
Use of supplier collaboration	5.46388	1.05883	5.16	0.00***
*** = significant at 0; ** = significant at .01, * = significant at .05				

The ratio of probability of survival of a firm utilizing supplier collaboration compared to that of a firm without the use of supplier collaboration under medium tech turbulence is *4.91*.

The above results support hypothesis *H1*, which states that the use of supplier collaboration under technology turbulence influences the market share, perceived quality and viability of the focal firm. Due to technology turbulence, the product life cycle of the new products decrease (Tushman and Anderon 1986). In order to cope up with the reduction of life cycle of the new product, supplier collabaoration can be used as competitive strategy to reduce the development time of the new products (Mabert et al 1992) which can help to increase the product release frequency.

Hypothesis 2 (H2): A firm utilizing a supplier collaboration strategy in conjunction with a sourcing strategy utilizing with more suppliers per product module will experience higher new product performance, than a firm utilizing a supplier collaboration strategy combined with a sourcing strategy emphasizing fewer suppliers per product module.

The influence of number of suppliers available to innovate each type of supplied product modules, on the firm perceived quality, market share, and viability of a firm is evaluated in the following experiment, where the number of suppliers per product module is varied between 7, 9 and 11, and the use of supplier collaboration is also varied bewteen the value TRUE and FALSE.

Table 8 ANOVA: Influence of Number of Suppliers available to innovate on Firm market share

Source of Variance	SS	DF	MS	F
SupplierTechAcquistion	0.2355	1	0.2355	2.06
Number of suppliers	0.0506	2	0.0253	0.22
CompetitorTechAcquisition	2.8478	1	2.8478	24.89***
Error	81.8141	715	0.1144	
Total	**84.9480**	**719**		
*** = significant at 0; ** = significant at .001, * = significant at .01, ^= significant at .05				

Table 9 ANOVA: Influence of Number of Suppliers available to innovate on Firm perceived quality

Source of Variance	SS	DF	MS	F
SupplierTechAcquistion	0.00172	1	0.00172	0.16
Number of suppliers	0.05348	2	0.02674	2.42
CompetitorTechAcquisition	0.30713	1	0.30713	27.81***
Error	7.89637	715	0.01104	
Total	**8.25870**	**719**		
*** = significant at 0; ** = significant at .001, * = significant at .01, ^= significant at .05				

Table 10: Logistics Regression: Influence of Number of Supplies available to innovate on Firm Viability

Source of Variance	Coefficient	Standard Error	Z Value	Pr(>|z|)
Intercept	2.24868	0.571423	3.94	0.00***
SupplierTechAcquistion	-0.307908	0.320582	-0.96	0.337
Number of suppliers	0.0000000	0.0490620	0.00	1.000
CompetitorTechAcquisition	-1.80553	0.323736	-5.58	0.000***
*** = significant at 0; ** = significant at .01, * = significant at .05				

From the above results we observe that there is no influence of number of suppliers available to innovate each of the product modules on the market share, perceived quality and viability of the firm through the use of supplier collaboration.. This can be attributed to increase in coordination efforts for collaboration and selection of suppliers becomes complex as the number of suppliers increase *(Zirger and Hartley 1996).*The overhead cost of managing more number of collaborations increase and it is difficult to control the product development as the number of suppliers increase.(littler 1995). The competitor technology acquisition capability is highly significant. As the capability of its competitor to assimilating technology increases, the

market share, perceived quality and viability of a firm reduces due to release of technologically advanced products by the competitor which are more appealing to the customer, and a winning of market away from the firm.

Hypothesis 3 (H3): A firm utilizing suppliers with a higher rate of technology assimilation from its environment will have higher higher new product development performance than a firm utilizing suppliers with lower technology assimilation rates.

The influence of technology assimilation by suppliers on the market share, perceived quality and viability of a firm is tested by simulation experiment in which the variable tech assimilation success in a year for the supplier firm, competitor firm and focus firm takes values 0.1, 0.4, 0.8 and the use of supplier collaboration takes values TRUE and FALSE.

Table 11 ANOVA: Influence of technology acquisition on firm market share.

*** = significant at 0; ** = significant at .001, * = significant at .01, ^= significant at .05

From the above results we observe that the use of supplier innovation, technology assimilation capability of the suppliers, firm, and competitors are significant factors on the market share and perceived quality of a firm. As the technology assimilation capability of its competitor increases, the market share and perceived quality of the firm decrease due to the inability of the firm to develop sufficiently attractive products as compared to its competitors. As the technology assimilation capability of a firm increases, the market share and perceived quality of the firm increases due to its ability to develop products using acquired technology. Interestingly there is significant interaction between the use of supplier innovation and competitor technology assimilation. From the results we argue that supplier innovation can be used as a strategy to compete with competitors who are capable of assimilating technology at high rate.

CONCLUSION

In our research of literature we categorized the variables and characteristics associated with the involvement of supplier in the new product development. In our experiments we investigated the influence of the following factors, use of supplier innovation, number of suppliers per module, technology assimilation capabilities, and technology turbulence on the long-term product development performance of a firm. From our experiments we found that sourcing from more suppliers to reduce technology risk has no influence on the performance of a focus firm. Our research suggests that supplier innovation can be utilized as competitive strategy to cope up with technology turbulence, and to reduce the development time of the product thereby retaining the competitive position in the industry. Under the conditions of technological turbulence in the business environment, costs and risk involved in new development can be shared between the suppliers by using supplier innovation strategy. The ability of a firm and its suppliers to assimilate available technologies in their environment was found to be a highly significant contributor to long-term product development performance, perceive quality, market share, and viability of a firm.

COHERENCE IN CONTROL OF INFORMATION SECURITY (COINS)

Yngve Monfelt, Stockholm University, Sweden
yngvem@fc.dsv.su.se

ABSTRACT

The paper content is based on experiences from a study Feb. 2008 to Jan. 2011 on aspects how to implement (IPL) the information security (ISC) management (MGT) system standard (ISMS) objectives for Swedish governmental agencies' organizations. The following legend – being written contemporarily but independently of the study's final report – based on this author's experienced interpretation of meaning (MNG) and relevance – expressed through syntaxes (STX) the ISMS A5 … A15 control (CTR) objectives (OBJ). The acronyms sign intentions to be operationally (OPE) effectuated (ECT): The paper title associates with 'COINS' for efficient (EFY) use of available (ABY) funds for effective (ECT) abilities. Hence, abilities become treated as real assets (AST) to be authorized (ATH) for an enterprise's (EPR) principal executive (EXE) entity's (ETY) mission intentions as quality of service (QoS) performer. Then, the provider – customer 'conditional statement' relations being noted as [P|Q] about necessary/accompanied attributes or realities/imaginaries or affects/effects. Realities are measurable and hence easier for a provider (P) to get pay or credit for in mission transactions. But, to identify (IDY) realities it is often difficult, even for a QoS questioning (Q) part. The difficulties have its roots in more or less strength (STR), opportunity (OPU), weakness (WEK) or threatening (TRT) environmental events (EVT), culture, (CLT) ethic (ETH), laws or rules (LAW) and objectives (OBJ). The meanings (MNG) have to be messaged (MSG) in technical data communication (DCT) sessions about the OBJ realities; i.e., what QoS realties have to be effected (ECT) in when, where, by whom, how and why contexts (CXT). This is what the communicative information (INF) life cycle processes (LCP) deal with: Achieving ECT to get credit for in sustainable socio-technical (SoT) trustworthy Human Right (HUR) emphasizing relations for safety (SAF). Security (SEC) is treated as an achieved dependable SAF state through EFY in efforts to achieve keyword OBJ MNG ECT.

Keywords: Audit, Authorization, Cognition, Dependability, Account.

PRESUPPOSITIONS

Coherence Conditions

Any molecular or atomic entity (ETY) organization, as a firm enterprise (EPR), needs adaptivity (APT) to organismic environmental events (EVT) through strength (STR) and opportunity (OPY) abilities to compensate weaknesses (WEK) against threat (TRT) in principal/ agent mind to mind communication (COM) relations.

The EPR strategy (STY) ought be toward confidence (COF), integrity (ITY) and availability (ABY) in dependable (DPY) behavior (BEH); i.e., a manageable (MGT) variety in the ETY

quality of service (QoS) abilities as assets (AST) for the life cycle mission performances (LCP), through dependable (DPY) information safety (SAF) protection (PRT) of which rely on, by public accessible (ACS), meaning (MNG) and effect (ECT) in the relational syntaxes (STX). The operational (OPE) action (Act) occurrences (OCU) have to be monitored (MTR) and accounted (ACT) per ETY identity (ETY_IDY). These ACTs together with observation of the EPR relevant environmental (EVM) events (EVT) constitute the audit (AUD) process of the EPR LCP BEH.

The Aim is to Emphasize Enterprise Realities

In this paper, study results in general are treated as enforced or gained knowledge (KNW) being imaginary affections in participating human's minds. The paper content is based on KNW from a study Feb. 2008 to Jan. 2011 for conditions for implementing (IPL) the information security (ISC) management (MGT) system standard (ISMS; ISO/IEC 27001) into Swedish governmental agencies' organizations (EPR ORG). But the KNW has – through experienced perceivers' (PCV) contextual (CXT) experience – to, through KNW MGT, be communicated (COM) for cognition (COG) of the actual enterprise's (EPR) unique realties. The study value (VUE) is dependent on systems' thinking (Lawson, 2010) abilities as assets (AST); i.e., practitioners as real VUE producers.

The Reason

The reason for the study was the Swedish National Audit Organization (SE-NAO) report (RiR 2007:10) about how – relatively to the ISMS – ISC MGT is IPL and maintained (MIT) in a number of agencies in Sweden. On basis of the report, the government directed the Swedish Civil Contingencies Agency (MSB) to take initiatives for ISMS' IPL. The study began – thanks to competitive access to MSB funds – with the money associating 'Communication of Information Security COINS' approach, of which has been reported as 'Controlled Information Security, COINS' (Yngstrom & al 2009a, b) associating with the ISMS' controls (CTR) A5 … A15.

Now, in the paper's title 'coherence' prefix is to emphasize that CTRs rest on, and are for communication (COM) effects (ECT) in general of which are on some way related with a firm's or an agency's economical benefit; i.e., flow of COINS through effectiveness in management of bit carried messages (MSG).

Acronyms and Figures Emphasize Operational Effect Achievement Importance

Acronyms and Figures in the paper are for signaling intentions to achieve operational (OPE) action (Act) effect (ECT). In the study, agency's Acts are treated as enterprises (EPR) with its communication (COM) architecture (ECA). Supposedly, an EPR has three decision levels;

- EXE-0, the principal, for "what may be" (Odelstad, 2008; p. 5) or "what can be" (V. Renssen, 2008; pp. 14f) knowledge (KNW) or strategy (STY),
- EXE-1 for "what shall be" MGT tactic (TAC), and
- EXE-2 for "what is" operated (OPE).

The “what has been” value (VUE) is KNW by audit (AUD) of environmental events (EVT) and accounted (ACT) occurrences (OCU) of monitored (MTR) entity (ETY) behavior (BEH). But, KNW shall be realized for appropriate effect adjustment in cognition (COG; Yadin, 2007) processes.

This paper about the study is outlined as an enterprise (EPR) of its own example.

STRATEGY

“A new [e.g., information security [ISC] management standard (ISMS)] standard in itself does not solve business [EPR] issues. The main issue is that companies should manage [MGT] their information [INF] in electronic form and as a separate asset [AST]. A standard for the definition of information [INF] is just an enabler for such information management [MGT]. ... “ (V. Renssen, 2008; p. 13)

In the current paper, information (INF) meaning (MNG) is conveyed by messages (MSG) being automatically or manually processed (ADP, MDP). So, INF MGT is an adaptation (APT) of ECA's ADP or MDP; MSGs for i.e., data communication technology (DCT).

Securing of Trustworthiness through Protection of Dependability

Approach

Security (SEC) is an earned state, achieved through evaluated (EAL) protection (PRT) of dependencies (DPY); i.e., PRT of ETY_IDYs as assets (AST) against probable risks (RSK, PCY) in AST's safety (SAF). The ASTs are the abilities of which synergy (SGY) effect (ECT) contributes to the EPR's value (VUE) as QoS performer (PEF). The VUE is created in communication (COM) sessions (PCS) through exchange of messages for meaningful (MNG) effect (ECT); i.e., information SEC (ISC):

- ISC {COF: confidence or confidentiality, ITY: integrity in system behavior (BEH), ABY: asset (AST) ability availability (ABY), AUD: audit of accounts (ACT) of monitored (MTR) action (Act) occurrences (OCU) and observed environmental events (EVT)}.

Strategy for the Study

The strategy (STY) taken for the study – by SU/DSV and Swedish Defense Research Agency (FOI) in corporation – was to classify (CLS) it as a socio-technical (SoT) system to be established and managed in a life cycle period (LCP) as an application (API) to the general system theory (GST) framework. The SoT-system has to be available (ABY) in an evaluated assurance level (EAL) secure (SEC) state most of its LCP time. Its LCP sustainability is conditioned by the SoT system components as assets (AST). The ASTs and their relational attribute's synergy reliabilities (RBY), maintainability (MBY) and adequate maintenance (MIT) in the environment (EVT) situational circumstance contexts (CXT) constitute the dependability (DPY) of the SoT system.

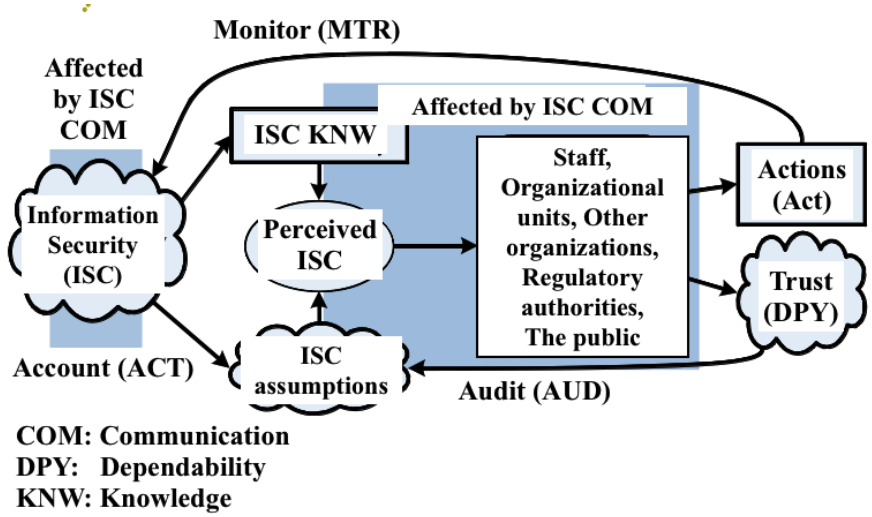

Figure 1: The socio-technical (SoT) system feedbacks (FEB)

DPY is achieved and withheld due the achieved ISMS (ISO/IEC-27001, 2005 Annex A) A5 ... A15 CTR objective ECT and feedback (FEB). FEB is a (Figure 1) three level process;

- monitoring (MTR) operative (OPE) actions (Act) occurrences (OCU),
- accounting (ACT) MTR-data per Act entity identity (ETY_IDY) action (Act), and
- audit (AUD) of ACTs and observed environmental events (EVT).

Cognition as Experienced Knowledge for Conditioning Human Rights Characteristics

Knowledge (KNW) is not enough for dependable Acts. But, it is a prerequisite for how to perceive phenomena and to cognize (COG) what shall be Act because of experienced KNW and hence transform affections to effect (ECT):

1. COG {knowledge (KNW),
2. comprehension (MNG),
3. application (API),
4. analysis SWT for SWOT (strength, weakness, opportunity, threat) of risks (RSK),
5. synthesis (SYN for synergy),
6. Evaluation (EAL)}. (Yadin, 2007; p. 5 adapted)

The MNG of KNW MGT may be an authorization (ATH) of KNW toward COG. Managers have ability and are assets (AST) for doing this. So, KNW may be enough for “can be/have” polices, but COG is necessary for “shall be/have” directives to be “is” in OPE by ATH ETY_IDY-s skill and given access (ACS) to available (ABY) and adequate AST for the contextual (CXT) situation (Monfelt, 2010; Figure 2).

Established Conventions for Coherence

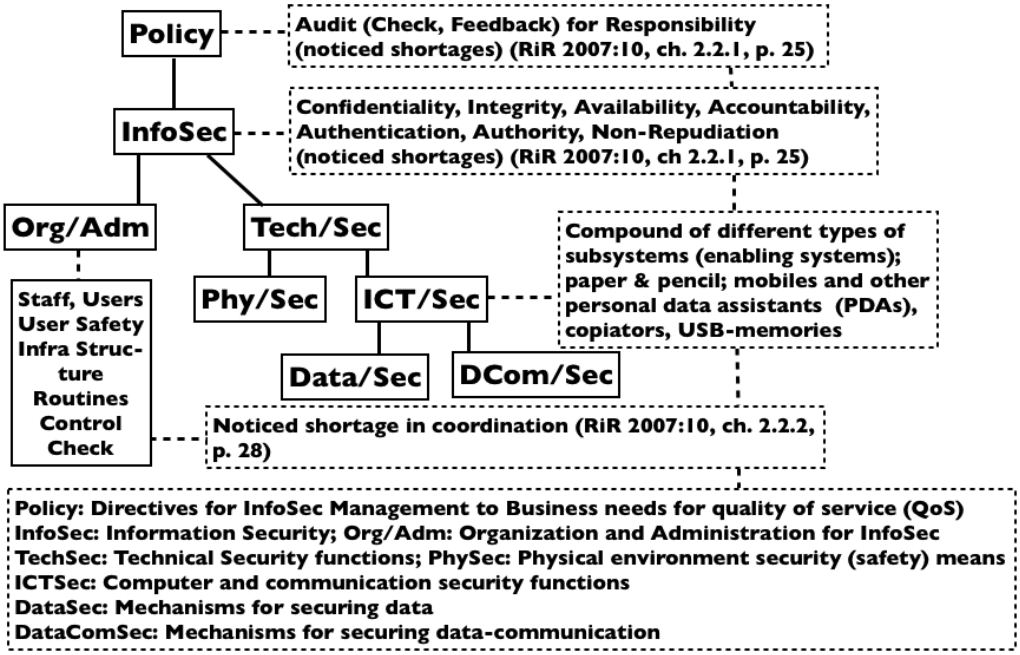

Figure 2: ISC structure (Swedish Standards Institute (SIS) HB550), adapted).

Above Figure 2 hierarchic structure for ISC (InfoSec) is adapted from the handbook (SIS-HB550, 2003). The SNAO report (RiR 2007:10) notifications are identified and classified with respect to the structure hierarchy. But, because the fact that ISC is of global society interest, the used terminology relies on open English dictionaries.

TACTIC

Hierarchy

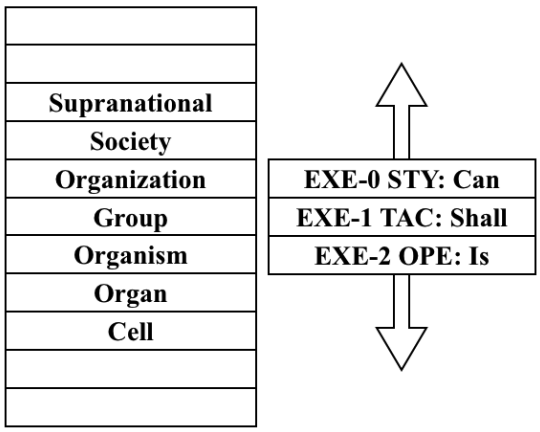

Figure 3: The three level decision hierarchies are relatively to its environment.

The AUD case (Figure 2) can be treated as a society feedback (Figure 3) EVT concerning the agencies as ORG and their PCY being implemented (IPL) and maintained (MIT):

- STY: EXE-0 risk (RSK) policy (PCY) for ISC (InfoSec) with respect to COM partners and environmental EVTs being AUD according to Figure 1.
- TAC: EXE-1 MGT of PCY directives through manually or automatically processed rules (MDP, ADP); i.e. Org/Adm respectively Tech/Sec in Figure 2 to be ACT according to Figure 1.
- OPE: EXE-2 OPE according to MGT rules for Phy/Sec and ICT/Sec in Figure 2 and being

MTR according to Figure 1.

Extension of Figure 1 Content

In Figure 4, the Figure 1 content is reorganized according to the Figure 3 hierarchy. In Figure 4, the 'Staff etc.' in Figure 1 is substituted with the enterprise symbol, EPR {EXE, QoS, ECA, DCT}. 'Message (MSG)' is introduced as a meaning (MNG) conveyor.

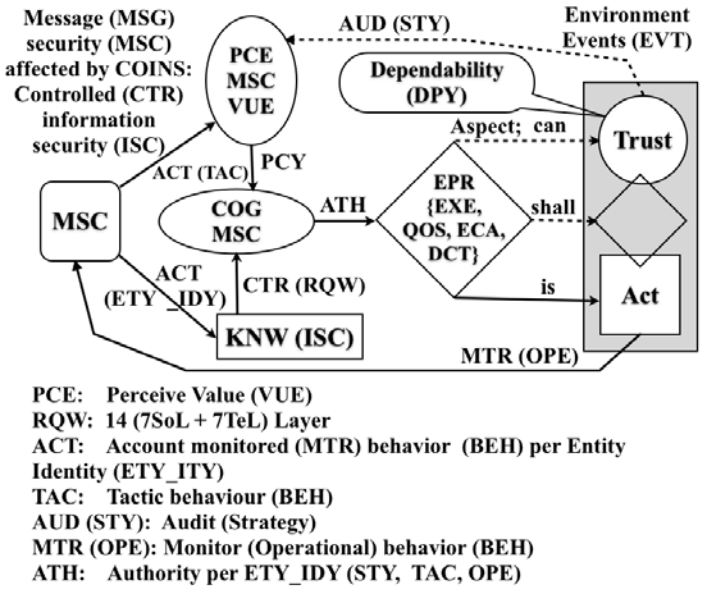

Figure 4: Operationalized Figure 1 for an enterprise, EPR {EXE, QoS, ECA, DCT} and its decision levels STY, TAC and OPE.

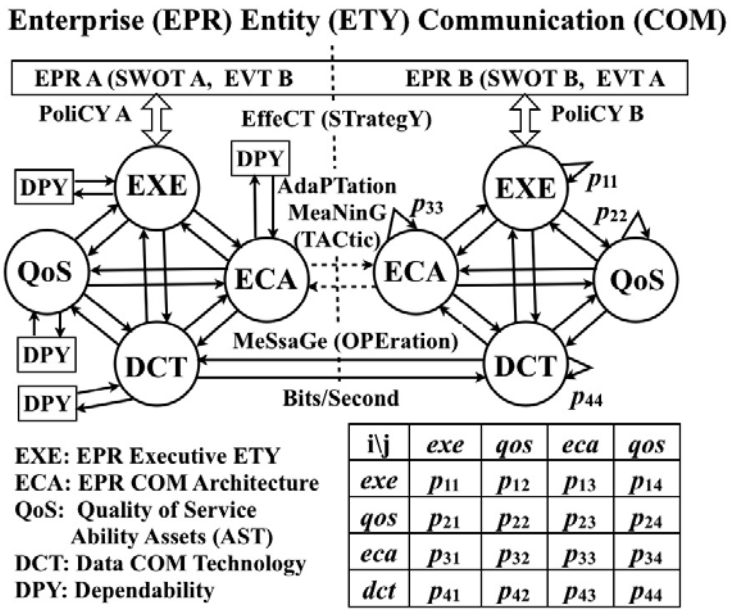

i\j	*exe*	*qos*	*eca*	*qos*
exe	p_{11}	p_{12}	p_{13}	p_{14}
qos	p_{21}	p_{22}	p_{23}	p_{24}
eca	p_{31}	p_{32}	p_{33}	p_{34}
dct	p_{41}	p_{42}	p_{43}	p_{44}

Figure 5: The EPR {EXE, QoS, ECA, DCT}

The Enterprise Communication Model

In Figure 5 (Monfelt, 2010; Figure 1, adapted), the left part ii-states are substituted by dependability (DPY; ibid, Figure 3) and the principles for hidden Markov models (More, 2003) for emphasizing DPY of each system component participating as ETY_IDY AST in the system as whole MTR behavior (BEH). The three decision levels are represented by;

- EXE for the EPR EXE-0 “can be KNW” STY,
- ECA and QoS for EXE-1 “shall be COG” TAC, and
- DCT for EXE-2 “is COG” OPE.

An Enterprise Scenario

STY: RSK PCY is conditioned by a ‘can be’ SWOT (SWT) analyzing process of observation, orientation, decision and Act (OODA, Lawson, 2010; Ch. 3) because of environmental events (EVT) as well as accounts (ACT) of monitored (MTR) of OPE Acts.

TAC: STY OODA ‘shall be’ ECA and QoS COM operationalized (OPE) in a plan, do, check and Act (PDCA, Lawson, 2010; Ch. 3) process for rules and directives with respect to ACTs of MTR DCT Acts.

OPE: The PEF according to TAC directives and rules as base for QoS PEF Acts being MTR.

Adaptation for Provider – Questioner Relations

The Communication Situation

The Figure 6 lower part – adaption from Shannon (1948, p. 2) – is about TeL between information source (INF SCE) and destination (INF DST). To INF SCE incoming MSG is encoded (MSG’) to transmitter (TRM) signals (SGN’) of which may be jammed (JAM), distorted or decoyed (DCY) or gathered (SGN INT) before (SIGN’’) to receiver (RCR) for decoding MSG’’ to information destination (INF DST).
An example of messaging archetype is about Web Servi-ces (Booth & al, 2004). Aspects on contents in MSG are in Sjoqvist (2008).

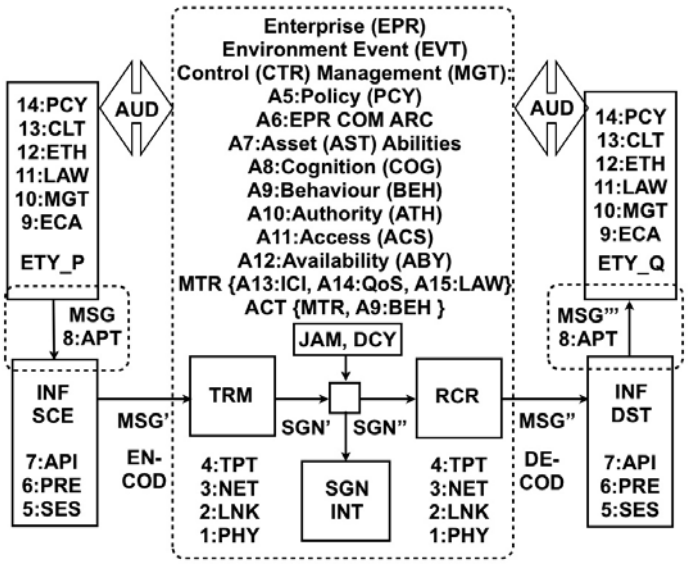

Figure 6: The communication situation (Shannon, 1948; p. 2, adapted).

The DCT 7TeL – open system inter-connection (ITU-X.200, -X.800 OSI) model – 7:applica-tion (API), 6:presentation and 5:session is for peer to peer INF SCE → INF DST actions (Act). In this essay the 7:API is of most interest because of its 8:APT to SoL 9 – 14 (Table 4). TRM → RCR OSI layers are; 4:transport, 3:network, 2:link and 1:physical media.

A Mechanized Analogy for the Communication Situation

In Figure 7 are the Figure 5 states

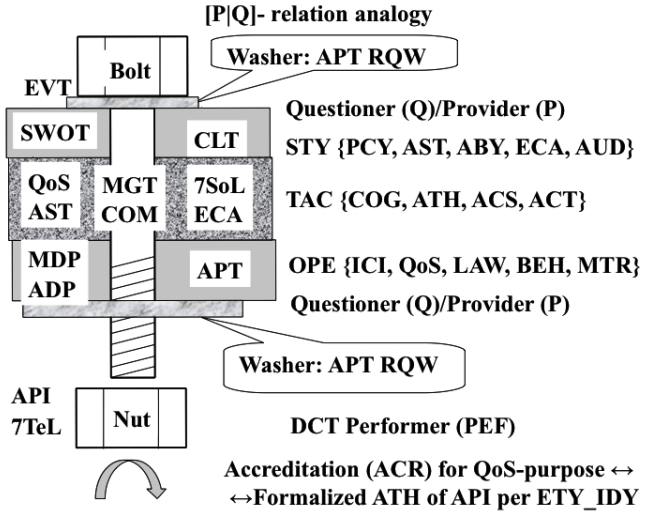

Figure 7: Bolt – Nut analogy of Figures 5 and 6 (idea adapted from Lawson, 2010; p11)

'mechanized'. All of the A5 … A15 ISMS CTR are included and distributed to the three decision levels. The CTRs are specified in Table 1 below. In the decision level (DCL) column, is pointed out which of the CTRs are treated as being of main interest to manage per DCL in correspondence with what is viewed in Figure 6. MTR, ACT and AUD are distinctions of the three level feedbacks (FEB) because of MTR OPE system integrity (ITY) BEH through ICI, QoS and LAW disturbances. The MTR data has to be TAC ACT available for STY AUD.

The two provider (P)/ questioner (Q) relations being marked out in Figure 6 have to be linked: Environmental EVT are Q_{EVT} on STY level to be SWT-RSK analyzed for P_{STY} to serve OPE Q_{OPE} for how to – with respect to eventual ATH asymmetry if another ETY_IDY – response; i.e., P_{OPE} MSG responding the EVT.

Adaptation Situations are Ubiquitous

P→Q situations are ubiquitous; e.g., analogous with principal/agent relations (IEA, 2007, Ch. 1 – 3). Each *P→Q* has to be contextually (CXT) interlinked and hence being APT to each other. If, the APT conditions are peer to peer then [P|Q] relation as viewed in Table 1.

Table 1: Conditional Statement or Modus Tollens or Implication Truth table (Monfelt, 2010; adapted).

P	***Q***	***P→Q***	**SWOT**	**COG Symmetry/Asymmetry**	**Benefit**
T	*T*	*T*	S	Symmetry, [P/Q], peer to peer	Equivalence (↔)
T	*F*	*F*	W	Asymmetry, [P|Q[	P
F	*T*	*T*	O	Asymmetry,]P/Q]	Q
F	*F*	*T*	O/T	Symmetry/ chance/ potentiality,]P|Q[	P or Q (ad hoc, open)

Begin Table 1 *P→Q* example:

"For example the fact P-1001 is [OPE aspect] a part of Process Unit U-1000
This is not 'data', but is an expression of a fact that thus provides information. It expresses semantics. Gellish English enables to express such facts and enables to manage their approval status and history." (V. Renssen, 2008, p. 14)

End Table 1 *P→Q* example.

Aspects of things are in Table 2. (V. Renssen, 2008, pp. 32f.). COINS comment column is inserted.

Table 2: General aspects for '→' (V. Renssen, 2008; pp. 32f.).

IDY	Aspect [STY: can, may be/have, TAC: shall be/have, OPE: is/has]	COINS
1	**Physical object:** Physical objects cover everything that obeys to the laws of physics. For example, a physical object can be an *inanimate physical object*, or an *organization* or a *lifeform* (which has as one of its subtypes *person*). In addition to its normal classification a physical object can also be classified as an *imagined physical object* (e.g. a design) or as a *materialised physical object*. However, in most applications this classification can be eliminated, because it is either clear from the context or can be concluded from the semantics of some relation types. For example, in technical design applications it is a general rule that - Each physical object is an *inanimate physical object*. - Each physical object is an *imaginary physical object*.	ETY
2	**Occurrence:** Occurrences cover everything that happens, such as an act (activity), a process or an event and also a behaviour of a physical object. Occurrences are actually special kinds of relations (interactions between interacting things). Subtypes of the involvement relation specify in what role an object is involved in an occurrence.	EVT OCU BEH
3	**Aspect:** An aspect is something that is possessed by a thing and that characterizes an inherent characteristic of the thing, or is a role that is played by the thing. It can be qualified by a qualitative aspect or it can be quantified.	CTR ASP
4	**Property:** A quantifiable aspect is usually called a property or a physical quantity. A property is typically qualified by a relation to a number on a scale (UoM). [unit of measure]	AST
5	**Quality:** A quality is a non-quantifiable qualification of an object. A quality is typically qualified by a qualitative aspect that is selected from a pick list.	AST QoS
6	**Text:** A text is a string of characters that form a word or a phrase (sequence of words) *or* a numeric value, which can be related to an object as a reference or definition or description (in a context).	MSG
7	**Information** (= **collection of facts**): Information is a collection of facts that can be expressed by a collection of relations. [ibid Figure 37, p. 125]	KNW INF
8	**Organisation:** An organisation can be seen as a structured collection of persons or the design of such a structured collection.	ECA
9	**Person:** A person is an individual life form who can be treated as a physical object, although he or she also possesses spiritual aspects.	ETY IDY
10	**Kind of thing:** A kind of thing (or class) is any subtype of physical object, or occurrence, or aspect, etc.	14L
The above examples are ambiguous if we would not apply the above-mentioned defaults. For example, from the defaults in a technical design context it becomes clear that P-1301 is meant to be a name of a specific imaginary physical object and not about an actual one.		

Control Aspects

An introduction to Table 3 CTR ASP and Table 4 14SoTL:

- The kind of physical object as spiritual person (ETY_IDY) shall (TAC) be authorized (ATH), authenticated (AUT) and adapted (APT) for actions (Act) and messaging (OPE, MSG) in the contexts (CXT) of SoTL14:ETH.

The A5 … A15 controls (Table 3, CTR) are treated as generics for properties; i.e., being metrics

in any $P \rightarrow Q$ for Table 4 14SoTL.

Table 3: A5 ... A15 Controls (CTR; ISO/IEC-27001, 2005; Annex A, adapted).

A	COINS	Control objective aspect	DCL
5	PCY	Policy (PCY) on basis of consensual SWOT/Risk (SWT/RSK) analyzes, by any enterprise executive entity (EXE) how to secure (SEC) mission performance (PRF).	STY
6	ECA	Enterprise Communication Architecture (ECA↮ organization, ORG) about assets (A7:AST) that constitute the enterprise mission performance ability in its organismic sociality (culture (CLT), ethics (ETH), legalities or rules (LAW), management (MGT), operations (OPE) and means.	STY
7	AST	Assets (AST ↔ confidential or confident, COF) means for quality of service (QoS) in mission performance (PEF) communications (COM).	STY
8	COG	Cognition (COG) for ability (AST) to recognize and perceive what enterprise missions are and how to handle these because of the SWOT based A5:RSK PCY.	TAC
9	BEH	Behavior (BEH) dependability (DPY) for entities (ETY).	OPE
10	ATH	Authority (ATH) in parity with an entity identity (ETY_IDY) need of access (A11:ACS) to abilities as QoS assets (A7:AST), cognition (A8:COG) and dependable (DPY) behavior (A9:BEH) and responsibility in parity with the authority (ATH).	TAC
11	ACS	Access (ACS) rights in parity with authority (A10:ATH).	TAC
12	ABY	Availability (ABY) in resources (A7:AST) for dependability (DPY).	STY
13	ICI	Observed incident (ICI) is a first detectable (error = ε>0) signal of change in feed-backed (FEB) performance (PRF) caused by unknown or ignored dependability (DPY) fault (FLT).	OPE
14	QoS	Quality of Service (QoS) account (ACT) is, because of uncorrected error (ERR) of which escalates to a fail (FAL) of which even can be a strength (STR) in mission performance (PRF).	OPE
15	LAW	Compliance (LAW) account (ACT) is policy (A5:PCY = feed forward, meta loop including SWOT) audit (AUD) fail (FAL) or strength (STR) in requisite variety width (RQW) with respect to PCY rules for protection (PRT) of the 14SoT layers.	OPE

The Fourteen Communication Layers to be Controlled

In the '14 layered framework' (Yngstrom & al, 2009; Clarke & al, 2010) adapted in Table 4, the 7TeL associates with the 'Open System Interconnection (OSI)' recommendation (ITU-X.200, 1994) accompanied with (ITU-X.800, 1991) security aspects (ASP). The 7SoL associates mainly with the information system framework (Falkenberg & al, 1998).

Begin Tables 3 and 4 examples:

Table 4 characteristics can or may be/have STY for shall be/have TAC for is/has OPE Table 3 control (CTR) objective (OBJ) for dependable (DPY) QoS mission performance (PEF).

Table 4 14SoT layers represent the complexity variety width. Each ETY_IDY shall have requisite 14SoTL variety width (RQW); i.e., COG in parity with the OPE PEF role to be authorized (ATH) and authenticated (AUT) for adaptation (APT):

- APT {ATH, AUT}
- ATH {ETY_IDY, COG, ACS, AST, DPY (ISC), ACT}

- ISC {COF: confidence or confidentiality, ITY: integrity in system behavior (BEH), ABY: asset ability availability (ABY), AUD: audit of accounts (ACT) or events (EVT)}.

End Tables 3 and 4 example.

L8:APT	MTR {A13:ICI, A14:QoS, A15:LAW, A10:ATH}	OPE

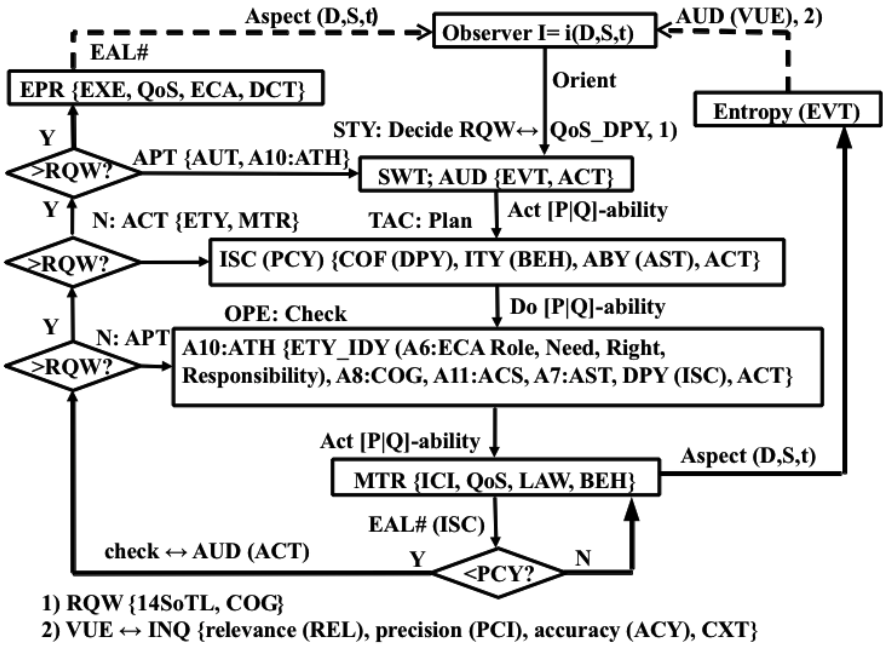

Figure 8: Control (CTR) management (MGT) taxonomy structure (Table 1).

The Table 5 characteristics are structured in Figure 8 with Table 1 *P→Q* conditions in mind:

- INQ: INF quality (Q).
- Observe, Orient, Decide, Act (OODA) and Plan, Do, Check, Act (PDCA) loops interconnection (Lawson, 2010) is utilized.
- Aspect (D, S, t) meaning is: I =i(D, S, t) ↔ COG =PCE(D, S, t) ↔ COG =PCV(MSG) (Monfelt, 2010).
- <PCY meaning is: Check IF OPE MTR(D, S, t) Acts are less than EAL# (ISC) <PCY, THEN APT {AUT, ATH} AND check RQW, ELSE check EVT.
- >RQW meaning is: **IF** the ETY_IDY's MTR Act is greater than its RQW ability **THEN** check the EPR EAL# with respect to EVT, **ELSE** ACT {ETY, MTR} **OR** check the ETY's authenticity **OR** authority: APT {AUT, ATH}.

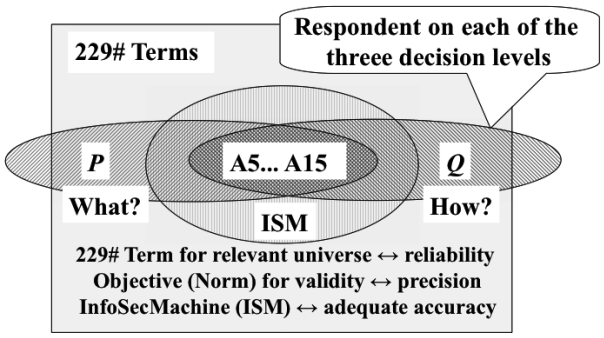
Ubiquitous Frictions in Communications are Security Issues
Figure 9: How do the respondents – in dedicated ISC roles on each of the DCLs – in an agency as EPR, perceive (PCE) the STY propositions (*P*) as PCY “can be“ meaning *Q*s for TAC “shall be” and OPE “is” ECT.

The study approach was taken to investigate how an agency COM about ISC; i.e., how INF is MSG PCE and articulated.

The information system (ISY) in general is defined in the framework (Falkenberg & al, 1998). Supposedly, the general definition is purely for how to create an appropriate ISY for dependable (DPY) mind to mind 7SoL conditioned COM to be developed for and APT for some EPR QoS mission PEF under environmental *P→Q* EVT LCP conditions. The framework is used for selection of the Figure 9's 229 terms or syntaxes (STX), of which COG in some way

contribute to the ISY usability as a 14SoTL COM system.

The Figure 9 evolution is motivated in the study reports (Yngstrom, 2009a, Ch. 5; & 2009b) and is presented in Clarke & al (2010) to be published (Monfelt & al, 2011). The InfoSec Machine (ISC – machine, ISM) symbol in Figure 9, is a mind model to be created by any EPR ETY how to manage its LCP mission PEF as QoS provider. Only ETY of its own – with principal EXE responsibility – is able to COG and CTR its EVT conditioned COM Acts. These are manifested trough CXT {what, when, where, who, how, why} MSG. Then, the basics for COM is to KNW the MSG MNG and, as an ATH OPE Acting ETY_IDY, having ability to COG the ECT thereof (Monfelt, 2010). The ISM purpose is for APT of the audit-able CTR-s to the EPR ETY. A general ISM example (Yngstrom & al, 2009b) is viewed in Figure 9. In Table 5 not A5 … A15 dedicated CTR; e.g., MTR, ACT and AUD are examples of which motivate ISM (Figure 10) as a tool for APT of A5 … A15 to the EPR.



1. ISM is based on the hits among the 229# term set.
2. Objective (Norm) is based on the ISM term hits among the normative A5 … A15 ISMS objectives.
3. *P*: Test (Statements) are an agency's propositions.
   Q: Test (Responses) are respondents (EXE-0, EXE-1, EXE-2) reaction on the pragmatic situation within the agency.

Figure 9: The study approach. (Clarke & al, 2010; adapted)

A DCT (Figure 5), as a 7TeL system component ETY, may be programmed for PEF of MDB or ADB routines. Web services architecture (Booth & al, 2004) in an example of that kind of MSG Acting. In Figure 5 CXT, the part-A's QoS and DCT states interact on EPR B ETY IDY's requests. The ETY_IDY may be satisfied if that kind of relation is acceptable for its CXT situation; i.e., with respect to the 14SoTL RQW. But, the preparation for mechanized interactions is 7SoL COM DPY conditioned:

- The MNG of DCT aided ISY is to effecting (ECT) the wanted QoS CXT VUE efficiently (EFY). For this the DCT→ECA RQW APT DPY has to be CXT maintained (MIT). The Web services architecture (Booth & al, 2004) views an example how to manage 7TeL MSG to be APT for an EPR mission purpose by, or by agents on behalf of, the EPR EXE-0. MSG content aspect principles are examined in Sjoqvist (2008).

OPERATION

The study approach was taken for how an agency as EPR COM about ISC; i.e., how MSG INF MNG is PCE, presented, exposed or articulated for appropriate ECT; i.e., become COG.

PDCA: Plan Do Check and Act the Interview Guide

Plan:
Semi-structured interviews were undertaken at the selected agency using a predefined inter-view guide. The following themes regarding information security issues were covered by the guide (Yngstrom & al, 2009a; Ch. 6 for '*P*' & Ch. 7 for '*Q*'):

Done:

A. Interview of ISY related decision structure to probe if an agency is concerned with focus on QoS COM or on DCT. (Reported in Yngström & al, 2009a; Ch. 5)
B. Interpretation of A5:PCY directives; i.e., '*P*' in Figure 9. (Reported in Yngstrom & al, 2009a; Ch. 6)
C. Interview if one security manager on each of the STY, TAC and OPE decision levels (DCL); i.e., '*Q*' in Figure 9. (Reported in Yngstrom & al, 2009a; Ch. 7).

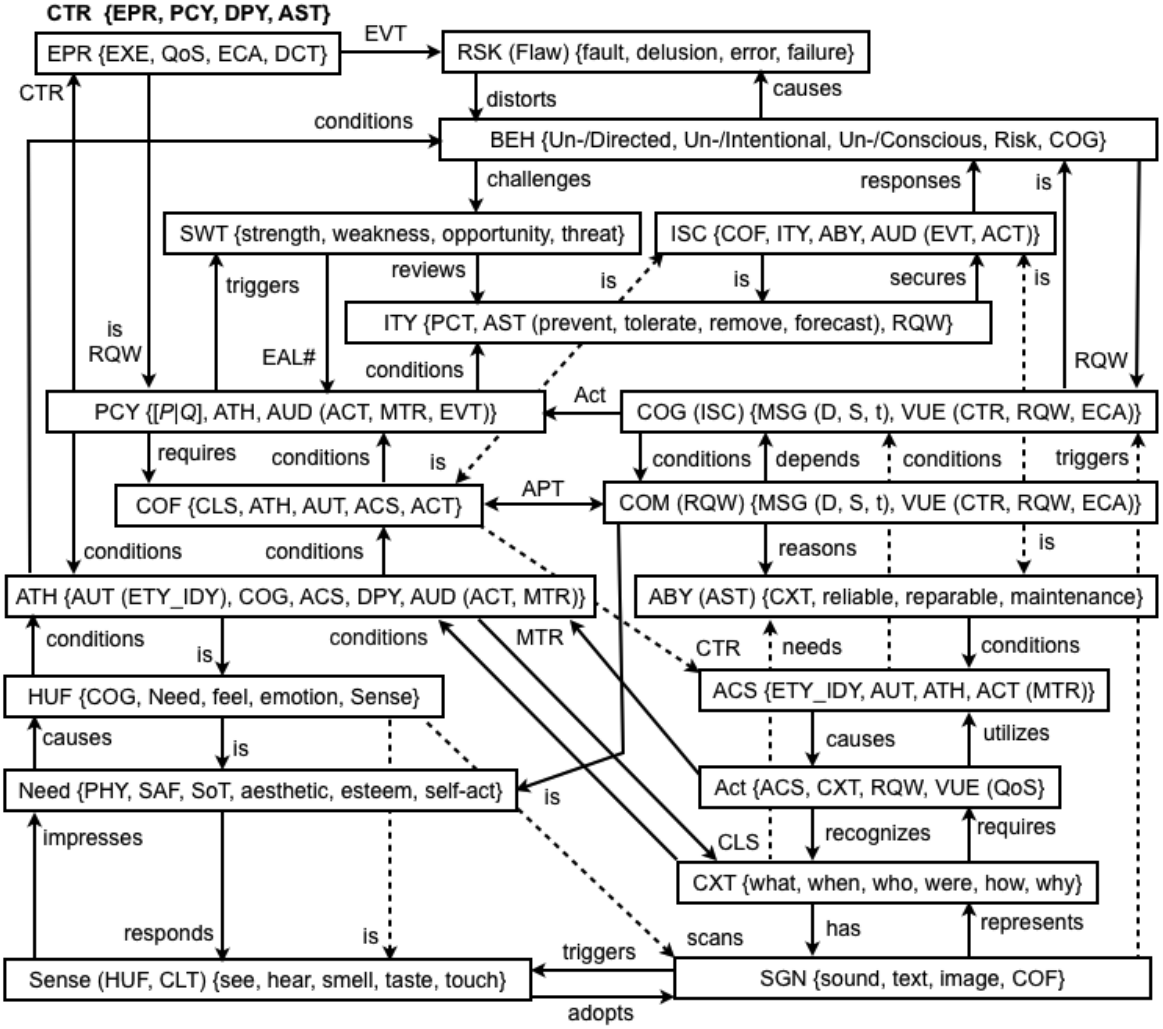


Figure 10: Information Machine (ISM) graph example associates with the EPR (Figure 5) structure (Yngstrom & al, 2009a, b).

Table 6: Interview guide and its use for *P*→*Q*.

'***P***'	**Interview guide aspect (comment)**	'***Q***'
*1	General information security work (EXE-0 STY),	72x
*2	Management information security work (EXE-1, TAC)	73x
*3	Operative information security work (EXE-2, OPE)	74x
*4	Information security needs (L14:RSK, A5:PCY)	75x
*5	Problems and needs for change **('*P*' is not appropriate)**	76x
*6	Information security communication structures (ECA-0, ECA-1, ECA-2)	77x
*7	Assessing information security (DCT or QoS COM focus, **no '*P*'**)	78x
*8	Concepts and terminology (basic for COM of COINS, **no '*P*')**	79

Check:

D. An agency selected for test of the interview guide (Table 6)

Table 7: Compound of interviews for '*Q*' (Yngstrom & al, 2009a; Ch. 7)

Id	Header (Report 7.12-7.19)	ISMS (A5- A15)	ISC-Machine (ISM)	Hits #
721	InfoSec perspectives and associations	Business (enterprise)	Risk (EPR)	36
722	Goals, visions and decisions	Policy (A5)	EXE (PCY)	13
731	Tasks and responsibilities [Authority]	Access (A11)/ Communication (A10)	ACC (ATH) [ACS]	39

OODA: Observations, Orientations, Decisions and Acts

Observations

Table 6, rows *5, *7 and *8 have no '*P*' directive. These facts may indicate probable distinct inbuilt inconsistencies among others as reported in Hallberg & Lundholm (2009):

"... The models show that many interactions within the agency involve entities which are very broadly defined, e.g. "agency personnel". With entities like this in the organizational model it is hard to assign responsibilities for actions connected to these interactions. …" (Hallberg & Lundholm, 2009; Summary)

The above distinct inconsistencies may directly impact aspects in Table 7; i.e., 761 -765, 781 - 784 and 791-793.

Transcript Example 781b:

"781b/ X0: X0 says that there is not systematic process for measuring and evaluation InfoSec activities at the [X0|C0]. However, there are present attempts to control follow up InfoSec matters and to introduce InfoSec measures. Often the internal regulations are used as a measure and different activities are measured against them. Perceived deficiencies are reported to the highest management together with suggestions on how to improve things. The respondent in particular mentions the PDCA-method and is control phase. He hopes this method will provide the [X0|C0] with new tools for controlling and measuring large amounts of information, the "overall picture". But a problem is that the method will not be fully implemented until three years from now." (Yngstrom & al, 2009; Ch. 7.3)

Then, what issues in Table 8 have to be focused on. Notable discrepancies are 'STY' and 'TAC' columns. The reason may coincidence with the above observed inconsistencies.

Orientations
There have been face to face dialogues about the interview transcriptions and presentations in seminar form at fall 2009 and at winter 2010.

Decisions
Within the interviews there were decisions made like that what is noticed in the above 781b example.

Acts
The spring 2010 follow up interviews have the meaning that things are in progress for being better. This is by the current author been noticed for concerning [*P*|*Q*] relations, authorization (ATH) and audit (AUD) with related monitoring (MTR) and account (ACT).

CONCLUSIVE AUDIT

Realize the Strategic and Tactic Approaches through Control Management Taxonomy

Security (SEC) is an earned state, achieved through evaluated (EAL) protection (PRT) of dependencies (DPY); i.e., PRT of ETY_IDYs as assets (AST) against probable risks (RSK, PCY) in AST's safety (SAF). The ASTs are the abilities of which synergy (SGY) effect (ECT) contributes to the EPR's value (VUE) as QoS performer (PEF). The VUE is created in communication (COM) sessions (PCS) through exchange of messages for meaningful (MNG) effect (ECT); i.e., information SEC (ISC) through Table 5 control (CTR) management (MGT) 'shall be' intentions implemented in the Figure 8 structure for;

- ISC {COF: confidence or confidentiality, ITY: integrity in system behavior (A9:BEH), A12:ABY: asset (A7:AST) ability availability, AUD: audit of accounts (ACT) of monitored (MTR) action (Act) occurrences (OCU) and observed environmental events (EVT)}.

Social Life Depends on Mechanism Adaptation

"... [T]he power conferred by technique [DCT, 7TeL] is social [7SoL], not individual; an average individual wrecked on a desert island could have achieved more in the seventeenth century than he could now. Scientific technique requires co-operation of a large number of individuals organized under a single [EXE-0] direction. Its tendency, therefore, is against anarchism and even individualism, since it demands a well knit social [ECA] structure. Unlike religion, it is ethically [ETH] neutral: it assures [EAL] men that they can [STY] perform wonders, but does not tell them what [EPR] wonders to perform [PEF]. In this way it is incomplete. In practice, the purposes to which scientific [OPE] skill will be devoted depend [DPY] largely on chance [SWT]. The men [EXE] at the head of the vast organizations which it necessitates can, within [EVT] limits, turn it this way or that as they [PCY] please. The power [ATH] impulse thus has a [SWT] scope which it never had before. The philosophies that have been inspired by scientific *technique* are power philosophies, and tend to regard everything non human as mere raw material. Ends [LCP] are no longer considered; only the [OPE] skillfulness of the process is valued [VUE]. This also is a form of madness. It is, in our day [1946 > WWII end], the most dangerous form, and the one against which a sane philosophy should provide an antidote. ..." (Russell, 2000, pp. 481f)

Current CXT conclusion:

- APT of each API has to be formally ATH; i.e., DCT /ECA implementations have to be accredited (ACR) and AUD.

[*P*|*Q*] relation

P→*Q* relations are supposed to associate with principal/ agent (P/A) ditto (IEA, 2007). Following citation from the spring 2010 follow up (above OPE PDCA G) interviews exemplifies the situation at the studied agency. The example is related with Tables 6 and 7⁄ 79x (792) example:

"The procurement-delivery [P/A] model is an approach that EXE-0A perceives as a tool for the management process. The respondent, EXE-0A, believe that the provider side has an emphasis on technology, as the work most often regard service and administration (*LCP- maintenance*), that needs to be wrought towards a user perspective. Both respondents on EXE-2 level have a less positive to strongly negative view of the procurement-delivery model. Some of the reasons were that the model was applied to an organization that was not [COG] ready for it (2) and who did not have its communication structures (3) sufficiently clearly drafted. One of the respondents stressed that as the model is unclear within the agency, it will be even more unclear for subordinate agencies (4). This applies mainly to responsibility [ATH] allocation." (Spring 2010 interview)

Authorization

Tables 9, 10 and Figure 11:

- COG {Knowledge, Comprehension, Application, Analysis, Synthesis, Evaluation} (Monfelt, 2010 adaptation from Yadin, 2007 about Bloom's Taxonomy, 1956).

Table 9: The meaning (MNG) of Table 9 states.

i	j	Meaning (MNG) per state i, j
1	1	SoL11-SoL14 for A5:RSK PCY in parity with A7:AST for A14:QoS performance (PEF).
2	1	COG is contextual (CXT) experienced KNW for L9 ↔A6:ECA to be L10 MGT for ATH.
1	2	Uncertainty about what to do for DPY (resilience). May be caused by some kind of social engineering (SOE). Has to be MTR for ACT, AUD and SoL10:MGT towards OPE benefit. The state represents the (i, j) = (i, i) in the EPR Markov chain model (Figure 5).
2	2	OPE actions (Act) to be MTR for ACT purpose.

Table 10: States in Figure 11.

i|j	j=1: Ability (A7:AST)	j=2: Authority (A10:ATH)
i=1: Knowledge (KNW)	Strategy (STY)/Audit (AUD)	SOE/Audit (AUD)
i=2: Cognition (A8:COG)	Tactic (TAC)/Account (ACT)	Operation (OPE)/Monitor (MTR)

Authority (ATH) without ability as asset (AST) is treated as social engineering (SOE) in Table 9, (i, j) = (1, 2). Knowledge (KNW) has to be managed and trained in contextual (CXT) experience for requisite variety width (RQW) cognition (COG) of which is treated as neces-sary for being an available (ABY) ETY_IDY ATH (Table 5) being adapted (APT) for appli-cation (API) operations (OPE) Acts (Figure 11):

- ISC {COF, ITY, ABY, AUD (ACT, MTR)}.

Tables 6 and 7/ 72x and Table 8 example:

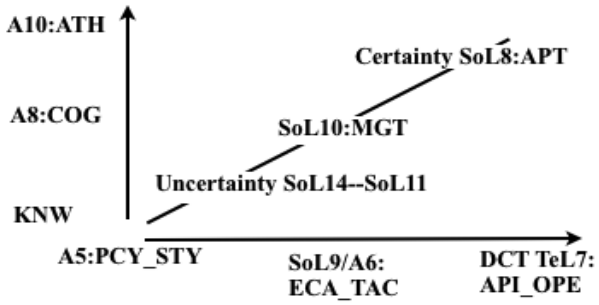

Figure 11: Variety (RQW) management (MGT) (V. Gigch, 1978; p. 381, Fig. 14.2, adapted).

"The EXE-2 respondents complain that management [MGT] does not work properly because of shortcomings in; e.g., (1) feedback, (2) current level of knowledge [KNW, COG], (3) unwilling-ness to allocate resources [abilities as assets (AST)], (4) ability [AST] to communicate [COM].
Regulations for security issues is the means of the management [MGT] to point at violations against the information security policy [PCY] performed, but the main effort by the management is to support organizational business [EPR] both on a daily basis and during incidents [ICI]. Respondents in the EXE-2 level highlights the negative consequences of the managements stubborn persistence on responsibility [ATH] being a management domain only (5) unwillingness to delegation, (6) inability [WEK] to communicate decisions, (7) no consequences at information security violations from the operational personnel or system owners [SOW]. The provider side has no mandate [ATH] to manage enforcement.

Respondent EXE-2K highlight the difficulty to distinguish between different related fields; e.g., (8) security-justice, and thus the responsibility [ATH]. The same respondent also points out that it is easier if you (9) know who in the organization who have responsibilities [ad hoc], be it official or not." (Spring 2010 interview)

Monitor, Account, Audit

Tables 6 and 7/ 72x, 73x, 74x, 79x and Table 8 example:

"All of the respondents know that the [ISMS] standard is a document that the agency is set to follow. They see the document as comprehensive and universal. All respondents believe that it must be adapted [APT] to the organizational [ECA] domain before it can be used. This means that it, in the form it has, can be used as verification of the agency current work, as a checklist of work in progress and as an idea bank / adviser for what can (should) be done." (Spring 2010 interview)

Proposed Structure Model

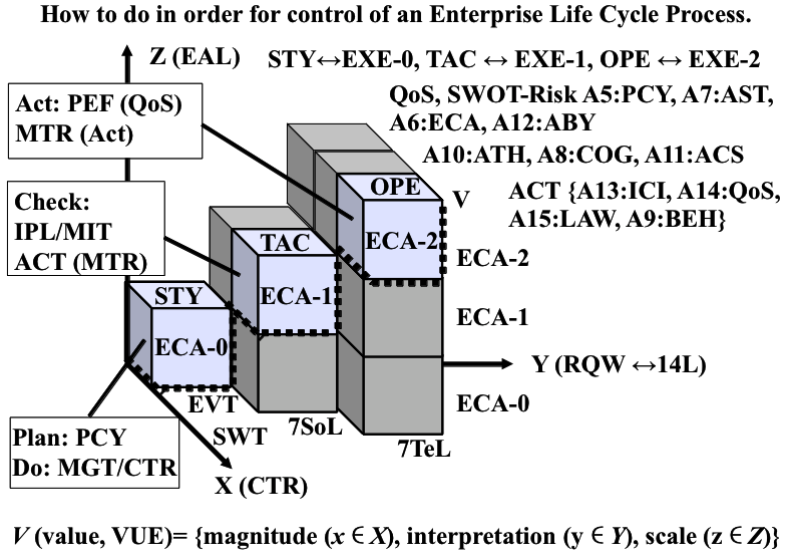

Figure 12: Communication (COM) is a target of evaluation: Z(EAL).

Tables 8 and 10 CTR order is include in Figure 12 of which MSG the idea that the COINS' cube thinking model (Hallberg & Lundholm, 2009) can effective the COM for APT ↔ #8 (14SoTL), because it has to be done for each of the APIs (Monfelt, 2010).
Controls (CTR) have 'can', 'shall' and 'is' aspects on formal authorization (ATH); – accreditation (ACR) – of requisite

variety width (RQW) in QoS performance (PEF) to be monitored (MTR) accounted (ACT) and audited (AUD) relatively to environmental events (EVT).

Using ISM functional operator '○', Figures 8 … 12 ISM may be expressed through:

- ATH (RQW)≈ can (CTR ∩ STY) ○ shall (CTR ∩ TAC) ○ is (CTR ∩ OPE) ↔
- (ATH) RQW≈ EXE-0 (PCY) ○ EXE-1 (ECT) ○ EXE-2 (PEF) ↔
- (ATH) RQW≈ STY (RQW) ○ TAC (RQW) ○ OPE (RQW) ↔
- ATH (RQW) ≈ ATH (RQW_{SWT}) ○ ATH (RQW_{SoL}) ○ ATH (RQW_{TeL})
- V = VUE (COM)≈ ECA-0 (ATH_{SWT}) ○ ECA-1 (ATH_{SoL}) ○ ECA-2 (ATH_{TeL})

A structure for going further with the SoT APT may be found in the Common Evaluation Criteria (CC) protection profile (PP) examples (CCRA, 2005).

ABSTRACT

In fast-evolving business areas, firms usually need networks to provide them with resources, respect and negotiation power they do not possess on themselves. However, firms should also avoid becoming too entangled in restrictive relationships. The paper examines how actors balance between embeddedness and independency in their relationships, and how this balancing and their willingness and ability to share social capital reflect on the networks they tend to form. Furthermore, the paper discusses the resource-bases of actors, and searches linkages between the actors' resources and their networking tendencies. The paper provides understanding on how independency and associability affect the formation of networks, and how the different resource- palettes of the actors correlate with this network formation. As a case, we study a group of biomass heating enterprises, where four groups with different networking tendencies are recognized and further assessed. The results provide evidence that depending on the set objectives, the actors tend to form different networks which differ from each other by the power relations and the openness of sharing social capital in them. In addition, the actors differ remarkably in their bases of resources, and different aspects are highlighted in their resource- palettes. This creates different motives for cooperation and networking.

Keywords: networking, resources, independency, associability, bioenergy business

INTRODUCTION

There is a global concern about increasing greenhouse gas emissions, and the prices and amount of exhaustion of traditional fossil fuels are continuously increasing. As a consequence, the use of renewable primary energy sources and improved overall energy efficiency play an important role in future energy production and consumption (Cowie & Gardner, 2007; Tekes 2008). One of the most promising options of renewable energy is the utilization of different biomasses. The bioenergy business offers new business opportunities increasingly, to existing actors as well as to the new ones. In addition, as in several other fields of business, also the significance of networking is becoming more evident in the bioenergy production solutions.

Cooperation and networking can provide a valuable source of support and information, as well as means of sharing resources (Fuller-Love and Thomas, 2004). Networks offer access to the assets and capabilities of other actors (Chetty and Wilson, 2003). Especially, emerging actors usually need external networks to provide a variety of resources, capabilities or legitimacy which they would need for successful survival, but which they cannot produce internally (e.g. Hite and Hesterly, 2001; Mei and Nie, 2008). Bioenergy can be characterized as a fast-evolving field offering several kinds of new business opportunities and models, and thus attracting existing as well as emerging actors. For the actors, networking usually offers a reasonable way to exploit new entrepreneurial opportunities or to develop existing ones by sharing resources and capabilities with each other.

The actors should avoid becoming too entangled in restrictive relationships, however (e.g. Staber, 2005), but maintain a certain level of freedom to secure their own interests. In other words, firms should be *embedded* (Granovetter, 1985) and *independent* at the same time (De Wit and Meyer, 2005). In addition, every actor has a certain level of *associability*, which means that they in general differ in terms of sharing social capital, which has an impact on their willingness and the easiness to form partnerships and networks (Leana and Van Buren, 1999).

The aim of the study is to complement the knowledge on the benefits and delimitations of networking with a two-step process. First, we look at the two aspects mentioned above, the actors' independency and associability, and examine the different networking tendencies based on them. Secondly, in order to examine the motives for networking in a fast-evolving business area, we take a look at the resource-bases of the actors, and search linkages between the actors' resources and their networking tendencies.

The research question of the paper is: "How does the resource-base of an actor correlate with its tendency to form networks?" Case study research (e.g. Creswell, 2007; Eriksson and Kovalainen, 2008) is used as the research strategy. The research data has been collected by theme interviews. As the case, we use a group of Finnish biomass heating entrepreneurs which we consider to represent well a group of actors in a fast-evolving business area. The research data consists of 26 semi-structured theme interviews with the biomass heating entrepreneurs and supportive material.

The study confirms that each actor has a certain level of independency and associability, and based on them, a certain tendency to form networks. These tendencies lead to formation of different network types. Among the studied enterprises in the biomass heating field, four groups with different networking tendencies are recognized and further assessed. These groups are: 1) actors in local networks of equal partners, 2) actors with strong relationships with heating plant manufacturers, 3) network developers/lead firms, and 4) independent actors.

In addition, we illustrate that the actors differ remarkably in their bases of resources, and also that different aspects are highlighted in their resource- palettes. This creates different motives for cooperation and networking, which are reflected well in the four networking types found in the studied field. On the basis of the analysis, correlations between the actors' resources and their tendencies to form certain kinds of networks can be found.

BIOMASS HEATING ENTREPRENEURSHIP AND CHP

Heat energy production is mainly considered as a local activity. Wood chips, which are the main fuel in the plants, are typically procured in the surrounding area. In addition, the plants may use supplementary fuels, such as peat, agrobiomass and oil. The heating enterprise may take care of all the steps from fuel procurement to the delivery of heat to real estates or the heating network, as well as the maintenance of the plant, or it may concentrate on the actual business activities of the plant, or something between these (Okkonen and Suhonen, 2010). Typically, a heating entrepreneur or enterprise is a single entrepreneur, an entrepreneur consortium, a company or a cooperative (Okkonen and Suhonen, 2010; TTS 2010). In this study, the terms 'heating entrepreneur' and 'heating enterprise' are used interchangeably, referring to all these possible forms of ownership. In Finland, the number of heating plants operated by heating entrepreneurs was 455 in 2009. The number of heating enterprises was a bit lower, because some enterprises operated in several heating plants. The average size of the plants was 550kW. 90 percent of the solid fuel used in the plants was wood chips (TTS 2010).

As in many other countries, the possibilities for small-scale combined heat and power production (CHP) have been discussed widely in Finland as well, also among the heating entrepreneurs. CHP is a process of producing electricity and usable thermal energy (heat and/or cooling) at high efficiency and near the point of use. CHP contains three elements: simultaneous heat and electricity production, high-efficiency performance, and proximity of the energy production unit to the customers (WADE, 2003). Various technologies using different primary fuels are suitable for CHP production. However, many of small-scale implementations still require significant R&D investments before they are feasible for possible commercialization (Motiva, 2010).

A small-scale bio-CHP could form a supplementary building block for a more sustainable future energy system in many countries. The economical and ecological performance of a small-scale CHP varies by technology and strongly depends on the implementation context.

All in all, regulations and institutional frameworks play a crucial role in the development and diffusion of small-scale bio-CHP technologies (Pehnt et al., 2006).

LITERATURE REVIEW

Networks offer access to the assets and capabilities of other actors (Chetty and Wilson, 2003), and cooperative activities and networking can thus provide a valuable source of support and information as well as means of sharing resources (Fuller-Love and Thomas, 2004). Especially, emerging actors usually need external networks to provide a variety of resources, capabilities or legitimacy which they would need for successful survival, but which they cannot produce internally (e.g. Hite and Hesterly, 2001; Mei and Nie, 2008).

Resources are tangible and intangible assets that a firm controls, and which it can use to conceive and implement its strategies. The capabilities of a firm enable it to take full advantage of its resources, and an individual firm's performance is thus built on its ability to achieve competitive advantage based on its unique resources. The sources for sustainable competitive advantage are resources which fulfill the VRIN-attributes, i.e. they are valuable, rare, inimitable and non-substitutable (Barney, 1991; Barney and Hesterly, 2006).

Thus, an essential component of benefiting from networks is how well the participants can utilize each others' resources, i.e. what are their networking capabilities (Rajala and Westerlund, 2009). But, on the other hand, firms must not become too entangled in restrictive relationships (e.g. Staber, 2005), but maintain their freedom to maneuver, bargain and even attack in order to secure their own interests. In other words, firms should be *embedded* in their relationships (Granovetter, 1985) and *independent* at the same time (De Wit and Meyer, 2005).

Power and dependence in networks

Kay (1993) argues that to understand the interaction between firms, it is highly important to gain insight into their relative power positions. Power is the ability to influence the other's behaviour. Power in relationships has been researched from many viewpoints, e.g. with sociological, psychological and managerial theories. However, Belaya and Hanf (2009) argue that regardless the origin, it is agreed upon that the one who has more power has access to more resources, such as higher esteem, praise and positive attention. Since the resources of actors are rarely equal, the outcome of any particular exchange depends upon the relative power of the participants (Davern, 1997; Belaya and Hanf, 2009).

Relationships can be examined in terms of mutual dependence between the parties, and power can be located at the interdependencies among the actors embedded in these relationships (Pfeffer and Salancik, 1978; Belaya and Hanf, 2009). De Wit and Meyer (2005) state that one way of measuring power in a relationship is to make a distinction between the closeness of the relationship (loose vs. tight) and the distribution of power between the two parties involved (balanced vs. unbalanced). This leads to a categorization of four specific types of inter-firm relationships, depicted in Figure 1.

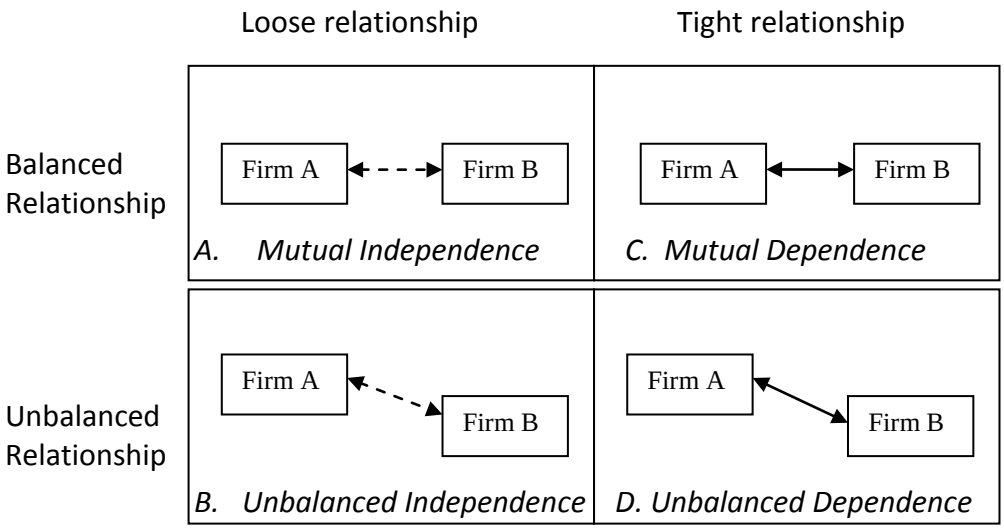

Figure 1: Relative power positions in inter-organizational relationships (De Wit and Meyer, 2005 (adapted from Ruigrok and van Tulder, 1995)).

a) Mutual independence: both organizations have full freedom to act according to their own objectives. Neither organization has significant influence over the other.
b) Unbalanced independence: a loose relationship, where Firm A has more power than Firm B, i.e. Firm A is more independent. Firm A's power gives it more freedom to act, while Firm B can be influenced by the powerful Firm A.
c) Mutual dependence = interdependence: the organizations have a tight relationship, in which they are mutually dependent on each other, having an equal amount of impact on their counterpart.
d) Unbalanced dependence: asymmetrical dependence, where one party will be able to dominate the other. The organization with the lower level of dependence will have more freedom to maneuver and impose its conditions than its counterpart. (De Wit and Meyer, 2005)

Associability in social networks

The networking capabilities of a firm presume building social relationships with the surrounding parties. Several studies suggest that social relationships and personal ties play a crucial role in developing business networks, especially those of small and medium-sized enterprises (see e.g. Hite and Hesterly, 2001; Vanhaverbeke, 2001). It is seen that with the right contacts e.g. the level of uncertainty can be diminished, the risks reduced and critical market information provided. Personal relationships also provide security and trust (Pikka, 2007).

Furthermore, a social network can offer the company business growth and new business opportunities (Pikka, 2007). Social networks help managers to recognize the knowledge possessed by different actors in the network and to understand the relevance of applying that information (Westerlund and Svahn, 2008). Through the actors' social networks, firms have opportunities to update their knowledge in dynamically changing markets and to detect future developments in the industry (Vanhaverbeke, 2001)

According to Nahapiet and Ghoshal (1998), social capital is the sum of actual and potential resources that are embedded in, available through and derived from the network by an individual or social unit. The nature of social capital thus both structures and facilitates the operation of networks and their actors (Anderson and Jack, 2002). Two main approaches emerge in the various definitions of social capital: the *public goods* and *private goods* approaches. In the *public goods* approach, the phenomenon is mainly studied at the macro and meso level, and individual benefits are secondary. Social capital is seen as an attribute of a social unit, and an individual actor either benefits from its presence or suffers from its absence (Leana and Van Buren, 1999). In the *private goods* approach, the social capital focuses on the individual (a person, a group, an organization or an industry) and his or her accrued social assets. The focus in terms of outcomes is always on the individual person or unit and the types of social arrangements and strategies that can work to his, her or its private benefit (e.g. Leana and Van Buren, 1999; Burt, 1997).

In this study, we follow Leana and Van Buren's (1999) view that the above-mentioned approaches need not be in conflict if properly managed. If individuals act in ways that enhance organizational social capital, or as applied in this study, a network's social capital, secondary benefits will accrue to them as well. This requires *associability*, which by Leana and Van Buren (1999) is the willingness and ability of actors in an organization to subordinate individual goals and associated actions to collective goals and actions. It means that individuals will subordinate their personal goals to collective goals which will then be reached for through collective action.

Associability requires more than simply interdependence between the participants; it combines elements of sociability (i.e. the ability to interact socially with each other) with willingness to subordinate individual desires to group objectives (Leana and Van Buren 1999; Wagner, 1995). It can thus be seen that a network's social capital will not appear from "somewhere" but it requires that the actors in the network will use their associability to form collective goals and plan actions to gather them. However, individuals differ in terms of associability (Wagner, 1995) which means that every social tie and every network is always to some degree dependent on the social assets of its participants.

RESEARCH DESIGN

The empirical study was conducted as a case study. Many authors state that case study is not a methodological choice, but a choice of what is to be studied (e.g. Eisenhardt, 1989). In case study research, the central feature is the construction of 'the case' or 'cases'; the research questions are always related to the understanding and solving of the case: what the case is about and what can be learned by studying it (Eriksson and Kovalainen, 2008).

Creswell (2007) sees a case study as an exploration of a bounded system which can be defined in terms of time and place, over time and through detailed, in-depth data collection, involving multiple sources of information which are rich in context. Case studies thus typically combine several data collection methods, such as archives, interviews, questionnaires and observations (Barton Cunningham, 1997; Eisenhardt, 1989).

Case research is particularly welcome in new situations where only little is known about the studied phenomenon, and in situations where current theories seem inadequate (Eisenhardt, 1989; Yin, 2003). According to Halinen and Törnroos (2005) the advantage of case studies over other research strategies is that case research allows the study of a contemporary phenomenon which is difficult to separate from its context, but which is necessary to study within the context to understand the dynamics involved in the setting.

The data for the study was collected during the summer 2010. The research data consists of 52 semi-structured theme interviews: 26 of them with biomass heating entrepreneurs and 26 with the biomass heating system manufacturers. Mainly the data concerning the biomass heating entrepreneurs is utilized in this study, but the main ideas of the interviews with system manufacturers are taken into account. The group of the chosen 26 heating enterprises consists of heating plants in different parts of Finland, with different plant sizes and ownership bases. It can thus be expected that the chosen group represents rather well the group of Finnish heating enterprises.

RESULTS

The results of the study are introduced in this section. On the basis of the theoretical background, two dimensions; independency and associability, were chosen for more profound examination, and on the basis of them, different networking tendencies of biomass heating enterprises were recognized and assessed. In addition, the resource-bases of these enterprises are presented, and the correlation between the resources and networking tendencies of the biomass heating entrepreneurs is examined and discussed.

Analysis of independency and development activeness

Firstly, the question of power relations and dependency on networks was examined by the *"independency"* dimension, which depicts the heating enterprises' tendency to lean on the other actors. Simply put, the more independent the heating enterprise is, the less its partners are involved in its activities. Secondly, the questions concerning the actors' associability were combined to a dimension called *"development activeness"*. This dimension depicts the enterprises' tendency to develop their business and network, i.e. their tendency to share social capital with others. The more active the enterprise is, the more it spends time for planning and developing activities, and the more willing it is to have cooperative goals and activities with its partners, and is also willing to find new partners. Suitable questions in the interviews depicting these dimensions were chosen for more thorough examination. In order to form clear entities and specify the assessment, some questions were combined.

Independency was examined through the following interview questions:

- ownership base: the plant and the heating network
- business activities of the enterprise (if independency was brought out)
- fuel procurement: procurement, delivery, and the enterprise's own forest property and its impact on procurement
- structure of the network and the enterprise's role in the network

- independence from the heating system manufacturer
- distribution of work in maintenance and repair
- (other questions where independency was brought out)

There are clear differences in the ownership base of the plants and heating networks. Some heating enterprises own the plant as well as the network, but in many cases, the network is owned e.g. by the municipality. Differences can also be found between the plants of a certain enterprise – some plants and networks can be completely owned, whereas in others the enterprise only maintains the plant.

Clear differences were also found in the ways the fuel is procured. In some cases, the enterprise seems to take care of the whole procurement chain, whereas in some other cases, the procurement is far outsourced. As regards the maintenance of the plants, some enterprises maintain their plants nearly completely on their own, whereas some have outsourced the maintaining activities.

The business activities and some other questions were also taken into account if aspects related to independency were mentioned by the interviewee. In addition, the network structure and the heating enterprises' roles in their networks, as well as their relationships with the system manufacturers were analyzed regarding their dependency on the partners.

Development activeness was examined through the following interview questions:
- business activities of the enterprise (if developmental activities were brought out)
- willingness to cooperate with heating system manufacturers
- opportunities and challenges of the development of cooperative networks
- planning of new heating plants or other activities
- future views
- (other questions where activeness was brought out)

The enterprises seem to differ in their willingness to cooperate with the system manufacturers and also in the amount of support they are willing to receive from them. In the question of opportunities and challenges of the development of cooperative activities, attention was paid to the interviewees' emphasis on opportunities/challenges and their views on the importance of cooperation. Clear differences were found in the amount of time the entrepreneurs spend on planning their future – some seem to be satisfied with the current situation, whereas others are constantly finding new business and cooperation opportunities, for example in combined heat and power production (CHP). The business activities and some other questions were also taken into account if aspects related to development activeness were mentioned by the interviewee.

In Tables 1 and 2, the heating enterprises are assessed by the above-mentioned dimensions. The sub-questions of both dimensions are assessed with the scale 1-5. The higher the number in the questions related to independency, the more independent the enterprise is. Correspondingly, the higher the number in the questions related to development activeness, the more actively the enterprise develops its network(s) and thus the higher its level of associability. The scores for the dimensions are averages of the scores of the used sub-questions, and in order to clarify the differences between the groups better (see e.g.

Figure 2), the averages have been weighted by 2. As can be seen, the level of independency varies from 5.13 to 8.96. Thus, the differences in this dimension are notable between the groups. Similarly, there are clear differences between the levels of development activeness, as the highest number is 8.49 and the lowest 5.83. The meaning of these differences is further discussed below.

Table 1: Assessment of the independency of the biomass heating enterprises.

BIOENERGY HEATING FIRM	GROUP	Ownership base: plant and heating network	Business activities (related to independency)	Fuel procurement	The structure of the network and the firms' role in it	Independence from the heating system manufacturer	Distribution of work in maintenance and repair	Other questions	AVERAGE	INDEPENDENCY (Weighted by 2)

25	Group 4		5	3	3			3.67	7.36
								3.37	**6.74**

Four groups of enterprises with different networking tendencies can be recognized on the basis of the assessment. For clarity, the enterprises have been already sorted by the below-presented categorization and indicated with group numbers in Tables 1 and 2. The four recognized groups are:

1) *Actors in local networks of equal partners*
   These actors tend to build networks locally, and form tight relationships with other local actors with a certain role in the network. The meaning of locality in the networks is emphasized, and all actors are rather equal in the power relations. In addition, the employment of local people and supporting of small actors are seen as important. This group also includes heating enterprises which are subordinate to a municipality – in these contracts the municipality owns the plant and the heating network, but the enterprise takes care of the business activities and the maintenance of the plant.
2) *Actors with strong relationships with heating system manufacturers*
   These actors tend to build strong relationships with the heating system manufacturers (later HSMs). The plants, with relatively small resource-bases on their own, actively exploit the manufacturers' networks in the maintenance activities of the plants. In addition, these enterprises have common research and development interests with the manufacturers, and they may operate as lead users for them.
3) *Network developers/lead firms*
   These actors are willing to extend the existing networks and build new ones. The networking activities also reach beyond the everyday business and maintenance, as these actors invest in research and development in cooperation with different instances, such as other entrepreneurs, different organizations and educational institutes.
4) *Independent actors*
   These actors tend to be quite cautious in building relationships with external actors. That is mainly because these actors are usually co-operatives or family firms which already have all the needed know-how and expertise on their own. The spheres of responsibilities are clearly divided between the partners. The meaning of personal ties in the formation phase is highly important.

In Figure 2, the enterprises are located in a coordinates where x-axis depicts the independency -dimension and the y-axis the development activeness -dimension. As can be seen, the four above-discussed groups can be easily separated as clusters in the coordinates. Thus, it can be confirmed that each of the researched biomass heating enterprises mainly follows one of the above-discussed networking tendencies.

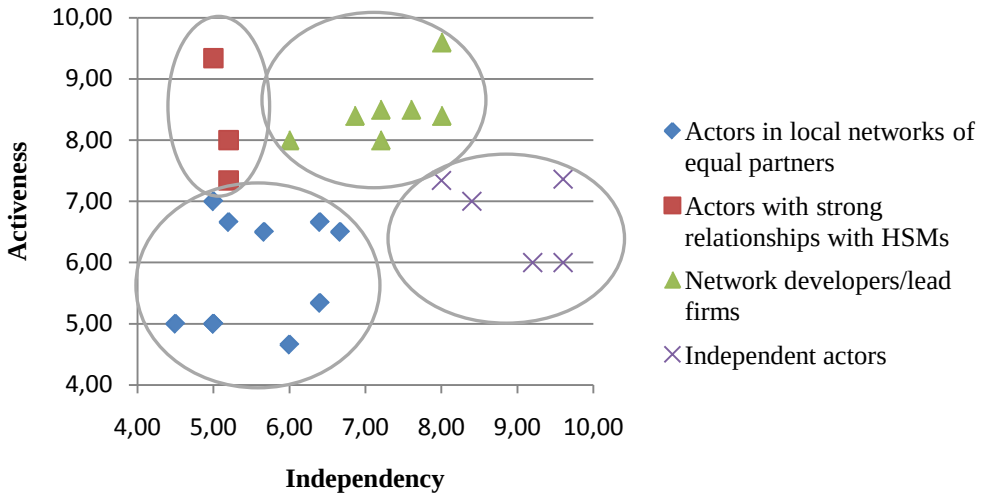

Figure 2: Grouping of biomass heating enterprises according to their networking tendencies.

Next, we look at these four groups more thoroughly on the basis of their relative power positions with their partners by using the framework of De Wit and Meyer, 2005 (see Section 2.1.). In Figure 3, the four groups with different networking tendencies are located in the framework according to the assessments of the groups' characters discussed above.

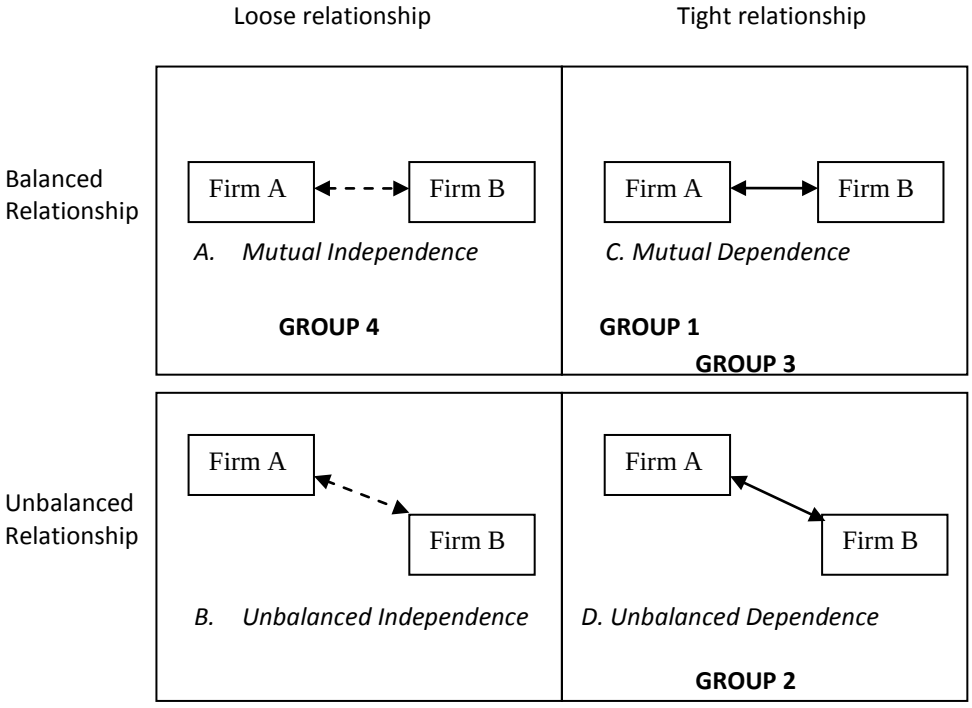

Figure 3: Relative power positions of biomass heating enterprises.

Group 1 (*Actors in local networks of equal partners)* and Group 3 *(Network developers/lead firms*) can be located in the "Mutual Dependence" box. As mentioned above, the actors in local networks tend to form tight and equal relationships with the surrounding actors. Thus, none of the actors in these networks has remarkable power over others. However, each actor in the network is highly important, because each of them has certain, and probably

unique, know-how or resources to share in the network. Group 3 is composed of firms with lively networks which are actively developing business for the common good. Although the networks may include partners rather big in size (such as educational institutes), these actors do not have power over the others, but they are considered as equal research and development partners. The actors are, however, clearly dependent on each other, because none of them is able to develop the business and the network on their own.

Group 2 (*Actors with strong relationships with HSMs)* can be easily located in the "Unbalanced Dependence" box. The networking activities of these actors are mainly targeted at the utilization of the existing relationships of the HSMs. Thus, these firms are not eager to build networks of their own, but they are willing to develop the business in cooperation with the manufacturer and its partners.

The relationships of the firms in Group 4 (*Independent actors)* can be characterized as "Mutual Independence", as these firms do not generally form tight relationships, but their cooperation with the surrounding actors is rather free-form; they occasionally use partners when they need to procure some additional know-how or resources. No partner in these loose networks has power over the others.

In addition, it is appropriate to discuss the level of associability of the groups more thoroughly. The actors in Group 1 (*Actors in local networks of equal partners)* share some of their social capital in their networks, and the operability of the networks is highly based on the unique know-how and assets of different actors. However, as can be noted in the discussion above, these actors are moderate with developing the business or the network from its present scale and scope, or setting cooperative goals for the future. Thus, the total level of associability in these networks is rather low.

At the first glance, the sharing of social capital in Group 2 (*Actors with strong relationships with HSMs)* may appear as open but rather one-way, as the heating enterprises utilize the know-how and social ties of the system manufacturers. However, it has to be remembered that the manufacturers have their own objectives in the cooperation: they can gain valuable information straight from their customers, which the heating plants share openly. In addition, both parties have interests in common development activities. Thus, the level of associability in these networks is rather high.

In Group 3 *(Network developers/lead firms*), associability can be seen as a prerequisite for the networks. The actors in Group 4 *(Independent actors)*, do not tend to share their social capital with others constantly. However, they plan the future and interact with suitable partners (e.g. system manufacturers) if needed. Thus, their associability can be characterized as moderate.

Analysis of the correlation between resources and networking tendencies

Next, we look at the resource- palettes of the biomass heating enterprises. Each enterprise was assessed by six categories of resources, based on the facts collected and comments gathered in the interviews. The examined resource categories are:

- *Human resources:* the number of associates and workforce in relation to the number of plants and their capacity. In addition, the division of active and passive associates is taken into account: how many participants are really involved with the operational activities of the enterprise.
- *Former experience and know-how:* former experience on heating entrepreneurship, entrepreneurship on the whole, or on working in a similar field. Education and theoretical know-how of the entrepreneur/associates.
- *The functionality of the network(s):* the number and activeness of the partners, division of work in the networks. Functionality of cooperation on the whole. The strengths and weaknesses of the network(s).
- *Relationships with HSMs:* amount and regularity of relationships and satisfaction with the cooperation with HSMs.
- *Interest and readiness for CHP:* interest on the whole, readiness of the enterprises' plants for CHP, cooperative activities related to the development of CHP.
- *Physical resources:* number of plants and their capacities.

The assessment of the resources of the biomass heating enterprises is presented in Table 3.

Table 3: Assessment of the resources of the biomass heating enterprises.

BIOENERGY HEATING FIRM	**GROUP**	Human resources	Former experience and know-how of the field	The functionality of the network(s)	Relationships with HSMs	Interest and readiness for CHP	Physical resources	**AVERAGE**	**RESOURCES (Weighted by 2)**
1	Group 1	3	2	3	3		2	2.60	5.20

The level of resources does not vary as much as the levels of independency and development activeness between the four groups. However, differences can be found in the averages, and especially, the groups seem to highlight different aspects and resource categories in their resource palettes. These differences are discussed next, and for clarity, they are also highlighted with darker colour in Table 3.

Group 1 (*Actors in local networks of equal partners*) has a rather moderate level of resources in all categories. A notable fact is that their physical resources are rather small, which is explained by their tendency to form rather small local networks with several other smaller actors. The meaning of these local networks is to provide energy for communities and municipalities, and thus the required capacity is rather low. In relation to physical resources, the group has a strong base of human resources, however. This is because each participant in the networks has its special and meaningful role in the business, and the activities are thus highly chained. In all, however, the level of resources is lowest in this group.

The levels of the human and physical resources of Group 2 (*Actors with strong relationships with HSMs)* are low. This is because these enterprises are rather small in size and they lean strongly on the bigger HSMs and their business relationships. However, the level of experience and know-how in this group is high, which is explained by the fact that these actors gain and develop their know-how together with the HSMs, for example by common R&D activities. Naturally, the relationships with the HSMs are considered as extremely valuable in the group.

Group 3 *(Network developers/lead firms)* has quite a strong resource palette. However, their own human resources are not very large, because their activities are well-networked and thus they utilize a lot of external human resources in their business. The functionality of the networks is naturally experienced as high, although the actors are well-committed to further development of their relationships and building new networks. The interest and readiness for CHP is rather high, and especially the strong physical resources support the development of new technologies – for example, many plants driven by these enterprises are rather big and have thus more potential to CHP production than the plants of Groups 1 and 2.

Enterprises in Group 4 *(Independent actors)* have a high level of human resources – a majority of the business is driven by own resources, and thus these enterprises also need a large amount of active personnel. In addition, their experience and know-how is notably high – their utilization of external forces is much lower than in the other groups and thus they need a strong basis for their business. This experience and know-how is gathered e.g. as a heritage in family firms, or it can be a coalition of differently experienced people from different fields who have gathered together and formed a company or cooperative where the spheres of responsibilities are clearly divided. Because the enterprises in this group do not tend to form long-lasting relationships with external parties, the functionality of the networks and the relationships with HSMs could not be assessed as thoroughly as in the other groups. However, according to the answers, the actors seem to be quite satisfied with the contracts they have had with external parties. In all, the level of resources is highest in this group.

Table 4 sums up the results. As can be seen, the resource analysis supports rather well the above-discussed characteristics of the four biomass heating enterprise groups with different networking tendencies. It can thus be stated that the resource-base of an actor correlates rather strongly with its networking tendency. In the case of Group 1, the actors lean on each other and form a tight network via which they can operate locally. The resource-bases of the actors are rather low, which makes the actors equal – none of the participants in the network has significant power over the others. Enterprises in Group 2 are rather small in size and they are thus dependent on the stronger partners, especially HSMs. However, they are also desirable partners for HSMs because of their strong experience and know-how in the field, and their willingness for cooperative R&D. Group 3 consists of enterprises with a rather strong resource base, which they also eagerly share with their partners. As the partners in their networks are mutually dependent on each other, they both give and gain a lot of their relationships. Enterprises in Group 4 stand strongly on their own feet, which is also shown in their resource- palettes – they possess a sufficient amount and combination of inner resources and do not thus have a need to form tight relationships. Although both the Group 3 and Group 4 have rather strong resource bases, their philosophy to do business is rather different, and this is also reflected in the aspects they highlight in their resource-palettes.

Table 4: Summary of the results.

Group	Type	Power relations	Level of associability	Level of resources	Specialities in resource palette
1	*Actors in local networks of equal partners*	Mutual dependence	Low	Low	Small physical resources
2	*Actors with strong relationships with HSMs*	Unbalanced dependence	Rather high	Moderate	Small human and physical resources Strong experience and know-how Strong relationships with HSMs
3	*Network developers/lead firms*	Mutual dependence	High	Rather high	Rather small human resources High functionality of networks High interest and readiness for CHP
4	*Independent actors*	Mutual independence	Moderate	Rather high	Strong human resources Strong experience and know-how

DISCUSSION AND CONCLUSIONS

Balancing between independency and embeddedness is not an easy task for firms, and the results of the study indicate that firms can solve this problem in many different ways. Every firm has its own objectives related to its independency and associability, which means that every firm tends to maintain a certain level of independency in its relationships, and that it also has a certain willingness and capability to share its social capital with its partners. These objectives lead to formation of different networks. In the researched group of Finnish biomass heating enterprises, four groups with different networking tendencies based on these objectives could be found. These objectives need to be taken into account when planning networked businesses – even though some firms might seem as perfect partners because of their business fields or technical prospects, they may have totally different aims related to their networking tendencies.

The results indicate that there is certain correlation between the actors' resources and their tendencies to form networks. For example, a rather small resource-base of a firm seems to lead easily to the formation of tight relationships with other small actors - the actors lean on each other, but none of the participants in the network has significant power over the others. In addition, because of the limited amount of resources, the networks do not have ambitions for wider development, and thus the level of associability in these networks is low. On the other hand, with a higher level of associability, a small firm can also network

with a more powerful firm (HSM) and concentrate on strengthening its experience and know-how through cooperative activities.

Actors with stronger resource- palettes seem to have two, rather diverging networking strategies, depending on their objectives of the independency-level, and their associability. In the network developers/lead firms' case, the activities are well-networked and the firms utilize a lot of external human resources in their business and do not thus have a remarkable number of human resources of their own. As the partners in the networks are mutually dependent on each other, they both give and gain a lot in their relationships, and thus the level of associability is high. In the independent actors' case, the situation is rather the opposite – these firms possess a sufficient amount and a suitable combination of inner resources, and because of their objective for a high level of independency, they do not need to build long-lasting relationships with other actors.

It must be remembered that the study has concentrated only on certain dimensions related to networking, and there might be many other factors impacting the actors' decisions. However, these dimensions were formed on the basis of a widely-discussed theoretical background and a relatively large set of interview questions. Thus, it can be expected that these issues are seen important and highlighted in the actors' aims of building business relations and networks.

Although the focus of the study was on biomass heating entrepreneurs, the results can be expected to reflect the situation in many fast-evolving business fields, and that way to offer fresh and wider knowledge on the issues under scope. For the actors themselves, the study offers a clear view on their tendencies to form relations and networks and thus helps them to develop their business better according to their objectives.

ACKNOWLEDGMENTS

The authors wish to thank M.Sc. (Tech.) Joni Vasama and M.Sc. (Tech.) Olli Viitikko for their invaluable work with the data collection phase of the research.

ABSTRACT

As the status of academic research institutions is changing, the way they operate must also be placed under scrutiny: the operating customs and organization cultures must be transformed so that they fit and support the role that the universities and their units have been assigned. To be able to change these customs, cultures and their outcomes, one needs to be able to evaluate them. The goal of this study is to create an evaluation framework to address this need.

In this study a model for the evaluation of university-industry (U-I) co-operation is created. To support this, success factors of U-I co-operation and benefits of evaluation are also studied. The presented evaluation framework is based on the European quality award criteria and modified to answer the characteristics of U-I co-operation recognized in the study and prior research. The framework is tested via a brief pilot study and through a comparison with the identified U-I co-operation success factors. The framework was found to be meaningful and understandable, and linkages to the success factors were identified. The results suggest that through evaluation the U-I cultural gap and the arising challenges can be met, and ways to improve university-industry co-operation can be systematically found.

Keywords: University-industry co-operation, university-industry, evaluation

INTRODUCTION

The interest in co-operation between industry and universities (U-I co-operation) has been increasing both in Finland and globally. The economic structure of universities has changed and it has increased the gap between public funding and research expense, making this co-operation even more necessary (Bonaccorsi and Piccaluga, 1994). Universities have started to expedite and prefer a variety of diverse collaborative by more formal structures which have brought about explicit leadership for knowledge and technology transfer as well as two-way knowledge flows (Santoro and Chakrabarti, 2001). For firms, universities are

important and natural partners and a source of new knowledge, technology and procedures (Confederation of Finnish Industries EK, 2009; Santoro and Chakrabarti, 2002).

Suggestions on how those relationships should be established and maintained have been proposed, but U-I co-operations have traditionally been informal, casual and based upon personal contacts (Mead et al., 1999). It has been suggested that the most common and natural reason for casual and non-systematic U-I co-operation is the lack of workable structures (Confederation of Finnish Industries EK, 2009). To move from a mostly ad hoc-based state into more systematic ways of collaboration one needs to be able to evaluate the current operations and results of one's methods of U-I co-operation. The goal of this study is to provide a framework for evaluating university-industry co-operation.

To support the creation of this evaluation framework, the following research questions are answered in the study:

1) What are the success factors of co-operation between academic institutions and industrial organizations?
2) How can university-industry co-operation benefit from evaluation?

It was decided that the evaluation framework would be built on an existing and widely used evaluation model. From the options available, the European quality award model (EFQM model) was chosen because of its holistic approach and the researchers' familiarity with the model. The research questions are answered through a literature review in chapters 2-4 and based on the answers and an evaluation framework is created in chapter 5.

UNIVERSITY-INDUSTRY CO-OPERATION

Co-operation between universities and enterprises takes place continuously. The aims of these different co-operative measures are always mutual benefits: a successful co-operative endeavour should deliver value for both participants. Unfortunately this is not always the case. Sometimes the collaborative effort fails to reach a sufficient level for both participants. Usually this leads to the termination or drastic restructuring of the collaboration. The imperfections of opportunity recognition are also an issue. Precious opportunities for value creation through co-operation are from time to time missed due to different reasons, but the reasons usually they have a common denominator as a root cause: the failure to recognize the possibility for and value in co-operation. A classic example of value in co-operation is the iterated Prisoner's dilemma, in which short-term lack of co-operation leads to a higher payoff but destroys the possibility for co-operation in the future. (Axelrod 1987)

University level research in itself clearly provides valuable results for industry and the society as a whole. Since the establishment of the university system in Finland (and elsewhere) the scientific communities enclosed within the university have provided the surrounding society with new findings, which in turn have led to new technologies developed either by the university or by an enterprise that utilizes the results. The latter is usually called university–industry technology transfer, which is a form of university-industry co-operation. (Siegel et al. 2003) Although a well-known form of co-operation, it is only a single form of multiple variations and options present in the university-industry-interface.

Although the options for the nature of the co-operative relationship are multiple, they still share many common factors.

Different forms of co-operation

The co-operation between a university and a company can have different forms. The modes of co-operation can differ vastly in their planned duration, which usually is the defining factor in addition to available resources (Aapaoja 2011). The relationship can be formed on the idea of doing research, developing new technologies or strictly solving a clearly defined problem. One could say that the stricter the aims and goals of co-operation, the smaller the scope and shorter the duration of the co-operation (not to say that co-operation is always discrete – it can be also continuous).

The reasons for choosing a mode of co-operation are multiple, but at the bottom both the need of the company and the offering of the university should match for a satisfactory result. Prior studies have shown a positive correlation between sales per employee and university co-operation in R&D for companies. (Belderbot et al. 2004) Despite this general positive effect of U-I co-operation, each case has to be considered individually to achieve success. For this purpose the offering, the services that a university can provide for a company have to be defined. The idea behind this definition or productization, if you will, is to make the offering transparent which in turn allows potential participants to deduce the potential value added of service usage or product acquisition. (Simula et al. 2008) If this weren´t the case, how could we even measure the joint performance? A university has to be able to define its offered services and the company has to know what it needs or the joint effort has little chance of succeeding satisfactorily.

The different actors on the industry side can be classified as collegial, aggressive or targeted players. Collegial players are strategically oriented, targeted players have an interest in operational problem solving and aggressive players, who have features from both collegial and targeted players could be said to be after competence building. The focus of co-operation is related to the nature of the player. (Santoro and Chakrabarti 2001)

We can specify five different forms of U-I co-operation. Santoro and Chakrabarti (2001) present U-I co-operation as having four possible forms: research support, knowledge transfer, technology transfer and collaborative research. We can also add educational interaction as a fifth possible mode for co-operation. (Aapaoja 2011) The objectives and goals for each relationship between a university and a company are different (and naturally, so are the contents of their co-operation agreements) (Valentin 2002). The co-operative endeavors can still be studied using the five different forms mentioned.

Research support is a co-operation form with little interactivity. It consists of donations from the industry to the university. Expectations for results and outcomes can be almost nonexistent. In the past, a research grant or donation could be given without clear specifications, although nowadays the research projects are usually specific. An entity supporting research cannot be sure whether the research will provide new technologies or competencies. Ergo, this is a form that suits the collegial players better than the others. (Aapaoja 2011)

Knowledge transfer is a long term mode of co-operation. It consists of highly interactive modes of knowledge transferring, e.g. participation on curriculum planning, personnel exchanges, consortia and information and knowledge transfers. Clearly the mode is one that demands time, resources for interaction and established relationship between the actors. It should be noted, that knowledge transfer can occur through informal relationships as well.
Technology transfer is a form in which the collaborators usually pair for doing new science with specific problems in mind. The co-operation can consist of short-term projects, solving of specific problems, joint ventures and consultation. It has features that can be found in collaborative research as well, but the modes differ in scope and duration. In collaborative research the company usually has a goal in mind and needs the aid of the university player for reaching said goal. Methods of collaborative research are thesis works made for the company, university support for R&D projects and operational analysis and finding new technological opportunities through research projects. (Aapaoja 2011)

The final mode of co-operation is educational interaction. In this mode the industry player offers its actual (small) problems for study purposes (e.g. cases), visiting lecturers, participates in seminars and organizes further education for its personnel. (Aapaoja 2011)

Success factors

We must bear in mind, that although co-operation between the universities and firms has been prevalent for a long time, actual interaction between the parties has not (and is) always not been a norm. According to theory the role of a firm in technology transfers is merely to commercialize the new technology for a financial gain through licensing (Siegel et al. 2002). This obviously presents some issues: if the industrial players are not influencing the research decisions, the possibility of developing futile technology is present. Also, marketing new technology to the industry incurs costs for the university – finding a partner willing to license the technology may be a hard task. Finally, the costs of negotiation can also be hefty: as a perfect agreement is nigh impossible to be written, there is always a risk of abusing the contract terms. The solution that Siegel et al. propose is the bridging of the cultural gap between academia and industry. Clearly, the best way of closing the gap is interaction between the actors. When building the co-operation through a continuous relationship rather than discrete events the risk of futile research and misuse falls. The partners must consider the needs of each other and share the goals and objectives. The development of a successful co-operation relationship is presented below in Figure 1 (Aapaoja 2011).

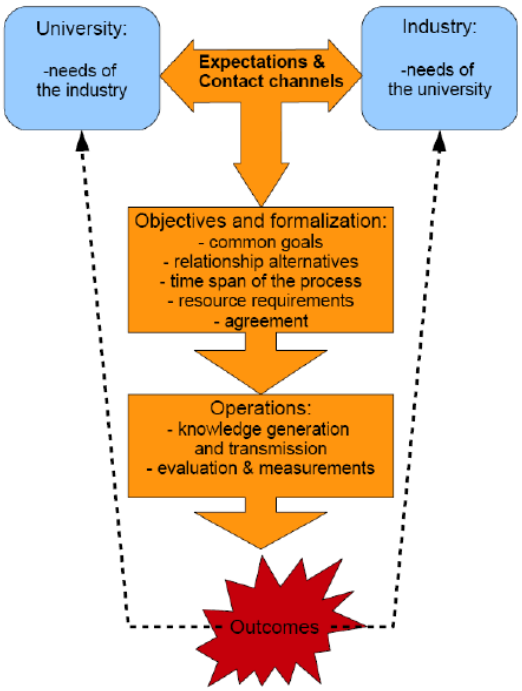

Figure 1: Development process of U-I co-operation (Aapaoja 2011)

It is quite intuitive, that the proper identification of the needs for both parties is important for success. If the needs are not identified to a sufficient degree, the goals set for the collaboration will most certainly be either insufficient in terms of e.g. financial attributes or plainly wrong. When the goals are set incorrectly, the results of the collaboration will be unsatisfactory for the party whose needs have not been identified correctly. This error in the identification process is a potential source for problems or conflicts in the co-operation. Therefore a great deal of attention must be paid to the identification of needs – only when the needs of the collaborators are clear can the goals of the co-operation be set so that they satisfy both participants' intentions.

The Confederation of Finnish Industries EK (2009) has identified some relevant factors that are helping to achieve the objectives of co-operation – figure 1 supports the following factors:

- Identifying needs and offerings of industry and universities,
- Members understand each other's roles, objectives and expectations
- Active information sharing and popularization by universities
- Multiple ways to co-operate
- Universities have a clear contact channel and rules for different collaborations
- Co-operation shares common perspectives and goals and it is aimed at long- term collaboration
- Firms provide sufficient resources for co-operation and to the commercialization of the results.

Siegel et al. (2003) mention the cultural gap between the industrial and academic organizations as a phenomenon that must be accounted for in U-I co-operation. Essentially the gap must be bridged, so to speak, through different actions by the participants so that

the language and essential nature of the organizations are clear to the collaborators. When the gap is successfully closed, the co-operation will most likely prove to be more effective and efficient, as the collaborating entities know each other thoroughly.

EVALUATION

To evaluate something is no trivial task. When one evaluates the actions, we must decide the evaluation criteria, the target of evaluation and the way the evaluation results are utilized for the evaluation to have a purpose. Obviously evaluations can be carried out for different reasons, but for our purpose it is reasonable to assume that the purpose of the evaluation is to better and further develop the actions of the organization. As Stufflebeam (1985) has stated: “The fundamental purpose of evaluation is not to prove, but to improve”.

When we evaluate a scientific organisation or its interaction with external stakeholders it is important to bear in mind the intrinsic nature of the organisation: its main task is to create and distribute new knowledge and information. The cycle of new knowledge creation is evidently a major element in the university context (Nonaka 1994). It is in the end continuously in use in a scientific research organisation. At a first glance it would seem that evaluating the outputs of the organisation would be a trivial task, but the tasks in the cycle are not so easy as they seem. The nature of scientific knowledge is often complex and highly specialised. Therefore codifying it to a communicable form can be difficult and more importantly, measuring the value and effect of said output - new knowledge or technology – is difficult. Nonaka et al. (2000) base their view of an organisation as a knowledge creator to the assumption that organisations interact with other organisations and their own environment. As knowledge is not static, but changed through interactions, we can assume that all occurrences of interaction have an effect on knowledge. The only way to evaluate an organisation accurately is to externalise knowledge. It would take a person not unlike Laplace’s demon to monitor the causalities and outputs exactly as they are, but if we codify the outputs of knowledge creating processes to a quantitative form or find indicators that represent the efficiency and effectiveness of said processes, we can also evaluate how the processes perform. In a nutshell, this is exactly what evaluation is about: find indicators that represent the evaluated phenomenon, measure, compare to targets and utilise the results.

Evaluation can be either external or internal. In the case of external evaluation common types are audits, assessments and reviews by outsiders. This is in contrast to internal evaluation, where the organization assesses its own actions. The use of internal evaluation can easily be justified – by judging the organizations actions critically can development take place. Internal evaluation can be an audit, a program evaluation or a self-assessment. (Kauppila et al. 2011)

The process of evaluation can be divided to 7 steps. These steps are 1) the assessment for the need of evaluation, 2) the formulation of the evaluation task, 3) the choosing of the evaluation concepts and building the evaluation criteria, 4) planning and launching the evaluation, 5) collecting and analyzing evaluation data, 6) reporting the results, conclusions and development recommendations and finally 7) the utilization of the evaluation information. (Virtanen 2007).

The evaluation process can be carried out regardless of the target of evaluation. When combined with e.g. the context, input, process and product evaluation model by Stufflebeam (2002), one gets a solid frame of reference on how to proceed with the evaluation task.

Stufflebeam's CIPP-model (Context, Input, Processes and Products) is an evaluation model that emphasizes improvement. It is a comprehensive tool for evaluating an entity's actions in their entirety. We begin by assessing the context: the needs, problems and opportunities. The purpose is to provide decision-makers with help in target and goal definition. The input evaluations focus on comparing different courses of action and their usefulness for achieving the objectives. The process evaluation phase assesses the effectiveness and efficiency of the activities carried out in the organization during an endeavour and finally the product evaluations assess the outcomes of the effort. (Stufflebeam 2004)

As per CIPP-model, the context, input, processes and products must be evaluated. Rossi's approach (1999) is very similar to Stufflebeam's model. According to Rossi et al. successful evaluation is based on accurate performance measurements that are compared to the chosen criteria. Obviously for such criteria to exist, the domain in which an evaluation is carried out must be assessed beforehand. These domains include the need for a program, the design of a program, the program implementation and service delivery, program impact or outcomes and finally, program efficiency. (Rossi et al. 1999: 35)

To evaluate the operations and actions carried out by the target of evaluation the scope and level of evaluation must be accurate. If trying to find out how to boost individual performance, for example, measurement at unit level will hardly give the evaluating party useful information. Virtanen (2007) points out, that evaluations can and are carried out at different organisatory levels. The scope of evaluation should be related to the level of evaluation: if we are to evaluate the performance of a unit or perhaps an individual, it is mandatory to draw the lines for the evaluation so, that the evaluated phenomena are ones that the target of evaluation has a real chance to effect with their actions.

EFQM EVALUATION MODEL

Evaluation is and always will be a task that demands a balance regarding the evaluated phenomena. Much research and thought has been given to the evaluation decisions that give an organization the possibility of effective decisions. Obviously for the management decisions to be correct, the information gathered through evaluation must give an accurate depiction of the actions measured. In another words, data from the processes and results must be processed to information that can be used as an aid for management tasks for controlled and planned management to be possible.

The EFQM model is the result of the collaborative effort by 14 major European companies. It is a model that has been developed for the purpose of intra-organizational self-evaluation. It is the view of many that to properly function, the TQM practices should be integrated, and not be a separate function ran alongside the main processes. The main philosophy of the EFQM approach is that quality management should be an all-encompassing activity in an organization for it to truly succeed. Quality should be managed, maintained and

implemented through actions throughout the whole organization's processes, the outcomes of which should always meet stakeholder expectations. (Davies 2008, EFQM 2003, Nabitz and Klazinga 1999)

The evaluation in the EFQM approach is targeted to the organization's processes and the outcomes of those processes. This twofold model ensures that the measurement is comprehensive. Data shows, that the use of total quality management approach is an effective management decision: when tracked for a five-year period quality award winners achieved significantly better results when compared to a control group. As the EFQM Model is very connected with the TQM principles and best practices, the model can be said to be a highly usable tool in the search of better results. (EFQM 2003)

It is good to remember, that the EFQM Model itself is no answer or a trick for achieving improvement. The results of assessment must be utilised for them to have an effect. The Plan-Do-Check-Act –cycle of management is a good rule of thumb. Begin by formulating a strategy, execute said strategy, assess the outcomes and act based on the results. (CAF 2006, Michalska 2008)

As mentioned before, the EFQM model is twofold: both the enablers (processes) and the results (outcomes of executing said processes) are assessed. The basis of the Excellence Model is the fundamental concepts of excellence, which are listed below (EFQM 2003):

1. Results Orientation
2. Customer Focus
3. Leadership and Constancy of Purpose
4. Management by Processes and Facts
5. People development and involvement
6. Continuous learning, Improvement and Innovation
7. Partnership Development
8. Corporate Social Responsibility

The fundamental concepts are closely linked to the evaluation criteria of the model. The evaluation criteria itself has nine categories, which show the links to the fundamental concepts at the first glance. The evaluation categories are presented Figure 2.

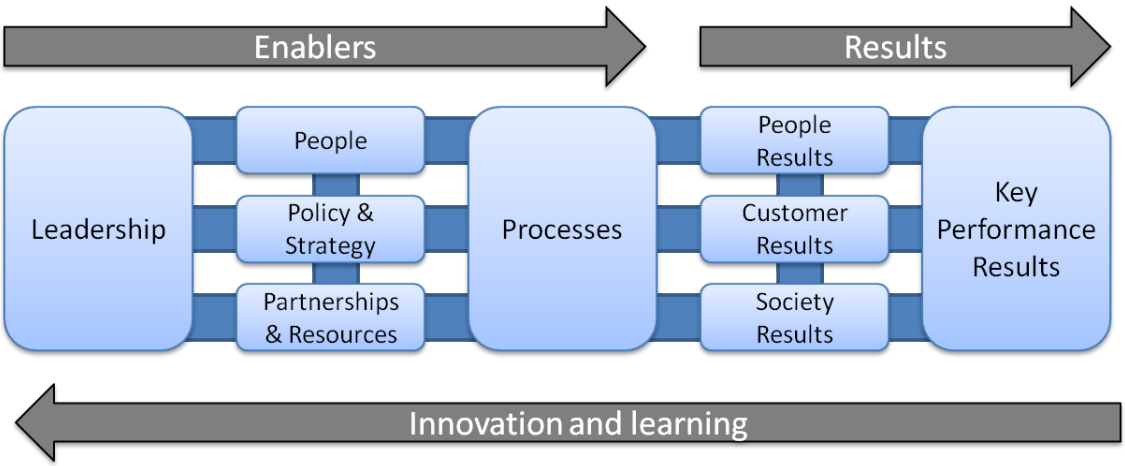

Figure 2: The categories of the EFQM evaluation criteria.

In the first evaluation criteria the assessment targets leadership: are the leaders doing their part in implementing and enabling the achievement of the strategy. According to the criteria the leaders should actively partake in interaction with the stakeholders that the organisation has, manage change and support a culture of Excellence within the organisation. Personal involvement in management system development, implementation and improvement is also seen as the role of managers and leaders need to take. (EFQM 2003)

The links within the model are evident. When we proceed to the next category, Policy and Strategy, the evaluation criteria are based on the consideration of stakeholder needs and expectations in addition to giving weight to the use of information and performance measurements in the formation of policy and strategy. in addition to the formulation of strategy the development, updating and thorough communication of the strategy are emphasised. (EFQM 2003)

The third category is associated with human resource management. Its purpose is to assess how systematic and planned the management of human resources is, how the knowledge and competence of human resources is managed, whether the workforce is empowered and involved and how the organization and the people it consists of interact with each other. In a sense it could be seen to be connected with the fourth category, Partnerships and resources, in which the usage and management of external partnerships, finances, assets, technology and information and knowledge. (EFQM 2003)

The fifth enabler category, Processes, focuses on the processes carried out in the organisation: how they are managed, developed and improved. The goal of an organisation is to create, develop and manage processes so, that the value they create for stakeholders increases continuously. An organisation that strives for excellence should have processes that are designed and planned, yet further improved as new possibilities for value creation arise. EFQM Excellence Model emphasises the stakeholder needs, and this category is no exception. According to the criteria the stakeholder needs and expectations should be the driving force behind Product and Service development efforts. Furthermore the customer relationships need to be systemically managed and developed to achieve Excellence. (EFQM 2003)

The second part of the twofold EFQM Model measures the outcomes of the so-called black box: the results of the processes that the organisation has carried out. When the results are measured, four categories are differentiated: People, Customer, Society and Key Performance. People and Society Results are measured by two factors, perception measures and performance indicators. The performance measures are e.g. career development, empowerment, employment conditions and working environment (for People) and image, performance as a responsible citizen, community involvement and reduction of harm from operations in (for Society) and finally for Customer results Image, Products and services etc. It is noteworthy, that the Perception measures are derived from how the workforce and society perceive the organization (ergo Perception Measures). The Performance Indicators on the other hand are the organisations own internal measures on how it conducts itself regarding personnel and the surrounding society. (EFQM 2003)

The Key Performance Results are possibly the most critical in terms of how organisation's performance is usually measured. They consist of Key Performance Outcomes and Indicators, which in turn hold different measures depending on how the organisation has decided to measure its results in internal reporting. The Key Performance Outcomes are e.g. financial outcomes such as sales, share price, profitability and investment and asset performance and non-financial outcomes such as market share, time-to-market, success rates etc. The Indicators are the set of measures used to evaluate the performance outcomes. These are financial indicators such as cash flow, depreciation, project costs and credit ratings and non-financial indicators such as process performance and cycle time, external resources available, technology available and information and knowledge available. (EFQM 2003)

CONSTRUCTION OF U-I CO-OP EVALUATION FRAMEWORK

During the study, an EFQM based framework for assessing university-industry co-operation was constructed. One of the aims of the framework was that it could be used to evaluate U-I co-op from both the university and the industry viewpoint. Besides the theoretical overview above, prior research conducted by Aapaoja (2011) as a part of his Master's thesis were also used in editing the model from the original EFQM criteria. A brief pilot of the model was also conducted. The model was reviewed against the recognized success factors to further validate its fitness for use.

Results from prior research

Co-operation presents valuable opportunities for both the university and the industry. The university/department can gain funding, create new networks and also gain new insights and knowledge through co-operation. The industrial participants can gain knowledge, new technologies, solutions to problems and e.g. new recruits. All in all, the co-operation can be mutually beneficial. Still, the co-operation is relying on personal contacts and interests and executed on an ad hoc –basis. The players (especially industrial players) rarely have a documented process or strategy for co-operation, which means that the co-operative efforts are discontinuous in nature. When the collaboration is formed on the personal contacts, relationships between the organisations become quite complex and tangled. When there are many contact interfaces and personal relationships, it can be hard to co-ordinate and most importantly measure the whole co-operative effort. Basically this means, that we must set the scope and level of the evaluation accordingly: we cannot expect to correctly measure the entire collaboration between e.g. a global telecom company and all its university co-operation. We must instead focus on unit and project level evaluation.

The activity of the faculty (professors, researchers etc.) and the employees in the private sector and the existing contacts between the department and the industry seems to be the key factor in the volume, nature and diversity of co-operation at the moment. The task is far from trivial, yet formal, documented processes are hardly implemented to aid in getting the job done. Due to the low level of organisation in the co-operative efforts leads us to a point where the evaluation, assessment and development of said efforts can be merely educated guesses and rather unorganised as well. Clearly a need for an evaluation framework exists. According to prior results in total quality management research and experiences in practice

in industry, the diversity in which the EFQM Excellence Model is usable evaluation framework is massive. The strength of the EFQM Approach lies in its relative simplicity and standardisation – the end result (evaluation framework for U-I co-operation assessment) should with minor changes be applicable to other U-I co-operation conducting organisations as well regardless of their role (university or industrial player) or position in the network.

Review framework for evaluation of co-operation

The review framework has been constructed following closely the EFQM Excellence Model. The RADAR logic is applied as it is presented in the EFQM Excellence model, and the criteria have been modified slightly so that they would represent and allow the evaluation of all phenomena occurring in the U-I –interface accurately. The weights appointed to different criteria are those of the standard EFQM Model and are listed in parentheses next to the criterion name.

1. LEADERSHIP (10 %)
a) Leaders develop, execute and implement the strategy of the co-operation and lead the effort in a way that gives an example Excellence.
b) Leaders drive the development and improvement of use of management systems in co-operation.
c) Leaders recognise and interact with the industrial/university stakeholders, research partners and surrounding society
d) Leaders communicate, support and inspire a culture of Excellence in co-operative endeavours.
e) Leaders identify the need and causes for change and execute change management successfully.

2. STRATEGY (8 %)
a) Information about the needs and expectations of the stakeholders is used as the basis for co-operation strategy creation
b) Performance measurement, research and learning are utilised in the formulation of co-operation strategy
c) The changing needs and context of operation are noted in the strategy process and used in co-operation strategy development
d) The co-operation strategy is communicated efficiently and clearly througout the organisation.

3. PEOPLE (9 %)
a) The people resources utilised are continuously developed.
b) The relevant skills, competences and knowledge of the people are identified. People are encouraged and enabled to improve said attributes.
c) People are empowered and involved.
d) The people have a way to shape the nature of collaboration. Dialogue between people and the organisation is genuine.
e) People are treated as individuals and rewarded, recognised and cared for.

4. PARTNERSHIPS AND RESOURCES (9 %)

a) The collaborative partnerships are managed
b) The financials of co-operative efforts are planned and managed
c) The equipment, materials and other assets used in the co-operation are planned and managed.
d) Technology is managed.
e) Information and knowledge available for and created through co-operation are managed.

5. PROCESSES (14 %)
a) The co-operation related processes are designed and managed
b) The processes of co-operation are improved according to the needs for better value delivery
c) The services offered are developed and designed according to stakeholder needs and expectations
d) The organisation's deliverables from co-operation are produced according to plans, delivered in a timely manner and support is provided as needed.
e) The co-operative relationships are managed and enhanced.

6. CUSTOMER RESULTS (20 %)
a) To what extent do we measure customer and/or co-operation partner satisfaction?
b) Do we have a sufficient set of performance indicators in use?

7. PEOPLE RESULTS (9 %)
a) Do we measure the satisfaction of employees in co-operation projects sufficiently?
b) How extensive is the selection of Performance indicators?

8. SOCIETY RESULTS (6 %)
a) Do we carry out surveys on how the surrounding society views our collaborative efforts?
b) How extensive is the selection of Performance indicators?

9. KEY PERFORMANCE RESULTS (15 %)
a) Do we assess co-operative performance extensively through a set of financial and non-financial measures?
b) Do we have an extensive set of key performance indicators for internal evaluation of co-operation?

During the research, the model was briefly tested and discussed in a meeting with representatives from DIEM and an industrial partner. Both parties agreed that the model seems relevant for evaluating U-I co-operation. It was pointed out that finding metrics is sometimes problematic, especially from an industry viewpoint.

To support the improvement of U-I collaboration, the model should be compatible with the success factors presented in Chapter 2.2. Table 1 illustrates how the areas of the evaluation model are linked to the success factors:

Table 1: How the evaluation framework is linked to the success factors.

Section of the framework	Success factors of U-I co-operation
1. Leadership	Through defined ways to lead U-I co-operation the problem of person-centred ad hoc co-operation can be lessened
2. Strategy	Clearly defined goals help to identify partnership opportunities and communicate when searching for common goals
3. People	The responsibilities, roles and competence required for successful U-I co-operation are defined
4. Partnerships and resources	The responsibilities and resources needed for U-I partnership management and the management of created knowledge are defined
5. Processes	The processes needed for successful U-I co-operation are made visible by, for example, recognizing and communicating various services offered and productization
6-9. Results	The goals defined in strategy are monitored through selected metrics and used in decision-making.

DISCUSSION

The evaluation of co-operation is, all in all, a task that at a first glance seems easier than it truly is. Prior research and the observations during this study suggest that the use of management and quality frameworks in the context of university-industry co-operation can have positive effects on the outcomes of co-operation in almost every conceivable aspect. The use of frameworks and systematic evaluation, be it different quality models and assessment criteria or management models can be utilised when working toward lowering the starting threshold of co-operation and more effective co-operation.

The use of frameworks and quality models can benefit all organisations indirectly as well: when the processes are documented and structured and the organisations use prior experiences to learn how to co-operate with one another, the learning curve can be steepened. When organisations gain experience in co-operation in the university-industry interface, the first phase of the relationship lifecycle can possibly be completed more swiftly when establishing a new collaborative relationship in the future.

The most challenging task regarding evaluation is to find the correct phenomena to measure and to decide the indicators for success or failure in those phenomena. As profit and other monetary gains occur in a relationship continuum at irregular intervals (if they occur at all), the indicators used to measure the success have to be such that the set of indicators does not favour indicators derived from financial figures too heavily. When measuring progress in a context such as that of university-industry co-operation, other indicators must be emphasised. This clearly presents an obstacle for the justification of U-I co-operation: as

companies are legally bound to strive to make a profit for the stockholders, a way to prove the benefits of U-I co-operation must be found. In practice this means, that the outputs of co-operation have to be possible to trace and measure. If the outputs cannot be easily transformed to a quantitative for, i.e. raw numbers, some other way must be thought of to determine the value of the outputs.

Although the use of frameworks helps to set up a structured, documented co-operation process, the ad hoc –nature of collaboration in the U-I interface will hardly vanish even if the use of quality frameworks is emphasised. The relationships are so strongly linked to the people in the organisations, that even if the knowledge of those relationships is codified and stored they're difficult to capitalise. When conducting and managing co-operation the existence of these two parallel processes must be kept in mind: they're not substitutes, but rather complement each other. Naturally they compete and utilise the same resources, so the opportunity cost for ad hoc co-operation is the loss of a systemically planned, structured and managed collaborative effort and vice versa (this is, of course a simplification but will suffice - the idea is quite intuitive).

It must be understood, that some amount of co-operation will always be ad hoc in nature – sometimes the scope, duration or economical significance of the co-operation can be such that a formal co-operation relationship might be overkill. Also, the nature of academia and industrial organisations (or rather the people that work for them) prevents a structured approach: either policies are not enforced, they're not taken seriously or do not exist in the first place. Ad hoc co-operation is troublesome in the sense, that at least for the industrial counterpart the assessment of the co-operation can be very difficult. If an organisation cannot learn from and apply its knowledge from earlier experiences, the endeavours into co-operation with academic institutions will likely result to unsatisfactory performance without exception.

CONCLUSION

The managerial implications of the evaluation framework are quite clear. In the beginning of the co-operation the framework provides assistance for the leaders of the co-operative efforts on deciding how to proceed: what are the processes that have to be established, how should we measure and evaluate the co-operation and how the co-operation should be developed. When the co-operation has evolved from the embryonic stage towards a more mature relationship, the framework functions as an assessment tool for the organisations conducting collaborative efforts. As such, the evaluation framework should be applicable to co-operation conducting organisations regardless of their branch of business or academic orientation: the criteria consists of basic, relevant areas of activity that need to be managed, planned and executed fluently in order to achieve excellent results and continuous improvement.

The factors or attributes that are characteristic for U-I co-operation are the cultural differences between the partners, the complex and indefinite nature of outputs of the co-operation and the highly ad hoc-nature of operations. The first characteristic is easily explainable: before the change in the university law that made universities autonomous and responsible for their financing the fiscal responsibilities of universities were understandably less strict. The nature of academia in Finland was seen as a scientific community that

conducted research and teaching from its own bases, with little influence from outsiders or third parties. The new university law is effecting change towards more strict financial management, but universities are still quite distant from the industrial organisations in terms of organisational culture. The cultural difference also shows itself in the ad hoc nature of prior co-operative efforts: as the academia and industry have been traditionally seen as merely co-existing but being worlds apart, systemic and planned co-operation has been rare and only occasionally well done.

The success factors to face these attributes and close the cultural difference gap are related to needs and expectations, objectives and formalization, operations and outcomes as demonstrated in Figure 1. During the research, success factors identified were 1) Understanding the needs of the partner and clearly defining the offered services and products, for instance through productization 2) Defining roles, responsibilities and goals related to U-I collaboration both internally and regarding a particular relationship 3) An active role by the university in information sharing 4) Common perspective in collaboration 5) Proper resourcing by all parties involved in U-I co-operation.

Outputs from the co-operation can be indefinite and/or complex and usually difficult to measure. For example if co-operation amounts to educational interaction the quantification of the outputs is difficult for the industrial counterpart. Even the definition of the output is hard: is the result of co-operation (e.g. educational interaction through a practical case assignment) the solution presented by the students or for example the PR that the company gains among the students? Clearly the nature of co-operation affects the choosing of the indicators when conducting an audit. The indicators must be sought out so that they represent the end results as well as possible.

Through evaluation of U-I co-operation the identified success factors can be systematically analyzed, as suggested in Table 1. In this study the EFQM Model was utilised to form a comprehensive and coherent assessment approach. In the pilot discussion regarding a particular U-I co-operation dyad the framework was found to be meaningful and understandable. It was seen as a potential way to develop U-I co-operation from both the university and the industry viewpoint. However as stated in the theoretical review, an evaluation must start from the context: what is being evaluated and for what ends?

This study opened up lots of questions that should be answered regarding the use of EFQM criteria in the evaluation of co-operation between academia and industry. For the industrial participants the correct outputs have to be found out so that the effectiveness and efficiency of development efforts and the co-operation itself can be measured. The same applies to the academic organisations as well to some extent. The effect that the lifecycle in the relationship has on the usability of assessment frameworks could also be studied: does the lifecycle phase affect how the co-operation should be evaluated? These are the two interesting topics for further research that came up during this study.

FINDINGS FROM EUROPEAN BENCHMARKING EXERCISES ON E-LEARNING: VALUE IMPACT AND GOING BEYOND

Ebba Ossiannilsson, Oulu University, Finland
ebba.ossiannilsson@oulu.fi

ABSTRACT

Benchmarking is becoming a more and more commonly used method for quality assurance and enhancement in higher education today. The aim of this study was to explore the impact and value of benchmarking e-learning in universities. Two European benchmarking initiatives, E-xcellence+ through the European Association of Distance Teaching Universities and the e-learning benchmarking exercise through the European Centre for Strategic Management of Universities, were studied using an exploratory multiple case study method and cross-case analysis of the findings. The open-ended research questions followed the themes of: why the University joined the benchmarking project, opinions of the process after its completion and drawbacks within the project process. The findings indicated the value and impact of a variety of aspects of benchmarking e-learning on different levels, and stressed the need for a holistic and contextual approach as both benchmarking and e-learning are complex and comprehensive phenomena. This study also shows that benchmarking, in line with national and international quality boards/agencies, is a powerful tool for making improvements to teaching and learning. Some characteristics which may not be mentioned as often in a positive light are the intentions, i.e. the meaning of the benchmarking process as such. The involvement of individuals within the organisation creates an impact on both individual and organisational levels, not least through critical reflection. The meaning of the concepts 'rhizome' and 'becoming' used in this study have leant other and new dimensions to benchmarking. Thus, this study is not only relevant to management, but to philosophy as well.

Keywords: Benchmarking, critical success factors, e-learning

INTRODUCTION

Major changes are taking place in European higher education today, and quality in education and research is the key to supporting development and innovation. Universities are facing new challenges in the 21st century, as they are required to be competitive not just in terms of their educational, social, managerial and technological aspects, but they are also called to work globally as drivers for innovation and to contribute to sustainable development. In this environment, in parallel with institutional, regional, national and international demands and challenges, improving the performance and quality of universities has become more important than ever. At the same time, respect for individual students and accountability for the use of funding has to be taken into account, in addition to contributing to economic growth (European Commission, 2009; van Vught, 2008a, b). Enhanced quality and increased transparency are strong driving forces behind competition in education and research.

Benchmarking has become a more commonly used method for quality assurance and enhancement in higher education, as it deals with identifying gaps and making changes, but also with improvement and successful implementation of new procedures and schemes (Bacsich, 2009; Ossiannilsson, in press, 2010a, b). In a recent study, Ossiannilsson (in press) advocated the use of benchmarking as a method and a powerful tool for making improvements to teaching and learning concerning e-learning/blended learning in the 21st century, and to support improved governance and management in higher education. Ossiannilsson and Landgren (in press) showed in their study on three international benchmarking projects that the identification of success factors for e-learning and its implementation in the educational arena is of the utmost significance.

This paper focuses on the value and impact of benchmarking e-learning in higher education, which until now has remained a fairly unexplored area. Moriarty (2008) argued that although the literature on benchmarking is overwhelming, research and evidence on the value and impact of benchmarking is still missing. This study uses as points for departure the experiences of two European benchmarking initiatives; *E-xcellence+*, which was carried out by the European Association of Distance Teaching Universities [EADTU] (Ossiannilsson & Landgren, in press; Ubachs, 2009; Williams & Brown, 2009) and the *e-learning benchmarking* exercise, carried out by the European Centre for Strategic Management of Universities [ESMU] (Comba et al., 2010; Ossiannilsson & Landgren, in press; Williams & Rotheram, 2010). The research does not claim to focus on benchmarks, indicators, critical success factors or methodologies as such, and neither has this study been conducted using a special method for analysing impact. This study is based on multiple case studies, together with cross-case analyses, in order to contribute to the formation of a deeper knowledge and understanding of the value and impact of benchmarking e-learning in higher education and to go beyond.

THE CONCEPTS OF BENCHMARKING AND E-LEARNING

Benchmarking has developed into an essential tool for organisations, and is regarded as a vital component of good management practice. It is internationally respected, not just in businesses, organisations and management, where the concept came from, introduced by the Xerox Corporation, but also now in education and higher education (Moriarty, 2008). Camp one of the most frequently cited scholars with regard to benchmarking (cited in Ossiannilsson, in press; ReVica, 2009; van Vught, 2008a), explored the benchmarking process using five continuous steps: determining what to benchmark, forming a benchmarking team, identifying benchmarking partners, collecting and analysing benchmarking information and finally taking action. Moriarty and Smallman, (2009, p. 484) stated that "*the ´locus´ of benchmarking lies between the current and desirable states of affairs and contributes to the transformation processes that realise these improvements.*" Furthermore, Moriarty (2008) discussed the fact that although the literature on benchmarking is overwhelming, research and evidence on the value and impact of benchmarking is still missing. The criticisms of benchmarking are, according to Moriarty (2008), based mainly on lack of information, difficulties with implementation and a lack of theory. He stressed that benchmarking may require another definition, and that benchmarking is intended to be a means towards the end of achieving a more desirable

organisational state of affairs. Benchmarking may identify the changes which are necessary to achieve that end. The concept of change seems to be inherent in benchmarking. Benchmarking is, however, not just about change, but about improvement, or as Harrington (1995) put it, '*all improvements is* [sic] *change, but not all change is improvement*' (cited in Moriarty, 2008, p. 29). Moriarty continued by stating that benchmarking is not just about making changes, as it is more about identification and successful implementation. Therefore, he suggested a provisional definition: '*Benchmarking is an exemplar-driven teleological process operating within an organization [sic] with the objective of intentionally changing an existing state of affairs into a superior state of affairs*' (Moriarty, 2008, p. 30). The ESMU has worked with benchmarking in several projects in different areas within higher education. Their definition is: '*Benchmarking is an internal organizational* [sic] *process which aims to improve the organization's performance by learning about possible improvements of its primary and/or support processes by looking at these processes in other, better-performing organizations*' (van Vught et al*.,* 2008, p. 16)*.* As shown in the definitions above, benchmarking is very much a process designed to enhance quality, to identify gaps and to bring about the implementation of changes. Benchmarking initiatives are often conducted as self-evaluations, including systematic data and gathering information from predefined benchmarks, as well as formulating roadmaps. The goal of benchmarking is to formulate, together with other colleagues, strengths and challenges for the purpose of improvement (Ossiannilsson, in press; van Vught et al., 2008b). The benefits of benchmarking were expressed by the ESMU in 10 statements: '*self-assess institution, better understand the process, measure and compare, discover new ideas, obtain data to support decision-making, set targets for improvement, strengthen institutional identity, enhance reputation, respond to national performance indicators and benchmarks* [and] *set new standards for the sector*' (van Vught et al., 2008b).

Participating in a benchmarking process can potentially lead to change in the area being investigated. In addition, an increased awareness, both individual and collective, of the organisation itself occurs as a result of participation, which can be considered as a direct and substantial value. This awareness can often lead to reflections. Reflections are crucial and can even be a method for organisational change (Højrup, 2004; Ossiannilsson & Landgren, in press). Benchmarking is a rather new phenomenon in higher education, with regard to e-learning (Ossiannilsson, in press; Ubachs, 2009; van Vught, 2008a, b). Quality assurance, quality indicators, benchmarks and critical success factors for e-learning have neither been taken seriously nor incorporated into regular quality assurance procedures in higher education. These concepts have not been conceptualised, and are even sometimes taken as being synonymous. The concept of quality in e-learning has been discussed, considered and managed in a very disconnected manner, and it has not been embedded in learning and quality contexts (National Agency of Higher Education in Sweden [NAHE], 2008; Sonila & Stalter, 2010). Ossiannilsson also showed in earlier studies (in press, 2010 a, b) that there is a lack of experience of the value and impact of benchmarking in higher education.

The concept e-learning is by its very nature both open and global and has implications on a vast number of fields in daily life. In a digital world, we act and interact differently. We learn through all our senses; by listening, seeing, discussing and doing but above all through learning in day to

day life and through networks. Learning must therefore to a larger extent be organised and tailored individually and in a flexible way. In the discourse on e-learning, revolution and a paradigm shift in education are often mentioned in the same breath. Higher education is facing a series of challenges in order to participate in the development which is taking place within information and communication technology among other things but also to be able to accommodate more personalised and flexible learning processes. In the 21st century and the new millennium, learners exist in a digital world, and the e-phenomenon has to be embedded in all learning and educational activities and in order to push the boundaries (Bates, 2010; Bonk, 2010; Ehlers & Pawlowski, 2006; Ehlers & Schneckenberg, 2010; Johnson, Smith, Willis & Haywood, 2011). However, research has shown that respect has to be given to critical success factors in educational environments in order for them to succeed in the field of e-learning and to benefit learners, teachers and management (Ossiannilsson & Landgren, in press). McLoughlin and Lee (2008) explored success factors under the headings of personalisation, participation and productivity. Bonk (2009) went a step further, and expressed this concept as ubiquitous learning (u-learning), with the focus in the 'you perspective' on personalisation and the learner's rights and responsibilities. The EADTU emphasises within their *E-excellence Associates* label four success factors regarding e-learning, namely accessibility, interactivity, flexibility and personalisation (Ubachs, 2009). Connectivism is also considered as a concept which is essential to success i.e. that knowledge is distributed across networks of connections, and learning therefore consists of the ability to construct and traverse these networks. The concepts and success factors related to e-learning in the 21st century will surely change the current learning climate, and may have an impact on how benchmarking e-learning in higher education will be conducted in the future and the kinds of quality-related issues which matter (Ossiannilsson & Landgren, in press). Management is fundamental regarding the integration and implementation of ICT (Orlikowski, 2007; Sangra, 2008; Ubachs, 2008). New challenges for universities in the 21st century include bringing together all of the aspects of e-learning in a holistic framework, and perceiving these concepts in context (Ehlers & Schneckenberg, 2010; ENQA, 2010; NAHE, 2008).

THE EUROPEAN PROJECTS: E-XCELLENCE+ AND THE E-LEARNING BENCHMARKING EXERCISE

Two European benchmarking initiatives regarding e-learning were recently implemented. The first one was the *E-xcellence+* project, carried out during 2008 through the EADTU (Ubachs, 2009). The second was the *e-learning benchmarking exercise*, carried out during 2009 by the ESMU in collaboration with the EADTU (Williams & Rotheram, 2010; Comba et al., 2010). Both initiatives aimed to identify good practices with regard to e-learning by learning from other participants.

The EADTU (Ubachs, 2009) initiated the *E-xcellence* project in 2004 as part of the e-learning programme on behalf of their members, who had indicated that specific e-learning criteria were missing from the current quality assurance systems in place in Europe. The *E-xcellence* instrument was developed in co-operation with The European University Association (EUA), UNESCO and ENQA, in order to complement the existing quality assurance systems in higher education, rather than to interfere with them. The quality benchmarking assessment

instrument which was developed covered pedagogical, organisational and technical frameworks, with special attention being paid to accessibility, flexibility and interactivity. After the piloting phase, and under the *E-xcellence Associates* label, also personalisation was highlighted. The instrument was based on a manual covering 33 benchmarks on e-learning, across three main areas: management (strategic management), products (curriculum design, course design and course delivery) and support (student and staff support), with indicators relating to benchmarks, guidance for improvement and references how to achieve excellent levels of performance. In addition, assessors' notes were included to provide a more detailed description of the issues and approaches, as well as the tools, comprising the online instrument, the quick scan and the full assessment. *E-xcellence* was piloting during 2008 in the name *E-xcellence+* at local seminars (Ossiannilsson, 2010 b), and three universities carried out the full assessment, together with site visits. Several universities carried out the quick scan. Universities who conducted the full assessment on the level of excellence and underwent site visits, worked out roadmaps and committed themselves to carrying out the benchmarking process for e-learning in higher education every other year awarded the *E-xcellence Associates* label.

The *e-learning benchmarking exercise*, devised by the ESMU in co-operation with the EADTU (Comba et al., 2010; Williams & Rotheram, 2010), was carried out by nine European universities during 2009-2010. This initiative combined the ESMU's collaborative benchmarking approach through a comparison of the good practices of different universities with the EADTU's more individualistic approach, as mentioned above. The exercise started with the self-evaluated quick scan from the *E-xcellence+* scheme (Ubachs, 2009). Furthermore, two workshops with international experts were carried out, and roadmaps for improvement were designed by the partners.

MATERIALS AND METHODS

In order trying to explore a multifaceted phenomenon in depth, this study used an exploratory multiple case study strategy, as described by Yin (2003). A mixed-methods approach was applied, utilising a combination of qualitative data sources and integrated methods for data analysis (Yin, 2003; Creswell & Clarke, 2007). The data were mainly processed using cross-case analysis, with embedded and multiple units of analyses.

Respondents

The cases for the current study were selected from both projects: *E-xcellence+* (three respondents) and the *e-learning benchmarking exercise* (four respondents). One of the respondents from the latter project took part in both projects (Table 1). The respondents from the *E-xcellence+* project were chosen because they had been the first in Europe to be awarded the *E-xcellence Associates* label. For the *e-learning benchmarking exercise* all nine partners were invited to take part in the study, and five of them agreed (one agreed too late to be included in this study). In the following the respondents are called Alpha, Beta, Gamma, Delta, Epsilon and Zeta.

Table 1: Respondents involved in the benchmarking projects, EADTU *E-xcellence+* and the ESMU *e-learning benchmarking exercise.*

Respondents	*E-excellence+*	*e-learning benchmarking exercise*
A Alpha		x
B Beta		x
Γ Gamma		x
Δ Delta	x	
E Epsilon	x	
Z Zeta	x	x

Data collection and procedure

A case study protocol was worked out for the data collection procedure, and sent to the respondents in advance. The procedures were carried out so as to increase the reliability of findings and to maintain the chain of evidence, in line with the work of Yin (2003).

Existing survey data. Basic information about the respondents and their universities was found out in advance, and more information was gathered throughout the projects and their completion. The experts' reports from the benchmarking exercises were used as additional data (Comba et al., 2010; Williams & Brown, 2009; Williams & Rotheram, 2010).

Additional data for this study were collected through in-depth qualitative interviews or more as narratives recorded through Adobe Connect. One interview was carried out at the respondents' office (in this case, two respondents were both involved in the dialogue throughout the interview, which is also the way in which they work and teach) and recorded with a manual audio recorder. The interviews were typed out verbatim. Following the case study protocol, open-ended questions on the following main themes were used for the interviews:

- Why did your university joined the benchmarking project?
- What was your opinion of the process after its completion?
- In your opinion, where there any drawbacks within the project process?
- Do you have any additional thoughts regarding the involvement in the benchmarking project?

Data analysis and process

The existing survey data served to illustrate the case studies. Subsequently, during the analysis process, the data sources were analysed and integrated in order to contextualise the findings (Creswell & Clarke, 2007) and to elucidate the issues regarding the value and impact of benchmarking on e-learning in higher education. Each case was first analysed on an individual

basis, followed by cross-case analysis (Yin 2003). The qualitative data from the cases were processed in the following way. In order to obtain a general and holistic sense of the whole situation and to become familiar with the information in the cases, the recordings and the transcriptions of the in-depth interviews were repeatedly listened to and read through case by case. Listening to the material repeatedly reminded is of its meaning and content, but also gave a sense of the feelings and emotions contained in the narratives. The essential statements which had been made i.e. regarding the significant issues (natural units) were distinguished (Yin, 2003), the words were counted and a '*wordcloud*' was made. The text, case by case, was further condensed into units of meaning in relation to the respondents' expressions which served to highlight certain issues. Using this method ensured that the findings stayed close to the original data. The findings were aggregated or clustered according to key issues, reflecting the value and impact of taking part in benchmarking exercises. The analyses produced a summarised description of each case. The descriptions were intended to reflect the respondents' narratives and core experiences as closely as possible. The findings begin with an overview of the six cases, and then the findings will be presented case by case. Finally, a cross-case analysis, exploring similarities, differences and variations, will be presented at the end of the findings.

FINDINGS

Overview of the cases

The six cases and all of the respondents were from research intensive universities and so-called traditional universities which employ a blended approach. Three of them were in a process of transformation, in that they were merging universities and faculties, which was one of the reasons for participating in the benchmarking exercises. They were also in the process of formulating e-learning strategies. Three of the respondents were from universities in which e-learning was not separated from other forms of learning e.g. in policies and plans; however, they strongly emphasised new technologies and e-resources. The universities had well-known international reputations for e-learning and distance education.

In the report from the *e-learning benchmarking exercise*, the experts noted that participation in benchmark exercises always involves reflections on the part of the institutions involved on the lessons learnt and on new approaches and methods that the experience can be expected to bring. They suggested '...*integration of benchmarking into strategic planning and to conduct benchmarking exercises as a regular practice to support on-going organisational evaluation and retaining a competitive edge. Such a change agenda depends crucially on strong leadership to set clear directions and ensure their implementation. Highly-performing higher education institutions use a variety of tools, including benchmarking, to better understand their operations and progress towards increased performance*' (Williams & Rotheram, 2010, pp. 29-30). The experts also emphasised the important lesson that, in reality, the most important work in the benchmarking process actually starts when the benchmarking procedures are over and the implementation phase begins i.e. when changes are made with regard to human capital and implemented within the organisation.

In the report by Williams and Brown (2009), they pointed out, in addition to their findings from the site visit, some problems with international benchmarking. Some of the problems to be aware of are, for example, the fact that benchmarks often relate to more than one point and thus require a multi-faceted response and a team-based approach. An important issue which they noted concerns the interpretation of languages and linguistics, as well as cultural interpretations. In this case (*E-xcellence*), some benchmarks were also lacking e.g. library resources and student involvement, which were reported back to the EADTU. Williams and Brown (2009) also expressed that university campus courses would gain a great deal if they had the same transparency as the e-learning courses which were involved in the benchmarking process. They emphasised the importance of commitment at the management level in question when starting a benchmarking exercise, as benchmarking is about the implementation of results and (eventually) about change.

Alpha

Setting the scene. Alpha expressed two reasons for joining the project (the *e-learning benchmarking exercise*). One of the reasons was the desire to be part of one of the leading universities in the country within the e-learning arena i.e. to measure performance and to measure value for the money invested. Some ranking aspects were also considered. Another reason was to learn from others and to network for the purposes of further collaboration.
Being a multi-campus university creates challenges when it comes to staff and student support and the organisation of competence development schemes for both administrative and teaching staff in the field of Internet-based communication, collaboration and learning. At the same time, the multi-campus situation provides a natural driving force for the implementation of online technology that can help to save time and money on transportation between campuses.

Experiences. Alpha expressed and referred to the 10 summarised values which were described above (van Vught et al., 2008b). However, Alpha expressed that one of the most important values was possibly decision-making (i.e. during and after a benchmarking exercise, when an institution receives basic data and documentation). Other core values were perceived as an increase in awareness and understanding at the individual, collective and organisational levels. This is a sustainable value, as it involves the internal involvement of stakeholders within the organisation. Alpha also expressed that they had obtained both explicit documentation and also tacit knowledge and understanding which, due to the benchmarking exercise, became explicit. In addition, Alpha articulated that when one undertakes a benchmarking exercise with benchmarks to relate to, and holds discussions and interviews with stakeholders in an organisation, a collective picture of the situation is gained, which had a fairly large impact. Relationships were strengthened and team members became closer to each other. According to this participant, benchmarking is very much a question of involvement. This has resulted in spin-off effects in other projects within the organisation.

Alpha also expressed that one of the lessons learnt was that, during the benchmarking itself, a great deal of attention was devoted to gathering data, collaborative discussions, writing reports and formulating action reports with a lot of valuable help received from partners and experts. Conversely, less attention and support was gained during the implementation phase. Choosing stakeholders is another important issue, especially with regard to organisational learning, when the management needs to be involved. Alpha stressed the importance of commitment at the managerial level. This is probably the most important step in terms of organisational learning and development. Alpha felt that they came out relatively well in the benchmarking exercise, both in terms of their self-evaluation and also compared with the others. Accordingly, they learnt that they needed to look even more at their practices, and that improvement and consolidations could be made. Additional lessons were to consider a more constructive approach to learning in relation to e-learning, and that learning needs to be more deeply embedded in educational processes (i.e. to focus on how learning can be enriched by technology, rather than how technology can enrich learning). The fact that a new project had been created within the organisation with the aim of implementing some of the results of the benchmarking exercise was an explicit result. The values of the exercise, for Alpha, lay in extended networking with partners in the project, which had led to spin-off effects such as new projects and collaborations.

Alpha emphasised the importance of benchmarking as a method for quality assurance, as it involves self-evaluation and learning through and with others. Nevertheless, it requires a large amount of resources. Alpha put forward the idea that, in this context, it is probably of value to consider the content and the number of benchmarks. The drawbacks were that there were too many extensive benchmarks. Another issue was the linguistic sense, (the benchmarks was in English), but also in the translated form, there were different cultural interpretations among the partnership, but also within the organisation.

Beta

Setting the scene. One of the main reasons why Beta joined the project was the desire to be able to compare their e-learning efforts with those of other universities (the *e-learning benchmarking exercise*). Other reasons to participate were a need to gain new inspiration and insights, and also to learn from others in a spirit of collaboration. Beta is also a multi-campus university, and so the same arguments apply as in the case of Alpha.

Experiences. Beta expressed a whole range of benefits for their university. On a personal level, Beta learnt a lot about their organisation. An unexpected advantage was that they became aware of some new contacts, for strategic and practical work, even within the organisation. They also appreciated that they gained a good overview of what they were actually doing within the field of e-learning, as well as their strengths and weaknesses, what could be improved and what targets to set for the years ahead. Beta expressed this as follows: "*I think it surprised me how many different benefits on so many different levels in the organisation we actually gained. It was valuable to focus on the entire organisation and the future of e-learning in the university."* At a managerial level, the report was seen as important, as the university

came out with good results. This also showed that the resources allocated to the area of e-learning at the university were meaningful. It focused their attention on quality and the need to link e-learning to quality management efforts and to secure the widespread use of e-learning. Within Beta's quality organization and quality committees, they ensured the involvement of stakeholders and the dissemination of the project. With this level of organisation and commitment, it was easier to work with the lessons learnt. However, this process was not perfect from the very beginning, but they caught up in many ways during the process. From the start, Beta was under pressure to come out as one of the best universities in the partnership.

However, having gone into the process and learnt more and more about the organisation, Beta felt that '*the lessons you learn and the knowledge you gain in the process is perhaps the most valuable part of the benchmarking process'.* Of course, they were happy to point out their strengths, but also to record that there were some points which needed improvement, '*so you do not just rest on your laurels*'.

Beta also gave voice to the fact that the benchmarking process and results motivated people to developments, either by continuing with current developments or through innovation. Beta articulated that there were some limitations to the ways in which the benchmarks were formulated, in that they were pragmatic and depended on a certain way of looking at e-learning. Thus, Beta would recommend more open-ended questions and also more time to work through and revise the benchmarks within the partnership. It should be more like a joint effort and a collaborative approach. It was also suggested that time frames could be added for the further development of the process.

In addition, Beta emphasised that the successful areas within e-learning are mainly based on backup from top management, with clear and obvious visions and strategies throughout the whole organisation. The development of teachers' competences within the fields of learning and blended learning are also of the highest importance, together with pedagogical and technical support. Well-implemented e-learning platforms and tools are necessary. Knowledge sharing and the sharing of experiences both nationally and internationally are furthermore of the utmost significance. Finally, Beta expressed that funding should be provided for pilot projects or the most innovative projects within a certain area.

Gamma

Setting the scene. Gamma expressed three main reasons for participating in the project. First, they expressed that they were in the middle of a major merging process, and that they were also reducing the number of their faculties. Second, they expressed that there was a wide variety of e-learning standards and procedures at the university. Getting involved in the benchmarking exercise was therefore one obvious way in which to gain an overview of what was going on and a way to commence internal co-operation. Finally, their participation was a way for them to generate a roadmap and to get some new ideas, thanks to this international co-operation. They had no expectations regarding how well their participation would go or

whether or not they would succeed. Gamma is also a multi-campus university, and so the same arguments apply as were mentioned for Alpha.

Experiences. Gamma articulated that, in principle, benchmarking had a great deal of value and a significant impact, as suggested by van Vught et al. (2008). The value for Gamma was not so much in learning with and from collaborators, as in coming to know one's own organisation, especially as they were in the process of an extensive merger (so they did not have any working practice to relate to). Therefore, the main impact upon Gamma was related to values and lesson learnt regarding how they formulated themselves. Gamma expressed that '*benchmarking is a great tool to point out flaws, to explore and spot missing areas and to raise attention. It is also a good opportunity to work with best practice and it is also a method to create inspiration*'. Gamma is in a phase of reorganisation, and due to this they had many ideas relating to the processes of innovation. Gamma suggested that benchmarking ought to be mandatory for universities, either on an annual basis or every other year. Benchmarking should take place in different areas in order to enhance quality and with the aim of being in the frontline. In this case, benchmarking is a great method for educational movement; enhancing quality and working processes in order to relate to best practice etc. in a more structured and more professional manner. Universities need to have benchmarks and indicators in order to speak the same language. In addition, benchmarking allows universities to extend their networks and to collaborate on setting up new projects or bilateral agreements (spin-off effects).

Gamma expressed some pitfalls of benchmarking, which of can be turned into opportunities as and when they became visible. Some pitfalls are language and cultural differences, but also the question of how to set benchmarks e.g. in this case, they were rather unfashionable, so Gamma had to go above and beyond in order to connect to their area and context. In order to improve, it is essential to consider cultures, such as the university's own culture but also international perspectives. The disadvantages also include that benchmarking is time-consuming and demands focus. However, Gamma expressed that if one spends time and focuses on the work in a benchmarking exercise, one will get more out of it and therefore gain more from it: '*What comes in goes out*'.

Gamma also stated that they now focus more on learning and how students interact with IT and the social media in their context. This raises questions about the contextualisation of learning and education. Therefore, in the event that a benchmark exercise should be set up again, they will consider these phenomena to a greater extent.

Delta

Setting the scene. Delta expressed that as they were selected to take part in the benchmarking project (*E-xcellence+*), they naturally appreciated the opportunity and wanted to join in. They were also curious with regard to obtaining an awareness of how far they had reached, even though they had established an international reputation many years ago, and had many international students enrolled. Second, they saw the advantages of the process, such as

obtaining an internal awareness and knowledge about their own organisation. The third driving force was the fact that there was an opportunity to attain official international recognition; this, of course, was a motivating factor. Another motivating factor was the future situation of the university, as they from 2011 have to charge tuition fees for students outside Europe. Competition will thus be more explicit, and there will be an even stronger drive to ensure that students get what they pay for. Being internationally distinguished is, in this context, very significant.

Experiences. Delta was the first university in Europe to be awarded the *E-xcellence Associates* label as a concrete recognition of the high quality of their e-learning programme. As a result of this, the level of their national and international collaboration, as well as student recruitment, was increased. The real impact of this will first be noted in a few years when the first students (who are paying tuition fees) enroll and they are asked why they chose this programme instead of others. In addition, students who are already enrolled are impressed and appreciate being enrolled in a programme which has been labelled as excellent. They have also articulated a positive response to the educational culture and level of professionalism they have experienced. Delta also emphasised that they had received an increased level of recognition for their work at different levels within the university, which has resulted in spin-off effects.
Delta stated that, in terms of their positive experiences, they have had the opportunity to undertake the benchmarking and internal processes, which increased their understanding and knowledge. To have the chance to reflect and to share within the centre, but also with colleagues within the university, was very valuable, and made their work more effective. In addition, it was valuable to perform a self-evaluation, as well as the documentation and the experts' report. This was also a way for Delta to gain an awareness of the areas in which they fall short. In addition, they had opportunities to review and improve their routines.

Thus far, they have not been involved with or taken part in the *Excellence Associates* club, but they will in the future and can see the advantages of such a network. The roadmap that they worked out has served as an inspiration and as a driving force. It is not a formal action plan, but a working plan and an inspirational document. They expressed that they have either worked through some of the actions or at least considered them. It is an honest document, referring to what they ought to do, considering time restraints and financial opportunities. They articulated that, during the process, they benefited from support and commitment from the management team, and they also stated that, without this support, it would be more or less impossible to carry out changes or improvements in relation to the benchmarking exercise. Other issues were that the exercise was so time-consuming due to the need for data gathering, internal discussions and analyses that support and commitment were needed. They expressed that they had experienced continuous support, even now the real work has started with the implementation and transition phase.

Delta emphasised the importance of involvement and teamwork during the process. The benchmarking exercise was as such also important due to the need to '*attract attention, gather and spread information and engage staff and students (three core concepts)*'. Delta articulated that the benchmarks were comprehensive, but maybe too comprehensive. On the other hand,

this contributed to discussions, interpretations and the development of knowledge within their own educational culture and context. If Delta were to undertake the exercise (or a similar exercise), again, they stated that it would be valuable to estimate time requirements, and probably also to have a more explicit overview of the process. The drawbacks of the exercise, when one is sensitive to them, can be turned into opportunities. Another issue is whether the university could or should market and raise awareness of the benchmarking process to an even greater extent.

Epsilon

Setting the scene. Epsilon indicated three incentives for their participation (in *E-xcellence +* and the *e-learning benchmarking exercise*). First, they expressed that they wanted to obtain an awareness of what was state-of-the-art in the area. Second, they wanted to learn from others and to obtain an awareness of their progress in the area in an international context. Finally, they expressed that participating was a way to obtain insights and knowledge with an eye to the future.

They also expressed that their participation was a way of gaining both internal and external processes. They stated that benchmarking is an optimal method for raising awareness and understanding of what is going on, both internally and externally. Both advantages and disadvantages become explicit, but primarily and most importantly, potential areas for success and where quality can be enhanced become visible within the common understanding in an organisation.

Experiences. Epsilon expressed having found the exercise to be valuable both internally and externally, and that lessons can be learnt in and through both dimensions. For Epsilon, the projects had been extremely valuable. Benchmarking is a way of watching what is happening in the surrounding world. Regarding Epsilon's participation, it can be stated that they found it to be valuable on several levels; within departments, on the university management level, and on national and international levels. One example which was articulated several times in the in-depth interview was the fact that a new programme is going to be set up in collaboration with several other universities in the country. With this programme, there is a need for high quality work to be carried out with new technologies, not just for the purposes of content and inter-university collaboration, but also to create a model and to become part of an IT society in the 21st century. Even within other areas of the university, schemes are being implemented as result of the benchmarking projects in combination with the current discourse in this area.

Epsilon articulated that they found it interesting how many outstanding things had happened throughout their faculties and departments; it seems likely that these things have happened due to the fact that Epsilon is a decentralised university. They therefore expressed that freedom, enthusiasm and development on demand are crucial for a reflective and growing organisation. The key is not always efficiency, as sometimes quality enhancement is more important. Both bottom-up strategies and top-down strategies require flexible methods. Benchmarking helps universities to choose a direction. At a research intensive university, where

the teachers and programmes are at a variety of levels in terms of IT proficiency, from early beginners to those who excel, there are a variety of demands and requirements; however, there needs to be something for everyone, even at a central organisational level. The most important thing at a large university is to develop maturity and '*teaching environments to learning environments to web environments and also that it* [e-learning, new technologies, social media etc.] *is embedded in* [the] *curriculum*'. This journey has to take time. An awareness of maturity is of great importance, as if an organisation is immature, then no development will happen. There needs to be maturity, at both individuals and organisational levels. Each faculty/department has their own structures for dealing with demands and cultures. This is good. In addition, one has to make choices, and one has to be familiar with e-learning and technology development. When maturity has been reached, co-ordination can begin.

The fact that two of the programmes at Epsilon were awarded the *E-xcellence Associates* label indicates that they have been recognised both internally and externally. For the programmes that were awarded the label and already have large groups of international students from outside Europe, this award is very valuable and will have a significant impact as they are facing a new situation regarding tuition fees for students from outside European Union. Of course, this is due to other programmes as well. The *E-xcellence Associates* label supports the entire university in its strategic work towards achieving consolidation, internationalisation and distinction, as universities are striving to be world class. Epsilon stated that they valued all of the documentation which had been a part of the benchmarking projects, which they will now use for other purposes. One example is that when the National Agency for Higher Education conducted a survey of distance education in the country (Sweden), then the benchmarking reports supported the documentation required for this survey to a large extent.

Epsilon stressed the fact that e-learning needs to be user-friendly, integrated and embedded into courses and educational arenas. Epsilon stressed further the importance of freedom in a large organisation, as creativity grows and things happen when there is freedom.

Zeta

Setting the scene. The main reason why Zeta chose to participate (*E-xcellence+*) was to ensure the quality of its education and courses and to provide evidence that these were of the highest possible quality. The main reasons for this are due to student rights and student satisfaction. Other reasons were of both an internal and external character. The internal reasons were a desire to raise awareness of advantages and disadvantages concerning range, support and implementation of the e-learning arena at Zeta, and in addition student satisfaction, and through the process find gaps for possible improvements.

The external reasons were mainly a desire for international co-operation and networking, but also an attempt to learn from and through others. As benchmarking is a form of self-evaluation, it is more honest and the motivation to make changes is thus higher, as any criticism tends to be more constructive. There were also other reasons, such as the fact that each member of the staff including the students need to feel appreciated for their work. It is also important to note

who the actors are who initiated and took part in the benchmarking e.g. in this case, the benchmarking was initiated by the EADTU, the National Agency for Higher Education and the university itself. The chance to attain the *E-xcellence Associates* label was also an incentive to join the project.

Experiences. Zeta expressed that through the benchmarking project, advantages and disadvantages concerning range, support and implementation of e-learning became visible and ideas for changes were considered. The fact that Zeta earned the certification and the label was, of course, very encouraging, and the label demonstrated that the university had been recognised internally as well as in international collaboration and networking. In addition, more students are being recruited. This is, of course, a triumph, especially when the university was co-operating with countries that tend to distrust distance education. However, Zeta expressed that they might be able to market distance education to an even greater extent, but they already have more than enough students (i.e. more than they get paid for). Naturally, this was an occasion for self-evaluation and this influenced all staff and their work. Of course, the label as such is not as important as the knowledge and understanding of the work which the university is doing, as well as an awareness of their shortcomings. Nobody is happy with just the award itself. Zeta, therefore, articulated a very humble attitude towards its recognition. However, two of the leading staff awarded the university a prize for excellence in teaching and pedagogy in the following semester.

Zeta stated that the roadmap served as inspiration and not as a dogmatic document. Some of the actions have already been taken and some are being considered, due to limited time and resources. They expressed that they have been supported by the university, although perhaps not always at the closest administrative level i.e. the faculty level, probably due to a degree of mistrust, as they are too far ahead and too innovative in their course development and delivery. Maybe this had been the fact anyway, if they had been innovative and therefore succeeded in other areas, they would have experienced mistrust there as well.

Concerning the benchmarks, Zeta expressed that they were particularly extensive and that they worked in teams in order to get the staff and students involved. They used micro and mini meetings to go through everything and to discuss different aspects of the process. Zeta gives voice to the idea that one of the most important issues is flexibility at all levels and dimensions in any attempt to satisfy students. The ultimate goal is to satisfy students, and they frequently demand a high degree of flexibility. Satisfied students are important quality indicators. Flexible and boundless education with regard to pathways, time (even starting time), free resources, flexible materials/resources (texts, audio, video) etc. is of paramount importance and forms the foundation of the programme. Student evaluations have also shown that this flexibility is crucial.

One explicit impact was an inspection of the learning platform and the overall university administrative system in order to make communication more flexible. Zeta stated that when e-learning programmes begin, the most important aspect seems to be the learning dimension. This is natural, but when courses are scaled up, it is crucial that administrative systems communicate well.

Thus far, Zeta has limited experience of the *E-xcellence Associates* club, due to limited time and human resources. Obviously, such initiatives are of the highest importance. Zeta's final comment was that universities which are striving for the highest quality in an international field should certainly consider benchmarking.

Cross-case findings

Overall, the findings indicated many similarities between the universities, but also differences, or rather different ways of expressing experiences across the cases. The cases illustrated how different aspects interact to a varying extent and indicated the value and impact of the international benchmarking exercises which were conducted. In the section below, some of the key areas are summarised.

Internal processes and involvement

The benchmarking allowed the teams to maintain their focus. Involvement and shared responsibilities in the work with benchmarking enabled not just the benchmarking itself, but also contributed to commitment and appreciation among the co-workers within the institution. The fact that advantages and disadvantages in the field of e-learning became explicit supplied the motivation to make the changes which led to the impact of the scheme. In addition, the fact that the exercise was mainly a self-evaluation motivated the institutions to examine even negative issues, which often could be turned to challenges.
In addition, the solid documentation which was collected, as well as the knowledge and institutional awareness regarding e-learning was important and led to a significant impact. The institutions gained a lot from the solid work with its transparency, which could even be used and valued in other contexts. The awareness of the infrastructural support for e-learning, which was one of the results of the benchmarking exercise, was made explicit and this led to closer collaboration between the infrastructural units in question, as well as further collaboration with other faculties and departments, for example within pedagogical areas and e-resources. Additional benefits were clearly expressed regarding teamwork, creating a dialogue, policy making, quality assurance and transparency within the organisation.

Quality enhancement

Benchmarking is an advanced method, but the cases have indicated that it is quite easy to use with explicit opportunities for self-reflection. Even though certain steps have to be taken, one can set the structure within the partnership as either a smaller or a larger exercise; one can also define the benchmarks, partners and the time schedule. Nearly all of the cases reported that enough time and support was allocated during the project period. However, they emphasised that they misallocated time and support for the reflection and implementation phases. This process needs to be followed by reflections on the lessons learnt, which can provide incentives for further development in the institution. This may involve changes in structure, organisation and resource allocation, which may require strong leadership at all levels. Furthermore, the

importance of integrating benchmarking processes as a natural part of strategic quality assurance work was emphasised. The value of continuously following up earlier benchmarking exercises as well as committing to new projects was highlighted. All of the respondents agreed on the value of benchmarking as a method for quality assurance.

Management and commitment

The cases showed, to a significant extent, the importance of full support and commitment from all levels of the management team during the whole benchmarking process. Such support is necessary in order to maintain the focus on the project, to allow staff and students to be involved, to work in an interdisciplinary manner and award status for the ongoing work and dissemination during the process, but most of all with regard to data gathering and reports i.e. the implementation phase, if changes have to be made. In these cases, several departments were involved in full. They were therefore able to focus on and discuss common areas and processes, creating togetherness, trust, commitment and involvement. This will certainly contribute in turn to enriching the future employment situation and potential areas for development.

Collaboration and networking

When taking part in benchmarking exercises, universities have the chance to meet other institutions that are facing the same challenges as themselves. There are opportunities to approach one another, to learn from best practices and to take part in joint discussions on how to handle challenges. This can evolve into continued benchmarking on a smaller scale, where two or more universities from the group collaborate and formulate new benchmarks. Such new benchmarks can help the institution to improve important areas and can play a major role in continuing quality assurance efforts. On a more practical level, the knowledge exchange between benchmarking participants can lead to mutual inspiration and can help the individual universities to understand and handle topical issues within the field of e-learning.

In the benchmarking exercise, it became apparent that each university possessed best practices within certain areas that were of importance for all of the universities. These areas included pedagogy, technology, strategy etc. In the benchmarking exercise itself, there was unfortunately no time to study the best practices of the other universities in depth. However, the exercise itself provided a good overview of the strengths of each individual university. Mutual trust and understanding has been gained, and future activities such as joint applications and agreements for further co-operation will naturally be established. A network has come into being, in which participants can use each other as experts when knowledge of a certain topic is needed.

Cultural issues

As this was an international benchmarking initiative, English was the chosen language. All of the cases raised a problem with this. It was not just the language and linguistics as such, but also

cultural aspects of the language and how it is used in different contexts. The benchmarking was mainly carried out in teams, and even within the teams there were differences in how certain concepts were understood. Another issue was the somewhat old-fashioned concepts regarding e-learning. Nearly all of the cases work within a blended mode context. In addition, nearly all of the universities in question are decentralised, and thus there was not only one way of acting and performing.

Attitudes

Through the in-depth interviews, all of the cases voiced their enthusiasm and positive feelings regarding the exercise itself, but also regarding the methods. It was, for example, noted that during a comparatively short time, many lessons had been learnt, both about the institution themselves, but also about wider perspectives including other universities and the surrounding international context. Furthermore, it was articulated that they had also gained a deep understanding and knowledge in the area of e-learning through the benchmarks and indicators, areas which to some extend seemed to be tacit knowledge. In addition, they expressed their enthusiasm and interest in continuing to work, or as they put it, they had the energy to tackle future challenges. All of the respondents expressed that it would be useful to carry out the exercise again, but maybe on a smaller scale with time to define their own benchmarks in a more useful way.

DISCUSSION

The integrated case study findings provided critical information on the value and impact of benchmarking in higher education. Most importantly, this study showed the complexity of the value and impact of taking part in such exercises. The complexity of benchmarking e-learning in higher education is based on the fact that values can refer to either immediate or more long-term values. Furthermore, these values can apply to different aspects and different levels, and to both individuals and organisations. Moreover, some effects take years to evaluate.

One contribution of this study to our present knowledge and understanding of benchmarking as a method seems to be a recommendation that time, resources and maybe even the use of experts and/or co-partners is allocated for the implementation phase, as this is an important step in the benchmarking process. All of the respondents in the study clearly emphasised the lack of support they had received afterwards. Another contribution is the apparent importance of commitment from managerial levels. In the event that structural changes or other changes have to be made, resources will probably need to be allocated or re-allocated, and due to this it is extremely important to have commitment from the leadership. This works both ways; if the institution produced as ‘good result’, it is essential to communicate and market such benefits, internally as well as externally.

We are facing a paradigm shift within the 21st century, and e-learning as a phenomenon was considered among the respondents to have a very broad meaning. Therefore, the learning dimensions were emphasised. Changes in technology have to be considered in education, even

through a social-contextual approach. This study shows, therefore, that benchmarks must be chosen with care and that linguistic, cultural and contextual issues have to be taken into account. Even if this study did not aim to focus on benchmarks as such, critical issues within the area were articulated, in accordance with the success factors described by the EADTU (Ubachs, 2008) and Ossiannilsson and Landgren (in press). The need for flexibility in all of the concepts and dimensions was clearly highlighted. Even the structure of the partnership is crucial, as are similarities and/or differences within the partnership. How to choose benchmarks that provide direction is one of the aims within the benchmarking process. Trust, honesty and courage are of the utmost importance in benchmarking processes for fruitful and sustainable work and collaboration. As mentioned above, there can be pitfalls, but awareness and thoughtfulness can turn them into challenges.

This study showed that benchmarking is about change. It became explicit that the process as such and the involvement and collaborative learning at different levels within units as well within the partnership was of utmost value. In this study, the findings on the value and impact of benchmarking as described by the respondents were close to and in accordance with the 10 good reasons to conduct benchmarking as described by van Vught (2008b). Some more critical issues were also touched upon, such as the significance of the first and last phases of benchmarking; the identification and implementation phases. Furthermore, the value and impact of tacit knowledge (Elliott & Stemler et al., 2011) were explicitly expressed. However, they were not only expressed; the possibility of sharing this tacit knowledge, as well as knowledge and experiences, was articulated as a possible impact. The case studies indicated the importance of support and management when making changes, as Sangra (2008) also argued. Contributions to the transformation processes that realise improvements require commitment, but also reflection. Through the cross-case analysis, the respondents experiences in this study indicated that a process of philosophical interpretation is required, and that there is a need to modify the theoretical assumptions concerning benchmarking. Høyrup (2004) argues that there is a need for a learning organisation to reflect, but he distinguished between reflection and critical reflection. He emphasised critical reflection in particular as one of the core processes of organisational learning. He stated, moreover, that critical reflection was necessary on both the individual and organisational levels. Critical reflection includes social, cultural and political aspects and concerns the *why*, *the meaning*, rather than questions about how to act or perform. The meaning of reflection and the importance of reflective practices for change was also clearly expressed in the study. Another dimension of critical reflection can be seen through Deleuze's concept of 'becoming' (cited in Giger, 2010). Becoming share the common meaning of becoming which even is true in this context. Thus, the process of becoming is about changes, just like benchmarking is about changes. Becoming, as a more philosophical concept, has something to do with becoming us as individuals. The rhizome concept, also put forward by Deleuze & Guattari (cited in Giger, 2010), was described in brief as connectivity and multiplicity. Both concepts are new dimensions which are valuable for understanding of benchmarking and organisational changes.

CONCLUSIONS

Benchmarking is a powerful strategic tool used to assist decision-makers to improve the quality and effectiveness of organisational processes. Since the results from benchmarking of e-learning within higher education have not been documented to any large extent until now this research contribute to a deeper understanding of benchmarking, quality work and quality enhancement of e-learning in higher education and to go beyond, although it does not aspire to be exhaustive.

This study showed that the quality of e-learning has to be considered and must be embedded in suitable contexts. In the case studies, the respondents expressed that the benchmarking process had significant impacts i.e. the power to make changes. The results indicate some key areas which have to be considered in benchmarking processes, areas as internal processes and involvement, quality enhancement, management and commitment, collaboration and networking, cultural issue and attitudes. Other issues which have to be acknowledged are the choice of objectives, how the benchmarking is organised and set up, how to choose partners and how to choose benchmarks. In addition, how to generate commitment and allocate time and resources during the entire benchmarking process, including the implementation phase has been emphasised in certain cases. Some characteristics which may not be mentioned as often in a positive light are the intentions, i.e. the meaning of the benchmarking process as such. The involvement of individuals within the organisation creates an impact on both individual and organisational levels, not least through critical reflection. The concepts of 'rhizome' and 'becoming' used in this study have leant other and new dimensions to benchmarking. Thus, this study is not only relevant to management, but to philosophy as well.

For benchmarking, as for all quality assurance work, follow-up is of central importance**.** This is why, after participation in a benchmarking project, extensive work is undertaken to reflect in different ways on what has been learnt and to use this information for further development and change in the higher education institution concerned**.** The gains from benchmarking projects are numerous**.** One benefit that should be specially emphasised is the collaborative learning process**.** This happens on different levels, both within the various organisations and between the participating cooperative partners. Through the opportunity to find out about one another's best practice, but also through confirmation of one's own activity, good conditions are laid for further development. In addition, cooperation and contact during the course of the project can give *spin off* effects on the local, national and international levels even after the project has been concluded.

In discussions on e-learning higher education, challenges as revolution and a paradigm shift are often mentioned in the same breath. Results from the projects make it clear that complexity and a holistic perspective should characterise high-quality e-learning/*blended learning*. An approach that involves all the various success areas together is essential for students who are studying their programme via the internet and who wish to be in a position to take active responsibility for their own learning. Both strategic development (*management*), course design and implementation (*products*) and student and lecturer support (*services*), together with the consequences these have for borderless learning, globalisation and sustainable development,

should be taken into account in the planning, implementation and evaluation of e-learning in higher education. Transparency with regard to structure, materials and resources among other things, is also emphasised as significant for quality in the field of e-learning. The challenges for higher education no longer consist in doing what they already do, just with the help of digital media. Instead, they must change and develop the educational culture so that students can study, work and live independently of time and space in an extended digital environment and with the diversity of resources from the entire world at their disposal. In this way, higher education contributes not only to sustainable development but also to boundary-crossing activities.

PRODUCTIZATION OF UNIVERSITY SERVICES

Aki Aapaoja*, University of Oulu, Finland

ABSTRACT

The constantly tightened competition and shortened life-cycles of technologies have driven firms to co-operate with educational institutes and universities. Concurrently the changing economic situation and emphasizing of the third mission of universities as a social influencer have driven universities to collaborate with firms. Co-operation between industry and universities has been increasingly discussed and the literature emphasizes the importance of this line of research, but the development of co-operation has been faced many challenges e.g. unclear and undefined service offering of universities, the missing of mutual content and structures.

In this research we suggest how productization can be used to improve university-industry co-operation. Productization refers to analyzing the needs of the customers, designing the product and developing the ability to produce it so that offering and results could fulfil the expectations of the customers. Through the productization of university services several benefits can be achieved: better quality and management of services leads to more stable, effective and manageable processes; the communication with customers is much easier and customer perspective can be taken more deeply into account, and services are partially standardized and partially customized. As a managerial implication is proposed that university should increasingly make an effort to productization of their services in order to achieve and increase both side benefits and value.

Keywords: productization, U-I co-operation, university services, university-industry co-operation, university-industry

INTRODUCTION

Intense global competition, rapid technological change and shorter product life-cycles have transformed the current competitive environment (Bonaccorsi & Piccaluga, 1994; Santoro & Chakrabarti, 2002). Organizations have faced increasing challenges in order to sustain their long-term success and prosperity relying solely on internal resources (Santoro & Chakrabarti, 2001). To meet those challenges, universities and firms have started to establish more formal and effective co-operations instead of informal methods Mead et al., 1999).

Co-operation between industry and universities has been increasingly discussed and studied. The necessity is commonly known, because the economic structure of universities has changed and it has increased the gap between public funding and research expense (Bonaccorsi & Piccaluga, 1994). Universities have started to expedite and prefer a variety of diverse collaborative by more formal structures which have brought about explicit leadership for knowledge and technology transfer as well as two-way knowledge flows (Santoro & Chakrabarti, 2001). For firms, universities are important and natural partners and a source of new knowledge, technology and procedures (Confederation of Finnish Industries EK, 2009; Santoro & Chakrabarti, 2002). Suggestion how those relationships should be established and maintained have been proposed, but U-I co-operations have traditionally been informal, casual and based upon personal contacts (Mead et al., 1999). As a consequence of those, exchange between educational institutes and industry has been undefined.

In service business, productization is the natural predecessor for successful market entry and it needs to be done before services become successful (Simula, Lehtimäki & Salo, 2008). Success in productization will create increased demand for services, which makes it one of the key factors behind success (Flamholtz & Aksehirli, 2000). The main output of productization is to bundle offerings and deliveries together in well-defined packages so that the value that the expectations of the customer are better fulfilled. Productization creates a positive signal that the service provider understands customer requirements and is willing to respond accordingly (Grönroos, 1984; Simula et al., 2008). The strength of universities lies on the wide variety of services they can offer and productize; different kind of business-to-business (B2B) services e.g. consultations, research projects as well as public services like education. Therefore the objective of this paper is to examine how can university-industry co-operation be enhanced through productization?

To achieve that task, firstly the paper will take a look on the key features and elements of U-I co-operation. Then the theory of the productization and the benefits of it will be elaborated. The challenges of U-I co-operation that can be solved through productization are also discussed. The empirical part illustrates a case study which concentrates on the productization of universities' services. The phenomenon has been examined from the perspectives of the University of Oulu, the department of industrial engineering and management (DIEM) and their main partner. In the concluding part, the answer to research question and the discussion about the findings, implications and further research ideas will be presented.

UNIVERSITY-INDUSTRY CO-OPERATION

New technology and knowledge development on intra-organizationally has become increasingly difficult in more intensive competitive markets and it has increased the needs of firms for inter-organizational co-operation (Barnes, Pashbym & Gibbons, 2002; Santoro, 2000). University-industry co-operations can be seen as a powerful way to increase both side benefits. In addition, U-I co-operations have usually made a positive contribution to innovations and help to return the investments of research and

development (R&D) (Balconi & Laboranti, 2006; D'Este & Patel, 2007; Santoro & Chakrabarti, 2002).

The forms and objectives of U-I co-operation

The success of co-operation is always a sum of many things and requires investments by all participants. By U-I co-operation: Firms are trying to gain competitive advantage and addressing business growth, whereas universities are trying to fulfil their mission to create new science and offer education.

U-I co-operation can be divided into five different categories: research support, knowledge transfer, technology transfer collaborative research (Santoro & Chakrabarti, 2002) and educational interaction. Basically research support is only one-way co-operation which is served by firms. Also knowledge transferring includes some one-way co-operation, but collaborative research and technology transfer always insists on at least two participants.

Nowadays "blind" research supporting and financing is very rare, because firms want answers to specific problems or possible future technologies. According to a few Finnish surveys (e.g., Confederation of Finnish Industries EK, 2009; HSE yrityspalvelut, 2009) corporate presentations and infobits have been seen one of the most important ways to co-operate. Those give aspects about firms and their business, but also opportunities for students. By that firms are able to be more attractive employer and are able to recruit highly motivated and educated employees and interns. These internships are very important to both universities and firms.

Knowledge transferring contains recruiting, consultations, personnel exchange and information sharing. In addition, such interactions can be both formal and informal. The objectives are intangible, because knowledge transfer is aiming on spreading and sharing of information. According to Santoro and Chakrabarti (2002), knowledge transfer helps universities and firms train students in state-of-the-art techniques. Knowledge transfer is long-term co-operation, which is many times looking for something new in ancillary fields and areas. Therefore multi-organizational consortia are typical.

The next two categories are technology transfer and collaborative research. Those categories consist of almost every possible way to do research and new science. Many times this is "invisible" for those who are not working with universities. Technology transfer and cooperative research are probably the most important or at least the most concrete groups for firms. By those universities and firms are carrying out more specific and coordinated projects, which have an agenda and a formal network (Santoro & Chakrabarti, 2002). The objective of such projects could be the service modelling where university and participant(s) try to create new business opportunities.

The last group is educational interaction, which is added to entail the educational mission of universities. For students this group is probably the most interesting because it provides possibility to have current and actual cases to solve. Cases can be little

problems, which solving can also benefit firms (Mead et al., 1999). Those kinds of little researches by students are highly appreciated in Finnish firms (HSE yrityspalvelut, 2009).

Visiting lecturers are a very good way to keep students interested in topics and real world examples always give objective aspects to those. Visiting lecturers can also be firms' personnel, who are looking or studying for updating education. Possibility to updating education is one of the most classical and appreciated form to co-operate (HSE yrityspalvelut, 2009). Further education can be short-term, for example some basic courses. However, it can also be long-term, which is aiming to some degree, for example MBA or doctor's degree.

Despite forms of co-operations, it can be generalized that co-operations and relationships, especially long-term, are based on trust, good experiences and breadth of interactions, because customer satisfaction and revenues are common evaluation categories (Bruneel, D'Este & Salter, 2010; Mead et al., 1999; Santoro & Gopalakrishnan, 2001).

The benefits and challenges

Co-operation must be beneficial and valuable for both firms and universities. Mead et al. (1999) have stated: "there are significant benefits derived from the interaction of universities and industry to meet the professional development education and training requirements". Universities and industry can be seen as complementary and beneficial partners. Because of that, U-I co-operation offers so more benefits than possible problems and challenges. One of the most important things to remember is that co-operation must always ensure both side benefits in order to be long-term and successful. It is also good to remember that the mission of universities is not to serve industries' instant needs, but do the basic research.

U-I co-operation serves multiple benefits and there are many reasons to build these relationships. For example, firms can access to highly trained students and new technologies; increase their resources; enhance firm's image and growth in business. The competitive advantage is usually achieved with lower costs of R&D when co-operations are carried out with universities. In contrast, universities can obtain research funding, the latest knowledge and practical problems for students and researchers. In summary, in order to do basic research and be able to create new design and concepts, university researchers must be familiar with industrial technology and firms have to be capable of creating relationships with universities. Table 1 illustrates the most important benefits to both university and firm.

Sometimes value or benefit is very difficult to measure or identify, because always the outcomes are indirect or intangible. In addition, different forms of co-operation can be related to each other or some co-operation can lead to another. Many times firms and universities have a strategy which is aiming on all-round benefiting in many different sectors (HSE yrityspalvelut, 2009). However, it is not a problem, because sometimes the objective can be somewhere else than in tangible outcomes. Such objective can be, for

example, in networking or a better employer image. For those reasons, all the main forms, which were introduced in the previous chapter, are absolutely important.

Table 1: The benefits of U-I co-operation.

University	Description
Funding and support	Financial funding, gifts, upgrading/building of laboratories.
Information and knowledge	Current and new information about on-going challenges and areas of interest.
Research projects	Short- and long-term researches: solving of immediate business problems or seeking for completely new knowledge.
Development of know-how	Better understanding of a business world. Combining of theory and practice.
Networking	Wider and better contacts to the industry and to a business world.
References	Increased visibility among firms and in the media.
Industry	
Reduced costs of R&D	Universities are able to execute R&D projects more cheaply than private firms.
Competitive advantage	Competitiveness by products, services and procedures.
New innovations	Access to the latest knowledge in an early phase, and exploding of it in the R&D projects.
New employees	Academic researchers and graduates.
Employer image	Co-operation and interaction with universities and students.
Networking	Possibility to discuss and co-operate with other firms and universities.

Most things are beneficial, but there are also some challenges to solve – especially in the implementation. Probably the most natural reason for casual and non-systematic U-I co-operation is the lack of workable structures (Confederation of Finnish Industries EK, 2009). Clear contact channels or content are missing, because co-operations have used to be bonded to some specific people, and therefore the needs and offerings don't always meet and firms seemed to find suitable partners elsewhere (Confederation of Finnish Industries EK, 2009; Vironmäki & Jokinen, 2009). Structures of co-operation can contain multiple things like project planning, methods for problem solving and administrative, the terms of contract, offering, outcomes and information exchange. Clear structures, rules and methods create mutual trust and decrease uncertainty, because trust relies on strong bonds of mutual understanding and adjustment (Bruneel et al., 2010; Chakrabarti & Santoro, 2004).

The content of doing is the name of the game; then the results and outcomes are serving all participants. All firms cannot be pleased, so it is better to concentrate on specific competence areas and interests (Johnston & Clark 2008; Parantainen, 2007). The interests and needs of industrial firms must take into account in the planning of research objects and themes. Firms usually seek deeper information for their business whereas universities are trying to get current data and information from industry. Finding and mapping out of the content and interests demands active two-way information flow and discussion. In addition, academic researchers have also seen the major and classical problem in the differences in orientations. University research is often very theoretical and it is perceived long-lasting (1-5 years) while firms are usually concentrated on short-term research, because their needs are mostly pragmatic

(Bonaccorsi & Piccaluga, 1994; Confederation of Finnish Industries EK, 2009; HSE yrityspalvelut, 2009; Meyer-Krahmer & Schoch, 1998).

All the challenges of U-I co-operation are not common. That is why those cannot be solved together, but those need to be taken care of by native organization. Challenges in industrial firms are quite simple in comparison with challenges in universities. The problems are usually financial and are connected with the economic situation of firms. The complexity is the reason why problems in universities could have a bigger affection for the implementation of U-I co-operation. Table 2 represents the challenges of U-I co-operation and separates them to their origin.

Table 2: The challenges of U-I co-operation.

<table>
<tr><th colspan="2">Challenges are originated from…</th></tr>
<tr><td>…university:</td><td rowspan="2">…university and industry:</td></tr>
<tr><td>People with good personal connections fears that systematic U-I co-operation jeopardize their personal connections or they have to share (resistance of change).</td></tr>
<tr><td>Unclear and undefined service portfolio and - offering.
Slow and undefined internal processes and procedures of universities.
How take the size and needs of different firms into account.
Long-term orientation (>1y)</td><td rowspan="3">The missing of mutual content and structures</td></tr>
<tr><td>…industry</td></tr>
<tr><td>Rapid changes of organizational structure (disappearance of the key players).
Perpetual hurry and lack of resources.
Rapidly changing needs.
Short-term orientation (<1y)</td></tr>
</table>

Personal connections act a crucial role, because many co-operations come through those persons. In literature, those kinds of people are called champions and their role is crucial especially when co-operation is initiated (Mead et al., 1999; Santoro & Chakrabarti, 2001). Good personal relationships should take care of, but at the same time, those should support mutual benefits and the significance of those should not be crucial. Instead of protecting the contacts too tightly, attitudes should change. The organization and co-operation would work more effectively if information and contacts are more widely available.

PRODUCTIZATION OF SERVICES

Productization of services is differing from product productization. A product is something which is manufactured in production, while service is something, which someone is offering to someone. It is intangible and does not result in the ownership of anything (Kotler, 1997). People haven't got used to call services as a product and the selling of expertise is not seen as a selling of products (Sipilä, 1995). However, if services are wanted to sell and offer effectively, those need to be made more product-like.

Productized services

The productization, or service concept, is an essential element in defining of offering and it starts from the deep understanding about services and customers. It demands

analyzing the needs of the customers, designing the service and developing the ability to produce in order that mutual objectives are met (Johnston & Clark, 2008; Sipilä, 1995). Therefore productization is a key factor that demonstrates the potential value, quality and benefits of the service for customers (Johnston & Clark, 2008; Saaksvuori & Immonen, 2008).

Sipilä (1995) has recognized four different levels for productizing. On the first level, internal productization, organisations try to make sure that planning and development is executed well at the first time and after that there is no need to do it again (Lehtinen & Niinimäki, 2005). Internal productization is a natural phase, if services are wanted to produce as effectively and well as possible. In addition, standardized and defined internal processes make possible to repeat service multiple times as defined (Saaksvuori & Immonen, 2008).

Second level is the developing of supporting processes. Organization develops such methods or information systems that enhance the effectiveness of customer cares and situations. On the third level service is fully productized and the property rights or licence can be resold. Services are also defined and forming clear entities, which could be offered to customers as such or modified (Saaksvuori & Immonen, 2008; Sipilä, 1995). The total chain of processes must be able to handle and described if services are wanted to produce and provide effectively (Johnston & Clark, 2008).

The fourth and the last level is repeatability, which means that service is packaged in specific form to be delivered via distribution network and so on. All those phases and levels are not necessary as long as the quality and effectiveness of the processes can be ensured, but this depends on organization's strategy, customers and competition situation (Saaksvuori & Immonen, 2008; Sipilä, 1995).

Productization can describe the nature of services provided by the whole organisation, or just an individual service as a part of a service portfolio (Johnston & Clark, 2008). However, well-structured and productized service portfolio and concepts can be seen as a potential driver of agility. Portfolio strategies are often created concurrently with other organizational capabilities making most services architectures idiosyncratic and extremely difficult to imitate (Voss & Hsuan, 2009).

How to create a well productized service

Service production and delivery have become more productive and responding to fierce competition is demanding ever better services. In addition to the growing need of services, the need to customize service for the individual customer remains (Saaksvuori & Immonen, 2008). The mere idea about good service is not enough, but it must be concretized into customers' mind. That is the issue to which productization helps (Johnston & Clark, 2008; Parantainen, 2007). Parantainen has listed six common and typical milestones to create well productized services. Milestones help service providers to check out, which phases they have achieved and where they still need to improve. In some extent, milestones supplement levels that Sipilä (1995) has introduced. According to Parantainen the milestones are following:

1. Some procedures are starting to stand out. It means that service providers start to use or copy such procedures, which have worked well in the past,
2. service gets a name and it takes a shape. Smaller and simpler services can have even a price, but usually it still depends on the case,
3. the content becomes stable, which makes the solidifying of the price possible,
4. this phase is the first one, which consists of real signs of productization; services start to multiply inside of the company, from person to person,
5. services start to multiply outside the company. This is the first step what is done in purpose, while first previous steps can be unintended. At this moment, steps and phases of services must be well documented; only by it, repeating of service is possible outside of the company – with or without developers. Usually in this phase, service is divided into modules to help the customization and
6. the sixth phase can be compared with Sipilä's (1995) fourth level, because in this phase, services are ready for resold and delivered via distribution network.

Productization serves multiple means to improve value creation and make it easier; for example, by it comes also the standardization and scalability. Without productization and standardization, it is possible to over engineering the processes; this usually decreases the effectiveness (Saaksvuori & Immonen, 2008; Simula et al., 2008). Scalability comes by the customization, which helps to fit services for every customer and helps to manage supply chain better (Hsuan, 1999).

Productization is not just putting services in well-defined packages; it is the set of interrelated tasks that together create a service. At the same time, it is a continuous improvement process for both universities and firms. The purpose of the productization is to provide a clear picture about the offering of organization and what the customer receives. Productization specifies services and guarantees the shared understanding about provided and received value of the services. It has found out that good service reduces conflicts and increase customer loyalty. Such customers are less likely to change a service provider.

Johnston and Clark (2008) have demonstrated: "At an elemental level a university provides lectures, food, accommodation and books, but what its customers are looking to acquire is something much greater an 'educational experience'. Through productization and service concepts, universities make their offering much more desirable and holistic. Basically, productization is a mechanism that links operation, processes and marketing together (Johnston & Clark, 2008).

INDUSTRY CO-OPERATION AT THE UNIVERSITY OF OULU

Emphasizing of the third mission of universities and changed economic structure has forced universities to reconsider the positioning of industry co-operation. At the moment, co-operation between the University of Oulu and industry is good and fruitful too, but it is casual and mainly bonded to a few people. The issues faced by firms are often impossible to simulate in laboratories and as a consequence research in technological and applied fields, like the Industrial Engineering and Management (IEM)

require contact with industry. In order for universities to influence society (D'Este & Patel, 2007; Vironmäki & Jokinen, 2009) and to achieve the objectives of teaching and research, industry co-operation is a very important role.

Case study

The research data was decided to be collected from interviews. The aim of this study was to study the need and possibilities for productization in the context of U-I co-operation. That is why interviews were decided to be conducted in the DIEM at University of Oulu, and one case company, which can be considered as one of the main partners. The case company is one of today's most highly valued electronics and high-technology brands in the world. The company has stated that the strength of the Finnish innovation system comes from the wide-scale co-operation between universities and industry in Finland. The potential of universities and institutions should be utilized better and the number of creative co-operations could be increased.

In this research, a case study strategy was decided to use. A case study is an empirical research tool that studies a phenomenon within its real-life context. When research is in the early stage and the boundaries between the phenomenon and its context are not clearly evident, case study is appropriate and can provide new insights. Evidences can be collected from multiple sources (Ahola et al., 2008; Eisenhardt, 1989; Yin, 1989). As earlier stated, there is not much of research or data on the subjects of co-operation frameworks and how those are organized.

Thirteen interviews were carried out: three for university representatives, three in DIEM and seven in the case company. Every firm representative was experienced and high-ranking. University and DIEM representatives differed from researcher to professor, but every one of them have lots of experiences about U-I co-operation. Interviews were made for one person at a time, except one interview where two people were present. The amount of interviews was not limited in any way, but the purpose was to get enough data that answer and propositions start to accumulate. Because natural discussion and flexibility were seen very important for this research and interviewees, the questions were quite broad and the interviews were held quite loosely defined. For the purpose of credible and reliable research, all interviews were recorded and transcribed. The interviews concentrated on the following topics: the present situation, experiences, organizing, benefits and the development of U-I co-operation. The main focus was still in the development of co-operation through the productized services of universities and how productization was seen fit for U-I co-operation.

Results

In general, U-I co-operation was seen important for every participant and even for the development of local area. Experiences have been good and the personnel of firm and university were willing to continue it. Interviewees also believed that co-operation have had a positive impact on competitiveness, but especially in long-term it has been very difficult to measure or proof. Traditionally, co-operations have been concentrated on different kind of thesis and short- and long-term research projects.

Instead of benefits that have appeared, U-I co-operation seems to be in “a depression” at the moment. Co-operation has been carried out a lot and in many ways, but all potential has not exploited and it has not served the needs of the participants as well as possible. The problems are mainly related to the challenges that have been already been recognized in this paper:

- No clear content and objectives for co-operation,
- co-operation bounded in personal contacts and interests,
- the common and mutual structures are missing and
- co-operation should be wide-scale and more synergistic.

Many firm representatives said that U-I co-operation is fully bonded to personal interests and connections. That could be one reason why there were not any signs of tight objectives for co-operations. Only some qualitative objectives were stated, for example, that co-operation should be carried out only with top-research or top–universities. However, many interviewees, mostly from university, said that there should be some goals and objectives to ensure the effectiveness, success and organizing of relationships and co-operations.

It was made pretty clear that information must be spread more effectively between university and a firm in order that mutual content can be found. If co-operation is wanted to last and to be valuable, there must be some content and meaning on co-operation. Content can not be created from a scratch, but it must be related to partners’ competencies and interests.

Compared with normal service providers, many of the universities have not brought out and advertised their expertise and offering. One of the university representatives mentioned: “Profiling of our skills and competencies is crucial if our know-how is wanted to promote for co-operators”. If universities want to act as a service provider and co-operation is wanted to develop, there must be something concrete that can be presented for firms.

According to interviews it seems to be clear that universities should productize their services and create a service portfolio. If long-term industry co-operation is wanted to be more systematic and appropriate, information should be spread more actively and universities or departments should be able to present their service offering and portfolio clearly. Productization of expert services is absolutely a solution for that; a clear “service menu” could solve and clarify many problems.

Productization of a course assignment

It has been shown that U-I co-operation has essential benefits for both industrial firms and universities, but it suffers from the lack of structures and awareness of services as well as from the common challenges that U-I co-operation has usually faced. Thus, it is justified that the productization of services is one possible way to unify and systematize

the offering of universities. This would enhance U-I co-operation and concretize the offering for customers and help finding the mutual content and structures.

Based on findings of this research, one of the DIEM's course assignments was decided to be productized to overcome challenges related to industry-university co-operation. The need for such productization was well justified: multiple student groups were carrying out the same task in different firms. Basically the brochure about the assignment was created in order that every single firm would get a clear conception about the requirements. In table 3 elements of productized university services are shown and also one example is given. Elements are very much familiar with the literature, but in the case of university services, the value for students and university must be emphasized, because the objectives of services may be educative – for example in small assignments.

Table 3: Elements of productized university service.

Element	Description	Empirical example: course assignment
Name		
	Service must have a name, so that it could be recognized.	**A course assignment about project business**
Person in charge		
	Good results and quality demands some person in charge.	**Professor X**
Availability of service		
	When services is available and executed.	**Spring 2011**
Description and implementation		
	Service description and how is it executed	**The assignment will be executed in a group of 4-6 people and it will contain both theoretical and empirical part, which is carried out by the interviews of firm personnel. The results will be presented in the final seminar.**
The content and objectives of service		
	Clearly defined content concretizes service in customers' minds while objectives describe the purpose of service.	**The themes of an assignment: the special features of a project business, business models of a project based firm, sales and marketing of projects. The objective is to solve some problem related to firm's business and generate the improvement suggestions.**
Value creation for industry / customer		
	What can be achieved through the service.	**A solution for a specific problem; the enhancement of an employer image; straight contact with students.**
Value creation for university		
	Why service producing and offering is important for students and university.	**Students will get acquainted with real business problems and phenomena and have a chance to analyze the influence of those. In addition, students are getting familiarized with real problems and practices. Solving and applying of**

		those is necessary for the development of expertise.
Resources		
	The number of resources that are needed from the firm and resources provided by university.	**University provides 4-6 highly motivated students to carry out the assignment. Required resources from firms: Involving in choosing the topic/problem; 1-3 people for being interviewed; giving feedback.**
Price		
	The price is usually the first thing which is asked for. Because of customization, fixed price is not necessary, but service must have some sort of indicative price, what can be told for a customer.	**Free.**
Results		
	All results and outcomes are always confidential.	**The best assignments and results can be published, but firm has a right to forbid it.**

DISCUSSION

According to both current literature and empirical findings, U-I co-operation was seen very important from both industry and university perspective. These challenges are often related to lack of systematic way to provide services and make the offering visible for both parties in service production. Productized services are one possible way to maximise value and objective achieving (Simula et al., 2008). Value of productized services is much easier to measure and identify with productization, because services are clearly defined and the content is well-known. Table 4 discusses about the challenges that can be solved through productization.

Table 4: The challenges that can be solved through productization.

Challenge:
• **Solution through productization?**
Long-term orientation (1-5y) vs. short-term orientation (3mm-1y)
• **Defined services help to determine the content and objectives.** • **Suitable services and forms can be easily found.** • **Different types of orientations and requirements can be taken into account.**
Theoretical approach vs. pragmatic approach (long-term vs. short-term)
• **The theoretical approach is a standard part of any university's research procedures. Such things are defined and explained in the service description.** • **Services can be modified to match the needs of the customer with customization.**
Bonded to some person & variable organization structure
• **Services are clear entities that are available and accessible to all people.** • **Personal connections and variable organization structures won't be restrictive things anymore.**
No clear contact channels and content
• **Productized services and concepts are concrete and easily exploitable.** • **Productized service contains plenty of details, such as contact information.**

Productization is a continuous process, which aims to cost efficiency and customer orientation. Harshly, productization can be divided into two steps: inbound and

outbound productization. Before services are being offered and value can be produced, internal processes must also be productized. After that, effective value producing and service offering, outbound productization is possible (Simula et al., 2008). With those two steps, universities are able to implement productization as a part of their key processes (Valminen & Toivonen, 2007) and the most of the challenges in U-I co-operation can be solved or at least be reduced. Although the benefits of productization are undisputable, it is surprising how few organisations have clearly defined service concepts (Johnston & Clark, 2008). Thus, it can be argued that with productization universities can define their service portfolio and concepts more systemically and enhance their role as a service provider.

The benefits of productization based on well-defined procedures and services packages, which leads to the following things:

- Better quality and management of services leads to more stable, effective and manageable processes,
- the communication with customers is much easier and customer perspective can be taken more deeply into account and
- services are partially standardized and partially customized; standard parts ensure flexible and efficient processes while customization ensures the fulfilment of customer requirements.

Those inevitably lead to the better competitiveness and more valuable results. Usually, a good service reduces conflicts and increase customer loyalty. In addition, such customers are less likely to change a service provider (Johnston & Clark, 2008).

Sadly, the U-I co-operation has been bounded to personal contacts and in some extent it has had a negative impact on the number of co-operations. Personal contacts are important, but those may not be limiting factors. Productization enables that processes for co-operation will be standardized and stated. Naturally, this means that more people can benefit from the co-operation and it would be less dependent on the competence of individual experts.

Productization makes the implementation of co-operation easier and enhances the significance of co-operation. Because universities have already recognized the importance of U-I co-operation, the most important thing is to emphasize universities as considerable partners. When universities or departments clearly present their service portfolio and use it as “a menu”, any firm – especially new applicants – could be aware of service offering. We can presume that when the gaps and risks are minor, it encourages firms to start or increase the amount of co-operations. By that, universities would be more capable of serving firms and people in their region and act as a social influencer, which is also the third mission of universities. It could be assumed that the more partners’ universities have the more they will get funding.

In spite of benefits, productization is not the key for the opening of co-operation, because effective co-operation demands that offerings and needs meet each other. The implementing and opening of the co-operation demands active and two-way

communication. In that phase, productization has the biggest influence. It concretizes the offering, help fulfilling needs and finding the content and structures. In addition, clear structures, rules and methods create mutual trust and decrease uncertainty, because parties see the relationship itself valuable and are more willing to establish. Such things could have major and positive affection for the U-I co-operation and sustainability of it.

Managerial implications

The major managerial implication of this research is that universities should pay more attention to the productizing of their expertise and services. At this moment, it appears that industrial firms are not aware of offering and services that the universities could offer (Confederation of Finnish Industries EK, 2009). Productization would develop universities internal processes and procedures, which have a direct impact on the quality and effectiveness of working. Productization also set clear requirements for industry: how to purchase services and what kind of resources are required from them in service production. This emphasizes that service production is always co-operation between the supplier and the customer.

Productization also helps to take the variable needs of industrial firms into account and make sure that the results meet the requirements better. In addition, the improvements of productivity are one way to measure the effectiveness of the productization. At the same time, by more systematic co-operation, the personal relationships and changes of organizational structure are not as a big role as those are now. Because of the decreased workload, the better quality and productivity of co-operation, it can be argued that after the productization firms would have more time and will for U-I co-operation.

With true productization, the needs and objectives of industrial firms could be fulfilled better. However, firms should remember that the main mission of universities is to do research and new science instead of subcontracted work for industry. That is why universities' approach is usually perceived very theoretical and research areas can be completely new, hence satisfied results cannot always be guaranteed. The risks of conflicts can be decreased with a good preplanning and an effective two-way communication.

CONCLUSIONS

In this paper, the main focus has been to examine is the productization of university services as a way to enhance and develop U-I co-operation. Based on our research findings, university offering should be clearer and better defined; thus the missing structures and content could be easier to find. The lack of clear understanding what university can provide for industry leads to perceptions that university research and co-operation too theoretical for them (Confederation of Finnish Industries EK, 2009).

Productization is not a solution for all the challenges in industry-university co-operation. Many of those can be solved inside the university or the department, but we still need to map out the needs of the firms and the common content for co-operation. In the

interviews active information sharing was suggested being a solution for the discussion about needs and offerings. Probably, the only way to success, is the continuous communication between universities and firms, where the productized service portfolio act as an element supporting the objectives and interaction. That kind of arrangement could work quite well, because it would be easier respond to customers' requirements and achieve the objectives of own. These create a basis for the long-lasting and mutually beneficial co-operation.

ABSTRACT

Problem-based learning method is widely used in different levels of education. In this article we examine what is the role of psychological traits in problem-based learning. In the measurement of personality we used a questionnaire based on the Myers Briggs Type Indicator (MBTI) framework. MBTI framework consists of four dichotomous types that differentiate between how individuals mix with others on a social basis (extroversion vs. introversion), how individuals search out information (practical vs. creative), how individuals make decisions (analytical vs. beliefs), and how individuals relate to the environment (structured vs. flexible). We have collected and analyzed data on psychological characteristics and learning performance measures of 179 master level university students who participated in one of the three Project Management-courses provided in the University of Southern Denmark (SDU) between 2009 and 2011. In all of the three courses problem-based learning approach was used as the principal pedagogical method. Results show that females perform better than males, but when analyzing psychological characteristics statistically significant differences were not found. Still it can be said that structured students had somewhat better grades than the flexible ones. The implications are discussed.

Keywords: problem-based learning, psychological preferences, project management

INTRODUCTION

Problem-based learning (PBL) is widely applied learning method. It has been used in higher education for over forty years as a method of teaching the practical application of knowledge in a real-world setting. It originated first at Cleveland, Ohio (Case Western Reserve University) in the 1950s but one of the Canadian medical schools, McMaster University (Hamilton, Ontario), is more commonly mentioned as the origin of PBL. First references to PBL in McMaster University can be found from 1969, but by the 1990's it had been adopted to other North American, European, and Australian schools of medicine, engineering, architecture, business and management, and law (Barrows, 2000; Boud and Feletti, 1997; Hansen, 2006; Hmelo-Silver, 2004; Prince and Felder, 2006; Smith, 2005; Torp and Sage, 2002). The method is widely applied in management education, and business

schools can be actually seen playing a leading role in developing the method (Gilbert and Foster, 1997).

There is growing body of research focusing both outcomes and challenges related to problem-based learning method (see e.g. Bigelow, 2004; Boud and Feletti, 1997; Hansen, 2006; Hmelo-Silver, 2004; Kloppenborg and Baucus, 2004). However, research has not addressed how suitable PBL as a learning approach is for different types of students. According to type theories people can be categorized into discrete personality types (Eysenck, 1991). The psychological preferences can be determined by using Myers Briggs Type Indicator (MBTI), which is a psychometric self-report method widely used to measure psychological preferences to relate to world and process information (Myers and McCaulley, 1985). The basis for this method is derived from the 1920's typological theory by C.G. Jung (1971).

Existing research on learning and personality types in other context suggest that student apply different learning strategies and thus psychological preferences may affect learning outcome (see e.g. Opstad and Fallan, 2010; Taherr et al., 2011; Tyagi, 2008). We continue this line of research by analyzing the influence of students´ psychological differences on learning-performance in the context of problem-based learning. We aim to answer the following research question: "What is the role of psychological preferences in problem-based learning?"

In order to answer to the research question we have collected and analyzed data on psychological characteristics and learning performance measures of 179 master level university students who participated in one of the three Project Management-courses provided in Denmark between 2009 and 2011. In all of the three courses problem-based learning approach was used as the principal pedagogical method.

The structure of the paper is following: First we review some basic facts from the theory of problem-based learning and psychological preferences. Then the methods and data is introduced, and in the empirical part we discuss how psychological characteristics impact on learning performance when using PBL as learning method. Finally in the discussion part the implications are discussed and conclusions are drawn.

PROBLEM-BASED LEARNING IN PROJECT MANAGEMENT EDUCATION

PBL has been defined as "the learning that results from the process of working towards the understanding or resolution of a problem" (Barrows and Tamblyn, 1985). Problem-based learning method activates and challenges students to solve complex, real world problems independently by identifying the problem, acquiring the needed information for solving it and reproducing knowledge as teamwork while teaching personnel only supports the learning process as being a resource available. Teaching personel can for example establish criteria for acceptable task quality and team performance, provide advice, and encourage and recognize specific accomplishments (Peterson, 2004). Therefore PBL is based on a fundamentally different learning process than traditional classroom teaching in which instructor transfers his/her knowledge to students.

When using PBL method the problems are ill-structured (Boud and Feletti, 1997, Peterson 2004). At first, the problem is presented to the students by a faculty member. In some cases, the problem may be so fuzzy and complex that additional questions and discussions are required in order to even identify the problem. In the next step, the students identify the facts that are provided in the problem, analyze it, and seek for information to solve the problem. Several possible solutions can be generated and iterated until the best solution is decided. (Hansen, 2006; Hmelo-Silver, 2004; Milne and McConnell, 2001). Finally the solutions of the student groups can be discussed together to see and compare different kinds of outcomes. (see Figure 1)

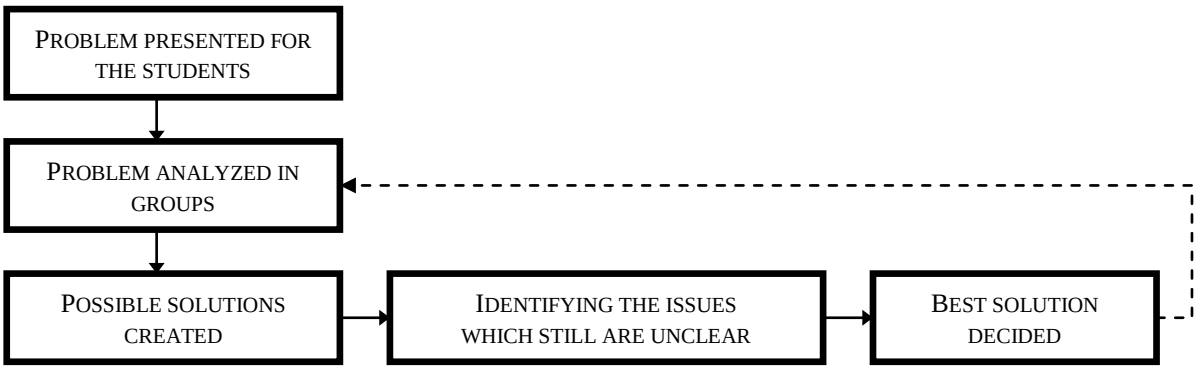

Figure 1: Problem-based learning process.

There are many variations of PBL process (see e.g. Bigelow, 2004; Boud and Feletti, 1997), but in the end the PBL core process is quite simple (Hansen, 2006; Hmelo-Silver, 2004). PBL method has also been applied in different kinds of situations. It is used in specific learning events within a course as well as a system level application in which a whole curriculum is based on PBL; and of course individual course level too (Kloppenborg and Baucus, 2004).

Furthermore, PBL is based on the assumption that students learn best in teams. Learning is cooperative and self-directed (Kloppenborg and Baucus, 2004; Hansen, 2006), and problem solving as team work, especially in case of a challenging problem, requires all team members to participate in discussions, engage in information sharing and be involved in research of literature or other sources (e.g. interviews of practitioners or discussion with faculty members). The students need to take an active role in the learning process, and it can be quite frustrating for students, as they face a lot of uncertainty in the process (Peterson, 2004). However, if successful, through this kind of process students gain deeper understanding of the subject and afterwards, will remember what they learned (Bridges and Hallinger, 1997; Woodward, 1997).

When talking about life-long learning, PBL is one of the most effective learning methods (see e.g. Albanese and Mitchell, 1993; Dolmans and Schmidt, 1996; Smits and Veerbeck, 2002). Benefits of PBL method has been widely studied (e.g. Dolmans and Schmidt, 1996; Woodward, 1997; Bridges and Hallinger, 1997; Blumberg, 2000; and Duch et al., 2001) and for example Smith (2005) has summarized the benefits into nine aspects: 1) Problem solving skills, 2) Knowledge retention and recall, 3) Understanding of material, 4) Thoughtfulness, 5) Focus on practice-relevant knowledge, 6) Knowledge integration, 7) Teamwork, leadership,

and social skills, 8) Life-long learning skills, and 9) Motivates student learning. For further details see Appendix A where Kujala et al. (2010) have introduced ways to achieve the benefits of PBL in the advanced course in project business.

The suitability of PBL as learning method in engineering education has been widely studied (see e.g. Hadgraft, 1997; Johnson, 1999; Mills and Treagust, 2003; Perrenet et al., 2000; Woods et al., 1997). Williams and Williams (1994, p. 361) have been summarizing the similarities between PBL learning method and the teaching design in engineering programs:

- Both have a large number of phases or stages through which to pass during the project or problem.
- Both start with an identified problem or situation which directs the students' area or context of study.
- Student initiated research is relied upon for the student to progress through the project as well as for their own learning.
- Both require high levels of student initiative, students need to develop motivation and organization skills.
- Both lend themselves to long-term projects, PBL may be used over a short time frame but this does not detract from its ability to be used effectively over a longer time frame, as is usually associated with technology projects.
- Both are open ended with regard to outcomes, allowing the student the opportunity to choose, after appropriate research an outcome that interests them.
- Observational skills are identified as having a high priority, especially in the initial stages during identification of the problem.
- Student reflection is an important aspect of both models, the student is encouraged to evaluate fully the outcome they have achieved.
- Both rely upon group work.

Problem-based learning method is related to other pedagogical learning approaches, for example work-based learning, and especially with project-based learning (Helle et al., 2006). In both methods students face complex real world problems without clear definitions or only one correct answer, and teaching personnel have a supportive role in the problem solving process (Thomas, 2000; Milentijevic et al., 2008). However, PBL focuses on understanding the phenomena behind the problem and solving the problem itself is subsidiary. In project-based learning the aim is to carry out an output, for example report or thesis, and the problem needs to be solved. (Helle et al., 2006).

All in all PBL is widely used, versatile method which can be used in different levels of education. Still it has not actually been studied how it fits to different people. In the following section, theory of psychological preferences, we describe, how people can be classified into different groups, and finally we combine these two theory aspects in our research.

PSYCHOLOGICAL PREFERENCES

Psychological preferences have been used in prior studies to explain learning of individuals. Initially Jung classified people only into extraverts and introverts but later on added the distinctions between sensing vs. intuition (practical vs. creative) and thinking vs. feeling (analytical vs. beliefs). Myers and Briggs further extended the descriptive theory with the addition of judging vs. perceiving (structured vs. flexible). MBTI framework (Myers and McCaulley, 1985), which is a dynamic framework, consists of these four dichotomous types. The framework goes further into type dynamics, thus not only focusing on where an individual stands each opposite type descriptions but looking into the implications behind 16 possible preference-combinations. The use of MBTI as a meaningful measurement tool for psychological preferences requires the consideration for the dynamics between all four pairs of preferences. However, when it comes to research, these strict requirements have often been overlooked and the pairs of preferences have been investigated separately. The research questions have often not been tied to the dynamics of MBTI. This is also true for the studies on psychological preferences and learning.

The studies on psychological preferences in MBTI and preferred learning style show some differences. Extroverted students rather collaborate with others and seek advice on how to proceed than work alone (Elliott and Sapp, 1988). They favour learning environments that provide active participation and experimentation (Gordon; Coscarelli and Sears, 1986; Hinkle, 1986; Luh, 1991; Penn, 1992). On the other hand, introverted students like to observe and reflect upon their observations in a more private manner (Hinkle, 1986) and thus adapt more easily to traditional lecture environments (Fourqurean et al., 1990).

Practical types seem to prefer rather systematic and process-like approach to learning and they like to know and master the existing facts (Drummond and Stoddard, 1992; Beyler and Schmeck, 1992), whilst creative types are more innovative (Jacobson, 1993) and holistic learners (Beyler and Schmeck, 1992). According to type theory practical learners can create new ideas and be creative but usually only after first carefully reviewing all the existing knowledge. Conversely creative types get inspiration from brainstorming without any limits and then later they search for the missing facts.

Those making decisions analytically have a systematic approach to learning, whilst those making decisions more based on beliefs prefer holistic learning (Gordon et al., 1986; Beyler and Schmeck, 1992). Analytical types like to learn independently and appreciate assignments that are logically understandable. For the belief-based types supportive learning environment is of special importance.

Those with structured approach to environment have been found to prefer systematic learning settings with clear structure and independency that allow them to plan ahead (Fourqurean et al., 1990; Drummond and Stoddard, 1992; Beyler and Schmeck, 1992). Alternatively, those with more flexible approach to environment like unstructured and more unpredictable teaching methods that do not set constraints to study methods (Drummond and Stoddard, 1992). Flexible learners are also more collaborative (Elliot and Sapp, 1988) and holistic (Beyler and Schmeck, 1992).

Psychological preferences in relation to how an individual would like to learn new things gives us important information on what motivates certain kinds of students. However, it does not tell us about how these students actually perform. The link between dichotomous MBTI types and actual learning has been studied by looking at performance on standardized aptitude tests, such as IQ test and Scholastic Aptitude Test (SAT), but also by looking at real classroom performance and achieved grades. Analytical types seem to exceed in mathematical parts of SAT (Gallagher, 1988), which can be easily understood through their analytical style. Flexible types seem to exceed the structured types in aptitude tests, whilst the more structure-seeking types rank better on real achievements (Myers and McCaulley, 2009).

Considering the broader picture, introverts and creative types show consistently superior performance (e.g. Myers and McCaulley, 1985; Kalsbeek, 1987). Their superiority is particularly apparent in verbal and abstract tasks (e.g. Schurr and Ruble, 1986; Schurr et al., 1988). A part of the explanation for the better performance of the intuitive types could be that they trust their intuition more and form quick overall impressions as opposed to practical types who need to double-check and work through questions more slowly. Standardized tests and exams are often time-limited. Another noteworthy point is that, exams have traditionally required silent and independent working through the exam. This type of an environment is more readily suitable for introverts than extraverts.

Interestingly, Schurr and Ruble (1988) found that academic achievement in more practical and applied courses was actually better in extraverts and practical types. In their study introverts and creative learners obtained higher scores only in more abstract and theoretical courses. Thus, one could argue that there could be interaction between personality preferences and different kinds of learning environments and teaching approaches.

METHODS AND DATA

Participants and procedure

The data for this study is drawn from three master level project management courses conducted in University of Southern Denmark (SDU) between 2009 and 2010. Each of the courses applied problem-based learning method in teaching. Two of the courses were 7,5 ETC in size and one 10 ETC. In each course lectures were given mainly by same lecturer and during each lecture students were given theoretical introduction that was followed 1 to 2 ill-defined problems that students were asked to solve in groups of 3 to 4 persons. Student´s solution to the given problems were discussed and reflected at the end of the lecture. The course structure for each of three courses is attached in Appendix B. In two of the courses (course 1 and 2) the length of the lecture was 90 minutes and in one course (course 3) 135 minutes. The full list of lectures by course is attached in Appendix B.

The final sample of the study consists of 179 students. The students represented wide range of different study programs including; economics, business administration, public health, tourism, and environmental management. From the students 37.6% were male and 62.4% female.

Learning performance evaluations

The learning performance was measured through course grade. Assessment of the course grade was based on the results of 72 hours take home group assignment and individual oral examination. The take home assignment was done at the end of the course in a group of 3 to 4 students. In each course, the assignment consisted of project proposal that students were supposed to prepare based on the given data present for fictive decision-makers. For each student groups, students were asked to divide the results into number of parts that corresponds the number of members in the group. The take-home assignment was followed by 20 minutes individual oral examination. The oral examination included two parts. During the first part student were given 10 minutes to present the results of the group work. The part of the group work to be presented by each student in a group as well as the order of examinations was not known before by students. During the second part of the examination that followed the presentation, each student were asked questions to test their theoretical understanding of the topics covered in the course as well as their ability to understand and apply the concepts in the given case.

The students were evaluated using Danish 7-point scale. In the Danish seven point scale grade 12 refers to "*an excellent performance displaying a high level of command of all aspects of the relevant material, with no or only a few minor weaknesses*". Grade 10 is given for "*a very good performance displaying a high level of command of the most aspects of the relevant material, with only minor weaknesses*". Grade 7 correspond "*a good performance displaying good command of the relevant material, but also some weaknesses*". For the grade 4, student is expected to show "*a fair performance displaying good command of the relevant material, but also some major weaknesses*". Grade 2 refers to "*a performance meeting only the minimum requirements for acceptance*". Grade 0 is given for a student who shows "*a performance which does not meet the minimum requirements for acceptance*". Finally, grade -3 refers to "*a performance which is unacceptable in all respects*".

Two assessors evaluated the learning performance of each student in an oral exam. The exam grade consists of assessment of both written case report and oral examination of the understanding related to the course area. Each student was evaluated separately. In each assessment two evaluators gave grade for the student separately and in case of grades given by assessors were different the final grade consists of average of two grades round up to next full grade. The average grade for the sample was 8.1 with a standard deviation of 2.9. The distribution of grades is summarized in Table 1.

Table 1: Distribution of grades.

Grade	**-3**	**0**	**2**	**4**	**7**	**10**	**12**
Count	**0**	**1**	**5**	**32**	**55**	**52**	**34**
%	**0**	**0.6**	**2.8**	**17.9**	**30.7**	**29.1**	**19.0**

Questionnaire on psychological preferences

The measurement of personal traits was developed based on the 4 personal dimensions proposed by Myers and Briggs (1995). The data on personal traits for each student was collected during the course in one of the lectures. The assessment of personal traits was

facilitated by lecturer that was responsible for the lecture. We assessed the personal traits of students dimension by dimension by asking them to compare one by one pair of adjectives related to a specific trait, e.g. “gets energy from other people” vs. ”gets energy from own ideas”, and to decide which of the two adjectives would describe them better. After comparing set of adjective pairs related to a specific dimension, e.g.” relations to others”, students were asked to calculate the number of adjectives that matched two both two trait, e.g. “extroversion” and “introversion”, and report, which of the two traits had more adjectives that would match their own personality. The full list of adjectives that was used in evaluating personal traits is attached in Appendix C. Descriptive statistics related to four personal traits are summarized in Table 2.

Table 2: Distribution of personal traits.

	Relation to others		**Information gathering**		**Decision-making**		**Lifestyle**	
	Extrovert	**Introvert**	**Practical**	**Creative**	**Analytical**	**Beliefs**	**Structured**	**Flexible**
Count	**104**	**75**	**107**	**77**	**101**	**78**	**91**	**88**
%	**58.1**	**41.9**	**57.0**	**43.0**	**56.4**	**43.6**	**50.8**	**49.2**

Data Analyses

The relationship between four personal traits and learning performance was analyzed using T-tests. In the analyses we focused on the main effects. Thus, the interaction between the traits was not assessed but rather the effect of each preference was looked at individually. In addition, we controlled for the effects of gender on learning performance as prior research has shown that females get on average better grades (see e.g. Dayioğlu and Türüt-Aşik, 2007; and Sheard, 2009).

RESULTS

The means, standard deviations and T-test statistics of learning performance related to personal traits are depicted in Table 3. The mean values indicate that the learning performance of students with introvert trait is slightly better than students with extrovert trait. The results of the T-test, however, indicate that the observed difference in mean values is not significant. From the information gathering perspective practical students had on average better grades than those that are characterized by creative tendency. The differences between the two groups are not statistically significant. In similar vein analytical versus beliefs based decision-making did not show significant effect on learning performance, even though the analytical students received on average better grades than those with beliefs-based decision-making. The highest differences in learning performance were found when comparing students personal tendencies related to lifestyle. We found that structured students were granted on average with better grades than those with flexible lifestyle. The observed differences on learning performance are not statistically significant, but indicate clear trend.

Table 3: Means, Standard devistions and T-test statistics of learning performance by personal traits.

	Relation to others		Information gathering		Decision-making		Lifestyle	
	Extrovert	Introvert	Practical	Creative	Analytical	Beliefs	Structured	Flexible
Mean	8.0	8.2	8.2	7.9	8.2	7.9	8.4	7.7
SD	3.0	2.8	2.8	3.0	2.9	2.9	2.8	3.0
t	-0.46		0.67		0.62		1.64	
p	n.s.		n.s.		n.s.		< 0.1	

We also analyzed the effect of gender on learning performance. The average grade for female students was 7.2 (SD 3.1) and for male students 8.6 (SD 2.7). The observed difference is statistically significant ($t = -3.16$, $p<0.1$).

DISCUSSION AND CONCLUSION

Previous research has suggested that psychological traits have an impact on preferred learning styles and thus they may influence learning performance in different type of teaching settings (Beyler and Schmeck, 1992; Hogan, 2009; Taher et al., 2011; Threeton and Walter, 2009). In this research, our objective was to study the role of psychological traits in the context of problem-based learning. Our results suggest that problem-based learning is an effective learning method for individual with different type of psychological traits. Although structured students were granted on average with better grades than those with flexible lifestyle, it can be claimed that problem-based learning method supports varying learning styles.

PBL provides an applied setting for learning and for demonstrating skills and knowledge. The cases that portray real life business challenges imitate problems that people face in post-modern working life. These problems are not clear-cut or in isolation from the reality. Changing one part changes another part in a systematic way and this must be kept in mind when working on an assignment. The approach differs from the more traditional teaching environment whereby learning is more deductive and theoretical and where students can safely set limits between knowing the facts and knowing how to use the facts. PBL environment also assumes that students have social skills and motivation to collaborate and participate actively, just as is the assumption in modern-day working life. All in all, one could assume that practical extroverts have an advantage in PBL environment in the vein of the research by Schurr and Ruble (1988). However, based on our empirical findings practical extroverts did not show superior performance in the PBL environments.

On the other hand one could be equally surprised that creative introverts did not show their superiority in course grades as they tend to do generally better than practical extroverts (e.g. Myers and McCaulley, 1985; Kalsbeek, 1987). More traditional exams extend through the course of a few hours, whilst PBL approach is based on a longer period of time that allows for a more extensive information seeking and longer contemplation and experimentation time. Thus, the advantage that creative types might have in traditional exams by trusting their intuition and performing quicker in very constraint time-limits, could be out ruled in PBL assignment that extends over a weekend. Likewise, the traditional advantage of monitored silence for concentration and individually performed exams that

has been favoring introverts is not enabled in PBL approach. All in all, one could argue that PBL approach could attenuate the perhaps unequal advantage that being an introvert and being a creative type has given to students in the past years. However, this is pure speculation at this stage and yields for more research.

Our analysis imply that complex problem-solving in applied context benefits from a mix of different preferences, so that introverted, extroverted, analytical, belief-based, creative, practical, structured and flexible learning approach all are compatible with the problem-based learning process. Personal traits may also affect which type of roles, such as plants, resource investigator, coordinators, shapers, monitor evaluators, teamworkers, implementers, completer finishers and specialists (Belbin, 2011), students take in problem-solving teams. However, in this research we did not analyze how assignment of students with different psychological traits in problem-solving teams affects team performance and individual learning. Further research could identify whether problem-solving team composition is an important factor for explaining learning performance.

It also might be that statistically significant differences between psychological preferences and learning outcomes were not found because some other factors explain why some students learn better than others. Our findings show statistically significant difference between learning outcomes of male and female students, which should be further analyzed. Also, previous research has suggested that psychological preferences might not effect directly to learning performance but it might support different learning strategies. Individual students learn new things in different ways and it might affect on learning outcomes. PBL as a learning method provides opportunities to use different type of learning strategies and students may take different roles in problem-solving teams. Therefore we suggest that future research could explore what is the relationship between psychological preferences and learning strategies in problem-based learning environment.

Appendix A: Ways to achieve the benefits of PBL in the advanced course in project business. (from Kujala et al., 2010)

Potential benefit of PBL (Smith, 2005)	**… and how to achieve these benefits in the context of an advanced project management education**
Problem solving skills	A student centered process that involves solving complex real world problems is an integral part of the course design.
Knowledge retention and recall	Students have limited practical experience and they will not be able to use acquired knowledge in their work. Students learn to recall and apply learned concepts and approaches when they face similar situations during the course (and hopefully in future work).
Understanding of material	Study material is used mainly in solving complex problems, which cannot be analyzed based only on "common sense", which leads to a more in-depth understanding of the relevance of the study material.
Thoughtfulness	Students have more responsibility for both creating relevant questions/problems and providing answers those questions, have increased thoughtfulness – a tendency to deliberate, question and be critically reflective of the course content.
Focus on practice-relevant knowledge	Discussion and problems that are presented during the course need to be up-to-date and well connected to practice either through faculty member interaction, visiting lectures from industry or student assignment to solve real world problems in companies.
Knowledge integration	In the course topics related to different disciplines are presented and students are encouraged to apply all available material to understand complex problems.
Teamwork, leadership, and social skills	Problems are solved in the groups and students have to take full responsibility for how their groups functions.
Life-long learning skills	Not all of the material that is required to solve problems are provided to the students, but they are required to gather relevant additional knowledge and material by themselves.
Motivates student learning	Problems solved during the course are practical and consist of complex problems that project-based firms are facing or have recently faced.

Appendix B: Course structures

Lecture	*Topics: Course 1 (7,5 ETC)[1]*	*Topics: Course 2 (10 ETC)[2]*	*Topics: Course 3 (7,5 ETC)[1]*
1	Introduction to the course, Project management in an organizational perspective	Introduction, The concept of projects PM history & development , Project mandate	Introduction to the course, Project management in an organizational perspective
2	The foundation of the project, Project mandate	Project mission and goals, Structuring of the project, Project process	Project process, Project mission and goals, Project mandate
3	Project planning, Structuring the project, Milestones	Milestone planning, Activity planning	Structuring the project, Milestone planning
4	Project stakeholders, stakeholder management, Project risk and uncertainty management	Project stakeholders, stakeholder management, Project risk and uncertainty analysis	Activity planning and critical path method
5	Detailed level planning, Organizing the project	Organizing the project, Staffing the project	Project stakeholders, stakeholder management
6	Project success	Project controlling, Project communication	Project risk and uncertainty management
7	Project controlling, Project communication	Consulting tasks, modes and roles	Organizing and staffing the project
8	Project team and team leadership, Teamwork competencies	Understanding of group processes, task- and maintenance processes and using different types of interventions as a consultant	Project controlling, Project communication
9	SimulTrain Exercise	Exercise	Project team and team leadership, Teamwork competencies
10	Programme management and porfolio management	Planning the project management training	Different types of projects and related managerial requirements
11	SimulTrain Exercise II	Evaluation of projects	Management of multiple projects
12	Overview of PM tools and issues	Teambuilding, Team leadership, PM behaviour	Overview of PM tools and issues
13	Exam preparation, Closing down the module	Different types of projects and related managerial requirements	Exam preparation, Closing down the module
14		PM models and project models	
15		Exam preparation	

[1] Lecture duration = 90 minutes

[2]Lecture duration = 135 minutes

Appendix C: Assessment of personal traits

ATTITUDE: RELATIONS TO OTHERS (9 items)	
Extroversion:	***Introversion:***
1. Gets energy from other people	1. Gets energy from own ideas
2. Needs relationships	2. Needs privacy
3. Active, talks a lot	3. Quiet, concentrated
4. Easy to get know	4. Hard to get know
5. Expresses feelings	5. Does not express feelings
6. Interested on many issues but at superficial level	6. Interested on few things but deeply
7. Many friends	7. Only couple close friends
8. May act impulsively without considering consequences	8. May think unnecessary profoundly without any concrete results
9. Impatient with long and slow projects	9. Has patience for slow projects
INFORMATION GATHERING (7 items)	
Practical (sensing):	***Creative (intuition):***
1. Thinks facts and details	1. Thinks concepts and interdependencies
2. Prefers practicality	2. Prefers imagination
3. Lives in current time	3. Lives in future
4. Likes clearly measurable things	4. Sees opportunities
5. Works systematically step by step	5. Works impulsively and moves flexibly from one thing to another
6. Form an overall picture by collecting the pieces together	6. Tries to fit the pieces to the entity
7. Likes functioning routines	7. Likes change and variation
DECISION-MAKING (7 items)	
Analytical (thinking):	***Beliefs (feeling):***
1. Decisions based on reason	1. Decisions based on feelings
2. Logical	2. Personal values
3. Truth	3. Harmony
4. Critical	4. Tolerant
5. Observes	5. Participates
6. Good in analysing	6. Good in understanding
7. May seem as cold and distant (from others)	7. May seem as emotional (from others)
APPROACH TO ENVIRONMENT (7 items)	
Structured (judgment):	***Flexible (perception):***
1. Organized lifestyle	1. Flexible lifestyle
2. Order, structure, plans	2. Let´s see what will happen
3. Control	3. Curiosity
4. Decision, execution, next task	4. Keeps options open (shifted decision)
5. Clear limits and instructions	5. Searching new, going beyond limits
6. Schedules and anticipation	6. Last moment rush
7. May seem stiff and inflexible	7. May seem unorganized and confused

THE STUDY OF EL FEATURE IMPLEMENTATION IN THE KM PERSPECTIVE

ABSTRACT

The word of "e-Learning (EL)" has become common in these days. Delivery of learning materials and learning evaluation are relatively convenient and efficient with the use of widely-spread internet. EL happens to be a popular tool in higher education for enhancing learning capability. While knowledge management (KM) is recommended as a strategy to ensure that information and knowledge reaches the right people at the right time in the right format and to share them for improving the overall performance. Both KM and EL address the same basic goal, which is facilitating for improving learning performance. But, they approach the same problem with different paradigms. Indeed, KM and EL are complementary to each other, especially in the academic institutions. KM requires EL system to enhance KM effectiveness whereas EL has to improve its performance by the KM process. Therefore, the KM based e-Learning: the integration between KM and EL, one of interesting concepts for enhancing EL performance based on KM concept is proposed in this study.

In the KM perspective, EL is not only recommended as a KM tool for transferring knowledge but also a knowledge repository for storing, sharing and reusing knowledge. KM can enhance EL performance by applying effective supporting EL features. Therefore, universities should to implement EL features based on KM concepts such as knowledge transfer/sharing/exchange tools for supporting collaborative learning. However, enhancing EL performance by implementing only EL features may overlook the importance of the social aspects. EL features are just only supporting tools not solutions to improve knowledge sharing/exchanging within and between learners and learning networks. Learning materials cannot replace the deep tacit knowledge of human beings. Therefore, universities also have to implement supporting learning policies and activities to encourage and support lecturers and students to use their learning management system (LMS) more efficiently and open their mind to share knowledge with others.

Keywords: e-Learning, Knowledge Management

⊗ Corresponding author

INTRODUCTION

Many universities have adopted ICT and networking to support traditional classroom instruction by calling this new learning environment “e-learning” (electronic learning or EL). E-learning refers to the use of information and communications technology (ICT) to enhance and/or support learning activities (OECD, 2005). E-learning systems provide fulltime learning services that students can access and learn without requiring their physical location. The benefit of e-learning is to provide cost-effective ways of education and to improve quality of learning (Cloete, 2001). EL also focuses on learner-centered activities and system interactivity.

EL technology has been utilized in university since the end of last decade by using the information and communication technology as a key driver. The implementation of EL in universities is quite diverse based on university’s policy and basic technological infrastructures. Therefore, the issue of how to facilitate the information and communication technology for enhancing learning performance was not clear at that time.

In Thailand, students paid high respect to the lectures as the main and only source of knowledge, regardless of other learning resources. The person-to-person teaching in the traditional classroom has been the main instructional method for a long period of time. Person-to-person teaching is always referred as the best method for transferring knowledge from lecturers to students. As a result, the substitution of EL to conventional classroom teaching in Thailand cannot be as simply implemented and obtained satisfied and expected results as in other western countries.

As such, knowledge management (KM), the ability to create, store, transfer, and use knowledge, is likely to play a significant role to improve learning activities. In recent years, KM issues have acquired utmost importance in all sectors, especially in the sector of learning activity. The use of KM as a supporting strategy for EL is found related to increasing the learning capability. KM is becoming an even more critical to learning organizations for enhancing their learning performance. In summary, KM is recommended as one of interesting learning catalysts for EL. However, the relationship between KM and EL has not yet been fully understood and harnessed. Therefore, implementing KM to support learning activities in EL is also an interesting issue.

In this study, the EL features are considered as elements in knowledge management system for analyzing in the KM perspectives. The objectives of this study are to explore the usage of EL features of LMS used in Kasetsart University in Thailand and in the KM perspective and to propose recommendations how to improve their e-Learning performance by focusing on a systematic KM.

E-LEARNING AND KNOWLEDGE MANAGEMENT

e-Learning definition

Henry (2001) defined EL as an appropriate application of the internet to support the delivery of learning, skills and knowledge not limited to any particular courses, technologies, or infrastructures. Rosenberg (2001) also suggested that EL is the use of the Internet to deliver a broad series of solutions that increase knowledge and performance. Whereas Gunasekaran et al. (2002) referred to EL as Internet-enabled learning comprising of content delivery in multiple formats, the management of the learning experience, and a networked community of learners, content developers and experts. E-learning refers to the use of information and communications technology to enhance and/or support learning activities. E-learning also refers to both wholly online provision and campus-based or other distance based provision supplemented with ICT (OECD, 2005). In this study, EL is defined as innovative approaches that not only education delivery of learning contents via electronic forms of information that enhance the learner's capability, but also evaluation and personalization.

EL features: Online environment and EL features were also mentioned as a factor contributing to the success of EL. According to Fabry and Higgs (1997), the Internet access and its availability were claimed by the university teachers to be critical factors to the uptake of web-based instruction. Internet technology improvement and convenience to the access are perceived by faculty members and students to be the key to the success of EL system (Fabry and Higgs, 1997; Daugherty and Funke, 1998).

Many additional EL features have been designed and implemented to support and enhance learning activities for improving the performance of LMS. For example, Kim (2004) introduced a metadata for collaborative work and learning specific to video editing and authoring activity. Tamura et al. (2003) have also proposed a metadata CLEM (Collaborative Learning Entity Metadata), which describes static entities of collaborative learning. The communication technologies are usually integrated in several LMS to support asynchronous and asynchronous discussion board, shared whiteboard, and chatroom for exchanging information and knowledge among learners in learning networks. Tamura and Hirasawa (2006) conducted a metacognition acquisition support system as a feature to support problem-solving learning skill. There are several EL features in LMS for enhancing learning capability. However, different LMS tools may provide different EL features depend on LMS developers, usage objectives, and prices. Therefore, the characteristics of EL features are very important factors for university to select and implement in its LMS for supporting its learning activities and achieving learning objectives.

Knowledge Management and e-Learning

KM consists of several processes namely knowledge identification, knowledge acquisition, knowledge utilization, knowledge development, knowledge integration, knowledge transfer, and knowledge storage and maintenance (Numprasertchai and Igel, 2004). KM is also related to an organizational perspective, because it usually addresses the lack of sharing

information and knowledge among members by encouraging the individuals making their knowledge explicit which can be stored in knowledge repositories and share with others in learning communities. Whereas, EL emphasizes an individual perspective, as it usually focuses on the individual to access and acquire new knowledge for improving their capability through the Internet technology.

Many KM studies have addressed learning mostly as part of knowledge transfer/sharing process and focuses on specific forms of informal learning or on providing access to learning resources or experts. On the other hand, learning might also benefit from KM technologies. In the relationship between KM and EL, Poovarawan et al. (2006) suggested that EL is one of ICT based KM tools for enhancing university competitiveness. It is not only enhancing learning capability but also supporting university to manage a mandate in term of teaching/learning activities more efficiently. Therefore, a LMS should take into account the relationship between knowledge management and learning based on different learning environment.

CONCEPTUAL FRAMEWORK

Based on the previous studies, we assess and analyze the LMS of Kasetsart University (KU) by focusing on EL features in the KM perspectives. This is because Kasetsart University, one of Thailand's largest and most progressive public universities, has implemented its own LMS system namely "M@Xlearn" and used it as an e-learning support system for supporting learning activities since 2000. More than 44,000 students in undergraduate and postgraduate programs in four campuses have used this LMS in each year. This study focuses on the investigation into EL features that influence the implementation of contents and services in LMS and impact to learning capability. This study is also to propose various learning activities based on KM perspectives for enhancing LMS performance.

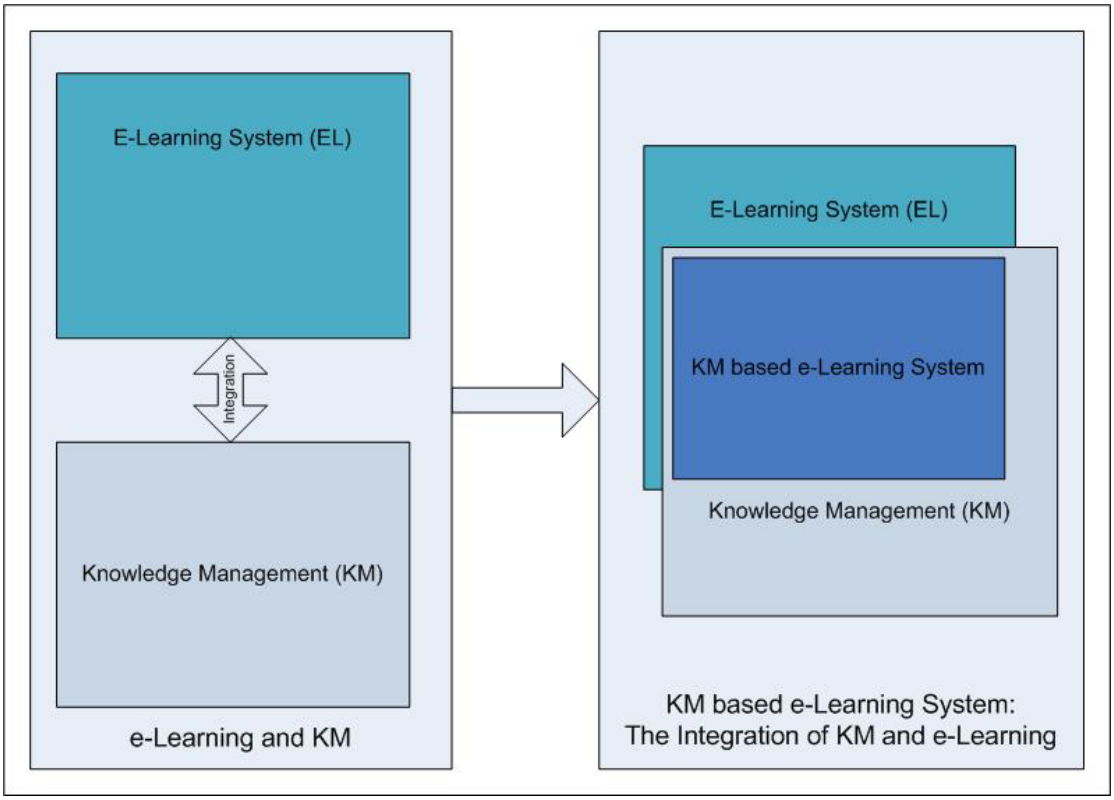

Figure 1 KM based e-Learning: The implementation of EL features based on KM concepts

METHODOLOGY

The study of e-Learning usage in KM perspective is quite new and there is only scattered empirical evidence. The case studies, a qualitative data collection method, was used to gain in-depth insights into the managerial practice of implementing EL features based on KM concepts in LMS used in Kasetsart University in Thailand. The reason for this approach is that there is an unclear boundary between KM and EL.

In this study, the implementation of EL usage and features of LMS of Kasetsart University was selected as case studies. The analysis was based on qualitative information that analyzed the EL usage and features affecting LMS performance based on the KM perspective. The findings and final results were reviewed and analyzed by educational experts, senior lecturers and executives.

RESULT AND DISCUSSIONS

EL Usage in KU

M@XLearn is Kasetsart University's powerful EL suite. Numprasertchai and Poovarawan (2007) suggested that M@XLearn is one of knowledge enabling tools in KM@KU4Learning which supports university's mandate in term of teaching and learning activities. This EL system has been implemented by researchers of the Faculty of Engineering to support e-University policy. The reason to create its own system is convenience to implement new and required features as request by lecturers or university's policy. There are numbers of

courses in M@XLearn for undergrad and graduate students. Students can learn, communicate with their lecturers and classmates, and submit their assignments through this e-learning system.

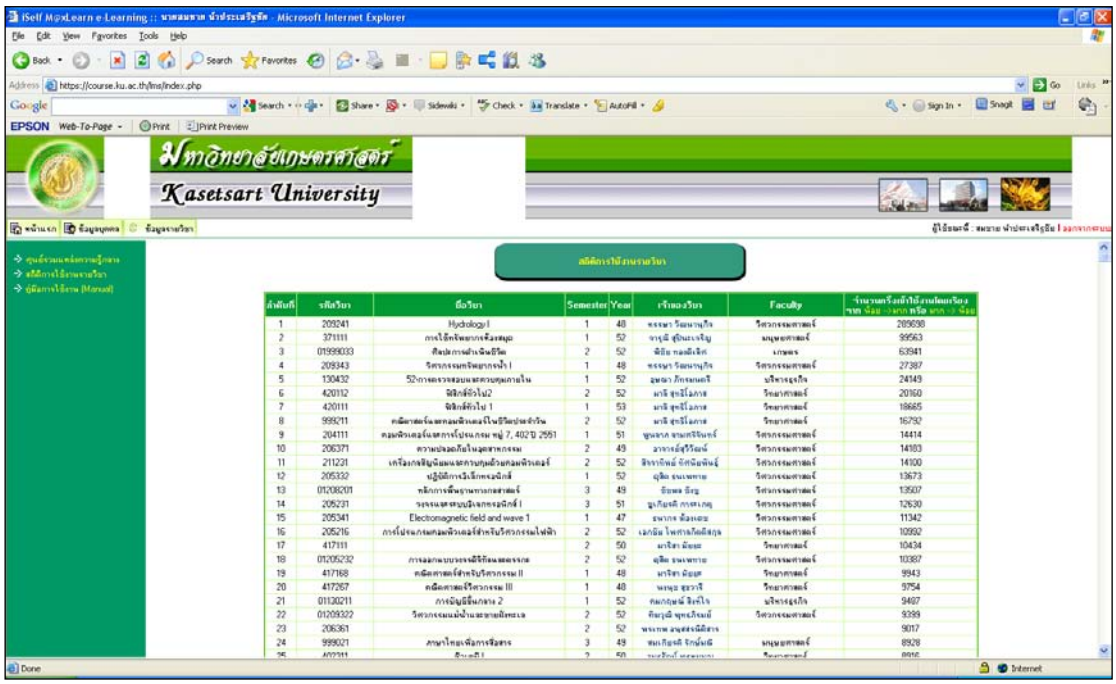

Figure 2 M@XLearn: A powerful EL suite of Kasetsart University

EL system helps lecturers manage their teaching resources and course schedule more conveniently and efficiently. Most KU lecturers have managed their course and class materials through this EL system. M@XLearn is not only LMS system for KU students but also one of commercial products of KU. M@XLearn has also been sold to other universities and the private sectors in Thailand.

Table 1: EL Characteristics in Kasetsart University.

Characteristics	M@XLearn (EL of Kasetsart University)
Type of university	Public university
Nation	Thailand
Class attendance	Required
Status of EL unit	R&D: Computer Center of Faculty of Engineering Operation: A workgroup in Office of Computer Service (OCS)
EL platform	In-house development (M@XLearn)
Responsibilities of EL unit	Provide training for instructors IT infrastructure matters EL system administration
Instructor's role	Content provider Online activities design Presentation design Online assessment Communication design
Instructor's incentives	Credited as an academic output Social recognition
Total classes in EL	Around active 2,000 courses
Major content in EL	"PowerPoint" presentation Syllabus Lecture notes in documentation Links to other learning resources Additional learning materials
Main objective of EL adoption	Enhance the in-class instruction Reuse of class material
Implementation Features	Initiatives are from individual instructors with limited supports
Level of integration of EL into the F2F teaching	Moderate integration in varied styles

EL Features

Internet access is becoming a basic requirement for learning in the university level. Lecturers and students of KU can access their LMS through the Internet more convenience through wireless and wire-line system by using computer services at computer centers in universities or their own mobile computers, and so on. Therefore, lecturers and students can access these LMS through the Internet from anywhere in anytime. Therefore, EL features of LMS are considered as main factors for success or failure in e-Learning system. Based on the study on LMS used in Kasetsart University and general EL system such as Moodle, there are several common features to support learning process show in the Table 2.

Kasetsart University has developed its own Learning Management System (LMS) called M@XLearn. EL features in this M@XLearn have been implemented and modified by administrators of the Computer Service Center of faculty of Engineering based on request and university's policy. For example, some EL features have been developed by creating links to another service system for reducing the redundancy such as student portfolio, online journals, and registration integration.

EL Features in KM perspectives

Based on the study on EL features used in Kasetsart University, several EL features support not only learning processes but also KM processes. Therefore, if the KM processes can be managed and improved, the more efficiency in EL processes will be improved. In this KM based EL system, EL features are considered as enabling tools for supporting lecturers and

students to identify, acquire, transfer, development, integration, use and store knowledge more efficiency for achieving learning achievement.

Table 3: The relationship between KM process and EL features/module.

KM Processes	EL Features/Modules
Knowledge identification	External links, Search within course
Knowledge acquisition	External links
Knowledge utilization/reuse	Self-assessment, Quiz module, Content sharing/reuse
Knowledge development/integration	Lesson module, Student community, Group work, White board, Discussion forums, Real-time chat, File exchange,
Knowledge transfer	Student portfolio, Student community, Group work, White board, Discussion forums, Real-time chat, File exchange
Knowledge storage/maintenance	File site storage

Knowledge identification

Knowledge identification is the process to identify the existing learning material and sources of knowledge required for each course. Web link and search within course in M@Xlearn and general EL system are the EL features related to knowledge identification. Students in both universities always search and access all required information and knowledge through these features.

Lecturers should identify a clear learning scope and objective in each course. They have to create a specific course portal using external link to help student to access useful learning materials from external resources more easily for achieving the learning objectives. EL features in M@Xlearn are easier for creating links for this purpose. Therefore, EL features in both LMS are fully support knowledge identification.

Knowledge acquisition

Knowledge acquisition is the process to obtain required knowledge from external sources to fill existing material developed by instructor. For EL course using M@Xlearn, lecturers have to create their links as a specific course portal to connect their class to various learning material from internal and external sources.

LMS in KU has been implemented to support an exchange standard “the Shareable Content Object Reference Model (SCORM)”. Therefore, they can acquire exchange and distribute learning material with other education institutes. Therefore, the improvement of knowledge acquisition depends on the quality of course portal defined by lecturers and quality of internal and external learning sources rather than EL features. Lecturers have to identify and select internal and external learning sources more carefully. They also have to encourage students to access and learn from external learning material.

Knowledge utilization/reuse

Effective knowledge utilization is needed for making better decisions to select the right learning material and knowledge from internal and external sources for teaching courses. Lecturers in KU can access and modify the teaching materials based on the class evaluation

from students and comment from peer-reviewed by other lecturers in the same and relate teaching area. They can use their own previous teaching materials as core teaching materials for current and future course. EL features help lecturers reduce time to prepare teaching materials. Some high quality and market potential teaching materials have been transformed to commercial textbook.

Knowledge development/integration

Knowledge development is the process to develop new knowledge through creating new teaching materials. While knowledge integration is a process to integrate knowledge from several sources for creating new knowledge is necessary to conduct the more complex teaching materials.

There are several EL features in both LMS in KU support a knowledge development process such as a lesson module white board, discussion forums, and real-time chat. However, many lecturers use their own previous electronic teaching materials without any changes. This is a reason why EL cannot support a knowledge development process and enhance students' learning capability.
University has to develop teaching strategies or policies to solve this problem by encourage lecturers to improve their teaching materials continuously. For example, Faculty of Engineering of KU has a supporting policy to encourage lecturers to develop new teaching material or improve the quality of previous teaching material and then publish as a commercial textbook by providing supporting funds and awards.

EL features also support students can improve their knowledge and skills through personalization by learning from each others in the learning communities by using real-time chat, whiteboard and discussion forum in LMS. However, most students don't want to discuss and exchange their knowledge and learning materials with the others. Lecturers should view statistical summaries of discussions displaying participation and encourage students to create more discussion groups and learning communities for group learning. In the strategic level, university has to improve the performance of knowledge development and integration by encourage lecturers to teach based on student-centric system.

Knowledge transfer

Knowledge transfer can be categorized as internal knowledge transfer among students and external knowledge transfer focusing on transferring knowledge to the public. Knowledge transfer does not only include transfer, sharing, and exchanging knowledge among people. Knowledge transfer is necessary for all learners.

Several EL features in LMS support a knowledge transfer process not only transfer knowledge from lecturers to students but also transfer knowledge among learners and lecturers such as student community, group work, white board, discussion forums, real-time chat and file exchange.

In this knowledge transfer process, lecturers can improve its potential by building informal learning communities in their EL course to encourage their students to share knowledge, individual learning material, and ideas with the others.

Knowledge storage and maintenance

Knowledge storage and maintenance is the process to preserve and validate learning material and knowledge for reuse and sharing. The aim of this KM process is to collect and maintain the knowledge in the organization. So that it is not loss if lecturers resign or retire. The stored knowledge and teaching material are vital to the present performance of the organization, and provide an important source for new knowledge development.

Knowledge storage and maintenance is necessary to support lecturers to share knowledge among their co-teaching teams and students. Database in EL system also help lecturers shorten teaching material implementation time. However, many lecturers in KU are also worry about the reliability and security of LMS. Therefore, they don't want to locate their overall teaching materials in LMS. EL unit have to manage trust between lecturers and the reliability of LMS.

CONCLUSION

Knowledge Management (KM) is essentially connected to the learning activities as strategies or processes for students to acquire, share, integrate, and use the various knowledge sources in their learning process for enhancing their learning capability. All KM processes are embedded in the EL activities. Each KM process is supported by several EL features. Some EL features support various KM processes such as discussion forum supports knowledge transfer, sharing, development and integration.

Especially, knowledge identification, acquisition, transfer development/integration, reuse and sharing were found to be the key processes which can enhance students' learning capability. Effective knowledge identification helps students to understand the learning scope and objectives clearly. Knowledge identification and acquisition also helps lecturers and students to identify and access required information and knowledge from various internal and external sources which relate to learning topics more conveniently. Knowledge development/integration support lecturers/students to improve their individual knowledge and skills by learning from several sources and learning communities. Knowledge transfer/sharing/reuse support students to improve their learning capability by learning from the others. Knowledge storage helps university collect and store teaching materials and knowledge although lecturers retired.

This study's findings indicate that it is crucial to implement EL system through integrate EL features which support KM processes for enhancing teaching and learning capability. With the specific implications above, it is hoped that this study will contribute to the continued development of EL in other educational institutions.

APPLICATION OF IMPROVED CFI MODEL ON ATTRIBUTES OF CUSTOMER SATISFACTION

Alemu Moges Belay, University of Vaasa, Finland
albel@uwasa.fi

Josu Takala, University of Vaasa, Finland
jot@uwasa.fi

ABSTRACT

The purpose of the study is to develop and apply improved model of Critical Factor Index (CCFI) on customer satisfaction in one of service provider in Finland. CCFI method is selected because it is comprehensive, practical, and considers the standard deviation and sees also the gap between the customer expectation and experiences. After the description of the method the current pitfalls of the model will be explained by comparing the existing CFI to the newly developed CCFI (corrected critical factor index). From the result of the study, the company identified the area to be improved based on the criticality of the attributes and give insight to balance the resource allocations accordingly. The methodology is Questionnaire/survey with relevant attributes and 150 responses are gathered with required information (15 are analyzed in this paper). The main motive of the paper is that, the old model doesn't consider the influence of number of responses whereas the new model takes in to consideration and bring some non-zero results. This helps managers to see the relative gap when one of the standard deviation (experience and/or expectation) becomes zero. Besides to that this paper introduces how control chart could help on identifying green, yellow, and red section based on the criticality of the attributes. Finally emphasized implementation index and its correlation will be presented.

Keywords: Corrected Critical Factor Index; CCFI, Customer satisfaction; Control chart, Service.

INTRODUCTION

No matter the type of services/products you are providing, decision making is done at any stage in the process. So, strategic service management of an organisation ought to have a sagacious view about the current situation and future improvement and development possibilities. Nowadays, service engineering has become an increasingly important part field of study to contribute to global economy. Enhancing service productivity become crucial as service sector becomes more knowledge based and service based. Substantial studies show that excellent service is widely recognized as a decisive factor on different business environment (Voss et al., 2004a; Vilares and Coehlo, 2003). According to (Newman and Cowling, 1996), service sector and quality is "essential to corporate profitability and survival" and Rosen et al., (2003) described as "not just a corporate offering, but a competitive weapon". Voss et al., (2002) and Johnston, (1959) indicated the complexity of service quality concept in service sector and there is no clear picture on the drivers for delivering in effective way.

final draft

Due to globalization and other factors the nature of competition in services is changing and unpredictable in some cases because the forces of deregulation and new technologies have restructured service industries in recent years. Therefore managers are always looking for the better way of doing things by implementing different approaches to tackle these challenges. For instance applying decision making indicator like CCFI can be taken as example. This added flexibility would help to ensure that the product or service delivered meets the customer's requirements and specifications. Another tool which is helpful for decision making is CFI which finally improved to CCFI. CFI method is a t tool to indicate which attribute of a business process is critical and which is not, based on the experience and expectations of the company's employees, customers or business partners (Ranta, Juha-Matti & Josu Takala, 2007).

In order to make the appropriate decision managers has been using several decision supporting tools. That is why the CFI (Critical Factor Index) has been developed to make a decision making in comprehensive way of current performances of business processes based on expectation, experience, competitor and other attributes. This tool indicates which attribute of a business processes or activities are critical and which are not. The CFI was developed on the basis of the Gap analysis and the implementation index (IMPL). The original idea, behind these measurement tools, was to develop a fast and reliable method for management purposes to sense and respond to customer satisfaction. Even though the method helps and applied on many different cases on identifying which attributes are critical within the business process and supports the management to make decisions on identifying which attributes should be improved. Having well defined attributes, the method can be used to measure all business processes and activities. As a weakness, CFI indicator is highly influenced by the standard deviation and it doesn't show the magnitude of the attributes if one of the standard deviation (expectation and/or experience) is zero. (Ranta, Juha-Matti & Josu Takala, 2007) also proposed in their case study about further development of the CFI in order to increase the reliability of the findings. This paper tries to avoid zero CFI and introduce a formal way of identifying three distinct areas (green yellow red). Then the method will be improved from CFI to CCFI that will avoid the non-zero deviation by integrating the sample error correction.

DRIVER FOR SERVICE ATTRIBUTES

Recently all type of businesses including service have become under extreme pressure to provide services to the client/customer quicker than ever before. With such an extreme pressure being applied to respond and implement services faster than ever before, companies that provide service can no longer afford or survive to perform work with limited resources or in non-reactive/responsive way to customers. For the last few decades, three factors Speed, quality, low cost is universal goals as long as there has been competition in any service and other business. There are many resource wastes in service sectors that directly affect the customers' attitude towards service provider. Minimizing the major resource wastes of the services and reducing complains of customers' need continuous and consistent endeavor. This is because seeing service through ones eye is not as an easy task as we expect in order to be a customer centered service organization. The big challenge in service is to identify, analyze and developing capability to understand service resource waste in systematic and organized way. Some of the wastes could be categorized in few

major areas like, over processing, transportation, motion, inventory, waiting time, defect, over-production, and information. One of the motives of this paper is to introduce the possibility of reducing resource waste linked with resource allocation based on the critical level of each attributes. In order to see and analyze in detail, these major attributes could be broken down in to several attributes and treated individually and based on the criticality it would be possible to balance the resources distribution. Having well defined attributes for each specific companies and situations, CFI would lead to right decision for optimum utilization of resources.

CCFI DETERMINATION IN SERVICE GIVING COMPANY

The case company is one of a strategic partner that provides mainly services and products to some extent. Its customers for long term services are from both domestic and international industries. The company is ISO certified and with a capability of peculiar products based on customers requirements and specifications. To carry out this research, questionnaires (sample table 1) with relevant attributes are used to gather the relevant information. As a matter of fact, each services and processes have its own attributes and it is difficult to have a single standardized questionnaire. Usually this is done in two phases. On the first phase the current performance of the services is investigated, personnel interviews and discussion will be made to come to common agreement on defining attributes which are going to be set. To achieve the overall objective, proposing development needs for certain attributes, the choice for them should be in line with the company's own strategy, vision, mission and values. In the second phase, all information that has been gathered will be analysed and critical factor index (CFI) measurement tools will be applied to determine the critical attributes that needs improvement. This will give an idea for managers to decide on balanced resource allocation in various activities of services.

Table 1: Sample questionnaire.

	Expectations	**Experiences**	**Compared with competitors (Please tick your option)**			**Direction of development (Please tick your option)**		
	(1-10)	(1-10)	Worse	Same	better	Worse	Same	better
Attribute 1	[ ]	[ ]	☐	☐	☐	☐	☐	☐
Attribute 2	[ ]	[ ]	☐	☐	☐	☐	☐	☐
•	[ ]	[ ]	☐	☐	☐	☐	☐	☐
•	[ ]	[ ]	☐	☐	☐	☐	☐	☐

Expectation = what is the expectation to the attribute
Experience = what is the experience of the attribute
Compared with competitors = Compare experienced value to the values of all other targets
Direction of development = Direction of the experienced values of the sample during the last three years.

$$\textbf{CFI} = \frac{\text{Standard dev. of expectation} * \text{Standard deviation of experience}}{\text{Importance index} * \text{Gap index} * \text{Direction of development index}}$$

$$\text{Gap index} = \left| \frac{\text{Average of the experience} - \text{Average of the expectation}}{10} - 1 \right|$$

$$\text{Direction of Development index} = \left| \frac{\text{Dir. of Devt. Better\%} - \text{Dir. of Devt. Worse\%}}{10} - 1 \right|$$

Importance index = $\frac{\text{Average of expectation}}{10}$

In the CFI model was applied in many applications on Quality, Maintenance, production, Knowledge management and etc. But the existing model would be a good critical factor identifying tool and appropriate when one of the standard deviations or both are non-zero. In order to improve the situation the sampling error correction can be taken from the model which is developed by miller (1955) and Basharin (1959) who derived an approximation for the expectation of a sampled uncertainty, AE(Hnb), that would be good for large sample n. The new developed model critical factor index with sample error correction (CCFI) can be rewrite as follows:

AE (Hnb) =Hg-$\frac{s-1}{2\ln(2)n}$

CFI = CCFI - S_{EC}

CCFI= CFI + $\frac{s-1}{2\ln(2)n}$,

Where s is the minimum number of sample in our case 3, and n is the number of sample (responses) actually analysed.

CCFI = $\frac{\text{Standard dev. of expectation} * \text{Standard deviation of experience}}{\text{Importance index} * \text{Gap index} * \text{Direction of development index}} + \frac{s-1}{2\ln(2)n}$

DATA ANALYSIS, RESULTS AND INTERPRETATION

The physical meaning of adding sampling error is to avoid zero CCFI. That is because with certain amount of input (resource) there must be some output in all extremes i.e. high critical or low critical. Unfortunately in our data analysis we did not get a zero STD on experiences and/or expectation. In such situation it may not be visible the significance of sampling error correction as all attributes have its own critical values. The essence of incorporating sampling error is to tackle the probability of getting zero CCFI. As we know the probability of having zero STD deviation is high as sample size goes lesser and lesser. A person collecting 100 responses and a person with 3 should not apply the same parameters and analysis. So, in this research the gap will be filled by balancing CFI by adding some value that takes the number of responses in to account. Control charts have been used for several applications and here we have used to identify the critical level or area. These help managers to clearly observe and answer which attribute, at what level and how much they are critical. Besides to that by varying different attributes level it could be possible to adjust the other attributes. For example, by reducing or increasing some values on most critical ones it would be possible to see the overall critical level change. In our case, if the company reduce the critical level of attribute 18 and 25 into 2, the lowest critical could become in to the green area. That means it could be possible to have significant influence on attribute 2, 3, 6 and 13 that they become in green area. In general out of 43 attributes, 6 each were in both extremes and the rest were in green areas.

Table 2: Results of the preliminary analysis.

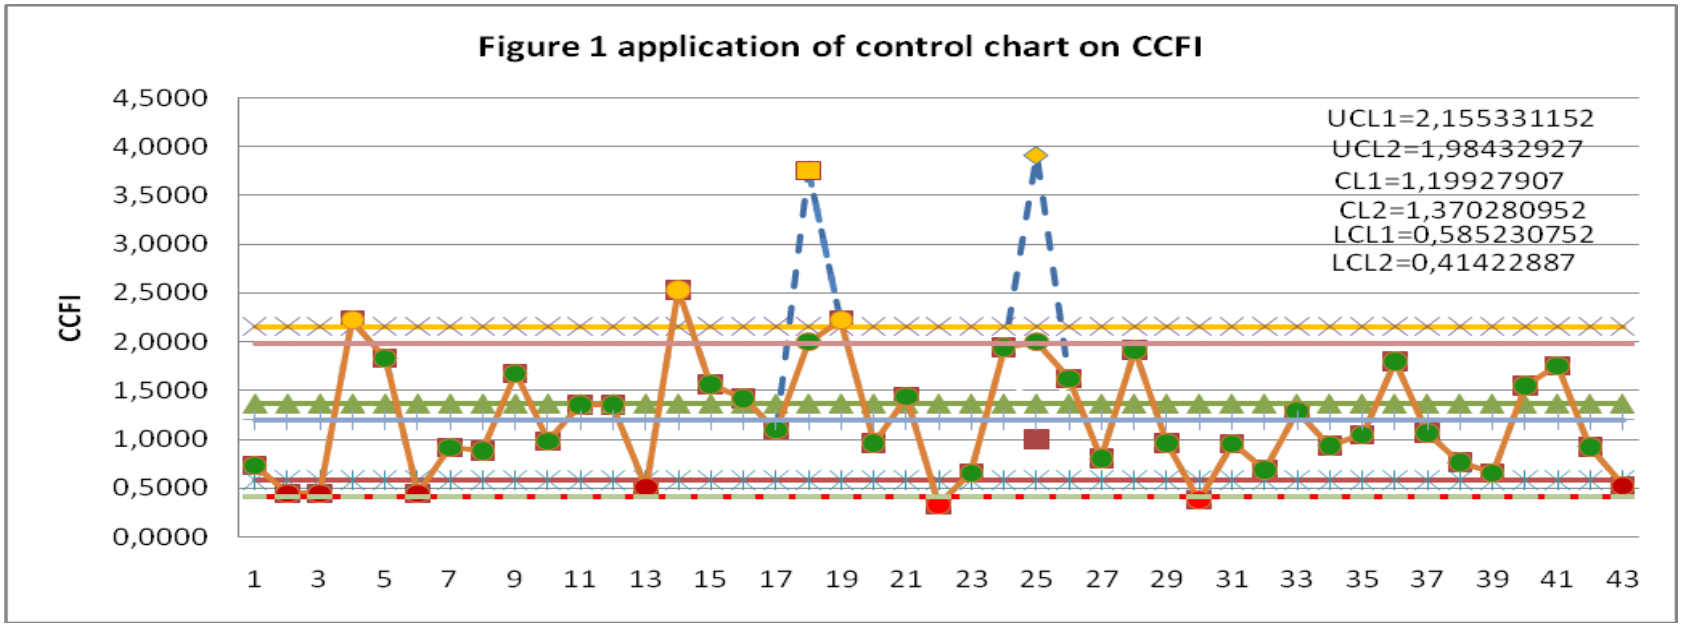

Figure 2 preliminary result of CCFI (with sample correction)

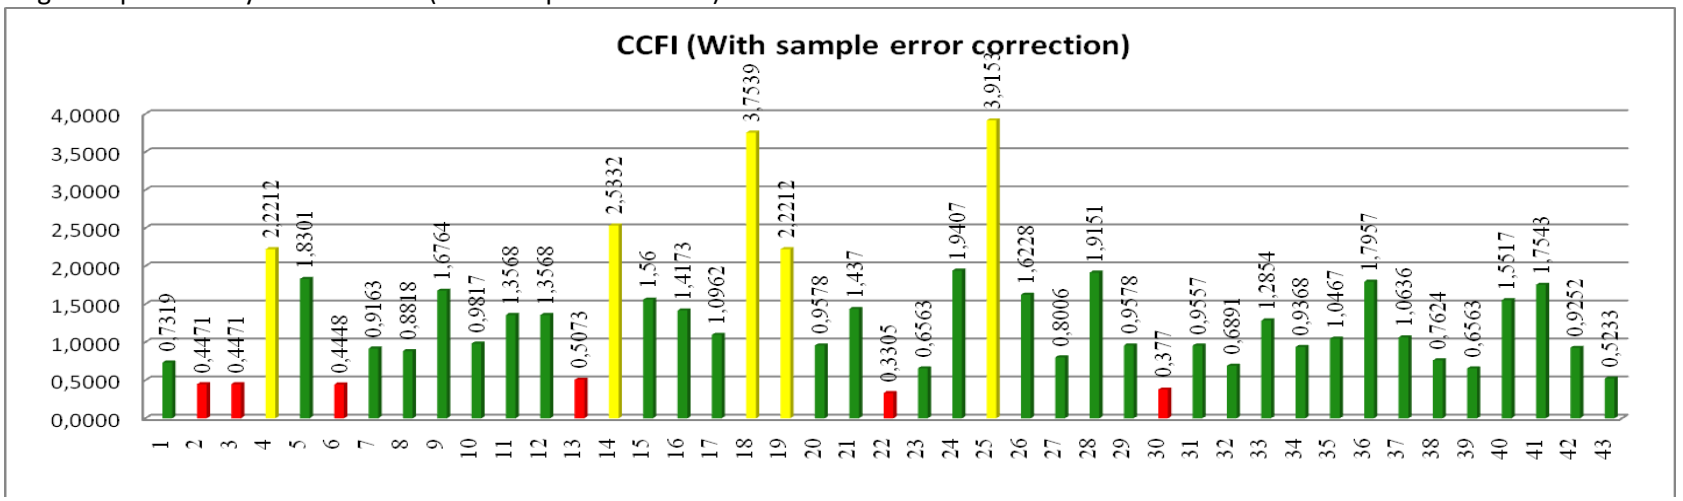

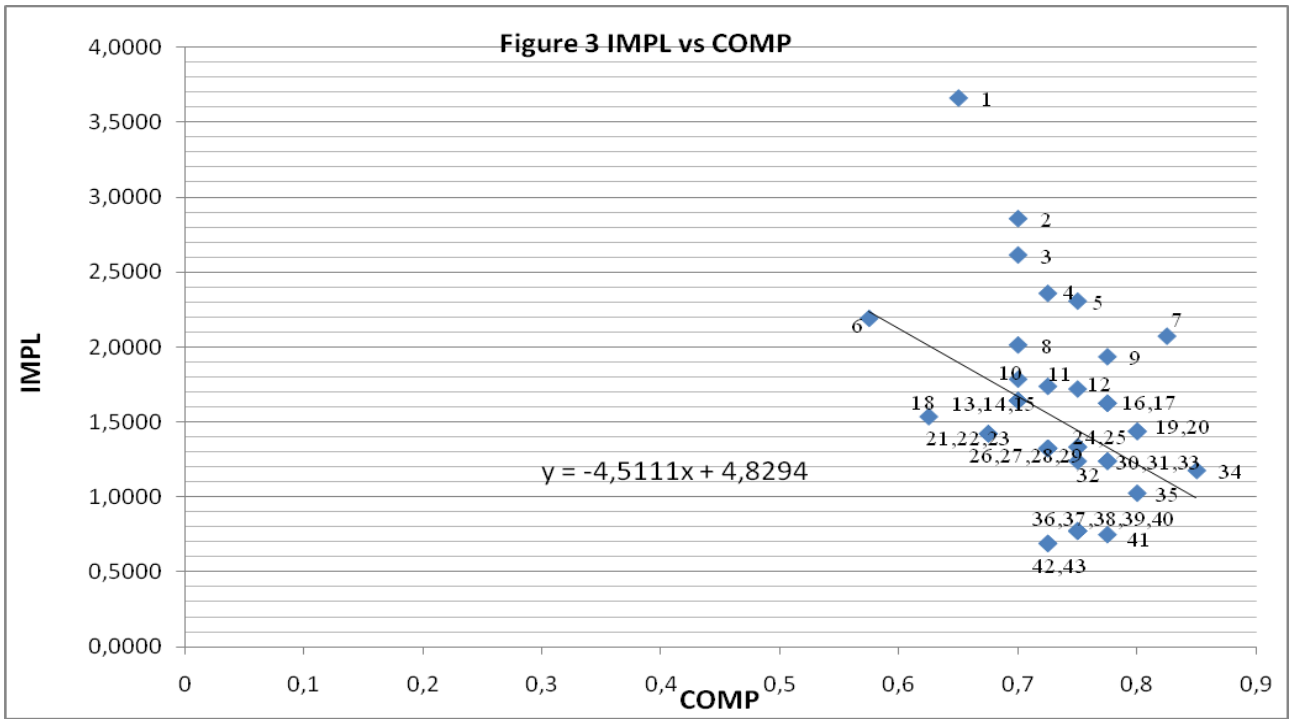

Though CFI and CCFI are highly dependent on STD, they are good critical attribute indicator in comprehensive way. The Managers can allocate resources based on the level or emphasis of criticality (balance with existing resources, new resources). Addition of sample error correction on CFI will give some insight for managers and avoid zero CCFI (If one or both of STD dev is/are zero). The negative correlation from IMPL vs. COMP indicates that the lesser the priority given, the higher critical the attribute and it needs amendments or remedial action to balance the resources. This was applied in communication and implementation of strategies on culturally influenced company (Takala, et.al 2006).

VISUALIZING CRITICALITY AND INTERPRETATION OF THE RESULT

Analysis has been made by using critical factor index that is utilizing expectations, experiences, competitor's performance, gap index, deviations and directions of development. This result is from modified model of CFI that takes in to account the sampling error correction and control limits to clearly see and make balance between high critical factors and lower ones. The managers can get a clue whether they need additional resources or can distribute available fairly from high critical to lower critical (from yellow to red) so as to make green all factors. For instance, assuming we have similar units for different factors e.g. amount of Euros which is allocated for each factor.

Higher critical (HC) = $\sum_{i=1}^{n} U_i - UCL_i$

Low critical (LC) = $\sum_{i=1}^{n} L_i - LCL_i$

Where HC= Higher critical

LC= Lower critical

U_i =Individual factors which are upper than UCL

UCL=Upper control limit from the control chart

$L_{i=}$ Individual factors which are lower than LCL
LCL= lower critical from the control chart
n = number of factors above or lower than UCL or LCL
i = individual factors

Over emphasized: If HC > LC, the company can adjust or balance the resource distribution with the existing facilities/resources under normal situation.

Less emphasized: If HC < LC, the company may face difficulties to adjust or balance the resource distribution with the existing facilities/resources under normal situation.

Fairly emphasized: If HC = LC, at this breakeven point the company may not need balancing or adjusting resources but it need a careful follow up because if one of the attributes/factors disturbed the rest could be affected in both extremes.

In our case, Higher critical (HC) = (2,2212-2,155331)+(2,5332-2,155331)+(3,7539-2,155331) +(2,2212-2,155331)+ (3,9153-2,155331) = 14,6448-10,776655=**3,868145**

Similarly, Lower critical (LC) = (0,585231-0,4471)+(0,585231-0,4471)+(0,585231-0,4448)+(0,585231-0,5073)+(0,585231-0,3305)+(0,585231-0,377)+(0,585231-0,5233) = 4,096617-3,0771=**1,019517**
To sum up, HC>LC so, the company can make resource adjustment/balance by the magnitude of
3,868145-1,019517= **2,848628** gap

CONCLUSION

Several writers indicate service is challenging because of its characteristics like intangibility (cannot be seen and or tasted), inseparability (produced and consumed at the same time), heterogeneity (produced and consumed simultaneously) and perishability (cannot be stored). That is why various technological innovations and its supporting tools and techniques are required on decision making processes. The development of service engineering and service science shows that choosing the clear development targets and creating appropriate indicators on service leads to success. While carrying out service activity assessment using CFI, there should not be too many attributes because the measurement process takes too much time and the target of the development may not come in to existence. In this paper CCFI is used and 6 attributes (red) are found the critical ones (with shortage of resources or under emphasized). On the other hand, 6 attributes were found to be in yellow region that implies the attributes are more than required (over emphasized). So, the manager can have an idea to balance the resources of these attributes by fairly distributing to make all factors in green. The merit of fast, comprehensive and reliable method to identify the critical attributes in order to make managerial decisions at low cost is crucial phenomena and will most probably lead to a further increase of interest of CCFI. However, it still requires further improvement and development and should be tested in various case studies as well. In this paper there are three deliverables, the first one is recognizing the influence of responses' number and avoid zero CFI by adding sample correction error. Secondly, the applications of control chart to determine the three distinct

areas (green, yellow, and red). The third one is application of IMPL vs. COMP that is analysis of emphasized implementation index and evaluation of importance for each attributes.

ABSTRACT

The popularity of the Internet facilitate virtual shopping as one convenience shopping choice for consumers. However, consumers would have different evaluation viewpoints on both shopping processes in term of emotions and shopping value. This study designed two scenarios (an virtual shopping website and a trial physical product) and adopted Consciousness-Emotions-Value (CEV) model to examine the effect of consumer emotion and shopping value on price sensitivity. Consumer innovativeness was proposed to have moderating effect on shopping process. Both online- and paper-based questionnaires were used for the field survey and 403 valid questionnaires have collected. The findings revealed that website quality and product usability have a positive effect on consumer emotions; a positive emotion also resulted in higher hedonic and utilitarian value. However, hedonic value had a negative influence on price sensitivity. This indicates that consumers perceiving a higher hedonic value in the shopping process will have a higher willingness to pay more. In managerial implication we suggested what the manufacturer should look into the product design such as to have more friendly and usable functions. For retailer, they should well trained their sales person to serve customer more professionally. Lastly for internet store, they should have a full information to enhance the confidence and trustfulness of the website. 3D panoramic photo should also included to attract consumer attention during the shopping process.

Keywords: Price Sensitivity, Innovativeness, Website Quality, Product Usability

INTRODUCTION

The online shopping market has grown rapidly for the last two decades. According to the Market Intelligence and Consulting Institute (MIC, 2009), almost 90% of the population have experience in shopping online, and the sales have increased 30% in that period. Taiwan online market has a large variety of product choices, including clothes (the largest market), beauty care (second) and consumer electronics product (third). Although online market offers more opportunities for interactive and personalized marketing compared to the

physical market environment. However, consumers are unable to touch and try out the physical products directly in the online environment. Due to insufficient of physical product knowledge, online purchases may be affected by information shortage, perceived risk of trade, perceived price of products, and may, as a result, ultimately affect their willingness of purchasing.

Alba et al. (1997) pointed out that online consumers are able to obtain more information about both price and non-price attributes, and ultimately increase consumer price sensitivity especially when they can obtain more information on price. However, if the quality of the product website is low (such as lacking in information and of poor design, among other faults), price sensitivity may not be affected in the shopping process. That revealed not only products information is important, but website quality may also a driver of consumer price sensitivity. Consumers will have higher price sensitivity when they obtain more information.

Several researches have adopted Consciousness-Emotion-Value (C-E-V) model (Holbrook, 1986) to study the similar area of online or physical shipping environment (Eroglu, Machleit and Davis, 2003; Fiore, Jin, and Kim, 2005). However, there are some areas remained unexplored. Firstly, the "consciousness" is always focused on either website atmosphere, image interactivity features or website social cues when it comes to online shopping (Eroglu et al., 2003; Fiore et al., 2005). And secondly, prior research on product price have mostly focused on online or physical shopping separately, and the product categories include grocery items (Wakefield and Inman, 2003), clothing (Ramirez and Goldsmith, 2009) and digital cameras (Grewal, Munger, Iyer and Levy, 2003).

This study adopted two consciousnesses (website quality and product usability) to examine consumer response toward a high-tech product when they involved in online and physical shopping which remained unexplored in the prior research. By doing so, the study designed two situations - online shopping and physical shopping with a trail physical product to examine consumer price sensitivity in both environments. It is very important to understand the concerns of consumer behavior from different viewpoints that what the elements are to influence their price sensitivity during the shopping process.

In addition, the study proposed consumer characteristic (e.g., innovativeness) have moderating effect on the online shipping process. High innovative or low innovative consumers would have difference behavior in searching and accepting of product information or even have different attitude towards purchasing a high-tech product. As high-tech products (e.g., digital camera) were used as research object, therefore, we try to adopt consumer innovativeness as moderator to examine its moderating effect on the relationship between consciousness and emotions when consumers shop in either an online or physical retail environment.

Digital cameras are one of the top ten products that people buy online (MIC, 2009). Consumers can easily purchase a digital camera from the online shopping websites such as Yahoo and PChome, as well as brick-and-mortar stores such as Carrefour or other electronic stores. Besides, digital camera is one of the most common and popular products in consumer electronic market, almost every consumer own one on hand in average (E-ICP

database, 2008). It has many configurations and designs that include exterior (e.g., color, weight, and shape) and interior (interface performance and ease of use). All these product designs will expect to affect product usability of the user, even the behavioral response. In addition, heavy Internet users are found to be younger, higher educated, and higher income (Porter and Donthu, 2006), which is similar to the characteristics of frequent purchasers of high-tech products (Meuter, Bitner, Ostrom and Brown, 2005).

Based on above discussions, the study conducted two studies to complement the research gaps. Study one established a virtual shopping environment (a website), and provided different level of product information except price for consumers to browse through. Study two provided a physical product (a digital camera) for consumers to try on. The study compared consumer price sensitivity for both online and physical situations by applying CEV model. The constructs included website quality, product usability, consumer characteristics (i.e., innovativeness), emotion (i.e., pleasure, arousal, and dominance), and value (i.e., hedonic and utilitarian) to examine different level of price sensitivity in both online and physical situations. The main objectives of the study are: (1) to propose a research model by using two antecedents (website quality and product usability) to examine their effect on price sensitivity through the path of emotions and shopping value. (2) to test whether consumer innovativeness has a moderating effect on the relationship between website quality, product usability and emotions. And (3) to compare consumer price sensitivity levels between online and physical situations.

LITERATURE REVIEW AND HYPOTHESES DEVELOPMENT

Consciousness–Emotion–Value (C–E–V) model

The Consciousness–Emotion–Value (C–E–V) model of the consumption experience is dynamic (Holbrook, 1986), with feedback loops between each component. The first component, *consciousness*, includes cognitions or beliefs about consumer products as well as mental events such as fantasies or imagery during the consumption experience. The second component, e*motion* expands beyond that affect (such as a favorable disposition toward shopping or enjoyment) including subjective feeling states, such as pleasure and excitement. The last component, *value* indicates what the consumer perceives as gains from the consumption experience. This includes hedonic value and aesthetic pleasure from sensory elements during consumption.

The shopping value (hedonic value and utilitarian value) is an issue of influencing consumer shopping behavior. In between product price is also the key to determine whether to purchase from online or brick-and-mortar stores especially high-tech products are always considered as higher price level products. Therefore, this study especially brings price sensitivity into the C-E-V model as a dependant variable and examines consumer price sensitivity in the shopping process with regard to high-tech products. Besides, personal characteristic such as innovativeness could be an element of influencing consumer decision making of purchasing high-tech products. As high innovative consumers are more likely to purchase high-tech products (Meuter et al., 2005); therefore, innovativeness was included in the C-E-V model as a moderator between the relationship of consciousness and emotions.

In line with a C–E–V approach, this study is designed to test the relationship between consciousness (website quality and product usability), emotion, value (shopping value) and personal characteristic (innovativeness) to examine whether different consumers who shop on the Internet or in brick-and-mortar stores can be stimulated by website quality and product usability consequently will have different emotions and shopping value that affect their product price sensitivity.

Consciousness - Website Quality

Research on website quality can be classified into two different research streams. The first stream is identifying the attributes that contribute to website quality and has resulted in the development and testing of instruments to measure website quality. The dimensions are including website appearance, content or information, and the quality of online technical websites, including such attributes as response time or interaction (Aladwani and Palvia, 2002). His results revealed that web quality could be measured by web appearance, web content (divided into special content, and content quality), and technical adequacy. *Web appearance* refers to website organization, proper use of fonts, proper use of colors, proper use of graphics, and graphics-text balance, among others. *Web content* includes special content that consumer can find contact detail about product information as well as consumer policy; and content quality refers to overall information about the product, such as its usefulness, completeness, and configuration, and etc.. *Technical adequacy* refers to security, availability, reliability, personalization or customization, interactivity, and ease of access, and etc..

The second stream is an examination of the website quality effect on consumer perceptions and intentions, which is not the focusing area of this study. Accordingly, this study adopts the four dimensions that stated by Aladwani and Palvia (2002) and defines it as users' evaluations of website features meeting their needs and reflects four degrees: web appearance, special content, content quality and technological adequacy of a website when they searching a high-tech product.

Consciousness - Product Usability

Consumer electronic products such as mobile phone, digital camera, and etc. have integrated various technologies into different areas such as video, audio, computer software and hardware. However, multifunctional product doesn't mean it has higher level of usefulness or usability. It can be more complicated and hard to use. This trend makes the usability become one of the most important design issues. Based on the concept of human-computer interaction (HCI), usability was originally defined as the degree of ease of use (by subjective assessment) and effectiveness of use (by objective performance) within the specified range of users, tasks, tools, and environment (Shackel, 1984).

Han, Yun, Kwahk, and Hong (2001) define product usability more specifically as the degree of satisfying the users in terms of both the performance and the image and the impressions felt. There are two dimensions have been proposed: performance, and image/impression. Performance can be classified into three categories: *perception/ cognition* consists of examining how well the users perceive and interpret the interface of a product;

learning/memorization explains how fast the users get used to the product and how well they remember its functions; and *control/action* represents the users' control activity and its results. Image/ impression also can be classified into three categories: *basic sense* includes the primitive image and impressions stemming from the product; *description of image* explains the image and impressions of a product that users will describe based on their experience; and *evaluative feeling/attitude* explains the attitude or judgmental feelings as a whole about the product.

Accordingly, the study defines product usability as the satisfaction level of high-tech product users with regard to both the performance and the image/impressions they feel. This study expects that these two factors will affect consumer emotions during the shopping process.

Emotions - Pleasure, Arousal, and Dominance

Consumer emotional contribution is an essential element for decision making when doing shopping (Zaltman, 2003). Emotion can be considered as a mental readiness that arises from appraisals of events or of one's thoughts (Bagozzi, Gopinath and Nyer, 1999). According to the environmental psychologist Mehrabian and Russell (1974), all emotional responses to physical and social environments can be captured with three dimensions: pleasure, arousal, and dominance (PAD). These three dimensions can adequately represent all of the diverse human emotional reactions to environment and measure one's feelings that, in turn, influence behavior.

Pleasure refers to the degree to which a person experiences an enjoyable reaction to some stimulus in the shopping environment; it consists of happiness, enjoyment, and satisfaction. Pleasure is found to have positive relationship with consumer behavior as they will spend extra time on shopping and consumption as well as on satisfaction (Liu and Arnett, 2002). *Arousal* is defined as a combination of mental alertness and physical activity which one feels stimulated, excited, or alert in the shopping environment. More specifically, arousal demonstrated to increase shoppers' intentions to remain and to spend money in conventional retail environments (Foxall and Greenley, 1998). *Dominance* refers to the extent to which the individual feels restricted/ unrestricted or in controlled or uncontrolled the shopping environment. Virtual online shopping environments are more technically complicated and information-intensive than traditional ones. It influences the extent to which online users perceive themselves to be able to dominate their interaction with the environments they encounter. Dominance specified in the environmental psychology model, has been also found to have significant impact on users' behavioral decision.

Shopping Value - Hedonic Value and Utilitarian Value

Shopping value is an evaluation subject after one has interaction experience with the activities, and it is a key outcome in a general model of consumption experiences (Babin, Darden and Griffin, 1994). Perceived value is defined as the consumer assessment of what is received relative to that which is given (Zeithaml, 1988), and it is recognized as an important marketing construct due to its relationship with quality, customer satisfaction and loyalty (McDougall and Levesque, 2000). As a starting point, consumer behavior researchers

recognize two pervading, dichotomous motivations for shopping: hedonic and utilitarian (Hirschman and Holbrook, 1982).

Hedonic value is an outcome related to spontaneous responses that are more subjective and personal (Babin et al., 1994). Hedonic values, such as entertainment, exploration, and self-expression (Ailawadi, Neslin and Gedenk, 2001), derive more from fun and enjoyment than from task completion and are non-instrumental, experiential, and affective (Chaudhuri and Holbrook, 2001). *Utilitarian value* results from the conscious pursuit of an intended consequence (Babin et al., 1994). It is primarily instrumental, functional, and cognitive and represents customer value as the means to an end (Chandon et al., 2000).

In the consumer shopping process, the hedonic motive relates to experiential shopping where the fun, entertainment and escapism of the shopping process may be paramount for acquiring products. Consumers often shop for an appreciation of the experience rather than simply for task completion (Childers, Carr, Peck and Carson, 2001). In contrast, the utilitarian motive underscores task-specific, rational and deliberate product acquisitions where shopping is perceived to be work or a necessity (Babin et al., 1994) and the task-specific use of shopping, such as purchase deliberation (considering the product, service, and price features before actual purchase) (Hoffman and Novak, 1996). Though usually prompted by one overriding motive, a shopping incident may provide both utilitarian and hedonic value (Babin et al., 1994).

This study examines consumer's shopping value in the high-tech product shopping process for both internet and brick-and-mortar stores. We define hedonic value as consumer experience fun, entertainment and escapism of the shopping process. As the study are not focusing on the price feature, we therefore define it as task completion, convenience and deliberate product acquisitions, except price, where shopping is perceived to be work or a necessity.

Innovativeness as a Moderator

Rogers (1995) defined innovativeness as the early adopter of new technology. Cotte, and Wood (2004) defined innovativeness as the willingness of embrace change, try, and buy new products more often and quickly than others. Personal innovativeness in some individuals means that they are willing to take risks. In innovation diffusion research, highly innovative individuals are showed to be active seekers of new ideas. They are able to cope with high levels of uncertainty and develop more positive intentions to accept. (Lu, Liu, Yu and Wang, 2008).

An alternate concept of innovativeness that proposed by Goldsmith and Hofacker (1991) as domain specific innovativeness (DSI). It has been found to have associated with wide range of innovation adoption. DSI aims to explicate the narrow facets of human behavior within a person's special interest domain (Midgley and Dowling, 1993). It captures the individual's predisposition toward the product class, and refers to the tendency to acquire new products or related information within a specific domain (Goldsmith and Hofacker, 1991). Of pertinence here, Goldsmith (2001), and Blake, Neuendorf and Valdiserri (2003) applied the DSI measure to online shopping. In this study, we defined innovativeness as the relative

willingness of a person to search, try or buy a new high-tech product regardless of the virtual or physical shopping environment.

High-tech products have higher uncertainty and complexity; consumers will need to put more effort and time to familiarize with it. When consumers venture into the adoption of new products, they face a dilemma between desirable and undesirable consequences of the product adoption and hence face a risky decision (Hirunyawipada and Paswan, 2006). Although several studies (Conchar, Zinkhan, Peters and Olavarrieta, 2004) have suggested that perceived risk may have negative influence against the decision to adopt new products, actual adoption is a function of consumer receptivity toward the specific product, and the perception of risk may not have much to do with actual adoption. However, it may lead to consumers seeking more information in order to ascertain the level of risk, mitigate the perception of risk, or manage the perceived risk (Hirunyawipada and Paswan, 2006). Therefore, consumer innovativeness serves an important role in the adoption of a high-tech product and determines whether they will accept the risks involved, even if this affects the consumer value toward the product.

Price Sensitivity

Price sensitive consumers seek low prices and are less likely to buy when prices rise. Contrary, less price sensitive consumers are willing to pay higher prices for the same goods than are price sensitive consumers and are more willing to buy if prices go up (Foxall and James, 2003). The definition of price sensitivity basically can be classified into two different categories. Firstly, Wakefield and Inman (2003) defined price sensitivity as individuals perceive and respond to the changes or differences in prices for products or services. And secondly, referring to the weight attached to price in a consumer valuation of a product's overall attractiveness or utility (Erdem et al., 2002). This study focuses on the effects of price sensitivity and does not examine the price changes. Therefore, we define it as the weight attached to price in a consumer valuation of a high-tech product's overall attractiveness or utility in the shopping process, which is similar to the second definition.

Price sensitivity is one of the behavioral intention factors that affect consumers' behavior. Not many studies have specialized in research on the effect of price sensitivity, linking consumer characteristics or shopping environments, especially in online websites, together with price sensitivity. Degeratu, Rangaswamy and Wu (2000) found that consumers who shop online have more price sensitivity than they do in physical environments and will compare prices carefully on websites. Digital camera is one of the high-tech products that upgrade rapidly. Consumers may need more information to compare each version, including the product configurations as well as prices. But not all online consumers are willing to purchase it online as they haven't seen the physical product and have no chance to try it. The study intends to examine the website factors (the website quality) and the physical product factors (the product usability) that may influence consumer price sensitivity while they are shopping online or brick-and-mortar stores.

Website Quality, Product Usability and Emotions

The first stimulus variable: website quality. Mehrabian and Russell (1974) classical affect model has supported the notion that stimuli in the physical environment influence people's emotions (such as arousal and pleasure responses) in brick-and-mortar stores (Baker, Levy and Grewal, 1992), as well as internet stores (Eroglu et al., 2003). Although in many instances, the dominance dimension is not included, probably due to Russell's (1979) recommendation that pleasure and arousal alone can adequately represent the range of emotions exhibited in response to environmental stimuli. In the online retail context, it is possible that shoppers choose online rather than traditional retail outlets for the increased control over the shopping situation. Conversely, online shoppers may feel a decreased level of dominance in situations where download times are slow, when there is no way to contact the retailer for more information, when the site is difficult to navigate, or when links are missing or inactive.

Recently, research has cited many examples showing the relationship of website quality to emotions. For instance, Fiore et al. (2005) found the image interactivity feature of shopping websites to be a stimulating experience that was positively associated with the level of emotional arousal and pleasure. Ethier et al., (2006) showed that website quality had a positive impact on the cognitive appraisal of a situational state, which in turn influenced emotions experienced by consumers while shopping online. When consumers have a more positive evaluation of an online shopping experience, they experience a higher level of the intensity of emotions such as enjoyment, joy and pride. However, the more negative the evaluation, the higher the intensity of dislike and frustration. Hence, the first hypothesis is proposed:

Hypothesis 1: Website quality can positively affect the emotions (pleasure, arousal, and dominance) of high-tech product shoppers.

Another stimulus variable is product usability. Depending on the level of expectancy confirmation or disconfirmation on important benefit dimensions, a product may evoke positive, negative, or a mixed set of emotions (Bagozzi et al., 1999; Chaudhuri, 2006). Many researches emphasize the effects of product performance and design (i.e., product form, product appearance, product usability) on consumer response. Such as, Bloch (1995) pointed out that product design can affect consumer cognitive and affective responses, include positive and negative aesthetic responses. Besides, Garber (1995), and Crilly, Moultrie and Clarkson (2004) argued that product appearance, product categorization, product form (e.g., colors, texture, materials), and visual perceptions can affect consumer cognitive and affective responses effectively.

In more recently, the Pre-purchase Affect Model (PAM) (Seva, Duh and Helander, 2007), a conceptual model of product emotion that includes product attributes, purchase criteria, pre-purchase affect and purchase intention was proposed. This model connects product attribute with pre-purchase and accepts the positive relationship caused by purchase criteria as the moderator. Seva et al. (2007) suggested that the product attributes of a mobile phone positively affect pre-purchase emotions. For example, the width of the phone's body significantly affected feelings of contentment and encouragement to buy. This

study expects product usability (performance and image/impressions) would have positive effect on consumer emotions (pleasure, arousal, dominance) toward the physical shopping process. Hence, the second hypothesis is proposed:

Hypothesis 2: Product usability can positively affect the emotions (Arousal, pleasure and dominance) of high-tech product shoppers.

Moderating Effect – Innovativeness

Rogers (1995) noted that people are more innovative when they feel comfortable with technology. When consumers feel anxiety, fear, and apprehension in using technology tools, they will avoid to change, buy, and use a new one (Meuter et al., 2005). These consumers therefore possessed a negative attitude towards technological products. Researchers have noted that adoption of online shopping methods is a functional behavior not only of attitudes, needs, and experiences, but also of personal characteristics such as innovativeness (Robinson, 2005). More specifically, consumers who have higher innovativeness are more likely to seek multiple sources of information and new experiences that stimulate their senses as they form their perceptions toward a technology (Agarwal and Prasad, 1998).

This study proposes that innovativeness will have moderating effect on the relationship between consumer perception regarding shopping website quality, product usability, and emotions. Therefore we infer that high innovative consumers are easy to fall into the enjoyment of high-tech product shopping environment (such as surfing on the high-tech product website). Besides, we also believe that when the consumers once use the new product, they will be more likely trying it. That will result in the consumer perceiving the stimulus and experiencing a higher degree of emotions than the consumers with low innovativeness. Therefore, the study infers highly innovative consumer would perceive website quality and product usability to have more intense emotions when the website or the product designed fantastically. The study proposes that the high innovativeness of consumer characteristic has moderating effect on the relationship between product usability and emotions. The higher the consumer innovativeness is, the stronger relationships will be between website quality, product usability and emotions.

Therefore, this study examines “high-tech product innovativeness” as the moderator between website quality, product usability and emotions. Hence, the third and fourth hypotheses are proposed:

Hypothesis 3: Innovativeness has moderating effect on the relationship between website quality and emotions of high-tech product shopping process.

Hypothesis 4: Innovativeness has moderating effect on the relationship between product usability and emotions of high-tech product shopping process.

Emotions and Shopping Value

Increased arousal, heightened involvement, perceived freedom, fantasy fulfillment, and escapism all may indicate a hedonically valuable shopping experience (Hirschman, 1983).

Pleasure should increase consumer hedonic value through fun or entertainment and/or their utilitarian value by facilitating of completing product acquisition (Isen, 1987). Hedonic values are an expression pleasure and anticipation; while utilitarian benefits are related to task completion and are not necessarily pleasurable or anticipated, but instead merely indicate tolerance or sometimes apprehension.

Babin et al. (1994) found that the emotions of shopping process are positively correlated with both hedonic value and utilitarian value. They found not all consumer behavior is directed toward satisfying some functional, physical, or economic need. In addition, the validity of hedonic and utilitarian shopping value is supported by its correspondence with a number of theoretically related individual difference characteristics, behavioral measures, and situational factors. Wang et al. (2007) investigated how the social cues inherent in avatars influence affects and shopping value. They found social cues induce perceptions of website socialness, leading to increased pleasure and arousal, both of which positively influence flow, hedonic and utilitarian value, and patronage intentions. Thus, this study predicts the following hypotheses:

Hypothesis 5a & 6a: In the online shopping situation, shopper emotions (arousal, pleasure and dominance)can positively affect their hedonic shopping value (H5a) and utilitarian shopping value (H6a).

Hypothesis 5b & 6b: In the physical shopping situation, shopper emotions (arousal, pleasure and dominance)can positively affect their hedonic shopping value (H5b) and utilitarian shopping value (H6b).

Shopping Value and Price Sensitivity

Interestingly, the price elasticity of detergent is quite a bit larger than the food and toiletries, which are relatively more hedonic categories (Tellis, 1988). The differences in elasticity for these products may also be influenced by varying promotional frequencies of functional and hedonic goods. Wakefield and Inman (2003) suggested that consumers are lower prices sensitive when making a hedonic purchase. Because hedonic products always provide hedonic value such as entertainment and enjoyment, we propose that the hedonic value for a consumer will be higher as a result of experiencing an online shopping website and that price sensitivity will result to be lower.

When the product performance and function fit the user needs, we then consider utilitarian value to have a negative relationship with price sensitivity; however, the negative degree may be lesser than that of hedonic value. Bigné and Andreu (2004) pointed out that when consumers are experiencing greater pleasure and arousal that will show an increasing level of satisfaction as well as more favorable behavioral intentions, meaning loyalty and willingness to pay more. This reveals when consumers perceive the service or product have great quality, they experience positive emotions toward the shopping process and have more willingness to pay more. Hence, this study suggests that both hedonic and utilitarian values will influence price sensitivity negatively.

Hypothesis 7a & 8a: In the online shopping situation, shopper hedonic shopping value (H7a) and utilitarian shopping value (H8a) have negative relationship with their price sensitivity of purchasing high-tech products.

Hypothesis 7b & 8b: In the physical shopping situation, shopper hedonic shopping value (H7a) and utilitarian shopping value (H8a) have negative relationship with their price sensitivity of purchasing high-tech products.

RESEARCH FRAMEWORK AND METHODOLOGY

Research Framework

The study adopted Consciousness-Emotions-Value (C-E-V) model to examine whether the process of online and physical shopping such as consciousness, emotions, and value would have effect on consumer price sensitivity. We designed two stimuli (online website and physical trial) to carry out the study as consciousness; the elements included website quality (Study A) and product usability (Study B). The conceptual framework of the two studies was showed in Figure 1.

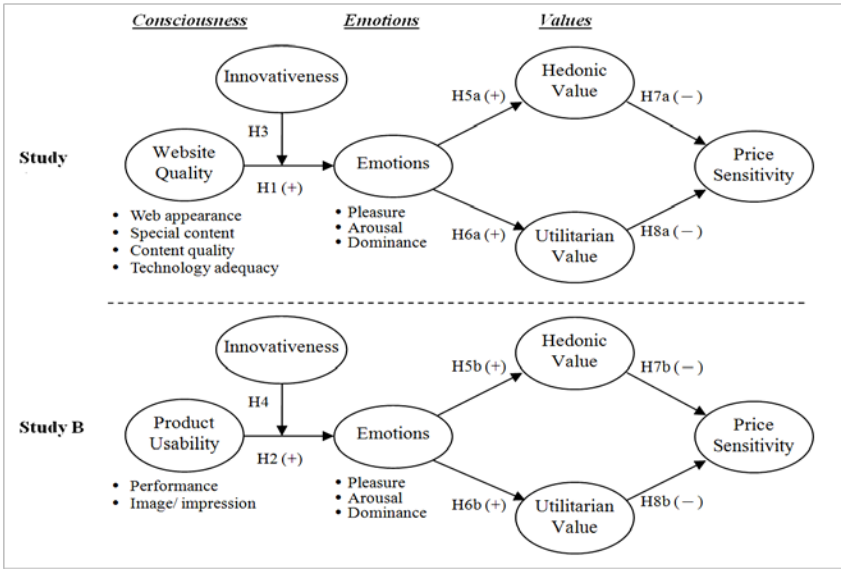

Figure 1: Conceptual Framework of Study A (online) & Study B (physical).

Research Design

The study adopted previous research measurement to measure all research constructs, and modified them based on the study scenario. Participants who had experience in online and physical shopping were legitimate to respond to the study. The participants were asked by both online- or paper-based questionnaire to express their opinions of shopping experiences. All measurement used seven point Likert scale, except for the construct of price sensitivity. There were eight items to measure this construct, the first five items were seven Likert scale, but the last three were asking the price range, such as “how much you willing to pay for the digital camera?” which adopted from Grewal et al. (2003).

Stimuli Selection

First of all, two different types of digital cameras were chosen based on the E-ICP data-base (2008), which were the top ten most popular brands in the electronic market. We named the two products as product "A" and "B". For Study A, the website quality stimulus, three different levels of shopping website (including information, content, and appearance) were designed to distinguish the consideration of C-E-V line more efficiently, and the product price was not showed. Participants were randomly select a questionnaire and linkage for surfing and answering the whole questionnaire except for the product usability section.

For Study B, the product usability stimulus, each participants were assigned one of the products randomly and asked to try on the functions such as taking picture, adjusting the monitor light, photoflash or night scenes photo and etc.. The brand names were covered to avoid any influenced by the brand perception. It is believed that respondents could experience the digital camera interface on trail, and evaluate the product design such as the color, weight, shape, and comfort, which were related to the product usability performance, and image/ impression dimension. Participants were then asked for answering the whole questionnaire except for the website quality section.

Pilot Test

Before the formal questionnaire was formed, a pilot test was conducted to ensure the measurement reliability. There were 33 questionnaires have collected for Study A, the website situation, and 30 for Study B, the product situation. All questionnaires were valid except for two from the Study A. The results of pilot test showed all item-to-total and Cronbach's alpha were close to or above the thresholds (0.5 and 0.7) except for the item 4 and 5 in website quality dimension – technical adequacy scale, and the item 4 in the product usability dimension – image/ impression scale. Therefore, these three items were deleted from the formal pool of questionnaire. In order to improve the items' reliability, we also modified those items that lower but close to the threshold.

RESULTS OF DATA ANALYSES

The study used online-based questionnaire for Study A and paper-based for Study B. As results, Study A had collected 312 responses and Study B had 161 responses. There were 59 invalid for Study A and 11 for Study B. The invalid respondents were mostly categorized as such due to incomplete questionnaires or answering the reversed items in the same direction.

The demographic analysis revealed that the gender proportion was almost equal (Males=51.4%, Females=48.6%) and that majority of age range was from 20-29 (81.4%). Most of respondents had earned a bachelor's degree or higher (93.3%). Due to the fact that the majority of the respondents were students (53.8% student, 42.8% working), their incomes were mostly below US$600 (72.5%).

Confirmatory Factor Analyses (CFA)

The study used AMOS 5.0 and adopted two-step approach for the formal data analyses. Before proceeding to test the CFA, we firstly check out the items reliability by using the thresholds of item-to-total (0.5) and Cronbach's alpha (0.7). As results, five items were deleted due to low item-to-total, and all alpha value were above the threshold.

Under the CFA assessment, we used chi-square (χ^2/df = < 3) to examine the model fit. Due to the significant level of chi-square is affected by increasing of respondents; therefore, more indices are used. Table 1 exhibited the criteria and the results of model fit.

Table 1: Measurement Model Fit for Confirmatory Factor Analyses.

Model Fit Indices	Study A	Study B	Recommended Value (Hair et al., 2006)
Chi-square/ *df*	2.058 (*p*=.000)	1.862 (*p*=.000)	≤ 3
Goodness of Fit Index (GFI)	.854	.810	> .80
Adjusted Goodness of Fit Index (AGFI)	.816	.793	> .80
Comparative Fit Index (CFI)	.954	.925	> .90
RMSEA	.065	.076	< .08

The CFA results including standardize factor loading magnitude, and convergent validity analysis: average variance extracted (AVE) and composite reliability (CR). All factor loadings were significant (t > 3.84) and above the threshold of 0.5 (Hair et al., 2006). We assessed AVE and CR value separately by the Study A and B as showed in Table 2. The results showed all AVE and CR value in both studies were above the thresholds of 0.5 (Hair et al., 2006), and 0.7 (Fornell and Larcker, 1981) respectively, except for the construct of product usability of Study 2. The study found that the respondents were mostly answered different directions for the questions of the product usability's dimensions (performance and image/impression). This might be the reason why it had lower AVE and CR value.

Table 2: Convergent Validity and Reliability Analysis.

Observed Variables (Study A and Study B , *n*=403)	α	Study A		Study B	
		AVE	CR	AVE	CR
Website Quality (Study A, *n*=253)	.956	.705	.904	-	-
Product Usability (Study B, *n*=150)	.938	-	-	.433	.604
Emotions	.915	.552	.774	.629	.835
Hedonic Value	.920	.838	.935	.682	.867
Utilitarian Value	.929	.833	.935	.627	.868
Innovativeness	.891	.536	.887	.575	.904
Price Sensitivity	.902	.776	.911	.749	.898

Discriminant validity, the study calculated the AVE for all pairs of constructs and compared the square root value to the correlation between the two constructs of interest (Fornell and Larcker, 1981). In order to demonstrate the original value of correlation estimation, the square root of the AVE was used as a diagonal value to contrast with the original value of the correlation estimation. As the results all correlation estimation for both studies was slightly higher or lower than the diagonal value, except for the product usability of Study B

as showed in Table 3. That revealed product usability had correlation with other constructs. Due to the nomological reasons that the concepts of product usability was adopted from Han et al. (2001), and several prior studies had applied it to examine consumer electronic products such as MP3/CD players (Eraslan, 2009), mobile phones (Yun et al., 2003) and screening products (Han and Yang, 2004). Therefore, this construct should be suitable for our study. Hence, we remained it for further analyses.

Table 3: Discriminant Validity Analysis.

Construct	Inter-Construct Correlation					
Study A	WQ	EM	HV	UV	PS	INN
Website Quality	**.839**					
Emotions	.834	**.743**				
Hedonic Value	.808	.754	**.910**			
Utilitarian Value	.836	.773	.903	**.913**		
Price Sensitivity	-.585	-.683	-.718	-.680	**.880**	
Innovativeness	.036	.152	.133	.069	-.223	**.732**
Study B	PU	EM	HV	UV	PS	INN
Product Usability	**.658**					
Emotions	.982	**.793**				
Hedonic Value	.943	.744	**.826**			
Utilitarian Value	.953	.728	.725	**.792**		
Price Sensitivity	-.880	-.642	-.695	-.597	**.866**	
Innovativeness	.556	.370	.419	.408	-.481	**.758**

Notes: Diagonal value was square root of AVE value.

Structural Equation Model (SEM) Analysis

The study used maximum-likelihood estimation to assessed SEM analysis. All coefficients were standardizing. A homogeneity of variance test had been conducted; the results revealed they have no significant different between the two groups of respondents. It revealed the two groups of data were appropriate for SEM analysis.

The same model fit indices and criteria were used in the full model analysis, such as GFI, AGFI, CFI and the RMSEA. The model fit results and the path analysis with standardize coefficients of Study A and B were showed in Figure 2 and 3. It revealed both models had good fit as all indices were above the requirement values. Besides, there were five paths for the main effect in each study. It revealed all hypotheses testing were significant and supported statistically except for the hypothesis 8a, and 8b which showed insignificant. Furthermore, the path of H2, product usability towards emotions demonstrated a beta value which larger than 1 (β = 1.094). Since in the earlier discriminant analysis was also not fulfilling; therefore, we intended to modify the model of Study 2 for further analysis.

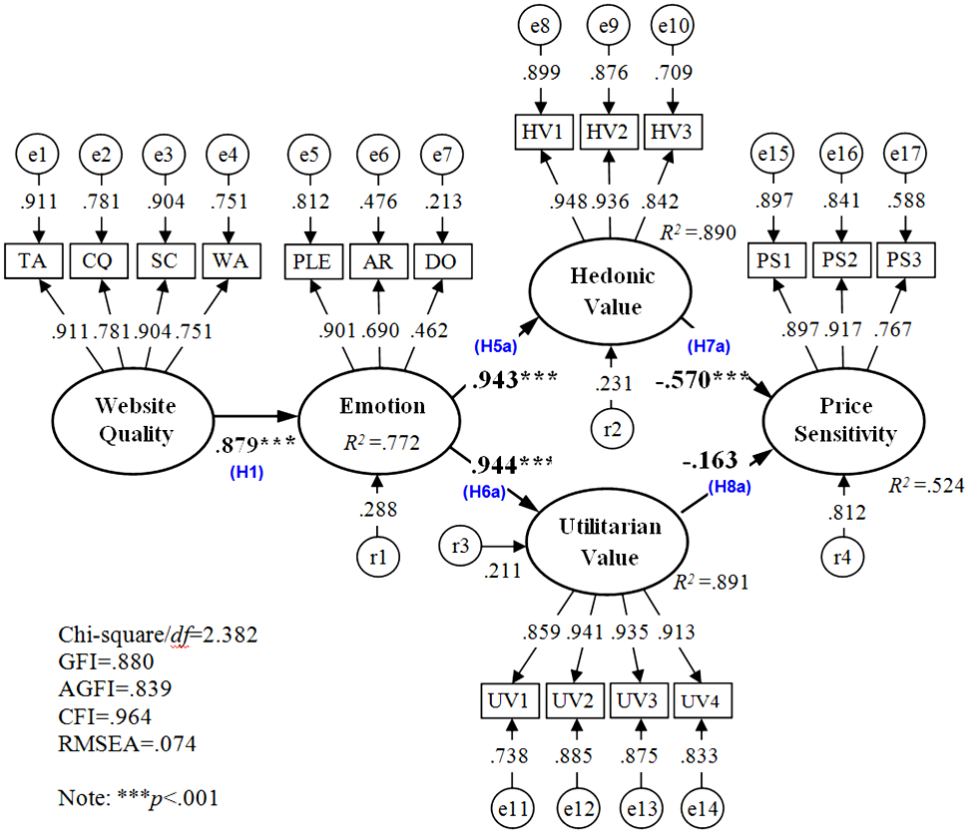

Figure 2: Results of Structural Equation Modeling- Study A.

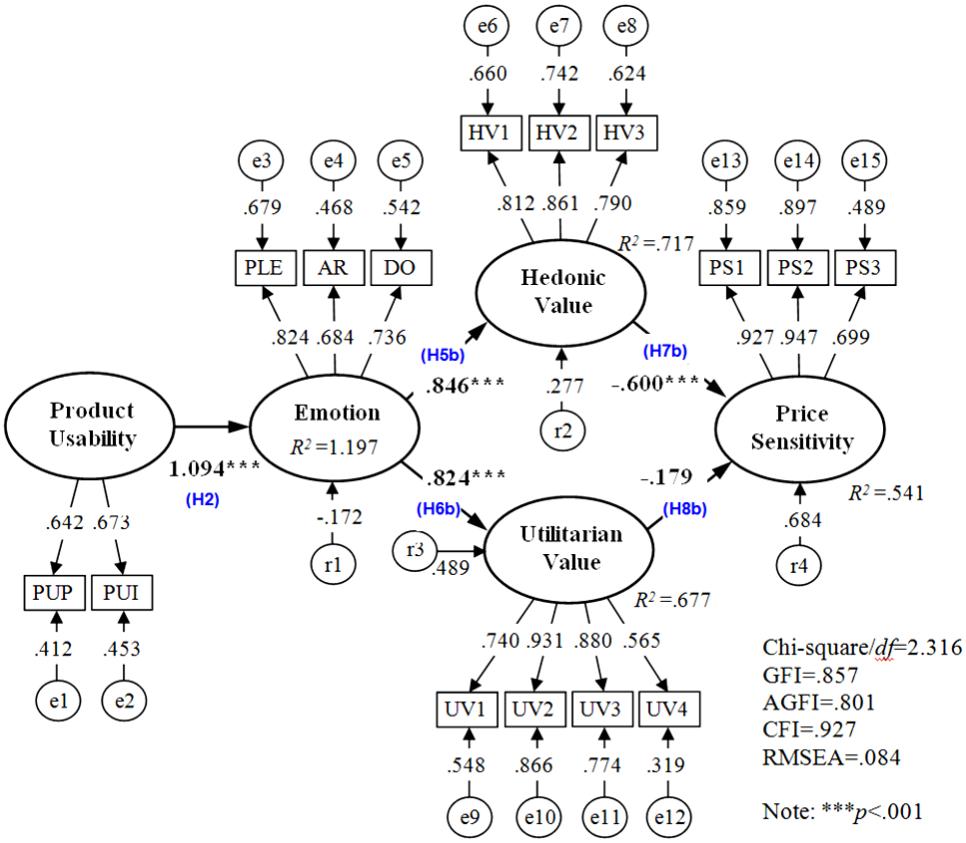

Figure 3: Results of Structural Equation Modeling- Study B.

As mentioned earlier, the respondents mostly answered the questions of the two dimensions of product usability (performance and image/ impression) in different directions. Therefore, we intended to separate the two dimensions into two independent variables to test the model. The hypothesis was named as 'H2p' for performance and 'H2i for image impression. The path diagram and model fit results of the modification model was showed in Figure 4. They had a better results for the hypothesis H2p (β=.472, p=.000) and H2i (β=.532; p=.000). It could explain that the product image/ impression would have higher effect on consumer emotion during the shopping process.

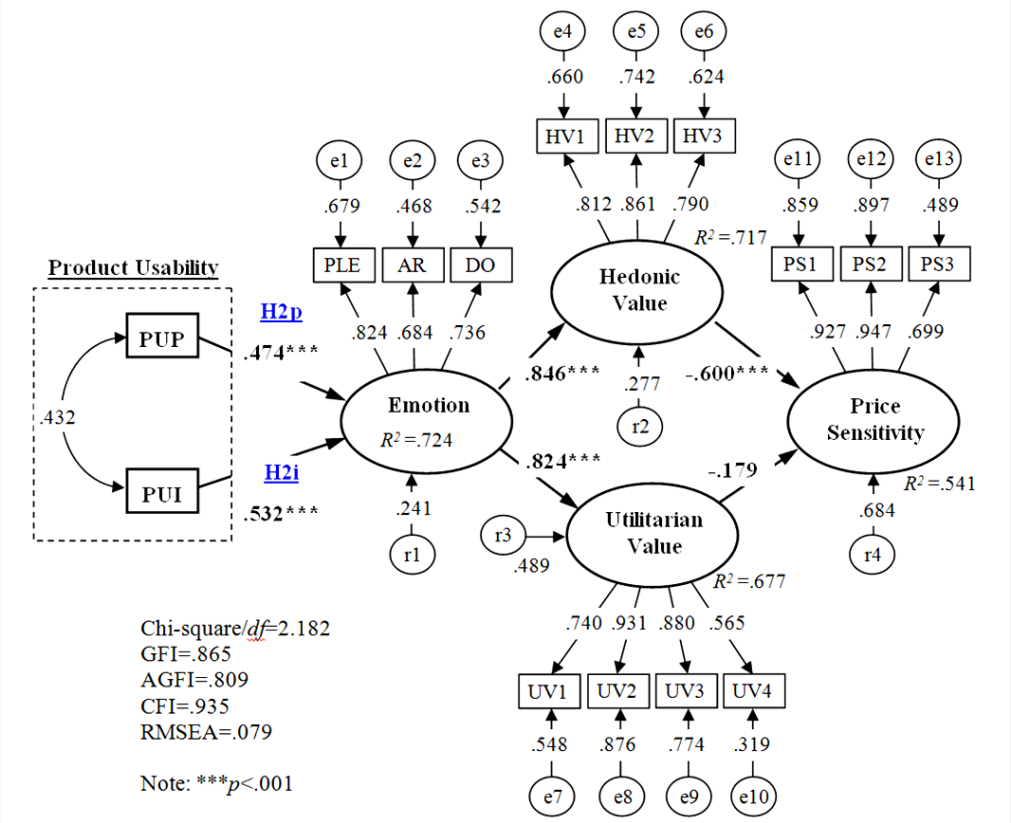

Figure 4: Path Diagram of the Modification Model (Study B).

Hierarchical Regression Analysis

The study used hierarchical regression analysis to test the moderating effect of innovativeness on the relationship between website quality, product usability and emotions. They were three models, model 1 and 2 comprised the independent variables of website quality, product usability and innovativeness; and the model 3 testing the interaction effects. Table 4 showed the results of both Study A and B. All direct effects were statistically significant except for the innovativeness on emotions in Study B. The interaction effects (model 3) for both studies also showed insignificant in the study. It revealed that innovativeness had no moderating effect on the relationship either between website quality nor product usability and emotions.

Table 4: Hierarchical Regression Analysis for Study A and B.

Predictor variable: WQ = Website Quality PU = Product Usability	Dependent Variable: Emotions					
	Model 1		Model 2		Model 3	
	Study A	Study B	Study A	Study B	Study A	Study B
Direct Effects						
Website Quality	.516***		.510***		.505***

Notes: ** p<.01 ***p<.001; all coefficients are standardized.

Comparison of Two Studies

The study used *t*-test to compare the mean values and examine the differentiation between two studies of all constructs. The results showed in Table 5. There were four constructs: emotions, hedonic and utilitarian value, as well as price sensitivity. As mentioned earlier, price sensitivity had two parts of items (part 1: seven points and part 2: price ranking); therefore, separate it into two. The results showed that emotions and the part one of price sensitivity items (PS1, PS2, and PS3) had no statistical difference between two study. However, hedonic and utilitarian value and the part 2 of price sensitivity items (PS6, PS7, and PS8) showed statistical difference between Study A and B. The mean values indicated that consumers shop with the physical products have significantly higher hedonic and utilitarian shopping value than shopping online. However, the price sensitivity of online shoppers was significant higher than the physical product shoppers. It revealed that consumers who shop with physical products will have lower price sensitivity, and willing to pay more.

Table 5: *t*-Test for Comparison of Two Studies.

Dependent Variable	Studies	*N*	*M*	*SD*	*t*-value
Emotions	A	253	4.285	0.922	-.464
	B	150	4.329	0.924	
Hedonic Value	A	253	3.909	1.410	-2.132*
	B	150	4.160	0.948	
Utilitarian Value	A	253	4.317	1.427	-3.041**
	B	150	4.692	1.034	
Price sensitivity (PS1, PS2, PS3)	A	253	3.481	1.318	-.640
	B	150	3.564	1.177	
Price sensitivity (PS6, PS7, PS8)	A	253	4.520	1.218	2.057*
	B	150	4.270	1.195

DISCUSSIONS AND RECOMMENDATIONS

Discussions

Consciousness, Emotions and Shopping Value

Similar to the previous researches, the shopping consciousness such as website quality and product usability would have positive effect on the shopper emotions (Eroglu et al., 2003; Fiore et al., 2005). When consumers browsed through the shopping websites, the quality of the website, such as full of information (i.e., content quality), technical adequacy, and the appearance of the website, including colors, layout, and etc., would affect their shopping emotions. Fiore et al. (2005) also pointed out that the more positive the evaluation of online shopping experience, the higher the intensity of the emotions of enjoyment, joy and pride; oppositely, the higher the intensity of dislike and frustration would be.

From the view point of physical products, when consumers have an opportunity to physically try and hold the product would affect their shopping emotions. Especially in the Y generation, if the physical product possessed comprehensive functions (i.e., product performance), and modern design (i.e., image/ impression), it would be more favorable for these people to have one (Seva et al., 2007). Seva et al. also pointed out that the product attribute of a mobile phone positively affected consumer pre-purchase emotions.

Furthermore, the study revealed consumer emotions toward the website and the physical product have positive effect on their hedonic and utilitarian shopping value. In the shopping process, when consumers possess positive emotions (e.g., happy, enjoyment, pride, and etc.) , they would perceived the shopping activities as higher hedonic and utilitarian value no matter they shopping online or with physical trial products. It is rational that when one has positive emotions towards an activity, they will think it is worth for doing so because it brings them happy and in fact, they enjoy doing it. Therefore, we can conclude that positive emotions would have positive relationship with hedonic and utilitarian shopping value.

Shopping Value and Price Sensitivity

The study expects consumer shopping values (hedonic and utilitarian) would have negative relationship with price sensitivity. However, the study only found a supporting result on the hedonic shopping value; utilitarian value was not supported. Tellis (1988) pointed out that price elasticity is more negative for all other product categories other than for pharmaceutical products. Consumers would be more concern the product safety, effectiveness, and timing rather than the price. This indicates that consumers who are more rational, they will be more concerned on the product usability rather than the price. Based on some respondents' comments, they mostly search high-tech products on the internet for more information including price and configurations, but will visit the retailer to try the physical product performance. Because they believe it always have some differences between the internet and the physical one about the product image.

Besides, Wakefield and Inman (2003) pointed out that consumers are lower price sensitive when making a hedonic purchase. When the consumers perceived the shopping process has

hedonic value, no matter shopping online or with a trail product, they may have lower price sensitivity and higher willingness to pay more. Thus, we can conclude that perceptual consumers may have lower price sensitivity.

Moderating Effect of Innovativeness

The moderating effect of innovativeness was not supported by both studies. We think the digital camera that we used were not innovative enough (not the latest version). The products may not aroused the respondents feelings of innovativeness when they answering the questionnaire. This may be the reason why the moderating effects were not supported.

However, the some respondents comment that they willing to pay most for the new technology product such as iphone or ipad. They are just so excited to try new technology, therefore, price is not to most concern for them. Accordingly, we can posit that innovative people will have lower price sensitivity, and they are likely to pay more for the new technology products. Roehrich (2004) argued that innovativeness consumers were willing to change, try, and buy new products more often and quickly than others. As well as Goldsmith et al. (2005), they urged innovative consumers have negative correlation with price sensitivity.

Comparison of Study A and B

Based on the comparison results, consumers who shop with a trial product showed significant and higher mean score on hedonic and utilitarian value then the online shoppers. The results indicated that consumers will feel more realistic when they shop with a trial product. Hedonic value will be enhanced as they may enjoy in playing with it. Simultaneously, when the product functions can meet for their needs, which will enhance their utilitarian value.

Price sensitivity was significant when asking the respondents how much they would have willingness to pay for the product (item PS6, PS7, and PS8). These items are more direct and can reflect the ideal price of the product more accurately. The mean score of online shopping have higher price sensitivity. As mentions earlier, consumers can obtain products information from the Internet in all areas. They would also compare the internet price with retailer and will as the image of the physical product. That may increase their price sensitivity, and not willing to pay more due to the comparison of price. Shankar, Rangaswamy, and Pusateri (2001) pointed out that consumers will consider internet stores have lower operational cost, they should offer a cheaper price then the physical store.

Implications

Theoretical Implications

This study adopted CEV model to examine the linkages between website quality, product usability, consumer characteristics, emotion, shopping value, and price sensitivity toward high-tech product in online and physical shopping process. This study provides further understanding toward consumer price sensitivity between online and physical shopping process. Some related issues are discussed as below.

Firstly, previous researches have mostly discussed the willingness or intention of purchase (Fiore et al., 2005; Kulviwat et al., 2007). However, consumers will have more consideration (such as comparing the product price) to make purchase decision especially in buying high price products such as high-tech products. The study designed two consciousness issues (website quality and product usability) to compare the shopping process of online and with a physical trial product. This comparison research design method, which is rare in prior studies.

Secondly, product usability is quite a common but important construct in marketing journals. Several research (e.g., Mayhew, 1992; Nielsen, 1993) has used it in the human-computer interaction (HCI). Han et al. (2001) even adopted the concept on the research of consumer electronic products and developed a complete measurement scale for product usability. However, not too many studies have used the scale in consumer responses or behavioral intention research. Thus, we adopt product usability as antecedence to test its effect on emotions. The results found product usability has a positive effect on consumer emotions during the shopping process.

Lastly, several research have discussed price sensitivity of online and physical shopping, and focused on the products such as margarine, detergent and wine, which the low price products (Alexandru et al., 2000; Shankar, Rangaswamy and Pusateri, 2001). We used higher price products such as digital camera as research object, which was rare in prior research. Furthermore, we found that a price-range measurement of price sensitivity can be more direct and accurate to reflect the respondents' price perception on the products.

Managerial Implications

We suggest that the manufacturers and the retailer (including internet and physical) should take note on the managerial strategies to attracting consumers. The manufacturers such as Sony, Canon, Casio, and etc., they should survey on the consumer needs, such as what are the functions that consumer would consider usable. We believe that to design usable functions rather then add in too many functions that may not be useful but to make the product too complicated could have more attractiveness to the consumers. For instance, a user friendly interface would let all age range of consumers learn and use easily. Besides, the product images also an important issue especially for the young people. As digital camera to be more common nowadays, they would like to have a modern product, which easy to keep and bring. They can bring it a long all the time and use it whenever they need it.

For the retailer, we suggest that retailer should well train their sales person for wide range of products categories. They can serve and introduce products more professionally based on the customer needs, and also can give them full of solution when they have any question about the trial product. That would be more convincible and the consumer would be more enjoyable in playing the trial unit, and ultimately would enhance consumers' hedonic value during the shopping process, as well as utilitarian value when the product can fulfill their needs. That would eventually lower the consumer price sensitivity.

For the online Internet store, rich content and information are needed including detail of product configurations, the website contact, customer service contact, and etc.. Consumers would be more confident and the website would have higher trustfulness when the website have full of those contents. Besides, more photo image such as 3D panoramic photo should be included in the website. Consumers can play with the 3D image which resemble as the real product. They would feel more enjoyable and excited during the shopping process. Furthermore, we also suggest that online store should not implement price competition strategy to attract sales. They should rather highlight their service, such as convenience, fast response time, information richness and free access.

Limitations and Future Research

There are some limitations in this study. Firstly, the respondents, they were mostly students with lower income. As known young people will browse through the Internet for information when they have a need to make purchase. They may have bias on price sensitivity because they always can compare the price between online and the physical retailer for saving the cost. Future research should extend the population more widely with more age ranges. That would have difference outcome when the respondent have higher income.

Secondly, the research design, we conducted the physical trial product in a small lab, which is not a real environment of physical retail store. Future research should have conducted the study in the real store. That not only can have the results more realistic, but also can have wide range of respondents.

Third, the object (the digital camera) is too general and not the latest version. It may not arouse the innovative feeling of respondents. We suggest future research should use the product which is more innovative such as e-book, iPad, 3D TV, PDA, and etc.. The respondents should be more excited when playing these products.

ABSTRACT

Relationship marketing emphasizes the importance of developing a long term relationship with customers for selling product. Personalization is a tool for online vender to enhance customer relationship on the Internet. Prior research has treated personalized services as empathetic responses from the service provider to create customer intimacy for building a close relationship with the receiver. In this paper, we focus on investigating the process of customer intimacy development to explain the association between receiver attitudes and personalized services. The intimate experiences of the receivers are composed of cognitive intimacy that includes the perceived communication and perceived care, and affective intimacy that includes commitment, comfort, and trust. To examine the proposed model, we conducted a controlled laboratory experiment using personalized product recommendation through email advertising. The findings indicate that, compared with the control group, the receivers of the personalized service had a significantly higher intimate experience and more positive attitude toward the advertisement and the recommended products. This research significantly extends existing findings and can lead to the development of more comprehensive theories and guidelines for vendors to improve their customer services.

Keywords: Personalization, Customer intimacy, Relationship quality

INTRODUCTION

The marketing activities that are directed toward establishing, developing, and maintaining successful relational exchanges between vendors and customers are referred to as relationship marketing, which focuses on individual-oriented communication aimed at building relationships and increasing revenues (Morgan and Hunt, 1994). In recent years, personalization-related research has received increasing attention in the information systems field. With the rapid growth of Internet users, personalization is commonly used to establish one-to-one interactions. Personalization techniques enable the analysis of a customer's preference from previous purchasing behavior, so advertisers can tailor their ads to that customer's preference in future interactions. Providing personalized messages and product recommendation is considered to be an effective mechanism to establish customer relationship for customer acquisition and retention (Ansari and Mela, 2003; Kotler, 2000; Peppers et al., 1999). For example, researchers found that recipients perceive personalized

email as useful, and are willing to respond to it, which results in more effective advertising (Ansari and Mela, 2003; Tam et al., 2006).

An issue related to the effect of personalization on relationship management is to understand more about the change of vendor-receiver relationships. Personalization can be effective only if this relationship is enhanced. In other words, we can reasonably expect that the quality of this relationship is changed due to personalized services offered by the vendor.

The major purpose of this research is to propose intimacy as a proper measurement of this relationship and explore whether the enhancement does exist when services are personalized. As the Internet has become an indispensable element in our life, most users have built a very close relationship with this technology, but we still do not have a proper measurement to indicate the quality or nature of this relationship. In human relationships, intimacy is often used to indicate a feeling of closeness generated from intimate interaction in order to induce an individual to continue interaction. The extent of developing intimacy in an interaction is an indicator of relationship quality. The concept of intimacy can be used to investigate the relationship building between online service providers and receivers, which may be called *digital intimacy*. This is in line with the argument presented by Liang et al. (2009b). They contended that IT can be used as a personalization tool to build customer relationships and can be treated as an empathic response that results in customer intimacy.

Existing literature in human relationships and marketing has also proposed intimacy as a major indicator of relationships, which includes several cognitive and affective components (such as communication, comfort, caring, trust, and commitment). In this research, we adopt these concepts to postulate that the intimacy factors are strongly related to the positive attitude toward personalized recommendation. Our research questions are: (1) Can personalized services lead to the customer's intimate experience? and (2) Does the development of customer intimacy make personalized services effective in inducing positive customer attitudes? To examine our assertions, we developed a research model. The model was then evaluated in a controlled laboratory experiment to examine its ability to interpret the effect of personalized service delivered through email on customer attitudes.

The remainder of this paper is organized as follows: Section 2 reviews prior literature on personalization and introduces the intimacy construct as indicators of relationship quality for personalized services. Section 3 presents the research model and the hypotheses. This is followed by the description of our experimental design and the development of the measurement in Section 4. Sections 5 report the analyses, the results, and their interpretation. Finally, Section 6 outlines major findings, theoretical and practical contributions, and further future research directions.

LITERATURE REVIEW

Personalization

There are three major categories of research on personalization in the information systems area. The first focuses on examining different types of personalized services and their

potential applications in different marketing domains (e.g., Brusilovsky et al., 2007). The second is dedicated to designing technologies for personalized services with an emphasis on the receiver's profile, and then matching the personalized service with the receiver's needs by using tools such as data and text mining (Shahabi and Banaei-Kashani, 2003; Zhang et al., 2007). The third category evaluates the effect of personalized services on the receivers' attitudes and acceptance of recommendation intention (Komiak and Benbasat, 2006; Liang et al., 2006; Tam and Ho, 2005; Tam et al., 2006). While extensive research has described and analyzed the impact of personalized recommendation agents on email advertising and marketing, recent attention has been given to the issue of why personalization may influence customer attitudes. Therefore, it may be useful to develop theories that help interpret the relationship between personalization and its effect on customers from different perspectives.

In previous literature, there exist at least three perspectives in interpreting the effect of personalization: information and effort reduction, personal persuasion, and relationship building (Liang et al., 2009b). The relationship building perspective adopts the concept of relationship marketing, and treats personalized services as a tool for building a close relationship between the sender and the receiver. Personalized messages intend to develop positive affection between the sender and the receiver. This feeling may include care, trust, and other related emotions. For instance, Komiak and Benbasat (2006) proposed a trust-centered perspective in studying the adoption of personalized recommendation agents. Both cognitive trust and emotional trust have been found to influence the intention to adopt personalization agents. This finding indicates that personalized services can give rise to an individual's emotional process and give the user a sense of togetherness with the personalized service and its provider. In addition, Liang, et al. (2009a) found that perceived care (an emotional factor) was more influential than transaction costs reduction (a rational factor) on the perceived usefulness of personalized services offered by online bookstores. These findings suggest that personalization may have significant affective influence on consumer buying behavior.

Intimacy and Relationship Building

Intimacy is a widely used concept in social psychology and has been adopted for measuring bilateral relationships in relationship marketing, sociology and related fields as a crucial component for building close relationships (Felmlee and Sprecher, 2000). In the process of interpersonal interactions, if an individual perceives the other party as being able to respond empathetically (i.e., understand his/her needs, have concerns about him/her, or pay special attention to him/her), he/she will experience intimacy from the interaction because his/her mental and/or physical needs are satisfied (Laurenceau et al., 1998). Such intimate experiences, then, will stir his/her emotion and entice him/her to keep in touch with the other party so that their relationship can be improved gradually. Accordingly, relationship building is the process of developing intimacy, and intimacy plays a key role in a satisfying relationship (Reis and Shaver, 1988). Hence, it is useful to explain relationships, such as the interdependence of lovers, friends, and families, a bond between a customer and a vendor, or a connection between receivers and personalized services (Ansari and Mela, 2003; Laurenceau et al., 1998; Mittal and Lasser, 1996; Stern, 1997).

Reis and Shaver's (1988) contended that intimacy was an interpersonal process that involved sharing personal information and responding warmly. For the positive feelings to be elicited, one must perceive a partner's response as empathic. Based on this claim, Prager (1995) argued that intimate interactions include intimate behaviors and intimate experiences. He further proposed that intimate experiences in interaction could be divided into the experience of cognitive intimacy and the experience of affective intimacy. Cognitive intimacy refers to the perception of a partner's empathic responses, while affective intimacy refers to the positive feelings about the partner. Laurenceau et al. (1998) further argued that the perceived partner's responsiveness is positively associated with one's positive feelings toward the partner in an interaction. That is, in the process of intimacy development, one's affective intimacy is a result of his/her cognitive intimacy. Several other studies also support this contention (e.g., Gore et al., 2006; Laurenceau et al., 2005). Similarly, White and her colleague (e.g., Paul and White, 1990) have defined three components of intimacy: cognitive, affective, and behavioral. The cognitive component indicates the receiver perceives an emphatic interaction (e.g., good communication and caring), which can lead to positive feeling (the affective component), and intimate behavior. An excellent review of the cognitive-affective model of using information technology is available in Te'eni (2001).

In term of service relationship, Stern (1997) proposed that customer intimacy should include five components: communication, caring, trust (conflict resolution), comfort, and commitment. As the intimate experience is divided into cognitive and affective, the five components can be divided into two groups. By definition, cognitive intimacy is the speaker's positive perception of the listener's response to the speaker's intimate behavior. It is created when the speaker perceives the listener's response as empathic, that is, interprets the listener's response as understanding and caring. Hence, communication and caring can exhibit the characteristics of cognitive intimacy (Gore et al., 2006; Laurenceau et al., 2005; Prager 1995). Affective intimacy consists of the speaker's positive feelings toward the listener, and usually is regarded as the important indicator of relationship quality between the speaker and the listener (Gore et al. 2006). Three components could be used to represent affective intimacy including commitment, comfort, and trust. These three major emotional responses refer to the speaker's validation that the listener is acceptable and worth being in a relationship, and can be viewed as the positive feelings to the listener. To sum up, customer intimacy is composed of five components in two categories: cognitive components (communication and caring) and affective components (trust, commitment, and comfort). The process of intimacy development is the process of experiencing the interaction as intimate, and it could be verified by the effects on the five components.

Attitude toward Advertisement

In existing literature, there are two ways to measure the outcome of advertisement: effects and effectiveness. Wright-Isak and his colleague (1997) stated that effectiveness measures the cumulative contribution to an organization over time, but effects are short-term outcome from a particular event. Advertising effectiveness is concerned with making a tangible contribution (e.g., sales increase) to a company or a brand that must exceed its costs to be considered successful. In contrast, effects often measure immediate changes in consumer affects, attitudes, and behaviors. Therefore, most advertising research focuses on

measuring effects from a limited number of executions and exposures and typically is studied in controlled experiments that employ one exposure to single messages over a short period of time (Wright-Isak, et al., 1997).

A popular measure of advertising effects is the consumer's attitude toward the advertisement because it is found to be a mediating factor that affects purchase intention (e.g., MacKenzie et al., 1986; Bush et al., 1999; Tsang, et al., 2004) and advertising effectiveness (e.g., Metha, 2000). More favorable attitudes can lead to higher purchase intentions. This assertion is supported by many behavioral theories such as the theory of reasoned action (Fishbein and Ajzen, 1975), the technology acceptance model (Davis, 1989), and the planned behavior theory (Ajzen, 1985). Therefore, it is reasonable to measure attitude toward advertising as a good indicator of advertising effects.

THE RESEARCH MODEL AND HYPOTHESES

Figure 1 shows a schematic view of our proposed research model, which is based on the interaction process and on the five components of intimacy described earlier. Personalized response generated by a computer-based system may induce higher level of receiver's intimacy, which in turn induces a positive attitude toward product recommendation. In addition, the intimate experience begins with the perception of the personalized service provider's empathic response (cognitive intimacy), including the level of perceived communication and caring. These perceptions then contribute to the service receiver's feelings of commitment, comfort, and trust toward the service provider (affective intimacy). Finally, the positive feelings lead to the positive attitude toward the recommendation made by the service provider.

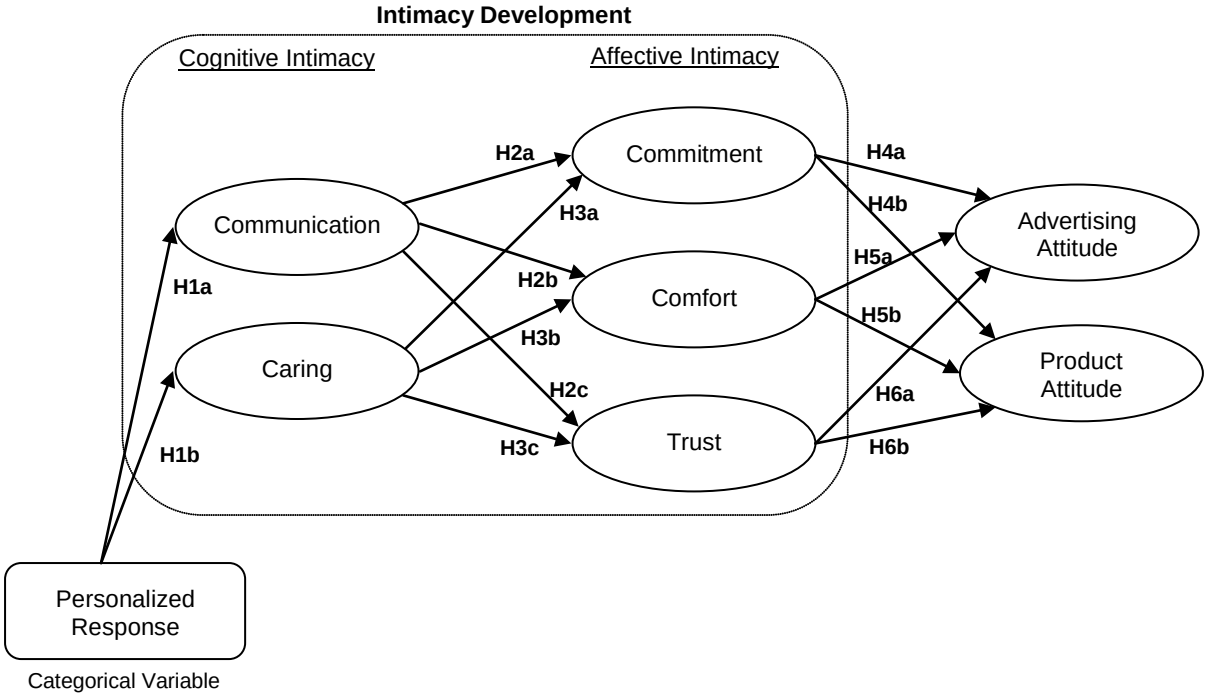

Figure 1: The Research Model.

The Effect of Personalization

The first hypothesis we need to test is whether personalization can lead to intimate experiences. As described earlier, a service provider that offers personalized recommendation should collect the receivers' personal information, so that the personalization agent could analyzes the receivers' preference and the services can be tailored to the receivers' needs. In such an interaction, personalized services that show concern and support can be viewed as an empathic response to the receivers' disclosure of personal information. Therefore, the personalized response will enable the receivers to perceive that they have been understood (validating the successful communication) and been cared for. This can be expressed as:

Hypothesis 1a：Personalized responses from personalization agents can generate a higher level of perceived communication than non-personalized responses.

Hypothesis 1b：Personalized responses from personalization agents can generate a higher level of perceived care than non-personalized responses.

The Influence of Cognitive Intimacy

As intimate interaction begins with one's self-disclosure, successful communication plays an important role in developing intimacy. Successful communication means that the information shared in an interaction has been understood (Stern, 1997; Te'eni, 2001). Communication contributes to the positive feelings for establishing relationships, where three common positive feelings indicate the strength of the relationship: commitment, comfort, and trust (Morgan and Hunt, 1994; Palmatier et al., 2006; Roberts et al., 2003). Commitment is a desire or willingness to attach to the other party and to bond with the other party. Comfort is a satisfied state due to being in a comfort zone with the other party. Trust is a feeling of confidence in someone, showing that an individual feels that the other party's response is genuine rather than pretended or false. In the context of offering personalized services on the Internet, when the service receivers perceive that the service provider has tried so hard to understand what they have to say, they will have a desire to bond with the service provider, perceive comfort in the interaction with the service provider, and feel the service provider is honest. This can be expressed as:

Hypothesis 2a：The level of perceived communication is positively associated with the receiver's commitment to the service provider.

Hypothesis 2b：The level of perceived communication is positively associated with the receiver's comfort in the interaction with the service provider.

Hypothesis 2c：The level of perceived communication is positively associated with the receiver's trust in the service provider.

Caring refers to showing concern in an interaction. In order for an affective interdependence to occur, a listener should not only present understanding and sensitivity, but also show consideration for the speaker's well-being and show willingness to help the speaker (Scharf and Mayseless, 2001; Sharabany, 1994). In terms of personalized services, when the service provider cares about the receiver's needs and welfare, his warm-hearted attitude will make the receiver feel friendly and kind to him. Therefore, the service

provider's benevolence will deeply affect the receiver and elicit the positive feelings from the receiver (Gore et al., 2006; Laurenceau et al., 2005). As mentioned above, commitment, comfort, and trust will also result from the perception of having been cared for. That is, when the receiver perceives that the service provider gives the individualized attention and shows concern, he/she will confirm that the service provider is acceptable and valuable. Accordingly, the receiver will have a desire to commit to the service provider, perceive comfort in the interaction with the service provider, and feel the service provider is honest and trustworthy. Hence, the following three hypotheses are posited:

Hypothesis 3a：Perceived caring is positively associated with the receiver's commitment to the service provider.

Hypothesis 3b：Perceived caring is positively associated with the receiver's comfort in the interaction with the service provider.

Hypothesis 3c：Perceived caring is positively associated with the receiver's trust in the service provider.

The influence of Affective Intimacy on Attitude

Commitment involves psychological attachment to the other party, and is the driver of supporting an individual in showing a particular attitude (Agrawal and Maheswaran 2005; Gustafsson et al. 2005). If an individual is committed to the other party, he/she will have a desire to maintain the relationship with the other party. Consequently, his/her attitude toward what the other party has done will tend to be positive due to the emotional need for satisfying that desire (Malhotra and Galletta, 2005). Drawing on prior research in relationship marketing, commitment has been seen as a vital predictor of a consumer's attitudes, intentions, or behavior from a relationship perspective. For example, several studies have argued that commitment positively affects consumers' behavior, such as retention and actual purchasing (Agrawal and Maheswaran, 2005; Gustafsson et al., 2005; Palmatier et al. 2006). Therefore, when the receiver has commitment to the service provider through intimate interactions, such psychological state will positively influence his/her attitude toward the recommendation made by the service provider. This can be expressed as:

Hypothesis 4a：Commitment is positively associated with the receiver's attitude toward the advertisement provided by the service provider.

Hypothesis 4b：Commitment is positively associated with the receiver's attitude toward the product in the advertisement provided by the service provider.

Comfort is a basic requirement for developing intimacy and it enables an individual to enjoy the interaction with the other party (Stern 1997). If two parties are not in the comfort zone in the process of building intimacy, they will not be able to have a comfortable level of closeness. That is, comfort can be viewed as a satisfied state resulting from the positive overall evaluation of an interaction. Since a sense of comfort refers to a positive feeling toward getting along with another, comfort could significantly influence one's behavior from an emotional perspective (Bhattacherjee and Premkumar, 2004; Gustafsson et al., 2005; Verhoef, 2003). In the context of the interaction between a personalized service provider and receiver, if the receiver feels comfortable with the service provider, such

feeling will lead to a positive attitude toward the recommendation made by the service provider. Therefore, we posit the following hypothesis:

Hypothesis 5a：Comfort is positively associated with the receiver's attitude toward the advertisement provided by the service provider.

Hypothesis 5b：Comfort is positively associated with the receiver's attitude toward the product in the advertisement provided by the service provider.

Trust in its version for intimacy refers to a feeling of confidence in someone, meaning that an individual feels that he/she can trust the other party in an interaction (Prager 1995). That is, the individual feels that the other party is honest. This feeling does not result from a cognitive process; rather, it results from an affective process. Accordingly, when an individual has the feeling that the other party's response in an interaction is genuine, he/she not only is able to experience the interaction as intimate, but also to positively affect his/her attitude toward the other party's behavior (Scharf and Mayseless, 2001; Sharabany, 1994). Therefore, when the receiver feels that the personalized service provider is honest, this feeling will lead to his/her positive attitude toward the recommendation made by the service provider. This leads to the following hypothesis:

Hypothesis 6a：Trust is positively associated with the receiver's attitude toward the advertisement provided by the service provider.

Hypothesis 6b：Trust is positively associated with the receiver's attitude toward the product in the advertisement provided by the service provider.

RESEARCH METHOD

Experimental Design and Procedures

An experiment was conducted to test the proposed model. Subjects were recruited online for receiving a personalized email. The experimental group received a personalized email that contained personal shopping report and an advertisement chosen based on their revealed preference, whereas the control group received a similar but non-personalized email that contained general report and a randomly chosen advertisement. The process began with an invitation to participate which was posted in online communities. Subjects registered and provided their personal demographics, their historical and intended buying preferences, as well as their request for product information. After that, participants were randomly divided into two groups: the experimental group that received a personalized response, and the control group that received a non-personalized response. A manipulation check for personalization was performed. Participants were asked to evaluate the email messages after reading the email. The difference between the experimental and the control groups was significant, which indicates that the manipulation was successful. Finally, there were 463 valid subjects (157 men and 104 women in the experimental group, 114 men and 88 women in the control group). The profile of the subject shows an average of 27 years old, 90% of them holding a bachelor or higher degree, 34% students and 76% non-students, an average of 11years of Internet experience and an average of 7.1 purchases in the past six months.

Instrument

The measurement items were adapted from existing literature. Communication assessed the perception of the degree to which the service provider expressed an understanding of the receiver (Duncan et al., 1998; Ramsey and Sohi, 1997), while caring assessed the perception of the degree to which the service provider expressed its concern (Doney and Cannon, 1997). Affective intimacy includes three elements. Trust was measured by the items adapted from Doney and Cannon (1997) and Komiak and Benbasat (2006), and assessed the degree to which a receiver felt the service provider is honest. Comfort assessed the degree to which a receiver was satisfied with "getting along" with the service provider (Roberts et al., 2003). Finally, commitment was measured the items that assessed the degree to which a receiver had an enduring desire to remain with the service provider (Gustafsson et al., 2005; Roberts et al., 2003). Attitude toward the email advertisement (advertising attitude) and attitude toward the recommended product in the advertisement (product attitude) are used to measure the effect of the recommendation. Advertising attitude was assessed by the items adapted from Brackett and Carr (2001), and product attitude was assessed by the items adapted from Berens et al. (2005). All questionnaire items were measured on a five-point Likert-scale, with 1 being least agreed and 5 being most agreed.

A pretest was conducted to examine the validity and reliability of the instrument. We received 129 valid responses and used a principal component analysis with varimax rotation to check the factor structure in our research model. All items converged into seven intended factors and did not load highly on other factors except one indicator for product attitude. In order to maintain the discriminant validity, the item loading highly on both product attitude and trust was removed from further analysis (Hair et al., 2006). Moreover, Cronbach's alpha values ranged from 0.84 to 0.91 for the seven constructs, indicating a high internal consistency considering a minimum threshold of 0.7 (Nunnally et al., 1994). Therefore, all questionnaire items were retained in the measurement model except the one for product attitude.

DATA ANALYSIS AND RESULTS

Construct Reliability and Validity

PLS was used for assessing the measurement model. As to construct reliability, the composite reliability values for all constructs exceed 0.7. This provided evidence for construct reliability (Hair et al., 2006; Nunnally et al., 1994). With respect to congruent validity, all factor loadings were highly significant in a t-test, and AVE values were greater than the recommended score of 0.5. To support the discriminant validity, AVE values for each construct were greater than the squared correlation estimates involving the construct. Taken together, this evidence supports the convergent validity and discriminant validity of the measurement model (Hair et al., 2006). Thus, our constructs are valid for further analysis.

The Structural Model and Results of Hypotheses Testing

Since personalization was operationalized as a binary variable in the experiment, its effects on cognitive intimacy can be evaluated by using the Student's t-test to examine the differences between the personalization and non-personalization groups. As shown in Table 1, both communication and caring levels differ significantly between the two groups. In the personalization group, the receivers' perception of communication level and caring is higher than the receivers' perception in the non-personalization group. This result indicates that personalized response was viewed as an empathic response expressing understanding and caring in an interaction with service receivers. Therefore, H1a and H1b are supported.

The relationships among cognitive intimacy, affective intimacy, and attitudes can be tested by Structural Equation Modeling (SEM). The resulting model estimations from PLS are shown in Figure 2. All paths are positively significant except the relationship between comfort and product attitude. This indicates that a higher level of cognitive intimacy will lead to the higher level of affective intimacy, which in turn will contribute to more favorable attitudes toward the advertising and product. Regarding cognitive intimacy, the perceived level of communication positively influences the service receivers' commitment, comfort, and trust. Therefore, H2a, H2b, and H2c are supported.

Besides, the level of perceived caring shown by the service provider also increases the receivers' commitment, comfort, and trust. That is, H3a, H3b, and H3c are also supported. With respect to affective intimacy, the receivers' commitment, comfort, and trust are all positively associated with their attitudes toward advertising and product expect that the impact of comfort on product attitude was found to be insignificant. Thus, H4a, H4b, H5a, H6a, and H6b are supported, while H5b is not supported. Finally, the R^2 in the model shows that the model accounts for 51 percent, 46 percent, and 28 percent of the explanation variance in commitment, comfort, and trust, respectively. The affective intimacy interprets 37 percent of the variance in the attitude toward advertising, and 24 percent of the variance in the attitude toward product.

Table 1: The Results of t Test for Two Dimensions of Cognitive Intimacy.

Variables		Mean	S.D.	I - J	t	Sig.
Communication	**P (I)**	**3.42**	**0.65**	**0.27**	**4.538**	**0.00****
	Non-P (J)	**3.15**	**0.63**			
Caring	**P (I)**	**3.38**	**0.73**	**0.68**	**9.979**	**0.00****
	Non-P (J)	**2.70**	**0.72**			

Note: S.D. = standard deviation

DISCUSSION AND CONCLUSION

In this paper, we have proposed a research model that presents the process of customer intimacy development to explain the effect of personalization from a relationship building perspective. In particular, we have adapted the intimacy theory as our theoretical frame to investigate the role of certain emotional components in the process of delivering and receiving personalized services. Intimacy is modeled to have two sets of components: cognitive (including communication and caring) and affective (including commitment, comfort and trust). Major findings and the contributions are discussed next.

First, the study has shown that the effect of personalized recommendation as measured by consumer attitude changes is partially due to the change in relationship quality derived in the online interaction process. This supplements the prior findings mostly verified that the effect of personalization is generated by cognitive and rational motivations such as least efforts and preference matching. In particular, we have found that intimacy is a good construct to capture the relationship change derived from personalized services.

Second, the ability to show understanding and caring, even when generated by a software agent, plays a crucial and positive role in building relationships with the service receivers. The effect of personalization on building a relationship is effective by means of showing understanding and caring to the receivers. This can have significant implications for the design and delivery of personalized recommendation in electronic commerce.

Third, the intimate experience is composed of two groups of factors: cognitive and affective. Cognitive components represent an individual's positive interpretation about the other party's response, while affective components represent an individual's positive feelings toward the other party. Cognitive components include communication and caring, with communication having a higher impact than caring. Commitment, comfort, and trust are the affective reaction to positive interpretation on personalized service, and are the major factors that affect one's attitude. Trust has the highest impact on consumer attitude,

commitment is second and comfort is the third. This is consistent with research findings in relationship marketing, which consider commitment, comfort, and trust to be major indicators to predict consumers' attitude.

This is an original research that intends to explore the effect of personalization from a relationship building perspective. Although we have done everything possible to ensure its validity, our work can certainly be improved in a number of ways. First, intimacy is an affective construct, which is difficult to define precisely and different researchers may have different perceptions or definitions of the construct for their own purpose. In particular, some people may perceive this to be a concept among human beings. In this research, we have defined it based on our understanding of its role in relationship building and found interesting results. However, the result may change if the construct is defined differently. The second possible limitation of the study is that the data was collected in an online experiment and the context in this study could be different from that of the real world. Therefore, several issues and constraints need to be kept in mind when the results are interpreted, which include: (1) A bias might exist as a result of the subjects being volunteers; (2) The sample may not represent the population owing to convenient sampling; (3) Subjects were offered a limited menu of 36 products and their favorite products may not have been included; and (4) The results might not hold true in different contexts or settings. Even though there are some limitations in this study, our work has extended our existing understanding of personalized recommendation and can potentially open a new lens to view online customer behavior in the Internet age.

ABSTRACT

Thanks to the vigorous development of Internet technology, Internet marketing has risen as a result. The performance of Internet marketing depends on the design of the web site itself, furthermore, another influential factor is how to attract visitors via web advertisements. It can be deduced that web advertising is a crucial communication tool and marketing medium of the Internet era, which should no longer be displayed at random. It should be able to respond to user preferences immediately and provide recommendations accordingly, which gives way to the idea of a recommendation system. Traditional recommendation systems emphasized on precision of recommendation, their objectives were to provide correct product information. However, the product information recommended only by key characteristics is likely to be consumed quickly and easily. That is why this research hopes to establish the association between terms using KeyGraph algorithm of chance discovery and locate nodes with chance discovery characteristics. These nodes are then used to recommend novel contexts with association network that users may not be aware of intuitively. Meanwhile, the use of web mining technology to analyse users' browsing behaviours helps to understand their preferences and degree of interests in the content of the web page. It can be based to expand the range of recommended advertisements. As well, the combination of web mining and chance discovery will ensure the diversity and continual increase in recommended items, thus providing uninterrupted recommendations.

Keywords: Web mining, Chance discovery, KeyGraph, Personalized advertising recommendation

INTRODUCTION

Because of the vigorous development of Internet technology, web pages have become the fastest growing media whose developing potential far exceeds that of the newspapers, television, radio, magazines, etc. How to utilize the Internet to strengthen the marketing capability of organisations, to communicate with existing customers efficiently as well as uncover potential ones have been the focus of development of organisations. Not only is the performance of web marketing dependent on the design of the web site itself, another influential factor is how to attract visitors, which involves the effect of web advertisements. Web advertisement can be regarded as a synthesis of traditional real-world advertising and personalised marketing. In comparison to traditional media advertisements, web advertising is cheaper, more flexible, more interactive, and allows around-the-clock contact with customers, which makes it easier to evaluate its effect. All of the above advantages make it a crucial communication medium of the Internet era (Timmers, 1999; Whinston et al., 1997).

It can be observed from the current development of web advertising that most commercial web sites have various web advertising display systems. But they generally lack the capability to uncover the potential interests of customers, which is adverse to the attraction of new customers. That is why this research adopts the idea of chance discovery to expand the domain for recommended advertisements in order to boost users' browsing desire. Following the interactions with users' browsing behaviours, the diversity and continual increase in the recommended items will be maintained, thus providing non-stop recommendations.

The objective of this research is to build a personalized web advertisement recommendation model, where real-time interactions are realised through user behaviour. Building such a system will promote user satisfaction in regards to web advertisement and expand the range of advertisements. The results will also boost users' browsing desire. What this research intends to achieve in the web advertising domain is the efficient extension and distribution of personalized web advertising technology, while providing a new direction and a viable operating structure for future research. The features of which are as follows:

(1) This research utilizes chance discovery to establish the association between word terms, and to further understand the potential association between word groups. Applying the chance word to be potential nodes in the association network can expand the domain of recommended advertisements, and provide the advertisements that meet users' expectation.
(2) Past recommendation systems emphasized precision in providing correct product information, but such information was likely to be exhausted. That is why this research

intends to employ the chance discovery theory to locate the novel items that have associations with each other but are not intuitively relevant and to stimulate users' browsing desire.

(3) By employing chance discovery and the continuous interaction concerning user evaluation, it is hoped that this research can discover user preferences and the influence of chance discovery in interaction, so as to introduce information regarding user experiences and group evaluation to the chance discovery ideology. As a result, the precision and functionality of recommendations will be improved and diversified advertisement information and combinations will also be provided.

LITERATURE REVIEW

Chance discovery

Chance discovery is an emerging research subject proposed by Ohsawa et al. (1998), who advocated it in the location of structurally significant information, which does not appear often under the original text mining mode. Such information normally cannot be discovered using the original text mining technology. On the other hand, it is achieved by analyzing information that is either low frequency or contains weak association so as to find out critical chances or information that is beneficial for future decisions.

The primary objective of chance discovery is to learn how to discover rare or novel events. Unlike any common or occasional events, they are exceptional situations that are easily overlooked. In addition to focusing on finding terms and association that appear frequently but are easily overlooked in data mining, chance discovery emphasizes on the discovery of terms and association that contain the features of being rare and structurally important.

In employing chance discovery, the emphasis is on the analysis of information importance from two perspectives. The first perspective is the term frequency that locates the rare feature, and second the structural relationships produced by association links. That is, the co-occurring frequency of terms and the location of "structurally important" characteristics. From there, information with a strong association and low frequency in relation to association network will be found, and professional knowledge will be applied to explain the information behind the association. The analysis of such information will aid decision-making. There are two kinds of definitions in chance discovery, they are elaborated as below:

(1) New event or situation which is assumed to contain chance or risk, and the information is likely to be a fragment.

(2) Ones that contain characteristics that cannot be explained by data analysis or data mining. From the perspective of frequency, they are data yet to be described or detected.

From the above two definitions of chance, it can be gathered that, Ohsawa (2002) believed chance discovery emphasizes the possibility of discovering events that are crucial in future decision-making under circumstances with no or very little past information available. For example, in the business field, with no past purchasing information available regarding the products, how does one predict customer needs accurately for a new product? This is exactly where Ohsawa (2003) deemed that chance discovery would play an important role.

KeyGraph

Chance discovery frequently relies on KeyGraph to analyze a large quantity of documents to find terms with high frequency, thus producing word groups with high relevancy among them. Terms that do not show up frequently but are keys to the structure of word groups are also disclosed. The utilization of KeyGraph is to discover feature terms that are rare and less frequent, but contain significant structure and are eventually turned into graphs, thus allowing decision-makers to excavate strategic plans that possess key chances.

KeyGraph is a document index or an algorithm of keyword extraction based on graph theory. Similar ideas have been applied on the extraction of English keywords, thus the applications of ideas expressed by KeyGraph on text mining are elaborated as follows:

(1) Find the most frequently appeared event among a series of events, and find the combination of co-occurring events with highest frequency. Such combination of events is regarded as a cluster (Wang and Zaiane, 2002). In text mining, it would be conducted by finding terms with top frequency of appearance and setting threshold values to eliminate words with low frequency. For instance, if the threshold value is set to be 3, then any terms appearing below 3 will be discarded in order to find event combinations that have appeared more than 3 times.

(2) In serial events, co-occurring event combinations will form different clusters, and the nodes that connect them are hubs which are crucial connectors, whereas the associations between clusters are called bridges. The application of this in documents is the construction of links by computing the weight values between high frequency terms. For example, node of term A and node of term B both appear in certain sentences and by translating them into a graph there demonstrates a link between the two nodes.

Web mining

In regards to the structure of web mining, Cooley et al. (1997) proposed the structure and classification of web mining. They divided web mining into seb content mining and web usage mining, which are adopted by this research. Web content mining processes the content of web documents and extracts useful information. Such document data need to satisfy the intended content, which include texts, pictures, audio data, video data or structural records. Generally speaking, a frequency threshold value of web page browsing will be set after the process of web content mining, and when the frequency browsed by a user on certain web pages exceeds this value, then the web content mining system will be activated to retrieve the page from web page database. User profile will then be built from the data obtained through mining, which will serve as a base of recommendation. Web usage mining, on the other hand, discovers the access modes of users from web site access log. It uses web site server logs to analyze and find users' browsing conditions and tendency once they enter the site, thereafter defines their access modes.

Personalized advertisement

Adopting personalized technology to provide personalized web advertisements, the most widely employed technique is the designation of advertisement attributes by advertisers. When users browse a certain page, the web advertising server will display similar advertisements based on the page type. However, such technology is not a user-centric personalized technique, therefore the result is not satisfied (Kramer et al., 2000; Manber et al., 2000).

Another technology that targets at the short-term use preferences of users is achieved on search-based web portals. Based on the search keywords entered and then the use of word matching technology, web advertisements that contain such attributes from web advertisement database will be displayed once the keyword entered and the feature term share a certain degree of similarity. The advantage of this is that it is real-time, whereas its disadvantage is that it does not cover user preferences in the long run and it is unable to record user interests. As a result, the chances to obtain user information will be lost (Langheinrich et al., 1999; Tomlin, 2000).

There is another personalized web advertising technology that applies an agent at user site. The agent retrieves and records user behaviour on the Internet, and displays personalized web advertisements accordingly. Such technology covers both long-term and short-term interests of users. However, it needs users to install an agent before being able to give any

recommendations, and users might consider this as an intrusion of privacy, therefore the challenge of this technology lies in winning user's trust.

The latest personalized web advertising technology adopts web mining to analyse users' browsing behaviours online as well as to obtain their preferences and interests. Li (2000) proposed the use of sequence mining in web mining to build browsing trees representing different user browsing behaviours. Under this mode, the information is classified according to past user characteristics, and browsing trees that are able to predict the behaviours of new users will be built, thus providing suitable advertisements. Such technology primarily determines the web page browsing sequence of users, but it does not take into account the accompanying degree of interest of each node within the browsing tree. Judging on the pros and cons of each method and technology, this research intends to employ web mining to conduct advertisement recommendations.

RESEARCH METHODOLOGY

One of the objectives of this research is to expand users' interests and browsing domains. The use of chance discovery can finds information that is otherwise difficult to find when using methods such as term frequency analysis or association rule analysis. It adjusts according to changes in users' interests and instantly recommends personalized advertisements. This research utilized data mining technology as the foundation for customer-targeted advertisement display. As illustrated by figure 1, such system has the advantages of being personalized and target-oriented in addition to being a real-time interactive recommender. Instead of analyzing the registered information of users, it analyzes user interaction online (as indicated by dotted lines in figure 1), and based on which recommends real-time advertisements.

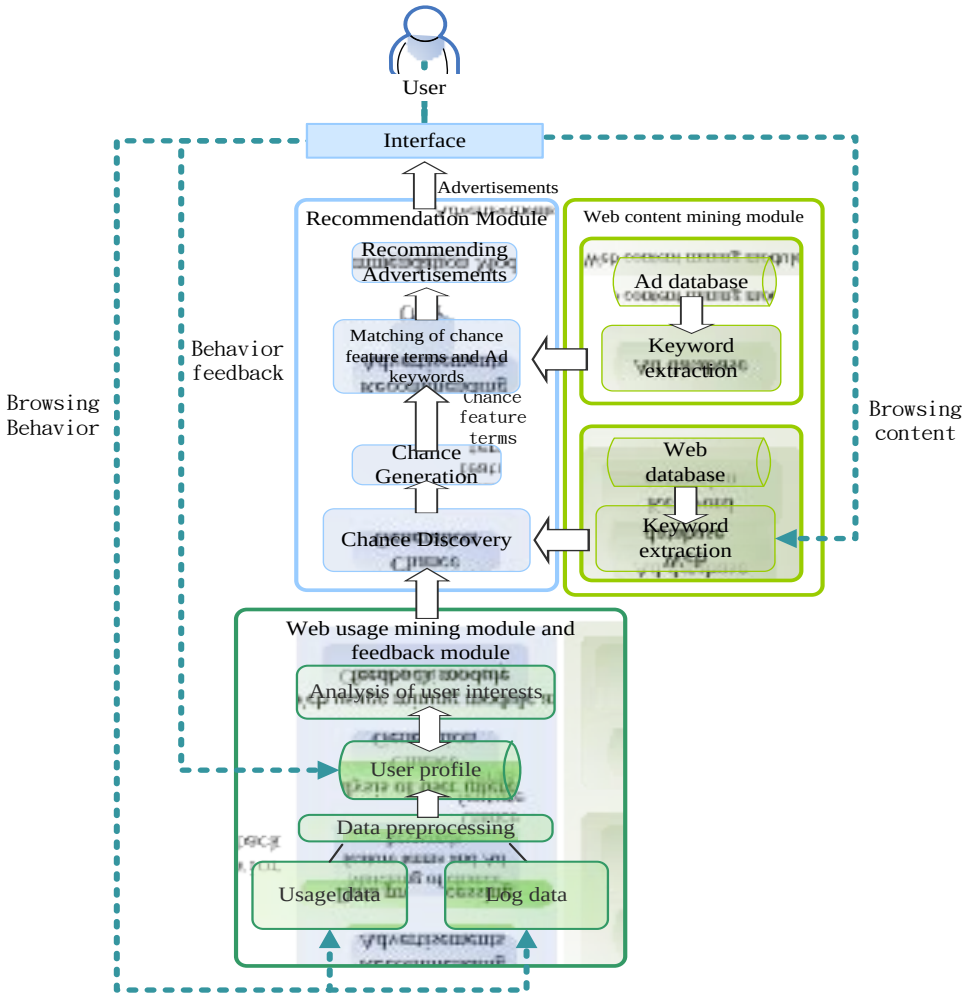

Figure 1: Recommending system of personalized advertisements.

The structure of this research can be divided into web content mining, web usage mining and chance discovery. The part of web content mining filters content and searches for representative keywords within web pages, whereas the part of web usage mining analyses user operation or browsing behaviour online to build user profiles. The degree of user browsing interests is obtained via web mining technologies and the system recommends different contents to different users who are browsing the same item. The chance feature terms, which are produced by chance discovery, are employed to search for advertisements that contain feature terms that are highly similar to the chance node information so as to enable advertisement recommendations (Madira et al., 1999).

Web usage mining module

When users browse a web page, they are aware of their responses to the article and its content, whereas user operating mode allows direct observation of such. That is why this research observes user operating habit online to estimate the degree of user preferences

regarding the web pages. In regards to user web usage mining, this research utilises instant online processing to uncover the behaviour.

Web content mining module

Currently very few researches supply information recommendation based on analysing web page content. But taking into consideration that users browse a certain web pages, because they contain ideas that interest them. That is why this research analyses web content.

In order to understand user interest, this research makes use of the CKIP system developed by Academia Sinica to analyse browsed web content and types. The use of CKIP filters through morphological features and gets rid of articles, prepositions, conjunctions as well as words that were irrelevant to the ideas of the documents, thus reducing meaningless feature terms. Thereafter, the research adopts TF-IDF weight approach as the standard to measure the importance of words, and only those within the top 40% are used as keywords of the web pages.

Similarly, web content mining is also conducted on web pages containing advertisements to allow matches with those chances produced by the chance discovery approach, and provide recommendations of advertisements with similar chances.

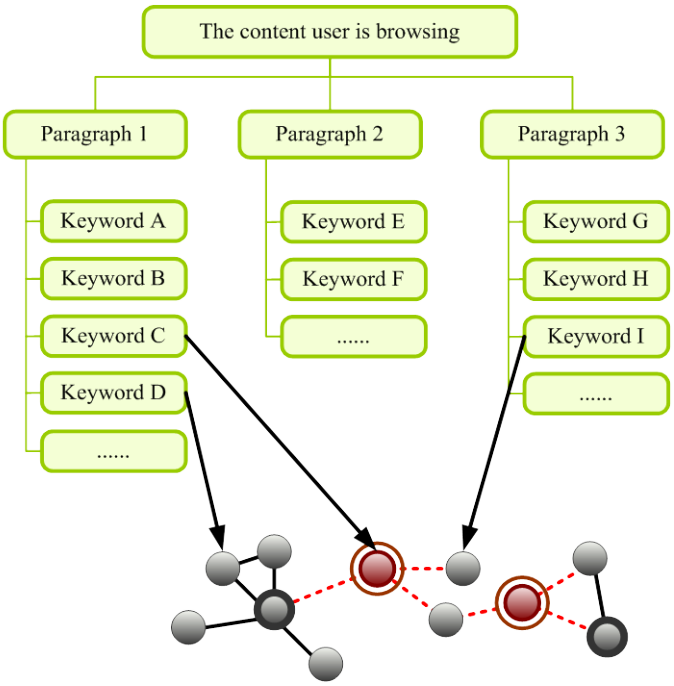

Figure 2: Web page change and its corresponding keywords.

Each web page produces different word segmentations, therefore the word segmentations of first paragraph in a page can be represented as ($P_{1,1}$, $P_{1,2}$, …, $P_{1,k1}$) and the word segmentations of n^{th} paragraph can be represented as ($P_{n,1}$, $P_{n,2}$, …, $P_{n,Kn}$). The length of each page varies, as a result the last word segmentation of the first paragraph is represented as $P_{1,k1}$, and the last one of the last paragraph as $P_{n,Kn}$. However, Kn varies in relation to the length of the content, therefore it is used to represent an unknown word segmentation integer, and the correlation between its keywords and web content is as shown in figure 2 (Salton & McGill, 1983).

Recommendation Module

What distinguishes the advertisement recommendation technology of this research from that of the traditional is that, it takes into account rare and meaningful information. That is, the employment of chance discovery to locate the relevance in features among web content, which ultimately produces chances. Potential domains of user interests are excavated by building the associational network among web pages, thus supplying advertisements that meet user expectations.

Past advertisement recommendations utilised basic user information as the basis of analyses, but this involves the issue of privacy and would cause inconvenience for users. In addition, users must log in to enjoy the recommendation services. As a result, this research adopts web content as the basis for analyses to recommend advertisements. The combining of web content and chance discovery are as illustrated in Figure 3. In terms of advertising information processing, feature terms that represent the web content of the advertisements are located, and an advertisement database is also built. When chances are produced by chance discovery, they would be matched with advertisement database to find identical feature term so as to enable recommendations.

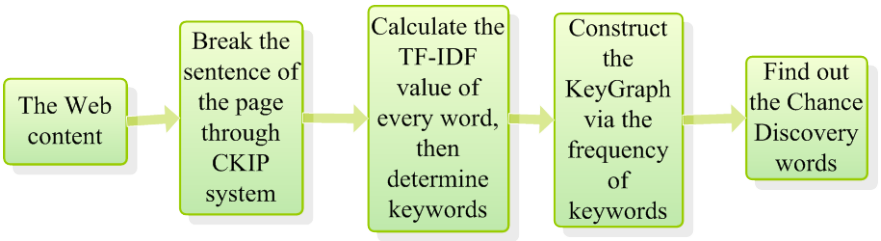

Figure 3: Keyword processing procedure.

Due to the fact that user browsing behavior is continual, this research uses web usage mining to record browsing history, so as to analyze the keywords within the page browsed and makes up a number of key graphs formed by web content, from where the chance nodes are located to perform recommendation. The chance discovery approach employed

by this research not only takes into account the content browsed by users at the time, but also those that are previous browsed. The browsing history is then merged into the analysis information. Furthermore, the evaluation given by other users is also considered, where opinion and feedback are included in the analysis.

Feedback Module

Other than basing the chance combinations of the advertisement pages on user evaluation and then provide feedback, the information contained in the advertisements would also be adjusted based on the evaluation. The value of such is computed using formula 5; when it is smaller than 1, it would not appear in the advertisement combinations of the chance discovery experiment.

DESIGN AND ANALYSIS

Research design

As illustrated in figure 4, the experiment procedure of this research will be elaborated further. Users are required to enter the experimental web site, and the log in information is not included in the analysis. The point of logging in is to observe the course of operation of the subject, and the reminders are given when required, or in the case of failing to complete the experiment the information is removed.

Figure 4: Experiment procedure.

Data source and experiment subjects

The experimental data of this research are collected from the shopping page of Yahoo!Taiwan (http://tw.shopping.yahoo.com/). The advertisement data from the site are used to simulate an advertising platform. There are 300 advertisements and 200 entertainment and recreational web content data collected. The data include user browsing content as well as log files, where the former is retrieved by web spider. To avoid confusion likely to be caused by multimedia objects, web mining would only be conducted on words in

order to obtain accurate data.

The duration of the experiment is one week and is divided into two phases. There are 75 subjects during phase one, and 35 in phase two that are made up of young and frequent users of the Internet. The structure of the subjects from both phases is identical, and their standard error is 0.087.

Experiment conditions

An advertising platform is designed, which allows subjects to access any web pages that might interest them, and based on the content, chance discovery as well as web content mining would then be conducted. User behaviour is recorded utilising web usage mining and an examination would then be made by taking the above as well as questionnaires into consideration. To avoid user fatigue from browsing excessive advertisements, the experiment was conducted in two phases. The first was done based on traditional high frequency and chance discovery advertisements; phase 2 then asked users to evaluate based on experiences and group chance discovery advertisements. After the application of KeyGraph algorithm, each web page can construct a key graph based on its content. As shown in figure 5, the chance discovery feature words retrieved from the content of the web page consist of “sites”, “travel” and “seafood”. “Scenery” and “itinerary” are the high frequency terms, the recommended advertisements would therefore be based on these words.

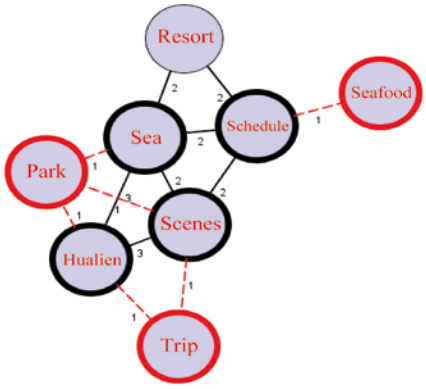

Figure 5: Web content key graph.

Initially, figure 5 is an example of “Hualien” (a city in Taiwan) travel page browsing, and based on the high frequency characteristics, travel advertisements highly relevant to the page would be recommended. In addition to providing relevant travel information, chance discovery would also provide that of other regions due to the low frequency of the recommendation basis. Advertisements associated with “Hualien” or travel will be

recommended. However, these advertisements are different from those of high frequency combinations. Based on the result of this experiment, chance discovery would locate advertisements associated to “parks”, “travel” and “seafood”. Technology products related to travel and food information related to seafood would be picked up.

The advertisements are resulted from the experiences from chance discovery of experiment three. The recommendations are based on “Japanese-style”, “fresh” and “parks” from figure 6, because the subject had previously browsed a page related to Japanese cuisine. As a result, chance discovery is applied based on the browsed web content to find the two pages that can be linked via the term “Japanese-style”. That is why the advertising from experiment three recommends information that contains the feature.

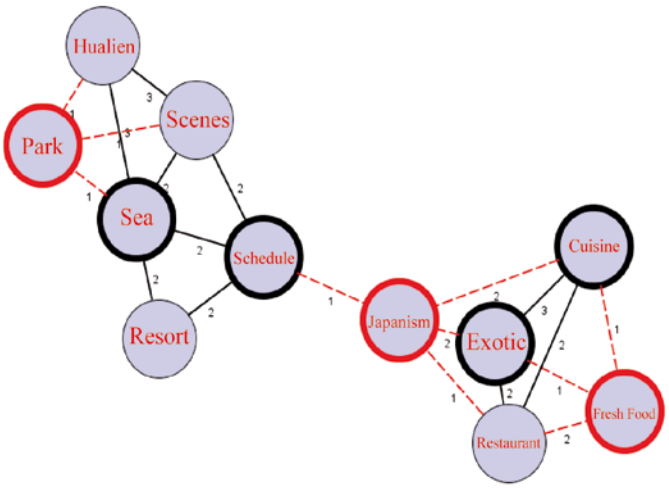

Figure 6: A key graph that combines experience from chance discovery of travel and food.

However, if the subject had previously browsed web content that contains digital appliances, then “Japanese-style”, “fresh” and “cameras” could become the bases of recommendations. As illustrated in figure 7, while browsing web pages about food or travel, users would receive advertisements containing that features. The advertisements within the dotted line in figure 8 are the group chance discovery from experiment 4. While browsing the “Hualien” web page, because other subjects evaluating the page and advertisements concerning “seaports”, “seafood”, “sites” and “parks” have the relevant features of chance discovery, therefore a key graph on the content of the two is constructed to locate the nodes of chance discovery.

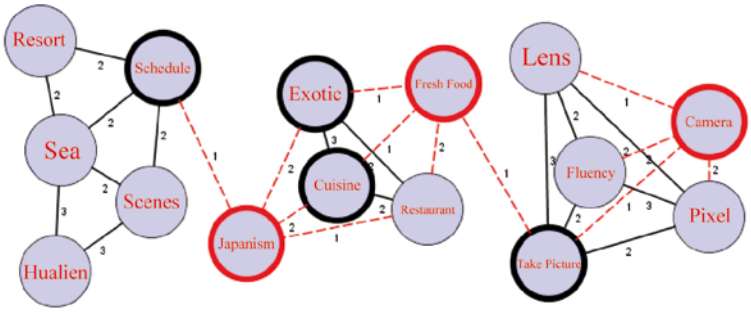

Figure 7: A key graph that combines digital products, travel and food.

As shown in figure 8, the nodes are “travel”, “seaports” and “sites”, thus the recommendations of advertisements contain these. Due to the fact that the experiment has many subjects, each web page would change its recommended advertising due to the varying user evaluation. If a new subject deems the “Hualien” web page and advertisements about off-shore island travel and the feature connection of chance discovery, then the key graph of the advertisement and the web page would be as illustrated in figure 9. The recommended advertisements by the group chance discovery of this page would be based on “off-shore islands”, “seaports” and “sites”.

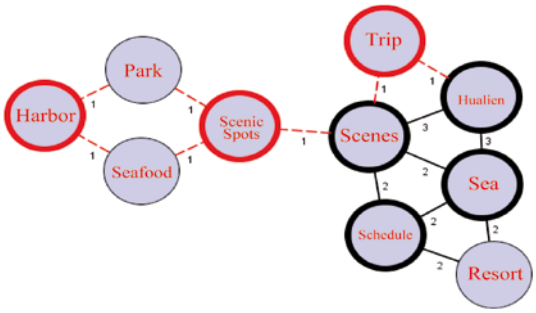

Figure 8: Key graph 1 of group chance discovery.

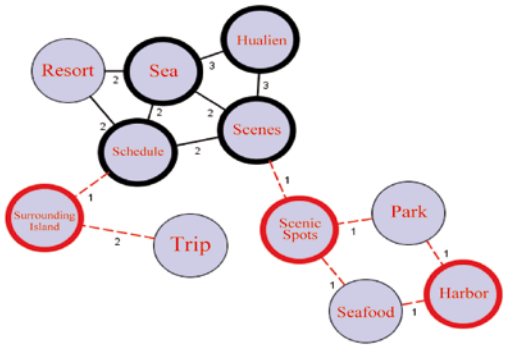

Figure 9: Key graph 2 of group chance discovery.

Experiment design

There are four kinds of recommendation experiments conducted by this research, which are elaborated below. The advertisements recommended are recorded in each experiment. Furthermore, if users do not undertake evaluation, then the evaluation data and information regarding users would not be included in the analysis.

Experiment 1: conventional high frequency feature recommendation

Based on the TF-TDF value after word segmentation, conventional high frequency retrieved the top 20% of keywords as the basis of advertisements search. Just like keyword advertisements, the advertisements recommendations were based on the keywords contained in the Web page

Experiment 2: conventional Chance Discovery recommendation

Based on the TF-TDF value after word segmentation, conventional Chance Discovery recommendation retrieved the top 40% of keywords as the characteristics of the Web content. Term nodes of low frequency and contained network connectivity were found utilising the key chart algorithm of Chance Discovery. The use of these nodes as the basis of advertisement recommendations enabled an extension to other advertisement types.
This research adopted Formula 1 to measure whether users regarded the advertisements corresponded to the feature of Chance Discovery, and utilising their evaluation to work out $Chance_{Value}$. The Formula is as below:

$$Chance_{Value} = \begin{cases} \dfrac{Interest_{Score}}{\mathrm{Re}lation_{Score}} & ,if\ (\mathrm{Re}lation_{Score} > 1) \\ 0 & ,if\ (\mathrm{Re}lation_{Score} = 1) \end{cases} \quad (1)$$

$Interest_{Score}$ represents the evaluation score users had given to the advertisements. That is, the degree of preferences or interest that users had towards the content or item. $\mathrm{Re}lation_{Score}$ represents the degree of relevance between the advertisements and Web content deemed by users. $Interest_{Score}$ and $\mathrm{Re}lation_{Score}$ were divided into 7 levels in this experiment, so as to allow users to reflect in details the degree of relevance between the advertisements and Web content.

Although the method of evaluation was tiered, errors were still likely in the judgement of relevance. But due to the difficulty involved in the using of questionnaires or other methods of response, this method was still adopted.

$Chance_{Value}$ represents the likelihood of the advertisement meeting the features of Chance Discovery as regarded by users. If it was 1, then the advertisement did not contain such features. If it was greater than 1, then the advertisement contained such features and a low frequency but important network connectivity. Even though the advertisement had no strong association with the Web content, it was still able to arouse user browsing interest.

If $Chance_{Value}$ was smaller than 1, then the connection between the advertisement and Web content was greater than user preferences, and would not be the desired information. If $\mathrm{Re}lation_{Score}$ equalled to 0, then the evaluation was given based on user preferences and had no relevance to the Web content, which would not be taken into account.
At this stage of the experiment, Web Usage Mining and Formula 2 would be employed to discover information containing representative and Chance Discovery features. In other words, information with $Usage_n$ greater than 1 would be recorded and used as the recommendation basis during the group experiment of phase 2 (Hou X. R. 2003) .

$$Usage_n = \frac{Content_n}{Average(Content)} \times \frac{Time_n}{Average(Time)} + \frac{Time_n}{37 + (2 \times Count(Ad))} \qquad (2)$$

$Content_n$ indicated the size of the Web content and $Average(Content)$ the average size of Web content in the database. $Time_n$ would be the amount of time that users spent on browsing the page, and $Average(Time)$ the average browsing duration of the page in database, which would enable the determination of the meaning of a particular user among the group information. The form of $2 \times Count(Ad)$ represents the advertisement recommendation feedback from users within each Web content. The inclusion of the experiment time allowed the estimation of the actual browsing time. $Count(Ad)$ indicated the advertisement quantity, with 2 being the shortest time value spent by users on each recommended advertisements plus 37 seconds to obtain the threshold value (MIC, 2001a), in order to work out whether the amount of time users spent on reading the Web page exceeded the threshold value. When $Time_n / 37 + (2 \times Count(Ad))$ exceeded 1, it indicated that users had greater interest in the Web page.

Experiment 3: experience Chance Discovery recommendation

This experiment utilizes personal browsing experience as the basis of recommendations As

gathering together web pages browsed by users would give an indication of their domain of interest, recommendations are supplied based on such information. When users continue to browse the next page, based on the browsing behaviour of the previous page, $Usage_n$ value is worked out to find out if any behaviour is already available for this page. If the outcome is positive, then the $Usage_n$ value from prior browsing would be added to this computation, otherwise only the $Usage_n$ value of this browsing would be taken into account.

Meanwhile, should user browsing behaviour be continuous, compare it with the chance from the previous page. If the two chances are identical, then utilise the chance and give recommendations. If the chance nodes of the two are different, get the record of this particular user and undertake a key graph computation of web content with the top 5 $Usage_n$ value, so as to find the information node of the overall chances to give advertisements recommendations.

Only current user experience information from experience chance discovery experiment would be used, therefore those from phase one would not be included in the analysis. When new users join as new subjects, advertisements recommendations would function based on its browsing experiences, and this would not affect the outcome of the experiment.

Experiment 4: group Chance Discovery recommendation

This part of the experiment is designed based on personal browsing preferences and group recommendation. Recommendations are based on user and group evaluation of the advertisements. This research employs formula 3 to compute the degree of chance recognition users have on the web content, and the use of formula 4 would estimate the chance recognition of the group. Both Formulae are demonstrated below:

$$Interest_{person} = \sum Chance_{Value}, Chance_{Value} > 1 \quad (3)$$

$$Interest_{Group} = \frac{\sum Chance_{Value}}{People_N}, Chance_{Value} > 1 \quad (4)$$

$Interest_{person}$ represents the sum of advertisement evaluation $Chance_{Value}$ that users have during this browsing. In other words, it is the degree of acceptance users have shown regarding chance discovery characteristics advertisements during the evaluation. $Interest_{Group}$ indicates the average $Chance_{Value}$ value of the advertisements on the web

page that all users have after browsing the page. $People_N$ represents the number of users, whereas $Interest_{Group}$ can be regarded as the average value that users have on the degree of chance discovery between the advertisements and web content

During the experiment, when $Interest_{person} > Interest_{Group}$, the advertisements recommendation of user's next web page would give preferences to chance discovery advertisements constituted by the user alone, thus all the information received would be focused on what the users prefer.

When $Interest_{person} < Interest_{Group}$, then preferences will be given to chance discovery advertisements constituted by the group, which means the degree of group chance recognition is higher than that of the personal, therefore the recommendation based on the group. Should the two values be equal, then recommendations would be based on the advertisements combination of individual and the group.

Feedback Module

As the experiment progresses, the advertisement evaluation given by subjects is recorded and examined utilising formula 5 to determine whether or not to recommend the advertisements.

$$Ad_{Value} = \frac{\sum Chance_{Ad}}{N} \times \frac{\sum Interest_{Ad}}{N} \quad (5)$$

Ad_{Value} represents the degree and $\sum Chance_{Ad}$ the total evaluation of chance discovery characteristics of the advertisement, whereas N is the number of appearance. $\sum Interest_{Ad} / N$ is the weighted concept, and $\sum Interest_{Ad}$ represents the sum of interest that users have towards the advertisement. When the chance discovery characteristics of the advertisement is greater than 1 and the higher the user evaluation, then the probability of it appearing is greater. If one of the values is smaller than 1, which means that the advertisement contain no characteristics of the chance discovery or user evaluation is not ideal, therefore it would not appear in the recommendation.

Experiment results and analysis

System efficiency analysis

Analysis and examination of the variances produce results as illustrated in Table 1. When the test statistic P-value of frequently browsed product information is smaller than 0.05, null hypothesis is thus rejected. It goes on to show that subjects, who frequently browse product information, demonstrate a clear association in the impression between recognising high frequency characteristics and chance discovery. If the test statistic P-value of dining is not smaller than 0.05, but is close to the threshold value, it can also be gathered that subjects demonstrate a clear association in the impression between recognising frequency characteristics and chance discovery.

Users browsing product information and those browsing dining would expect different information, and in addition to hoping that the system would provide searched content, it would also provide recommendations or relevant information. For example, users browsing dining pages would wish the system to recommend similar type of food after being presented with the search result, or they would like to know of other restaurants within a similar price range etc. On the other hand, users who browse product information would share the same mentality. So in hoping that the system would not only provide product information, the related products could also be presented. This can equip users with more information before making a decision.

Table 1: ANOVA on subject advertisement preferences and their most frequented web pages.

Most frequented web pages by users	DF	MEAN SQUARE	F Test	P'[-VALUE
News	2	0.180	1.251	0.292
Science and Technology	2	0.212	0.833	0.439
Travel	2	7.171E-02	0.280	0.757
Entertainment	2	0.278	1.110	0.335
Business	2	5.043E-02	0.291	0.749
Product information	2	0.812	4.484	0.015
Online Shopping	2	5.865E-02	0.234	0.792
Auction	2	0.127	0.547	0.581
Art and Culture	2	0.155	1.068	0.349
Dining	2	0.605	2.712	0.073
Health and Care	2	0.172	1.268	0.287

From the outcome of the analysis, it can be seen that utilising the advertisement feedback

module design of this experiment that user evaluation of advertisements was closely related to the relevance of the Web content. As illustrated on Table 2, the result meets the objective of the experiment. The system provides subjects with advertisement pictures, the advertisement itself as well as a combination of advertisement information. However, it seems that the subject evaluation of advertisements is influenced by the experiment topic, and does not base their choices upon personal preferences.

Table 2: Analysis of system efficiency.

System Efficiency Analysis		ANOVA Result
1. H1 Advertisement evaluation analysis		
H1-1：	The subject evaluation of advertisements is not affected by pictures contained in the advertisements.	P-value > 0.05, null hypothesis not rejected.
H1-2：	The subject evaluation of advertisements is not affected by objects contained in the advertisements.	P-value > 0.05, null hypothesis not rejected.
H1-3：	The subject evaluation of advertisements is not affected by the association between the advertisements and web content.	P-value < 0.05, null hypothesis rejected, which indicated a clear association between advertisements and Web Content and evaluation.
H1-4：	The subject evaluation of advertisements is not affected by advertisement combination.	P-value > 0.05, null hypothesis not rejected.
2. H2 Online habit analysis		
H2-1：	The Subject preferences of advertisements are not affected by the average of time spent online.	P-value > 0.05, null hypothesis not rejected.
H2-2：	The subject preferences of advertisements are not affected by browsing experience.	P-value > 0.05, null hypothesis not rejected.

System Satisfaction Analysis

As demonstrated in Table 3, the idea of Chance Discovery can indeed expand the range of advertisement recommendation. The use of browsing history can furnish users with interested advertisements, and a network can be constructed based on browsed domains.

Gathering from the experiment result, the coverage and chance discovery value of the group is higher, which means the design is capable of expanding the range of advertisements to diversity. It also means that the advertisements recommended are more likely to contain

characteristics of chance discovery. In other words, it is relevant to the web content, but is still able to recommend advertisements of other domains, as illustrated by Table 3.

Table 3: System accuracy indices.

			Conventional High Frequency Characteristics	Conventional Chance Discovery	History Chance Discovery	Group Chance Discovery
Average Error Ratio			6.85%	10.29%	6.32%	15.20%
Inversion Coefficient	Satisfaction Rate	High Inversion	0.68%	0.74%	2.11%	4.00%
		Low Inversion	4.79%	3.68%	2.11%	4.00%
	Degree of Relevance	High Inversion	2.05%	1.47%	2.11%	1.60%
		Low Inversion	2.05%	3.68%	0.00%	4.00%

In comparing the group chance discovery and historical chance discovery, taking into account the inversion coefficient and average error ratio, and the kurtosis and skewness of chance discovery, it can be discovered that the outcome of the latter is more stable and with little variability (Papagelis et al., 2004; Sarwar et al., 1998). The improved chance discovery can be divided into that of history and group during the discussion. It is understood from the experiment that users are relatively more satisfied with the advertisement recommended by the former. As shown in Table 4, the recommendation is based on the web content that users are browsing at the time. Therefore it is adaptable to the domains browsed.

Table 4: Satisfaction in system recommendation.

		Conventional High Frequency Characteristics	Conventional Chance Discovery	History Chance Discovery	Group Chance Discovery
Average Rate of Satisfaction		73.97%	63.97%	78.95%	74.40%
Accuracy		74.11%	59.96%	75.11%	75.98%
Advertisements Satisfaction	Average	4.31	3.88	4.32	4.24
	Standard Deviation	1.82	1.87	1.67	1.57
	Mode	4	4	4	4
	Kurtosis	-0.91	-1.08	-0.77	-0.60
	Skewness	-0.28	-0.04	-0.31	0.10

A detailed analysis of the characteristics of chance discovery in this experiment, while excluding samples that evaluate the advertisements solely on personal preferences, would

result in the trend and phenomenon of the three chance discoveries as shown in figure 10. The data indicated that the average of group chance discovery is higher, but its standard deviation and the distribution of kurtosis are evener, and its skewness shows that the distribution of its $Chance_{Value}$ is on the lower side. Although the average of historical chance discovery is not as high as that of the group one, its distribution is more concentrated; and judging from the skewness, its distribution is inclined to higher $Chance_{Value}$. As to conventional chance discovery, even though its kurtosis is more concentrated in comparison with that of the group and its skewness value lower, its standard deviation and average are both below that of historical chance discovery. As a result, judging from the outcome of the analysis, history chance discovery better matches the objective of this research.

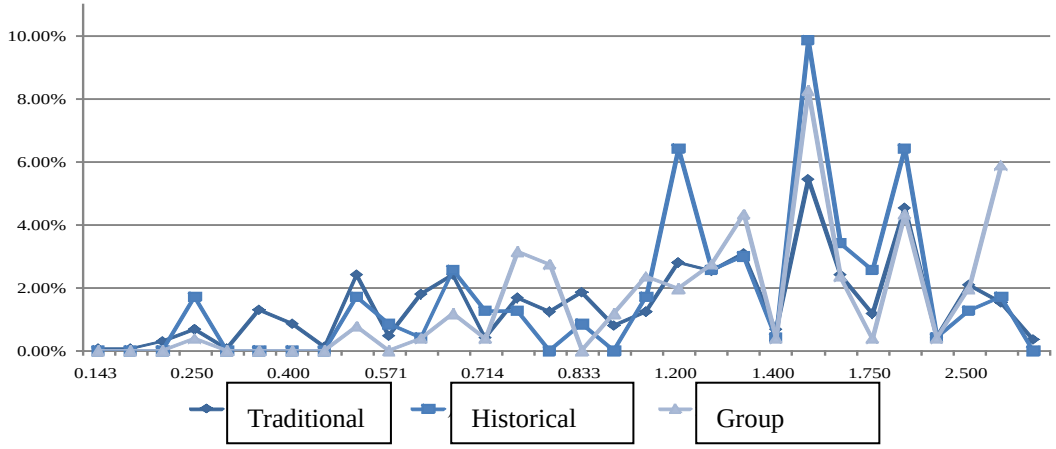

Figure 10: $Chance_{Value}$ from each experiment.

CONCLUSION

The reason behind building an advertisement recommendation is simple, to increase revenue. In order to achieve this, the recommendation system must be able to provide the accurate advertisements in the first place. In other words, the items in the recommended list must be relevant to consumer data or purchase history. If the information is correct and the consumer has such need, then the list will quickly run out. It is therefore important that the list contains items that are “associational but not relevant intuitively” and “fresh”, so as to stimulate the will to purchase. To maintain the diversity and richness of the list, the reciprocation between the addition of new items and the purchase behaviour was essential.

Gathering from the result of the experiments, the idea of Chance Discovery can indeed assist the expansion of domains recommended, and the use of Web Usage Mining helps to filter out meaningful of representative information, thus aiding the construction and correction of

web nodes within chance discovery.

The results of recommendations are likely to be limited by the incompleteness of information as well as the lack of features in terms and lead to the discovery of chance that is already known to users. If the recommendation study can retrieve terms at greater precision, so as to provide more detailed information for the analysis, then it is more probable to excavate the potential need that would otherwise be difficult to uncover.

Currently online advertisements are actively provided to users, but they do not necessary meet the demands of users, and often cause information overload. Although present day online advertisements are pretty self-sufficient, there still is a lack of understanding in terms of user interest. As a result, the recommended advertisements do not meet user need and their domains are limited, which leads to an inefficient outcome.

The contribution of this research lies in the proposal of a personalised advertising recommendation structure. Under the influence of uncertain decision-making in the dynamical circumstances, the proposal of Chance Discovery provides a novel and alternative solution.

ABSTRACT

Nowadays, Internet has become the best popular one of the consumers' shopping channels. However, there is different in online shopping situation is because of consumers in different cultures and countries have different online shopping behavior is worth to discuss. This study is to compare the cultures effect in different of online shopping situation between Taiwan and Malaysia. There were 120 questionnaires collected from Taiwan respondents and 118 questionnaires from Malaysia respondent respectively. Statistical analysis software SPSS 17.0 and AMOS 6.0 were used to analyze the impact among two countries on e-service quality, satisfaction, trust, and purchase intention. The model fit of this study was in an acceptable level, and this indicates that the theoretical model of this study supports the description of e-service quality for e-retailers that online shopping situation will be effected by trust and satisfaction. But caused by the cultures in online shopping situation and the relationship on e-service quality to trust and satisfaction have significant differences between two countries. Hofstede's culture dimensions analysis was used in this study and it shows that the uncertainty avoidance index of two cultures meets Hofstede's research. It makes the differences in culture affect the process in online shopping. The result of this study will be available for those who interested in developing a transnational e-retailer as a reference, as well as academic research on cross-cultural comparative analysis.

Keywords: Culture, Shopping Behavior, Trust, Satisfaction.

INTRODUCTION

With the development of information technology and the application of Internet become more and more popularity, the Internet population is increasing every year. Until 31 December 2009, the world online population has reached 1.8 thousand million of which was led by Asia, up to 7.6 hundred millions Internet users. Europe placed the second which has up to 4.2 hundred millions internet users. Among the Internet users in Asia countries which was led by China, up to 3.38 hundred millions Internet users. Malaysia and Taiwan placed at the ninth and eleventh which have up to 17 millions and 15 millions respectively (Internet Usage and World Population Statistics, 2009).

According to Nielson (2009), the number of Internet shoppers up 40% in the past two years and more than 85% of the world's online population has used the Internet to make a purchase. Among Internet users, the highest percentage shopping online is found in South Korea, where 99% of those with Internet access have used it to shop. Before year 2008, only 5.9% of Malaysia population has shopped online. From the survey, seven in ten consumers claimed to have made a purchase over the Internet before. In 2009, Taiwan maintained the growth trend of online shopping market. The market between Malaysia and Taiwan has a great gap in contrast.

This market trend has contributed many retailers know how to simplify the operation of the website to attract consumer. There is no frontier in Internet, so the retailers not just have to understand how the functions and services should be provided; they also have to find whether the same functions matched in other countries. This study attempted to do the evidence research and to be directed against the consumer of Taiwan and Malaysia's baby and children online store through online questionnaire. The purpose of this study is to test (1) the significance of relationships among e-service quality, satisfaction, trust, and purchase intention, (2) the comprasion effect of culture on e-service quality, satisfaction, trust and purchase intentions between online retailing websites of Taiwan and Malaysia.

LITERATURE REVIEWS

e-Service Quality (E-SERVQUAL)

The main purpose of running a business is to pursue a better goal and higher profits. Developed from Internet marketing and the traditional service quality literature, service quality is one of the key factors in determining the success or failure of electronic commerce (Yang, 2001). The concept of service quality in e-commerce, also called e-service quality, can

be defined as the consumers' overall evaluation and judgment of the excellence and quality of e-service offerings in the virtual marketplace. Parasuraman, Zeithaml, and Berry (PZB) (1985) developed a multidimensional service quality assessment scale known as SERVQUAL which define the term service quality as being the perception by a consumer of the difference between the expected service and perceived service such as reliability, responsiveness, competence, courtesy, communication, credibility, security, understanding, access and tangible.

Furthermore, Parasuraman et al. (1988) developed a definition of service quality as being "the overall evaluation of a specific service firm that results from comparing that firm's performance with the customer's general expectations of how firms in that industry should perform". As for e-commerce stores, a well-designed website will create a different value from the normal, and improve interest of a consumer access to the site simultaneously. Abels et al. (1999) proposed six operational definitions of user criteria for site design on library. Nevertheless, Santos (2003) used focus groups interviews to provide input for the development of the conceptual model of e-service quality. It is proposed that e-service quality consists of an incubative dimension and an active dimension using time – before and after a Web site is launched – as the criterion for separating the dimensions. A well design website will create profits and contribution to a company. E-service quality not only provides an e-commerce corporation a better advantage of competitive. It also enhances the relationship between producers and consumers through consumer quick respond to involve consumer into the process of product development. Ease of use, usefulness, appearance, linkage, structure and layout, and content will be used in this study as the e-service quality (E-SERVQUAL) that attracts consumers.

Satisfaction, trust, and purchase intention

Sysmanski and Hise (2000) summarized that convenience, product offerings and product information, site design and financial security are the antecedents of e- satisfaction by using focus-group interview. The empirical results of the study found that convenience, site design and financial security had the significance influence to e-satisfaction. Rust and Oliver (1994) suggest that customer satisfaction reflects the degree to which a consumer believes that the possession or use of a service evokes positive feelings. It is important to note that satisfaction could be further conceptualized as a transaction specific satisfaction or cumulative outcome or overall satisfaction (Kuo et al., 2009; Chang, 2005). Parasuraman et al. (1988), Cronin and Taylor (1994), and van Reil et al. (2004) consider overall satisfaction to be primarily a function of perceived service quality. Compared to transaction specific satisfaction, overall satisfaction reflects consumers' cumulative impression of a firm's service

performance. While Oliver (1981) states that satisfaction is a summary of psychological state originating when the emotion surrounding disconfirmed expectations is coupled with the consumer's prior feelings about the consumption experience.

Corritore et al. (2003) provide a definition of online trust that includes cognitive and emotional elements, with trust encompassing "an attitude of confident expectation in an online situation or risk that one's vulnerabilities will not be exploited" (Cyr, 2008). Furthermore, the design of a website to a consumer to trust and feel confidence is very important and "willingness to rely on the retailer and take actions in circumstances where such action makes the consumer vulnerable to the retailer." Cyr (2008) developed a model to examine the characteristics of culture and design including information design, visual design and navigation design as antecedents to Website trust, Website satisfaction, and e-loyalty in Canada, Germany and China. The result showed that design characteristics should be central consideration in Website design across culture.

Consumer browsing behavior will influence consumer's purchase intention and re-purchase cause from consumer's experience. Henderson, Rickwood and Roberts (1998) developed a visual online store to examine the theory of planned behavior and suggested that the purchase intention of consumers will be affected if the consumers unable to browse or access to the virtual online store at the first time. Lohse and Spiller (1998) observed 28 online stores and sorted out six categories of environmental design that attract consumers. Emphasized that the more simple and easy of user interface and the lower complexity of information will easily affect consumer's purchase intention

Culture

According to Hofstede, national culture is "the interactive aggregate of common characteristics that influence a human group's response to its environment" (Dan J. Kim, 2008). Hofstede developed an index model that identifies five primary cultural dimensions: individualism (IDV), power distance index (PDI), masculinity (MAS), uncertainty avoidance index (UAI), and long-term orientation (LTO). Although the Hofstede dimensions are the most widely used, they have been criticized for equating nation with culture and for falling short of describing all important aspects of national cultures. To enhance this present study of the effects of national culture on trust antecedents, therefore, a second dominant culture theory proposed by Hall and Hall is included. Hall and Hall differentiated "high context" and "low context" national cultures mainly focused on communication aspects, an important part of the innovation adoption process. Context refers to how individuals and their society seek information and knowledge. People from high-context cultures (e.g., Japanese,

Chinese, Italians, Latin Americans, Arabs, Africans, Koreans, Southeast Asians, etc.) obtain information from personal information networks such as friends, business acquaintances, and relatives, whereas people from low-context cultures (e.g., Swiss, Austrians, New Zealanders, South Africans, Americans, Canadians, etc.) seek information about decisions from direct information sources such as watching, reading, reports, and databases (Dan J. Kim, 2008).

Hofstede's (2003) research analysis (Table 1) showed that Taiwan has higher individualism and power distance index than Malaysia. It means Taiwan tend to be an individual actions and not centralized country. While Malaysia has higher masculine and uncertainty avoidance index than Taiwan. It means Taiwan tend to have entrepreneurship, the spirit of adventure, and need more stability on work. Furthermore, Taiwan has higher long-term orientation than Malaysia. It shows that Taiwan is a country with high persistence and it takes long-term orientation seriously and thinks time as a finite resource and thrifty.

Table 1: Statistic scores of national culture dimensions.

Country	PDI	IDV	MAS	UAI	LTO
China	80	20	66	30	87
Hong Kong	68	25	57	29	61
Japan	54	46	95	92	88
Singapore	74	20	48	8	72
South Korea	60	18	39	85	100
Taiwan	58	17	45	69	93
Malaysia	104	26	50	36	41
Phillipines	94	32	64	44	27
Vietnam	70	20	40	30	57
Thailand	64	20	34	64	32
Indonesia	78	14	46	48	62
India	77	48	56	40	51

RESEARCH DESIGN AND METHOLOGY

The research model (figure 1) is based on integration of literatures from many scholars' opinions such as the e-service quality proposed by Abels et al. (1999) and Santos (2003), and TAM model proposed by Davis (1986). Analyzed the relationship between the e-service quality provided by the online retailers, built up consumer's trust and meet the need of

consumer's satisfaction. The questionnaire used in this study was design according to related literatures and scholars' opinions. The questionnaire initially including 65 items was generated, consisting of 45 items for e-service quality, 5 items for satisfaction, trust, and purchase intention respectively. All items were assessed using seven-point Likert scales from 1 = "strongly disagree" to 7 = "strongly agree".

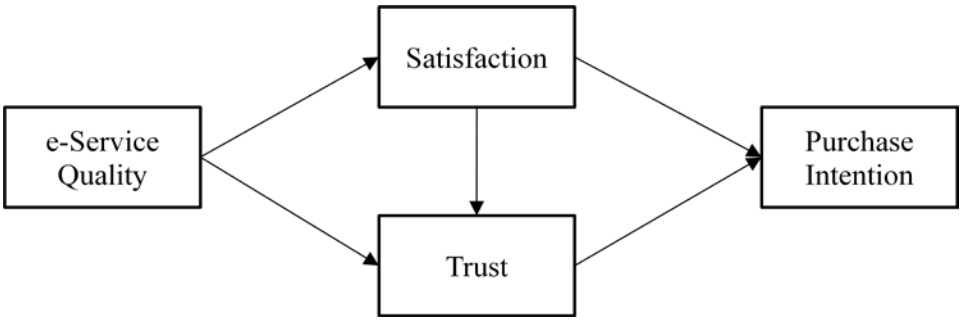

Figure 1: The research model.

The links for the online survey questionnaire were linked to Taiwan and Malaysia's infant and baby products' online store respectively. While the language used in this study was Chinese for online consumer in Taiwan and English for online consumer in Malaysia. The part of language translation was requested by the professor from the department of English application on behalf of audit grammatical errors and smoothness of the sentences.

DATA ANALYSIS AND RESULTS

Demographics of samples

The data were gathered through the internet questionnaire of Happy Home (http://www.hbhome.com.tw/front/bin/home.phtml) in Taiwan and Littlewhiz (http://www.littlewhiz.com/) in Malaysia. For the final survey, 120 survey questionnaires were collected from Taiwan respondents and 118 survey questionnaires were collected from Malaysia respondent respectively. The basic attributes of respondents are shown in this section: ethnicity, gender, age, online shopping experience since, marital status, intention of shopping online, average monthly online shopping, and average monthly online shopping expenses. In the aggregate sample for Taiwan respondent, 50.4% respondents are men and 48.8% are women. More than 60% respondents are people born between year 1980 to 1988, and most of the respondents have more than 3 years experience in online shopping. While in the aggregate sample for Malaysia respondent, 81.4% respondents are women and 18.6% are men. All of the respondents are between age 22 to 36, and most of the respondents have less then 3 years experience in online shopping.

Reliability and validity test

A Confirmatory Factor Analysis (CFA) using AMOS 6.0 was conducted to test the measurement model. Reliability and convergent validity of the constructs were estimated by composite reliability and average variance extracted (AVE) (see Table 2 and 3). The composite reliability for all constructs was above the recommended 0.70 level. Convergent validity can be assessed by the average variances extracted (AVE) and all were above the recommended 0.50 level (Fornell & Larcker, 1981), which meant that more than half of the variances observed in the items were accounted for by their hypothesis constructs. Convergent validity can also be assessed by factor loading.

According to Hair et al.'s (1992) recommendation, factor loadings level which greater than 0.50 were significant. All of the factor loadings of the items in this study were greater than 0.50 and each item loaded significantly on its underlying construct. Therefore, all constructs in the model had adequate reliability and convergent validity.

To examine discriminant validity, this study compared the shared variances between constructs with the AVE of individual constructs. Following Fornell and Larcker (1981), this can be demonstrated by the fact that the square root of AVE each construct should generally be higher than the correlations between it and any other constructs in the model. All results confirm to be discriminant validity as shown in Table 4. In summary, the measurement model demonstrated adequate reliability, convergent validity and discriminant validity.

Structural equation model (SEM)

This study employed structural equation model (SEM) to verify the proposed model and used AMOS 6.0 software to analyze this model. The dimensions of e-service quality, satisfaction, trust, and purchase intention were analyzed first. Later, the research model was analyzed and verified. In the model fitness test, measurement model test and structural model test were used. To test the normality assumptions underlying the maximum likelihood procedure, multivariate normality test were used to exam whether the data were normal distributed and the result indicated that data were normal (p-value>0.05). Then the confirmatory factor analysis (CFA) was performed to test the overall fit of the measurement model. As shown in Table 2 and 3, all the squared multiple correlations (SMC) of the

measured variables were larger than 0.50. Moreover, the completely standardized factor loadings all reached the level of significance.

In the structural model, Bollen(1989) pointed out χ^2/df below 5 is considered ideal fitness and the most widely used overall model fit indices are the goodness of fit index (GFI), comparative fit index (CFI), the adjusted goodness of fit index (AGFI), the root mean residual (RMR), and the normed fix index (NFI). Threshold values for these indices are above 0.90, above 0.90, above 0.80, ranging from 0.05 to 0.08, and above 0.90, respectively (Hair et al., 1998). Another measure that attempts to correct for the tendency of the Chi-square statistic with a sufficiently large model is the root mean square error of approximation (RMSEA), where values ranging from 0.05 to 0.08 are deemed acceptable (Jarvenpaa et al., 2000; Byrne, 2001). In this study, values of GFI, AGFI, CFI, and RMSEA are 0.572, 0.539, 0.777 and 0.080, respectively and value ofχ^2 and df (degree of freedom) is 2446.622 and 981, respectively. Meanwhile, χ^2/df is 2.494 falling within the recommended ranges.

Figure 2 and 3 show the estimated path coefficients of the structural equation model for Taiwan and Malaysia respectively. The result of this study shows that consumers in Malaysia are more concern about the performance on e-service quality of e-retailers than consumers in Taiwan. That is because of consumers in Taiwan have more experience in online shopping than consumers in Malaysia. The results in figure 2 and 3 seem to indicate that the interrelationships among e-service quality, satisfaction, trust, and purchase intention are specifically significant except for the relationships between satisfaction and purchase intention in figure 3 shows insignificant.

From above analysis, culture dimension will be used to explain the different online purchase behaiver between Taiwan and Malaysia. According to formula given from Hofstede's present studies is only uncertainty avoidance index adopted in this study. Based on Hofstede's culture dimensions, the online purchase intention of consumers is deeply affectd by different construct which is satisfaction and trust because of the different uncertainty avoidance index in the different countries.

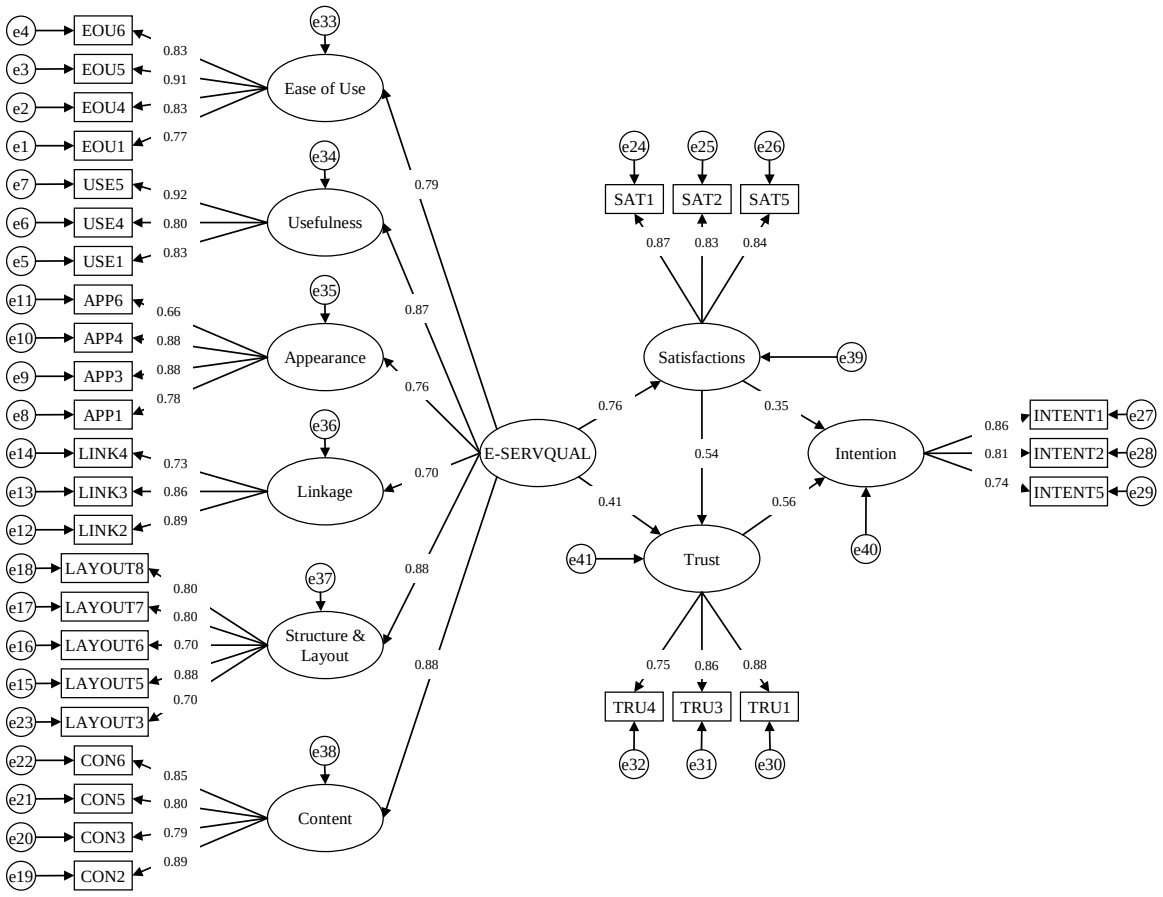

Figure 2: Taiwan's SEM model.

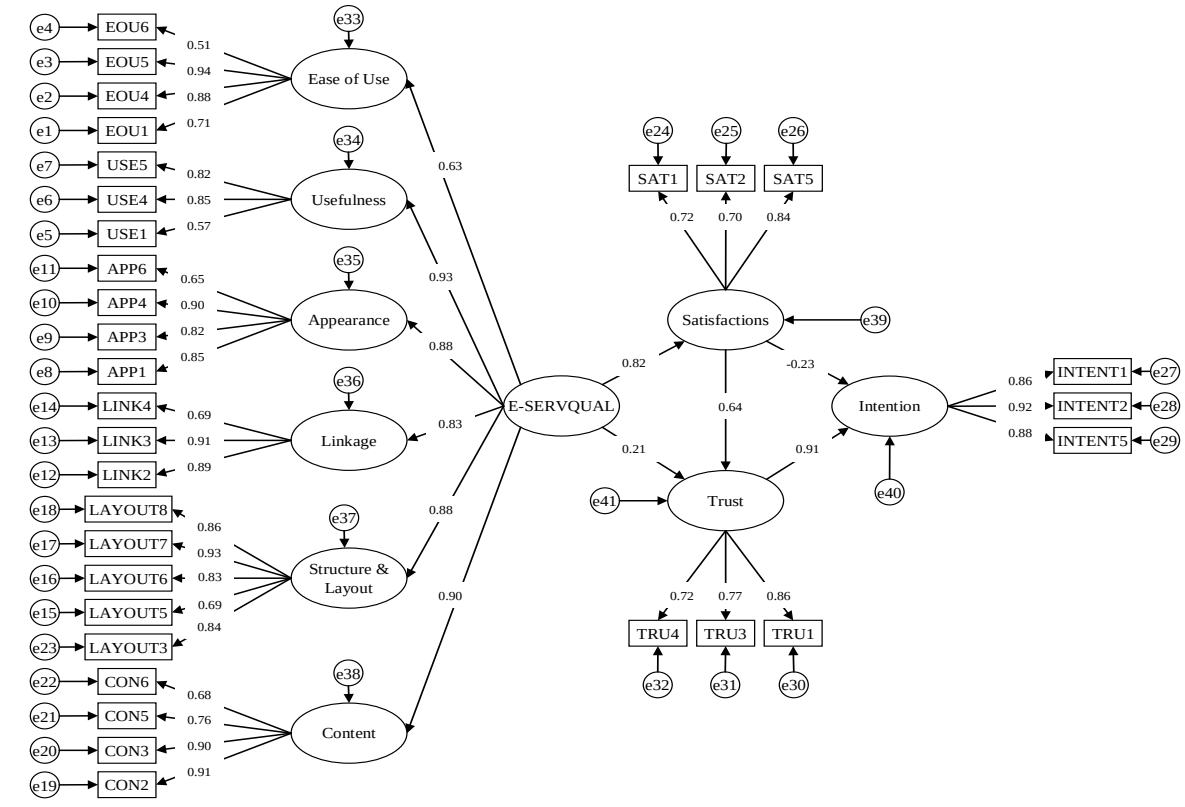

Figure 3: Malaysia's SEM model.

CONCLUSIONS

The major objectives of this study were to identify the interrelationships among e-service quality, satisfaction, trust, and purchase intention on the online retailing websites. Interestingly the SEM model between Taiwan and Malaysia are significantly different as shown in figure 2 and 3. As shown in figure 2, e-service quality of Taiwan model has significant effects on satisfaction and trust. While on the other hand, e-service quailty of Malaysia model has significant effects on satisfaction but not for trust.

For online consumers in Taiwan, purchase intention will be affected by satisfaction and trust of the website. However, as the network speed and experience in online shopping for consumer in Malaysia is not as high as compare to Taiwan. Purchase intention will not be affected by satisfaction but with the trust of the website. According to Hofstede's culture research, we found that Malaysia is a low uncertainty avoidance country while Taiwan is a moderate uncertainty avoidance country.

From the managerial implications, the e-retailers must take consumers' satisfaction and trust into consideration will be more effective than the advertising or worth of mouth. Avoid overly complicated of website design or need good quality of network for opening the website smoothly. Moreover, it will enhance the opportunity for consumer to shop at the website if the e-retail makes consumers feel reliable and comfortable when they first entered. As the age and the experience of shopping online are different between Taiwan and Malaysia, therefore it is important for e-retailers to provide a good service quality in order to enhance consumers' satisfaction and trust.

ABSTRACT

The purpose of this study is to enhance the current understanding about the new service launch process within telecom service industry. Further, the study examines the process improvements that product data management could offer in this context. This research utilised literature and case studies. The case company was chosen to present telecom service industry where well controlled launches have not always been the convention. Data collection was carried out through workshops and interviews. Product process and product/service launch process cannot be separated from each other. To secure full benefits from the launch, the whole service lifecycle has to be taken into account. Service businesses frequently lack rigorous development processes with defined milestones and checklists. Structured design methods, for instance particular perspective emphasising "Design for X", would bring value to the new service development and hence to launch. This is an exploratory research where literature offers only scattered knowledge regarding new service development (NSD), data management and especially the studied industry lacks defined best practices. However, the results provide a good view of what these could be. Elements and best practices of product data management (PDM) for the new service launch process within the case industry are worth further studying. Finally, all these measures improve the customer experience, time to market and the efficiency of development efforts. This study suggests that there are benefits in linking PDM and NSD process. Further research in this field is needed as both academic and industry practitioners are still missing the general view in telecom services.

Keywords: Product data, product launch, service launch, new service development, telecom service

INTRODUCTION

The deregulation of telecommunication services has altered competition and directed dissolving monopolies to develop and launch innovative services as they are exposed to

increasing pressure from software and content industries. Due to their background and owing to the customs of the service sector, telecommunication service providers have been developing new services through quite ad hoc and free-floating procedures. The typical ease of new service development has frequently led to the proliferation of product variants and unnecessary changes to customers and internal functions. (Kelly and Storey, 2000; Magnusson et al., 2003; Gallouj and Weinstein, 1997; De Jong et al., 2003; Allee and Taug, 2006.)

The launch as the final phase of New Product or Service Development (NPD & NSD) pursues to maximise the success of new products by promoting market acceptance (Guiltinan, 1999). The studies on launch are minuscule compared with the front end of NPD (Di Benedetto, 1999). Formal processes over the back end of NPD have still been perceived to contribute to new service success (De Brentani, 2001).

Increasingly sophisticated customer requirements necessitate a wider variety of offering and hence more delicate NPD to battle the development complexity and avoid introducing outdated products. Managing development duration, cost and quality demands cooperation between numerous teams which create and utilise product knowledge in multiple distant locations. Such NPD calls for product lifecycle management (PLM) to integrate different processes and their agents through a shared body of knowledge. (Ameri and Dutta, 2005). The effective sharing and utilisation of product data are necessary for enabling rapid product launches (Ouertani, 2010; Huang et al., 2004; Sulaiman, 2000; Philpotts, 1996). Effectiveness within product data management (PDM) calls for a unified schema to be used in electric data transfer (Saaksvuori and Immonen, 2008).

Within the early new product development, there should be guidelines regarding how to ensure that unnecessary changes to the supporting applications are not made. In telecom service context, these applications are called operation and business support systems (OSS/BSS) and include, among others, service activation, billing and service assurance (Tyrvainen and Frank, 2008). It is vital to plan and understand well prior to launch the behaviour of the new service within the delivery supply chain. This allows IT tools capability to be analysed and scoped according to the delivery volumes and specialities. Key questions derive from the peculiarities of telecom service business such as the billing and delivery/provision volume forecasts; service item maturity, network capacity monitoring, and application upgrade complexity. Processes within the operator business are highly automated and require data form multiple sources. This implies that well managed and structured data is fundamentally required to deliver the value promised to the customer.

The purpose of this study is to identify the gap between current and ideal states in the product process for new services that proceed to be launched within the case company in telecom service business. Current literature and practice have several approaches on launch execution. Examples of these viewpoints include new product/service development, productization, design for X and product data (what information and when? How is it maintained?). Product launch and product data management are not linked in the current literature. Therefore we have compressed our target to following research questions:

RQ1. How to internally secure that new services are successfully launched?

RQ2. How does currently the case company manage its new service launches especially regarding the internal stakeholders?
RQ3. How should the case company ideally launch its new services?

The first question has theoretical content with practical relevance compiled in the end of literature review. Second question follows the problem setup in case company and thirdly, a framework for improved launch management utilising PDM will be conceptualised. More accurate development process has been presented in research process description.

LITERATURE REVIEW: LAUNCHING NEW SERVICES SUCCESSFULLY

One cannot capture the meaning of services within a single definition because the range of services and service features is vast (Cook et al., 1999; Johnston and Clark, 2008). The term service product denotes the composite of service experience and service results (Johnston and Clark, 2008). One major distinction between goods and services is that the service is consumed during its production (De Brentani, 1991; Johne and Storey, 1998; Lenfle and Midler, 2009). Services are processes that occur either as a one-time performance or within a contract based customer relationship (Tiihonen et al., 2006). Grönroos (1990) manages to define the service by staying universal:

> [Service is] an activity or series of activities of more or less intangible nature that normally, but not necessarily, take place in interactions between the customer and service employees, and/or physical resources or goods and/or systems of the service provider, which are provided as solutions to customer problems.

Services can be divided in the terms of amount of interaction between the service provider and the customer (Goldstein et al., 2002). Vargo and Lusch suggest that "*goods are distribution mechanisms for service provision*", which signifies that every firm fundamentally serves its customers. I.e. "*goods derive their value through use - the service they provide.*" (Vargo and Lusch, 2004; Vargo and Lusch 2008).

The NSD literature favours the term *service concept* (Figure 1) to denote the expectations of customers and service providers on the service and customer needs. The service concept offers the foundations for the marketing content (*What?*) and operations content (*How?*) (Goldstein et al., 2002). According to Johnston and Clark (2008), the elements of a service concept are the direct *service experience* of the customer, *the results and the benefits of service* for the customer, *service operations* by which the service is delivered to the customer and *the value of service* which denotes the ratio of benefits to price. The service concept is closely related to the productization philosophy that is presented next.

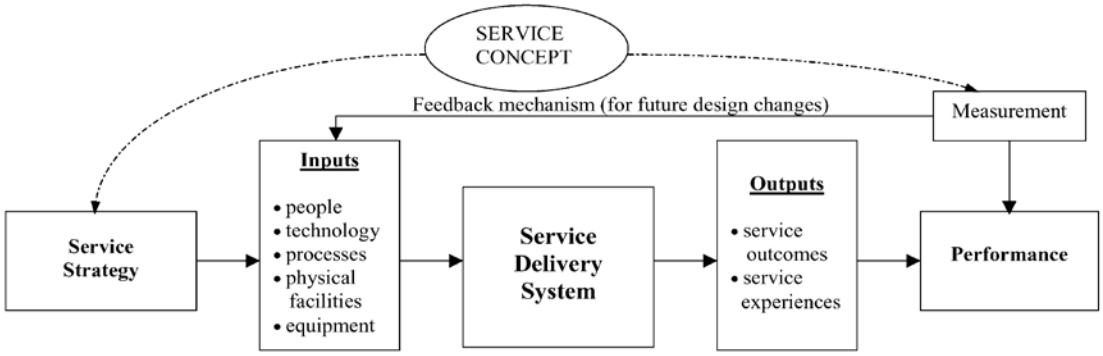

Figure 1: Concept based service design planning model (Goldstein et al., 2002).

Productization is a practical concept to support the communication between marketing and design people over the product development. The main idea behind productization is that after the company has fulfilled the basic NPD goal of importing well designed products into the supply system, it still has to seek means of selling them profitably. Internally this means matching the offering to the operations to improve efficiency. Marketing-wise, productization means building a more appealing offering. (Simula et al., 2008).

New Product Development Process

A closely defined and repeatable NPD process has been perceived as a significant success factor within the management of product and service development projects. This does not mean converting the existing ways of working into business process documentation but improving the methods conformable to best practices. (Cooper, 1996; Froehle et al., 2000.) Research within the field of NPD mostly agrees that the NPD process consists of series of development stages and evaluation gates (Tzokas et al., 2004).

Earlier NSD research proves that time and quality problems within service design are partly caused by the industry standard of weakly determined development methods (Gallou and Weinstein, 1997; Johne and Storey, 1998; De Jong et al., 2003; Dolfsma, 2004; Lenfle and Midler, 2009). De Jong and Vermeulen (2003) emphasise that service innovations are not frequently related to technology as great potential for advancements in services lies in service concepts, customer interfaces and delivery systems. Capacity creation and ramp up are suitable examples of tasks that more frequently extend NPD projects than NSD projects (Crawford and Di Benedetto, 2000.) Service development is thus possibly more effortless but also more common than the development of physical constructs. Yet Johne and Storey (1998) underline that the simultaneity of service production and consumption create demand for capacity planning as services cannot be held in stock. The frequently rapid development of service innovations allows services to be imitated very swiftly. Furthermore, the ease of implementing innovations may cause inadequate evaluations regarding the effects of new service features. (Voss, 1992; Johne and Storey, 1998). The intangible nature of services causes a need to 'tangibilise' the service concept so that it is not too abstract to be understood in consistent fashion (Menor et al., 2002).

It is clear that no modelling of the real NPD processes can be more than a crude estimation on the phenomenon. (Krishnan and Ulrich, 2001). Researchers have recognised two macro phases within NPD-projects i.e. "*the fuzzy front-end*" and "*the execution-oriented back-end*"

(Menor et al., 2002) or definition phase and realisation phase (Kalyanaram and Krishnan, 1997). At the early evaluations (gates) the projects are frequently measured against quite qualitative "*must have*" and "*should have*" criteria. As the project proceeds to the potential launch and starts to occupy more and more resources and stakes, the criteria gain respectively more financial and quantitatively reasoned profitability orientation. (Cooper, 1990). Further, the mortality rate of projects decreases as they proceed to launch (Barczak et al., 2009).

Consequently, the generic NSD model trying to describe the development processes has to be simplified as service provision forms an even more diverse group of industries than the manufacture of goods. The aforementioned two development phases provide enough precision. Here, these phases are named as search and implementation (Figure 2.) In the search phase, every idea would be treated as a promising opportunity for improved profits and ideal developer mindset would be creative and capable of sound decisions. The activities within the course of the search stage consist for instance of strategic positioning, idea generation and concept development and refinement. Over the implementation phase, the most promising ideas are converted to qualify being put up for sale. There creativity must yield to result orientation as the actual elements of the service delivery are adapted from prior capabilities, developed or outsourced. (Menor et al., 2002; De Jong et al., 2003.) Kuusisto and Riepula (2007) add that different phases of NSD should be considered parallel activities that vary in intensity as too much sequencing is artificial.

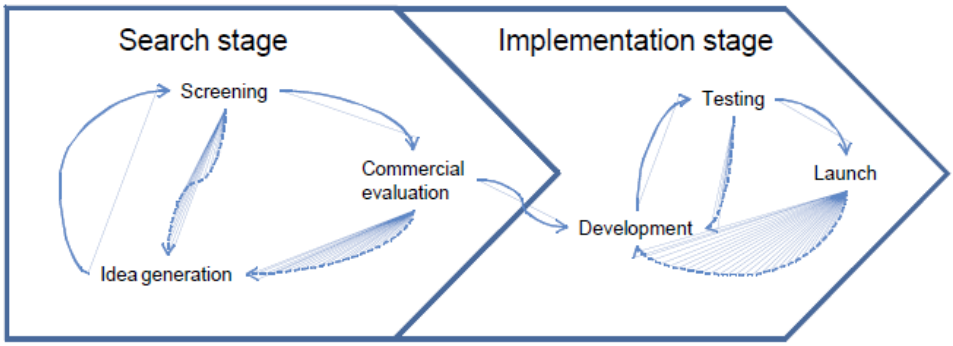

Figure 2 : NSD process model (de Jong et al., 2003).

Some design methodologies rooted in mechanical design, for instance, are general enough to be utilised in NSD processes. Tomiyama et al. (2009) highlighted a couple of concrete and general design methods on their design methodology keynote paper. These methods included Design for X (DfX) that focuses on concrete design goals within design and concurrent engineering which concentrates on design process management. For example, Menor et al. (2002) designate the optimization of service delivery as DfI (*Design for Implementation*).

Service Lifecycles

Service provisions frequently have a legal or social contract based warranty for extended periods of time. The warranty implies or expresses the promise that the exchange relationship will yield valuable service provision. Breaking the social warranty of service provision has "only" service provider's brand and customer relations at stake, but legal

contract may be the sole determinant of the conditions under which the life of the service may end. The service guarantee represents one type of *Quality of Service* (QoS) warranties which can be formalised in *Service Level Agreements* (SLA) (Vargo and Lusch, 2004; Voss, 1992; Dumas et al., 2003.) Provision of a service can for instance in mobile telephony be initiated and discontinued by a self-serving customer. Nevertheless, telecom operators rely mostly on their old rigid business and provision models. (Yelmo et al., 2007).

Product Data and Lifecycle Management

Product data is defined here as the type of data that is related to the product (Kropsu-Vehkapera et al., 2010). Product data is divided into product definition data, product lifecycle data and metadata. (Saaksvuori and Immonen, 2008). Two first-mentioned product data types can embrace both static and dynamic data. Static data comprises the information regarding product composition and processing. Static data can be relatively effortlessly captured into a PDM system. The task of keeping dynamic product data up to date is more laborious because it consists of events related to the product. (Yang et al., 2007.)

PDM helps companies to operate more effectively and efficiently. (Stark, 2005). Its most important task is to secure the availability of accurate product data (Kropsu-Vehkapera et al., 2009). PDM can be seen as an integration tool that delivers accurate product data in desired format timely to those in need of it (Liu and Xu, 2001). Subrahmanian et al. (2005) advise that PDM should engage in product information and even knowledge exchange to enable a PLM support system. Liu and Xu (2001) collected a summary of PDM benefits in the following topics: interdisciplinary collaboration, reduced time to market, reduced complexity of assessing the data of a company, improved project management, improved life cycle design (Design for X) and supply chain collaboration. Ameri and Dutta (2005) describe PLM as a knowledge management system that supports various lifecycle processes. PDM systems tend to be focused on certain aspects of lifecycle, typically design and manufacture. As a process, PLM incorporates larger scope as it supports the capture, organisation and reuse of knowledge through the product lifecycle.

Service Launch Success Factors

Process modelling improves development outcome quality. Further benefits are gained indirectly when the model reduces the impact of development task uncertainty on the quality of development. (Rai and Al-Hindi, 2000.) Di Benedetto (1999) observed both strategic and tactical launch management and discovered many activities that were well executed in successful launches (Table 1). The table also includes results from two other studies that are explained below.

Table 1: The most important determinants of new product performance (Di Benedetto, 1999; Voss 1992; Hultink and Robben, 1999).

Strategic Launch Activities	• Cross-functional teams make decisions concerning operations and marketing/sales strategy • Involving logistics in distribution strategy formulation, sales management coordination, inventory strategy development and after-sale service. • Decision to launch an innovative new product that belongs to the primary offering • A broad offering to cover varying preferences and budgets • Aiming to enter new or expand current high growth markets • Capitalising on the firm's or another brand's reputation, thus assuring broad acceptance • Fit with financial resources, sales and marketing capabilities, market research capabilities, existing delivery system, human resources, and managerial skills and preferences. • Formal post-launch evaluation
Tactical Launch Activities	• High quality of selling effort, advertising and technical support. • Well managed launch key activities (marketing plans, overall launch direction, launch itself, explicit market penetration objectives when launching to an existing market) • Well managed support programs (distribution channel activities, sales force training, appropriate pricing level, advertising program execution) • (Early) launch timing relative to competition and customers. Further, short NSD lead time • Penetration pricing • Project champion during launch • Securing resource availability • Full testing before release • Good cross-functional communications
Market Information Gathering Activities	• Phased market testing (customer selection, submitting the products to test customers, test market execution and analysis) • Studying customer feedback both during and after launch • Planning and testing advertising • Outsourcing specialised research work. • Explicit awareness of competitors' reactions to the launch. These reactions are visible to all market parties but are naturally uncontrollable by the manager introducing a new product. This needs to be set off against the clarity of the type and intensity of the reactions from competitors.

Hultink and Robben (1999) examined the relation between launch strategy and market characteristics, and new product performance. Overall, tactical activities were better managed, whereas strategic groundwork is frequently omitted in less successful launches (Di Benedetto, 1999). Voss (1992) studied performance under the service design and innovation topic, but found many similar results that fit under the launch topic.

2003 PDMA Best Practices Study proved that numerous overall NPD management methods at various levels are more widely used in the best companies than at the rest (Table 2). Further, no single practice was found to be either sufficient or necessary to guarantee the company's superiority in new products. (Barczak et al., 2009.)

Table 2: Most utilised NPD tools (most common first) (Barczak et al., 2009).

Market Research Tools	Engineering R&D and Design Tools	Technology Tools - Most utilised	Team Support Tools
• Beta testing	• DfM	• CAD/CAE	• Face-to face meetings
• Customer site visits	• Concurrent engineering	• Project management systems	• Teleconferencing
• Voice of the customer	• Failure mode effect analysis	• Document management systems	• Critical path, PERT, GANTT
• Alpha testing	• Value analysis	• Rapid prototyping systems	• Dedicated project intranet
• Lead users	• Quality function deployment	• PDM systems	• Team co-location
• Concept tests	• Six sigma analysis	• Performance modelling & simulation	• Videoconferencing
• Focus groups		• Resource management systems	• Groupware
• Gamma testing			• Team-building exercises
• Ethnography			• Interlocking teams
			• Parallel development

NPD Success Measures

Voss (1992) proposes that [service] innovations can be measured in two dimensions. These measures are the result of the NPD project and the determinants of success in the NPD process. Latter measures were discussed above under the success factors topic. Table 3 demonstrates some measures against which the development results can be evaluated.

Table 3: Examples of measures of the results of service innovation (Voss, 1992).

Financial Measures	Competitiveness Measures	Quality Measures
• Achieving high overall profitability	• Exceeding market share objectives	• Great realisability
• Substantially lowering costs for the firm	• Exceeding sales/customer use level objectives	• More user-friendly
• Performing below expected costs	• Exceeding sales/customer use growth objectives	• Resulting in superior service outcome to competitors
• Achieving important cost efficiencies for the firm	• Having a strong positive impact on company image/reputation	• Resulting in superior service experience to competitors
	• Giving the company important competitive advantage	• Having unique benefits, perceived as superior to competitors
	• Enhanced sales/customer use of other offering	
	• Achieving high relative market share	

Generally, successful development results emerge from successful development processes. Table 4 summarises some of these process measures. The development process should adjust to various development aims as, for example, strict conformance to process specifications can hinder innovativeness while it is certainly useful in more straightforward NSD projects (Voss, 1992).

Table 4: Measures of the process of innovation (Voss, 1992).

Criterion cost	Effectiveness	Speed
• Average development cost per service product	• How many new services developed annually	• Concept to launch time
• Development cost of individual service product	• Percentage new services that are successful	• Concept to prototype time
• Percentage of turnover spent on developing new services, products and processes		• Prototype to launch time
		• Time to adopt new concept from outside the firm

Di Benedetto (1999) measured new product success against overall profitability and profitability, revenue and market share in relation to the competition. According to Tzokas et al. (2004), the literature examining new product success tends to focus on post-launch

performance and omits to address how well the NPD project management and evaluation attain certain performance results.

The Cornerstones of New Telecom Service Launch Readiness

The literature review suggests that decent data management practices can substantially benefit the performances of the service launch process and the launched services. The latest PDMA study confirms that PDM systems are among the most utilized NPD tools (Barczak et al., 2009.) Stark (2005) and Philpotts (1996) argue that PLM or PDM is a necessary enabler of concurrent engineering practices.

Services possess some characteristic attributes that certainly need to be taken into account before launching the service publicly. Recalling a contract based service once it is delivered may pose difficulties. The provider may be stuck to provide low usage and low profit services for a long period (Voss, 1992). Further, Eul et al. (2010) suggest that complexity of services and product portfolio is the most significant external IT cost driver in telecom services. They argue that the complexity should be managed by fact-based and business case driven demand management, and lifecycle management focusing on cleaning the product portfolio. The latter may be strongly dependent on the decisions made before launch. The often substantial provision volumes in telecom services necessitate that the efficiency level of the service delivery system is considered closely. Generally, this means reducing the share of manual provision labour as the volumes grow. Internal productization and design for X, X denoting e.g. implementation or end-of-life, are among the concepts that would assist these efforts.

RESEARCH METHODOLOGY

This study was conducted as a qualitative single case study. The study is of exploratory nature which implies that it aims to generate research questions that are worth further research (Voss et al., 2002). Figure 3 illustrates the research process applied in this study.

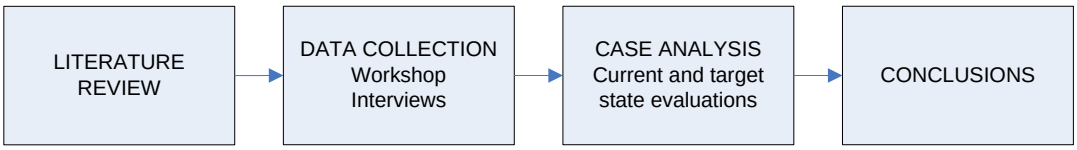

Figure 3: The Research Process.

RQ 1 is answered by summarising the potential benefits of service modelling and PDM to the new services. This is supported by the current state analysis of the case company. First empirical section aims to map the topical service implementation problems through a workshop where experts who face the challenges in daily life are collected from various organisations and. Experts are also asked to describe what development and implementation activities they find deficient. Further, the workshop builds a basis for the ideal service launch/implementation model. This is based on the identified best practises from the literature and completed by interviewing selected professionals from various functions of the case company.

The case company was purposefully selected to present the telecom service industry. The aim is to address the theoretical gap that exists in NSD data management in the selected industry setting (Eisenhardt, 1989.) The execution oriented back-end preceding the publication of new service is the unit of analysis and is here referred to as the launch phase. The study also examines the earlier NPD management as the antecedent of a successful launch. Here the product launch process is observed separately from technology life cycles. This distinction should be understood much better even tough it is not a driver in the launch phase.

The case company provides diverse telecom services. The range of services covers both mobile and fixed line connections, ICT services, outsourcing, and consultancy. Sales channels include both click and brick stores, which offer also supplementary communication device retail services. The company provides very high volume consumer subscriptions, customised unique deliveries for large corporate customers and everything in between with regard to service variety and customer contact intensity. This diversity definitely challenges NPD management, since any efforts to create common management concepts needs to take the very wide range of developmental needs into consideration.

The roots of the case company lie in tele- and data communications operator business but it is increasingly offering sophisticated information and expert services that cannot be configured and launched as swiftly as marketing department can prepare campaigns. The new service releases have to be of good perceived quality to further escape the pure price competition that the plain vanilla communications / subscriber connection business has recently featured.

The data was collected from a workshop of 24 employee participants and unstructured interviews *(and to lesser extent from personal observation, informal conversations and attendance at meetings)*. The workshop provided initial understanding about the current state of launch management in the case company and then outlined the ideal feasible state that would cure the current defects. The validity of this study was increased by using several data sources to the same questions (triangulation). In addition, theoretical orientation and assumptions were briefly clarified prior to the workshop to reduce bias. Based on the literature compilation of successful new service launch and practical challenges a list of practical requirements for telecom service launch is outlined (target stage).

NEW SERVICE LAUNCHES IN THE CASE COMPANY: CURRENT ISSUES AND PERCEIVED DEVELOPMENT TARGETS

Current State Analysis

The results in table 5 show that the cooperation between the new service development and operative organisational units should begin earlier and be stronger. A common process is missing and the progress of the development project is not visible to every stakeholder. Information regarding the product / service is available too late and is not validated by the stakeholders / data owners that are involved within the service after the commercial launch. The information here covers product / service data, product information reporting-specific data and all product documents that are required to sell, deliver, bill and maintain services.

In some cases, communication and training regarding the new service internally take place too late. This depends on time to market pressure and the magnitude of NSD. Generally, the training material is available but it does not reach every necessary stakeholder.

Measurement of the new service and its development process performance is performed but it is not standardised. This results from missing shared processes. The variance of development project magnitude ranges from service versioning to totally new service families and platforms.

Table 5: Detailed list of challenges of service launch process.

Business Organisation	Process challenges	Data challenges	Measurement challenges
New service development	• Visibility of customer expectations • Stakeholder involvement and communications • Product documentation availability prior to launch	• Product data availability • Information for e.g. product structure and reporting	• Documentation criteria and checklists • Attractiveness
Sales & Marketing	• Service maturity criteria to launch • Billing and pricing support • Training too late • Offer type definition	• Service maturity criteria to launch	• Service maturity criteria to launch • Checklist for front office training coverage
Delivery	• R&D cooperation • Extra work prior to launch to ensure delivery capability • Insufficient automation levels	• several iterations to ensure precise data cause additional costs	• Time measures for delivery subprocesses and launch subphases • Measures for service recovery (time to recovery. number of complaints and faults)
Support	• R&D cooperation • Help desk needs Preparation	• NPV data availability and reliability	• Help desk calls per number of sold services • Multiple formats of reporting

Target State

The summary of the target state discussion is presented in table 6. In the target state, all requirements of various stakeholders are recognised and documented prior to new service implementation. The best practice to pilot here could be the DfX concept. The product process supporting the whole product lifecycle and describing the dependencies and integrations between various organisation units and other stakeholders is in place and understood by all company employees. The process is supported by various milestones, checklists and audits. NSD projects are cross-functional across the enterprise. The balance between time to market and meeting the expected maturity of the service and the defined customer expectations is being monitored. New roles, for example delivery capability manager, are needed to realise the cooperation within the practical level.

Table 6: Surfaced long term development targets for service launch process.

Business Organisation	Ideal Processes	Data Management	Measurement
New service development	• Enterprise level new service development process described with roles and responsibilities • Early involvement of stakeholders	• Product lifecycle states defined • Structured information for products and reporting created and in use	• Milestone checklists and auditing
Sales & Marketing	• Development cooperation responsibilities defined		• Concurrent development of marketing and sales capabilities
Delivery	• Development cooperation responsibilities defined • Automation level optimisation according to volume forecasts	• Data quality ensured prior to launch • Data ownership handover ensured prior to launch	
Support	• Development cooperation responsibilities defined	• Data quality ensured prior to launch	• Business reporting capability ensured prior to launch

CONCLUSIONS

PLM/PDM related topics and product process development have started their breakthrough within the telecom service business over the recent years. The industry still lacks best practices in these areas whereas the manufacturing industries have well defined data management and product development processes that have evolved into an extensive solution where supporting applications and data models can be easily configured and implemented. The practices of goods manufacture cannot be directly adapted to the telecom service business as the latter involves some unique challenges. For example, the billing and order delivery of high volume services is of several complexity. NSD can be extremely agile modular product packaging or long-span platform innovations. The ideal NSD process for the case company could be relatively flexible. The best practices can only be considered once the current state has been analysed and the process development targets are accepted and piloted with measured benefits.

The greatest challenge within improving the product process is the change resistance across the enterprise. This is the reason to ensure top management sponsorship as it is the essential driver of change from the beginning. The telecom operators have typically been quick in adapting new concepts. The best practices considered based on the study could be the end to end product process with PLM and PDM coverage, DfX concept where delivery capability management is in the key position and the measurement at certain milestones is possible. The challenge here is not to lose the agility of bringing new services to the market but to conduct the launch more cost-efficiently while ensuring the product maturity to meet the customer expectations.

The study shows the need of further research within the area of lean product processes which support the above mentioned industry specific requirements. The discovery of best practices calls for close cooperation between academic and practical participants.

AN APPLICATION OF RESPONSE SURFACE METHODOLOGY ON ACCELERATED LIFE TESTING PLAN

Dr. Chau-Chen Torng*, Yunlin University of Science and Technology, Taiwan, ROC

ABSTRACT

Accelerated life testing (ALT) is an important approach to collect the lifetime data of products. To carry out ALT always requires longer testing time and expends higher cost. A faultless testing plan can reduce the time and cost. Response surface methodology (RSM) uses two-leve factorial designs to collect the observations efficiently. In the past literatures of ALT, the life-stress relationship models always disregarded the influence of stress interaction terms on lifetime. In fact, stress interaction terms may heavily influence the lifetime of products, and the application of RSM can analyzes this influence. In this research, experimental design is considered to plan the multiple-stress ALT and a polynomial regression model is used to fit the life-stress relationship model. Then, maximum likelihood estimation method (MLE) can be used to estimate parameters for the assumed lifetime distributions - Weibull distribution or the Log-normal distribution. An example is also provided to demonstrate the proposed methodology.

Keywords: Accelerated life testing, Life-stress relationship, Response surface methodology, Factorial design, Maximum likelihood estimation

INTRODUCTION

Many electronic parts are expected to have very long life. Accelerated life testing (ALT) is a proactive way of obtaining product failure information within a reasonable time frame. In ALT products are tested under stresses, such as temperature, voltage, humidity, load cycles per unit time, etc., that are much more severe than in a normal-use condition. The testing can be used not only for predicting product's reliability but also studying the effects of various stress variables on product's lifetime (Nelson, 1990; Meeker and Escobar, 1998). Design and analysis of accelerated life tests involve stress and stress level selection, sample size and testing time determination, allocation of testing units, and handling censored

failure time data, etc. It is typically more complicated than a traditional design of experiments (DOE).

Most of the previous work on designing ALT plan is focused on the application of a single stress. However, as components or products become more reliable due to technological advances, it becomes more difficult to obtain a significant amount of failure data within a reasonable amount of time using single stress only. Multiple-stresses ALTs have been employed as a means of overcoming such difficulties. Weis et al. (1988) employ two stresses to estimate the lifetime of silicon photodetectors.

Unlike the case of the single stress ALT, little work has been done on designing multiple-stresses accelerated life testing plans. Escobar and Meeker (1995) develop statistically optimal and practical plans with two stresses with no interaction between them. Park and Yum (1996) develop ALT plans in which two stresses are employed with possible interaction between them. The lifetime distribution of test units is assumed to be exponential. Elsayed and Zhang (2007) design two-stress ALT plans based on the proportional hazards (PH) model. No assumptions about the failure time distribution of the test units are made and the plans are optimized such that the variance of the reliability prediction is minimized. Guo and Pan (2007) formulate the D-optimal design for two-stress ALTs with Lognormal failure time distribution.

In this study, we develop the RSM-based life-stress models for multiple-stresses ALT by assuming a linear relationship between the life (response) and the stresses (design factors). The lifetime distribution of test units is assumed to be either a Weibull distribution or a Lognormal distribution. The model parameters are estimated by the Maximum Likelihood Estimation (MLE) technique. In the following sections, the approaches of life-stress model development and the parameters estimation are introduced. An example with simulation of right-censored failure data is also given.

ACCELERATED LIFE MODEL AND PARAMETERE ESTIMATION

In an effective quantitative accelerated life test, the practitioner chooses one or more stress types that cause the product to fail under normal use conditions. Stress types can include temperature, voltage, humidity, vibration or any other stress that directly affects the life of the product. For example, if a product normally operates at 290K and high temperatures cause the product to fail more quickly, then the accelerated life test for the product may involve testing the product at 310K, 320K and 330K in order to stimulate the units under test to fail more quickly.

Accelerated life model

Using the life data obtained at each accelerated stress level, we can use standard life data analysis techniques to estimate the parameters for the lifetime distribution that best fits the data at each stress level (*e.g.* Weibull or Lognormal). This results in an overstress failure density function for each accelerated stress level. Another mathematical model, the life-stress relationship, is then required to estimate the failure density function at the normal use stress level based on the characteristics of the failure density functions at each accelerated stress level. The practitioner must choose a life-stress relationship that fits the type of data being analyzed. Available life-stress relationships include the Arrhenius, Eyring and inverse power law models.

Arrhenius model

The Arrhenius life-stress model (or relationship) is probably the most common life-stress relationship utilized in accelerated life testing. It has been widely used when the stimulus or acceleration variable (or stress) is thermal (*i.e.* temperature). It is derived from the Arrhenius reaction rate equation proposed by the Swedish physical chemist Svandte Arrhenius in 1887. The Arrhenius reaction rate equation is given by:

$$R(T) = Ae^{-\frac{E_A}{K \cdot T}} \qquad (1)$$

where *R* is the speed of reaction, *A* is an unknown nonthermal constant, E_A is the activation energy (*eV*), *K* is the Boltzman's constant , and *T* is the absolute temperature (Kelvin).
The Arrhenius life-stress model is formulated by assuming that life is proportional to the inverse reaction rate of the process, thus the Arrhenius life-stress relationship is given by:

$$L(V) = Ce^{\frac{B}{V}} \qquad (2)$$

Arrhenius-Weibull model

Statisticians and engineers have developed life-stress relationship models that allow the analyst to extrapolate a use level probability density function from life data obtained at increased stress levels. These models describe the path of a particular life characteristic of the distribution from one stress level to another. The life characteristic can be any life measure expressed as a function of stress. For the Weibull distribution, the scale parameter

(η) is considered to be stress-dependent. Therefore, the life-stress model for data that fits the Weibull distribution is assigned to η.

The probability density function (*pdf*) for a Weibull distribution is given by:

$$f(t) = \frac{\beta}{\eta}\left(\frac{t}{\eta}\right)^{\beta-1} e^{-\left(\frac{t}{\eta}\right)^{\beta}} \tag{3}$$

The scale parameter (or characteristic life) of the Weibull distribution is η. The Arrhenius-Weibull model *pdf* can then be obtained by setting $\eta = L(V)$ in Eq. (4).

$$\eta = L(V) = C \cdot e^{\frac{B}{V}} \tag{4}$$

and substituting for η in Eq. (3),

$$f(t,V) = \frac{\beta}{C \cdot e^{\frac{B}{V}}}\left(\frac{t}{C \cdot e^{\frac{B}{V}}}\right)^{\beta-1} e^{-\left(\frac{t}{C \cdot e^{\frac{B}{V}}}\right)^{\beta}} \tag{5}$$

RSM-based life-stress models

RSM is a powerful technique for testing multiple process variables because fewer experimental trials are needed compared to the study of one variable at a time. Also, interactions between variables can be identified and quantified by such a technique.

The prediction equation for a two-factor linear main effect model with interaction takes the form

$$y = b_0 + b_1 x_1 + b_2 x_2 + b_3 x_1 x_2 \tag{6}$$

where y is the response, b_0 is the y-axis intercept, and (b_1,b_2,b_3) are the coefficients of the factors. These model parameters can be estimated by the Maximum Likelihood Estimation (MLE) technique.

To develop the life-stress model for the Weibull distribution (ARL-Weibull model), we set $\eta = b_0 + b_1 x_1 + b_2 x_2 + b_3 x_1 x_2$ and substitute for η in Eq. (3) to get Eq. (7). The similar approach can be applied to derive the life-stress model for the Lognormal distribution (ARL-Lognormal model). By setting $t_{median} = b_0 + b_1 x_1 + b_2 x_2 + b_3 x_1 x_2$ and substituting it into the *pdf* of

Lognormal distribution, we will be able to get Eq. (8).

$$f(t,x_1,x_2)=\frac{\beta}{b_0+b_1x_1+b_2x_2+b_3x_1x_2}\left(\frac{t}{b_0+b_1x_1+b_2x_2+b_3x_1x_2}\right)^{\beta-1}\times exp\left[-\left(\frac{t}{b_0+b_1x_1+b_2x_2+b_3x_1x_2}\right)^{\beta}\right] \tag{7}$$

$$f(t,x_1,x_2)=\frac{1}{\sqrt{2\pi}\sigma t}\exp\left[-\frac{1}{2}\left(\frac{\ln t-\ln(b_0+b_1x_1+b_2x_2+b_3x_1x_2)}{\sigma}\right)^2\right] \tag{8}$$

Parameters estimation with MLE

Notations

n ：the sample number

t_i ：the exact failure time of the i^{th} sample

t_i' ：the running time of the i^{th} sample with suspension

x_{1i} ：the first stress of the i^{th} sample

x_{2i} ：the second stress of the i^{th} sample

F_e ：the number of exact times-to-failure data points

S ：the number of suspended data points

Life-stress model parameters of Weibull distribution

The log-likelihood function of Weibull distribution can be obtained as follows:

$$\begin{aligned}\Lambda&=\ln\prod_{i=1}^{n}f(t_i;\beta)\\&=\sum_{i=1}^{F_e}\ln\{\frac{\beta}{b_0+b_1x_1+b_2x_2+b_3x_1x_2}\left(\frac{t_i}{b_0+b_1x_1+b_2x_2+b_3x_1x_2}\right)^{\beta-1}\\&\quad\times\exp\left[-\left(\frac{t_i}{b_0+b_1x_1+b_2x_2+b_3x_1x_2}\right)^{\beta}\right]\}-\sum_{i=1}^{S}\left(\frac{t_i'}{b_0+b_1x_1+b_2x_2+b_3x_1x_2}\right)^{\beta}\end{aligned} \tag{9}$$

The estimates of model parameters will then be found by solving $\frac{\partial\Lambda}{\partial\beta}=0, and\ \frac{\partial\Lambda}{\partial b_i}=0,$ for i=0,1,2,3 where

$$\frac{\partial \Lambda}{\partial \beta}=\sum_{i=1}^{F_e}\ \frac{1}{\beta}+\ln\frac{t_i}{b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i}}$$
$$-\left(\frac{t_i}{b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i}}\right)^{\beta}\ln\left(\frac{t_i}{b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i}}\right) \quad (10)$$
$$-\sum_{i=1}^{S}\ \left(\frac{t_i'}{b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i}}\right)^{\beta}\ln\left(\frac{t_i}{b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i}}\right)$$

$$\frac{\partial \Lambda}{\partial b_0}=\sum_{i=1}^{F_e}\beta\left(\frac{1}{b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i}}\right)+\beta\left(\frac{t_i{}^{\beta}}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})^{\beta+1}}\right) \quad (11)$$
$$-\beta\sum_{i=1}^{S}\ \left(\frac{t_i'^{\beta}}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})^{\beta+1}}\right)$$

$$\frac{\partial \Lambda}{\partial b_1}=\sum_{i=1}^{F_e}\beta\left(\frac{x_{1i}}{b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i}}\right)+\beta\left(\frac{t_i{}^{\beta}}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})^{\beta+1}}\right)x_{1i} \quad (12)$$
$$-\beta\sum_{i=1}^{S}\ \left(\frac{t_i'^{\beta}}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})^{\beta+1}}\right)x_{1i}$$

$$\frac{\partial \Lambda}{\partial b_2}=\sum_{i=1}^{F_e}\beta\left(\frac{x_{2i}}{b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i}}\right)+\beta\left(\frac{t_i{}^{\beta}}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})^{\beta+1}}\right)x_{2i} \quad (13)$$
$$-\beta\sum_{i=1}^{S}\ \left(\frac{t_i'^{\beta}}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})^{\beta+1}}\right)x_{2i}$$

$$\frac{\partial \Lambda}{\partial b_3}=\sum_{i=1}^{F_e}\beta\left(\frac{x_{1i}x_{2i}}{b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i}}\right)+\beta\left(\frac{t_i{}^{\beta}}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})^{\beta+1}}\right)x_{1i}x_{2i} \quad (14)$$
$$-\beta\sum_{i=1}^{S}\ \left(\frac{t_i'^{\beta}}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})^{\beta+1}}\right)x_{1i}x_{2i}$$

Life-stress model parameters of Lognormal distribution

The log-likelihood function of Lognormal distribution can be obtained as follows:

$$\Lambda=\ln\prod_{i=1}^{n}f(t_i;\sigma)$$
$$=\sum_{i=1}^{F_e}\ln\{\frac{1}{\sigma t_i}\Phi\left[\left(\frac{\ln t_i-\ln(b_0+b_1x_1+b_2x_2+b_3x_1x_2)}{\sigma}\right)\right] \quad (15)$$
$$+\sum_{i=1}^{S}\ln\left[1-\Phi\left(\frac{\ln t_i^{'}-\ln(b_0+b_1x_1+b_2x_2+b_3x_1x_2)}{\sigma}\right)\right]$$

The estimates of model parameters will then be found by solving $\frac{\partial \Lambda}{\partial \sigma}=0, and\ \frac{\partial \Lambda}{\partial b_i}=0,$ for *i*=0,1,2,3 where

$$\frac{\partial \Lambda}{\partial \sigma}=\sum_{i=1}^{F_e}\left(\frac{\left[\ln(t_i)-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})\right]^2}{\sigma^3}-\frac{1}{\sigma}\right)+\frac{1}{\sigma}\sum_{i=1}^{S}\frac{\left(\frac{\ln(t_i')-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}{\sigma}\right)\Phi\left(\frac{\ln(t_i')-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}{\sigma}\right)}{1-\Phi\left(\frac{\ln(t_i')-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}{\sigma}\right)} \quad (16)$$

$$\frac{\partial \Lambda}{\partial b_0}=\sum_{i=1}^{F_e}\left(\frac{\ln(t_i)-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}{\sigma^2}\right)\left(\frac{1}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}\right)+\sum_{i=1}^{S}\frac{1}{\sigma}\frac{\Phi\left(\ln(t_i')-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})\right)}{1-\Phi\left(\frac{\ln(t_i')-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}{\sigma}\right)}\left(\frac{1}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}\right) \quad (17)$$

$$\frac{\partial \Lambda}{\partial b_1}=\sum_{i=1}^{F_e}\left(\frac{\ln(t_i)-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}{\sigma^2}\right)\left(\frac{x_{1i}}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}\right)+\sum_{i=1}^{S}\frac{x_{1i}}{\sigma}\frac{\Phi\left(\ln(t_i')-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})\right)}{1-\Phi\left(\left(\frac{\ln(t_i')-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}{\sigma}\right)\right)}\left(\frac{1}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}\right) \quad (18)$$

$$\frac{\partial \Lambda}{\partial b_2}=\sum_{i=1}^{F_e}\left(\frac{\ln(t_i)-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}{\sigma^2}\right)\left(\frac{x_{2i}}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}\right)+\sum_{i=1}^{S}\frac{x_{2i}}{\sigma}\frac{\Phi\left(\ln(t_i')-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})\right)}{1-\Phi\left(\frac{\ln(t_i')-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}{\sigma}\right)}\left(\frac{1}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}\right) \quad (19)$$

$$\frac{\partial \Lambda}{\partial b_3}=\sum_{i=1}^{F_e}\left(\frac{\ln(t_i)-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}{\sigma^2}\right)\left(\frac{x_{1i}x_{2i}}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}\right)+\sum_{i=1}^{S}\frac{x_{1i}x_{2i}}{\sigma}\frac{\Phi\left(\ln(t_i')-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})\right)}{1-\Phi\left(\frac{\ln(t_i')-\ln(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}{\sigma}\right)}\left(\frac{1}{(b_0+b_1x_{1i}+b_2x_{2i}+b_3x_{1i}x_{2i})}\right) \quad (20)$$

EXAMPLE

In this section, we use an example to demonstrate the method developed in section 2. The life time of an electronic part is assumed to be affected by both temperature and humidity. A 2^2 full factorial design is applied on the ALTs to test system reliability of this product. The temperature stress is set at either a high level of 398K or at a low level of 375K. The humidity stress is set at either a high level of 0.8% or at a low level of 0.4%. The design matrix with failure data is given as Table 1. The following steps are then applied on the ALT data.

Table 1: Failure data of given test stresses.

Temperature(K)	Humidity(%)	Failure time (hr)
375	0.4	7929
375	0.4	9863
375	0.4	12501
375	0.4	20956
375	0.8	2883
375	0.8	3483
375	0.8	4442
375	0.8	6164
398	0.4	6054
398	0.4	9093
398	0.4	12204
398	0.4	15646
398	0.8	1480
398	0.8	1548
398	0.8	1625
398	0.8	4152

Step1. Both temperature (τ_1) and humidity (τ_2) are transformed into coded variables (x_i) with (21)

$$x_i = -1 + 2\left(\frac{\tau_i - \tau_{i,L}}{\tau_{i,U} - \tau_{i,L}}\right) \quad \text{for } i = 1,2 \qquad (21)$$

where $\tau_{i,U}$ is the high-level value, and $\tau_{i,L}$ the low-level value of stress *i*.

After the transformation, the high-level and low-level stress values can be indicated by +1 and -1 respectively. We then substitute the coded variables into Eq. (11) to develop ARL-Weibull model. The model parameters (β, b_0, b_1, b_2, b_3) could be found by solving the partial derivative equations (10) through (14) by the Newton-Raphson method. The parameter estimates obtained are $\beta = 0.97$ 、 $b_0 = 75505.5$ 、 $b_1 = -22853.5$ 、 $b_2 = -5086.5$ 、 $b_3 = 5033.5$. The scale parameters (η) under different stress levels are obtained by setting $\eta = b_0 + b_1 x_1 + b_2 x_2 + b_3 x_1 x_2$ and their values are shown in Table 2.

Table 2: Estimates of Weibull scale parameter (η).

Scale Parameter η (hr)	Temperature x_1 (coded)	Humidity x_2 (coded)
108479	-1	-1
88239	-1	1
52705	1	-1
52599	1	1

Step 2. The reliability software Weibull++ from ReliaSoft Co. is used to simulate the right-censored failure data. It is assumed that 20% of the test samples are suspended (without failure at the end of test time). The test sample group sizes of each specific test stresses ($\square_1,\square_2$) are set as 5, 10, and 40 respectively. By repeating the same parameter estimation procedure as in step 1, we will be able to obtain the results listed in Table 3. By substituting the model parameters (b_0, b_1,$\square_2$,$\square_3$) into Eq. (6), we will be able to get the life-stress model for the considered test stresses ($\square_1,\square_2$) under a given sample size.

Table 3: ARL-Weibull model parameters with 20% censored data for n=20,40,160.

Sample size, n	β	b_0	b_1	b_2	b_3
20 (2^2x5)	0.720	45106.18	-24794.00	-3161.31	-1416.70
40 (2^2x10)	0.858	54296.73	-11652.30	-5682.93	2128.39
160 (2^2x40)	0.832	55444.50	-21720.40	-8631.42	7614.46

CONCLUSIONS

In this study, we develop the RSM-based life-stress models for multiple-stresses ALT by assuming a linear relationship between the life (response) and the stresses (design factors). The lifetime distribution of test units is assumed to be either a Weibull distribution or a Lognormal distribution. The model parameters are estimated by the Maximum Likelihood Estimation (MLE) technique. From the example in last section, we demonstrate that the proposed approach is simple and straightforward to use in developing life-stress model with RSM first-order prediction equation. This method can be easily applied to other location-scale-based life distributions as well.

DIFFERENT INTENSITY OF INTER-FIRM COLLABORATION IN OPEN BUSINESS MODEL: A STUDY OF TAIWANESE CONVENIENCE STORE INDUSTRY

Kuo-Nan Hsieh, SPRU, University of Sussex, UK
kh87@sussex.ac.uk

ABSTRACT

This paper draws on a comparative case study design to investigate how Taiwanese convenience store chains use different intensity of inter-firm collaboration to develop new services with their suppliers. Using empirical evidence from case studies of the development of two e-commerce services (i.e. the online shopping with pick-up at store service and the multiple media kiosk service) developed by convenience store chains in Taiwan, this study found that the degree of intensity in inter-firm collaboration is influenced by the degree of task complexity and the degree of project newness. When the task is complex and is associated with a focal firm's development activities, case companies often collaborate more intensely with suppliers. Case companies also adopt less intense inter-firm collaboration with some suppliers when the development task is simpler and can be separated from the focal firm's development activities. In addition, when case companies developed different business modules for the MMK service, they also collaborate with suppliers on the basis of different degrees of newness in the project. Case companies adopt more intense inter-firm collaboration with the first entrant to identify its IT requirements and problems and share the related knowledge to reduce the technological uncertainty of a new business module. Once the requirements and restrictions of the new business module have been clearly defined, the case companies adopt lower degree of inter-firm collaboration with the second entrant, in order to quickly expand the scope of the existing business module.

Keywords: Intensity of inter-firm collaboration, Open business model, Task complexity, Project newness

INTRODUCTION

Recently, Chesbrough (2003) has proposed the open business model, which, compared with traditional business models, can help a firm reduce the development cost and time of innovation by tapping into external sources of knowledge and leveraging external knowledge in different phrases of new product development. Open business model encourages a firm to source valuable knowledge/resources from external firms or share the internal, valuable knowledge/resources of external firms in order to create value. In open business model,

firms must first recognize and access the external knowledge/resources that they need, using different ways (e.g. licensing, ventures, and spin-offs) to share internal innovation so that other companies can share the added value. However, the relevant studies of open innovation mainly use different types of openness to investigate a focal firm's behavior with external companies in the process of value creation (Lichtenthaler, 2008; Lazzarotti and Manzini, 2009). There is less empirical evidence to investigate how a firm adopts different degrees of collaboration intensity with external firms in open business model which facilitates the acquisition of relevant knowledge/ resource for value creation.

This paper aims to investigate what degree of intensity of inter-firm collaboration is employed by Taiwanese convenience store chains to cooperate with their suppliers in the process of new service development. The main research questions include: 1) What degree of intensity of inter-firm collaboration should be adopted to coordinate new service development activities with external actors and in which circumstances? 2) Does the adoption of intensity of inter-firm collaboration vary with different service developments? The present research adopts the classification of intensity of cooperation based on Fliess and Becker's (2006) research and incorporates the classification of coordinated development from Petersen et al. (2005). The most important forms of inter-firm cooperation include contract development, coordinated development, and joint development are selected and can be ranged from lower degree of collaboration intensity to higher degree of collaboration intensity. The different degrees of intensity of inter-firm collaboration are defined by indicating the different responsibilities of the supplier in the specification design associated with the decision making process. The contribution that this study aims to make is to enhance understanding of the adoption of intensity of inter-firm collaboration in facilitating sourcing external knowledge during new service development process. The adoption of collaboration intensity helps to distinguish more clearly the different firms' responsibilities, degree of interaction between firms, and decision making process in open innovation approach.

Taiwanese convenience store chains often collaborate with external firms, group companies or competitors in order to acquire and integrate multiple sources of knowledge and resources for service innovation. They combine acquired related resources with the existing advantages of 24-hour service, high store density, strong information system, and professional distribution systems to carry out "Clicks and Mortar" services, which in turn, help them respond quickly to market dynamics and consumers' needs. This study draws on empirical evidence from the four dominant convenience store chains in Taiwan. Two e-commerce services (i.e. the online shopping with store pick-up service and the multiple media kiosk service) were selected to address the issue of intensity of inter-firm

collaboration during service innovation process. Different degrees of intensity of inter-firm collaboration are identified and compared across four case companies and two selected services in this study. Semi-structured interviews were adopted in the data collection process which allows for two-way communication and the flexibility to probe for details as well as gaining a range of insights on research issues. Interviews were conducted with managers who were involved in the development of the aforementioned services from case companies and their collaborating firms. The interview data were analyzed by cross-case synthesis to summarize the findings from the individual cases and identify the similarities and the differences between the two service development projects.

The rest of the paper is set out in the following way: In the next section, the literature regarding open business model and intensity of inter-firm collaboration are reviewed. The methodology of the research is then described, followed by a discussion of the findings. The conclusions and managerial implications are discussed in the final section.

THEORETICAL BACKGROUND

Open business model

Open innovation can be seen as encouraging and searching for innovation opportunities from a broad range of internal and external resources and then assimilating these within a firm's capabilities and sources for delivering these opportunities via internal or external channels (West and Gallagher, 2006). Within the closed business model, firms recruit talented, intelligent people and invest much in R&D activities, which themselves develop and produce new business, in order to secure the market first and outperform their competitors in their field. This implies that successful innovation relies on control from the focal firm. The firm tends to control everything and invests in R&D activities to develop new projects internally in order to prevent its competitors from profiting from its ideas. In terms of specific knowledge related to product/service development which is widely distributed over different types of actor, different companies must be involved in contributing to it. The open business model can reduce the costs of developing an innovation by using external knowledge to tap into a firm's innovation process and can reduce the time taken to enter another market by adopting external channels to catch additional revenue. More specifically, an open business model facilitates new product or service creation and brings additional value to a firm or group of firms by aiding collaboration with external companies, with a view to taking internal immature or complementary technology to the market (Chesbrough, 2006).

The concept of open innovation encourages a firm to acquire complementary resources from external firms and share its relevant resources in order to create value at different phrases of the innovation process. This means that, for value creation, resources, knowledge and individuals can inflow and outflow between different companies. However, some studies argue the potential problems of open business model and criticize its concept (Dahlander and Gann, 2007; Trott and Hartmann, 2009; Lazzarotti and Manzini, 2009). Some writers argue that adopting the open business model may lead to the leakage of commercially sensitive knowledge, because it encourages firms to share their valuable knowledge/resources with external companies for commercialization (Trott and Hartmann, 2009). Moreover, Lazzarotti and Manzini (2009) also propose that adopting an open business model may increase the cost, because of searching and testing several solutions with external firms in the innovation process. They also argue that if the number of participating firm increases, the coordination and control between firms may also increase based on the transaction cost view. It would be interesting to explore what kinds of cooperation mechanisms are appropriate in the process of open innovation. This is because the concept of open innovation does not specify in advance how to manage the collaboration between firms in order to reduce such potential risks as hold-up risk and spillover risk.

In addition, some studies argue that the concept of open innovation, while a new concept on theoretical grounds, can be found in practice in many firms and industries (Trott and Hartmann, 2009). The concept of open innovation can be found in previous studies on innovation management which emphasize cooperation with external actors in order to acquire and share complementary knowledge/resources and to reduce development risks, showing that the innovation process often involves different degrees of openness (von Hippel, 1988; Faulkner, 1995; Tidd and Bessant, 2009). Firms in different industries can be found to adopt different types of cooperation and alliance, such as licensing, outsourcing, joint venture, industrial cluster and innovation networks. Moreover, some studies argue that the concept cannot be separated into a simple dichotomy between open and closed approaches (Dahlander and Gann, 2007; Trott and Hartmann, 2009). These studies suggest that further research should pay more attention to exploring the different degrees and types of openness and the extent to which a firm can benefit from external and internal resource/knowledge in the innovation process. This view provides an opportunity to investigate the use of various collaboration strategies open to a company and the types and contexts of sources of innovation (Lazzarotti and Manzini, 2009). Recently, some studies have begun to identify different types of openness (Dahlander and Gann, 2007; Lichtenthaler, 2008). For example, Dahlander and Gann (2007) claim that there are three types of openness, taking into account: 1) appropriability – different degrees of formal and informal protection; 2) the number of sources of external innovation; and 3) formal and informal

relationships with external actors. Lichtenthaler (2008) also defines two dimensions, the extent of external technology acquisition and the extent of external technology exploitation, to investigate a company's behaviour in the innovation process. However, the above studies mainly focus on using different types of openness to investigate a focal firm's behavior with external companies in the process of value creation. There is less empirical evidence to investigate how a firm adopts different degrees of collaboration intensity with external firms which contributes the acquisition of relevant knowledge/ resource between firms in open business model.

Intensity of inter-firm collaboration

According to Fliess and Becker's research (2006), several possible types of cooperation design can be distinguished according to the different type and intensity of the contractual relationship. The intensity of cooperation between firms ranges from internal development, know-how exchange, which have a lower intensity of cooperation, to coordinated development, joint development and contractual joint ventures, which have a higher intensity of cooperation. The most important three forms of cooperation, including contract development, coordinated development and joint development, provide better insights into the black box of supplier integration in new product development. These different forms of inter-firm cooperation can be classified by the different levels of responsibility between customer and suppliers in developing a new product. Contract development is based on the contract with suppliers who provide separated components/services of new service/product developments to customers. It is difficult for the customer to influence the development process, because the customer is involved only in coordination meetings. The form of inter-firm collaboration is used when the customer does not have enough resources/knowledge to develop new services/products. Coordinated development is defined as the kind in which suppliers focus on the separate components/services of new service/product developments and some tasks are developed by the customer. There are three type of coordinated development: asymmetrical cooperation, black box cooperation and systems partnership (Gerpott, 1999; Tani and Wangenheim, 1998). Asymmetrical cooperation can be defined as the kind in which detailed instruction is provided by customer to supplier. Black-box cooperation means that a single module is developed by the supplier for the final product. System partnership means that the supplier develops a complex module of the final product and integrated pre-suppliers. This classification of coordinated development implies that customers and suppliers have different levels of responsibility in new product development. However, the present research argues that the above classification of coordinated development is somewhat ambiguous, because the specification of the decision-making process in a new service development has not been

taken into account. Petersen et al. (2005) suggest that different levels of supplier integration are: 1) White-box cooperation, 2) Grey-box cooperation and 3) Black-box cooperation. White-box cooperation means that the buying company makes all the design and specification decisions but informally discusses the specifications with the supplier. Grey-box cooperation means that the buyer and supplier share related information and technology and joint decision making about specifications. Finally, black-box cooperation means that the buyer informs the supplier of his requirements and then gives the latter almost total responsibility to develop the project requirements. The buyer only reviews the specifications of the purchased items. Compared with contract development and coordinated development, joint development is based on regular cooperation, in which teams are formed by the supplier's staff and the customer's staff. These teams can work in the same place or cooperate by using a high level of information exchange and regular coordinated meetings to integrate supplier and customer from different places. The form of development could be adopted in a new service/product development if the development project cannot be divided into different modules and assigned to customer or supplier. Building on the above discussion, the present research adopts the classification of intensity of cooperation based on Fliess and Becker's (2006) research and incorporates the classification of coordinated development from Petersen et al. (2005). Three forms of cooperation (i.e. including contract development, coordinated development, and joint development) are selected to investigate the intensity of inter-firm collaboration between convenience store chains and their suppliers in the process of developing new services. In addition, the present research provides clear distinctions in the coordinated development on the basis of different levels of responsibility for specification design between the firms which are associated with the decision making process. Table 1 defines the degree of different intensity of inter-firm collaboration by indicating the different responsibilities of the supplier in the specification design associated with the decision making process. This can be used to clarify the different degrees of intensity of cooperation between the convenience store chains and their suppliers in the two selected service developments.

Table 1: The definition of different degrees of intensity in inter-firm collaboration.

Low ***Intensity of inter-firm collaboration*** High	**Contract development**	Customer and supplier based, with a contract to define the objects, tasks and restrictions between them. Supplier performs development activities separately from the customer.	
	Coordinated development	***Asymmetrical cooperation***	Customers directly provide detailed specification or instruction to suppliers for developing the final product/service.
		White-box cooperation	Customers informally discuss with suppliers the specifications and then make their own decisions about specifications.
		Grey-box cooperation	Customers and suppliers share relevant information/knowledge and then make decisions together about the design specifications
		Black-box cooperation	Suppliers take almost all responsibility for developing modules for the final product. Customers make known their requirements only and review the design specifications.
		Systems partnership	Suppliers develop the complex part of the final product/service and integrate the pre-suppliers in the development process.
	Joint development	Customers and suppliers regularly form a project team involved in the development activities.	

Source: Classification integrated from Fliess and Becker (2006) and Petersen et al. (2005).

The following questions will be answered in this paper:

1. What degree of intensity of inter-firm collaboration should be adopted to coordinate new service development activities with external actors and in which circumstances?
2. Does the adoption of intensity of inter-firm collaboration vary with different service developments?

RESEARCH DESIGN AND METHOD

This paper focuses on the intensity of inter-firm collaboration between Taiwanese convenience store chains and their partners in new service development process. For this purpose, this research uses a comparative case study design which facilitates an empirical inquiry into investigating a contemporary phenomenon within its real-life context (Yin, 2003). This research draws on empirical evidence from the four convenience store chains in Taiwan. Two e-commerce services (i.e. the online shopping with store pick-up service and the multiple media kiosk service) in the convenience store industry were selected to address the research questions.

Study Population and Unit of analysis

The study population of this research includes the Taiwanese convenience store chains and their cooperative firms involved in the selected service development. The four convenience store chains (including Company E, Company F, Company H, and Company O) which together control 95.51% of the market in Taiwan have been chosen in order to fulfill all the required data collection tasks in my research case. The unit of analysis of this research is the new service development project. Online shopping with pick-up at store service and multiple media kiosk service were selected for investigating how convenience store chains use different intensity of inter-firm collaboration with their suppliers for new service development. Their suppliers include logistic companies (i.e. third party distribution company and distribution company owned by convenience store chain), IT system supplier, applied IT system supplier, service content companies, and hardware manufacturing companies, etc. were also chosen to fulfill required data in the present research.

Data collection and analysis

Two methods of data collection were used in this research: documentation and interviews. Secondary data were gathered from periodicals, books, magazines, newspapers, research reports published by research institutes, corporate websites, and annual reports published by case companies and their partners. Semi-structured interviews were also adopted in the data collection process as they allow for two-way communication and the flexibility to probe for details as well as gaining a range of insights on research issues. In total, there were 42 interviewees from the four convenience store chains and their suppliers participating in this study. Interviewees include managers and section staff of convenience store chains and the staff of suppliers who were involved in the selected service development projects. Some informants were interviewed twice. All together, 52 interviews were conducted. Before data analysis, interviews were fully transcribed. Relevant interview extracts were translated from Chinese to English by one of the authors, who is bilingual.

The interviews were analyzed using the thematic framework approach (Gibbs, 2008). In developing a thematic framework which represents the patterns and relationships in the interview data, I drew on the existing literature and research questions to create codes and to identify key thematic ideas. The thematic framework was then applied to guide initial data analysis in order to understand how Taiwanese convenience store chains use different degree of intensity of inter-firm collaboration to acquire external resources/ knowledge and share internal knowledge with suppliers in the process of new service development. Moreover, cross-case synthesis (Yin, 2003) was chosen as the analytical technique to

summarize the findings from the individual cases. This technique is also useful in identifying the similarities and the differences between the two service development projects. The findings of this present study are presented next.

RESEARCH FINDINGS

Intensity of inter-firm collaboration between case companies and their suppliers

This section investigates the intensity of inter-firm collaboration between convenience store chains and their suppliers in the process of two selected service.

Online shopping with pick-up at store service

The four convenience store chains in Taiwan split up two groups to develop this service. To do so, Company E initially formed a project team with its affiliated companies. Company E finally authorized its affiliated company to take the main role in developing this service and coordinating with the other affiliated companies owned by Company E. The other convenience store chains formed a joint venture to develop this service and cooperated with suppliers (e.g. a third party distribution company and an IT system supplier) in developing fundamental functions (e.g. logistics and IT functions).

Regarding to the intensity of inter-firm collaboration between convenience store chains and their suppliers, the four convenience store chains played different roles in developing the online shopping with pick-up at store service. In the first stage, Company E originally used joint development with its affiliated companies (a logistic company and an IT system supplier) and formed a project team Due to concerns over service capacity and the security of the goods, Company E finally authorized its group company – Company P – to continue to develop it in the second stage and provided marketing support after this service was temporarily closed. Company E played a key role in coordinating the cooperation between the group companies (Company P, the IT service provider and the logistic company) and in controlling the quality and progress of the service development in the second stage. Unlike Company E, the other convenience store chains (Companies F, H, O and N) used joint development to establish a new company – Company C – to develop this service for them. They also used Company C to buy some goods on their behalf in order to reduce purchasing costs (joint purchasing).

As regards the IT system supplier, Company E used coordinated development (systems partnership) with its group companies in the first stage and then in the second stage

involved the applied IT system suppliers by using contract development to develop some functional systems. This was because the IT system of the service was split into a main IT system (the convenience store's internal system, for example a POS system) and functional systems, since Company E had to ensure that the main IT system operated normally. Unlike Company E, the actors of the other group (i.e. the convenience store chains, third party distribution company, e-shops) who were involved in the first stage in this service development connected individually with the IT systems of the other actors. Next, the requirements and format of the information transfer were decided and integrated by Company F's IT department and its third party distribution company (grey-box cooperation) in the second stage. Finally, this group used coordinated development (systems partnership) with an external firm to develop the IT system for integrating the information flow between the different actors.

The development of the logistic function can be separated into two routines. The third party distribution companies provided storage, packing and delivery services for the e-shops and delivered consumers' orders to the distribution companies owned by the convenience store chains if the e-shops themselves could not deliver the goods to the distribution company of each chain. The distribution companies owned by convenience store chains delivered the consumers' orders to the various convenience stores. In the first stage Company E began by using joint development with its own logistics to deliver the goods to each store. When Company E authorized Company P to develop this service, it used coordinated development (systems partnership) with its own logistics in developing the logistical function. It also engaged in contract development with a third-party distribution company. The other group in the first stage used contract development with a third-party distribution company. The third-party distribution company delivered the goods direct to the stores of Companies F, H, O and N. Given the service capacity of the third-party distribution company, this group invited a new third-party distribution company in the second stage using contract development and delivering consumers' orders either direct to the distribution company owned by Company H or to the stores of Companies F and O. In the third stage, the third party distribution company no longer provided a delivery service from the e-shops to the distribution companies owned by Company H. This group invited another third party distribution company (by contract development) to provide a delivery service and to transport goods from the e-shops to the distribution company of each chain. However, the previous third party distribution company (in the second stage) still delivered goods to Company F, which finally acquired it, and it became a self-owned distribution company. Third party distribution companies cooperated with this group by using contract development. Both of them (Company E and Companies F, H and O) developed by contracts with e-shops. Table 2 summarises a cross-case comparison between different companies in the

development of the online shopping with pick-up at store service.

Table 2: Cross-case comparison of the different degrees of intensity in the inter-firm collaboration between two groups in developing the service of online shopping with pick-up at store.

	Company E	**Companies F, H and O**
Service developer	1. Company E formed a project team with affiliated companies in the first stage. 2. Company P was authorized to develop this service in the second stage (systems partnership).	1. Convenience store chains used joint development with Company C in decision- making in the first stage. 2. This new company (Company C) grew in prominence as it developed this service in the second stage.
IT system supplier	1. Joint development with an IT system supplier in the first stage. 2. Coordinated development with affiliated companies (systems partnership) in the second stage. 3. Involving applied IT system suppliers to develop different functional systems by using contract development.	1. The IT specification was initially developed by Company F and its cooperative distribution company (grey-box cooperation) in the second stage. 2. Coordinated development (systems partnership) with an external company to set up an integrated IT system in the third stage.
Logistics	1. Joint development with a self-owned distribution company in the first stage. 2. Coordinated development (systems partnership) with a self-owned distribution company in the second stage. 3. Contract development with third party distribution companies.	1. Coordinated development (systems partnership) with self-owned distribution companies. Companies F and O strengthened the intensity of the inter-firm collaboration from contract development to coordinated development (systems partnership) in different stages of the development. 2. Contract development with third party distribution companies.

Multiple Media Kiosk service

Four convenience store chains individually cooperated with different actors (the IT system supplier, hardware manufacturing company and service content company) in developing this service. Company E authorized its affiliated company (Company Q) to lead and coordinate different affiliated companies (IT system suppliers) in developing this service. Company Q also cooperated with a hardware manufacturing company and service content companies in order to acquire the essential resources (i.e. hardware and service content). Company F used a cross-functional team within its company and cooperated with different actors (i.e. a IT system supplier, hardware manufacturing company and service content company) in developing this service. Company H also used a cross-functional team within its company and cooperated with a hardware manufacturing company and service content company for this service development. In contrast, Company O played only a channel role in this development. The IT system suppliers and a hardware manufacturing company formed a team and cooperated with Company O to develop this service. The following section identifies the responsibility of each actor and the different degrees of intensity in the inter-firm collaboration adopted by four convenience store chains to develop the multiple media kiosk service.

Regarding to the intensity of inter-firm collaboration between convenience store chains and their suppliers, Company E used coordinated development (systems partnership) with its group company – Company Q – to develop and manage this service development. Company E played a key role in coordinating the different affiliated companies, providing marketing support and controlling the service quality in the development of this service. Companies F and H used cross-functional teams within their companies to develop this service. Company O provided only some space in a convenience store where the hardware could stand and payment could be collected. To consider the development of the IT system, Company E cooperated with its group companies (in a systems partnership) which took responsibility for different domains of the IT system. Company F basically used coordinated development (black-box cooperation) with the existing IT system supplier and provided what the existing IT system supplier required (e.g. the service requirements and a checklist). The existing IT system supplier also informally provided the relevant knowledge and suggestions to Company F in developing its IT system. Company H developed the IT system within its company. Company O used coordinated development (grey-box cooperation) with its suppliers to develop the IT system.

As regards hardware manufacturing, Company Q signed a manufacturing contract with a

hardware design and manufacturing company and became involved in the specification and design of its own hardware. This can be seen as an example of coordinated development (grey-box cooperation). Company F also used coordinated development (grey-box cooperation) with its hardware supplier, which came up with a feasible specification and developed a prototype for Company F. Company H used coordinated development (asymmetrical cooperation) with a hardware manufacturing company and presented its requirements to this company.

To consider the cooperation between the service content providers and Companies E, F and H, the companies developed and signed a selling contract with some of the service content providers on the basis of their existing IT system or business module. The service contract provided suppliers with the specifications for developing a user-interface in the kiosk and connecting the IT systems, the operation procedure and the financial regulations. This is an example of contract development. The companies also used coordinated development (grey-box cooperation) with some service content providers when they mutually adjusted the IT requirements with their IT system supplier or developed a new business module in the kiosk. Table 3 shows different intensity of inter-firm collaboration between four convenience stores and their related partners in the development of multiple media kiosk (MMK) service.

Table 3: Cross-case comparison in intensity of inter-firm collaboration between four convenience stores in the development of MMK service.

	Company E	**Company F**	**Company H**	**Company O**
Service developer	Coordinated development (systems partnership)	Internal development	Internal development	Coordinated development (grey-box cooperation)
IT system supplier	Coordinated development (systems partnership)	Coordinated development (black-box cooperation)	Internal development	Coordinated development (grey-box cooperation)

Cross-case comparison between two selected service developments in the issue of intensity of inter-firm collaboration

From the above discussion regarding the intensity of inter-firm collaboration in the development of two selected services, it appears that the companies under review tended to use a high degree of intensity in their inter-firm collaboration (coordination development-systems partnership) with suppliers in developing fundamental functions (e.g. IT function and logistics) when they developed the two selected services. This is because the task of these functions of integrating different actors or pre-suppliers to contribute to the development of new services is very complicated. In terms of the task, which is complicated because of the relationship between the companies under review and these suppliers (e.g. of the IT system and the logistics), the companies cooperate with suppliers intensively for the sake of identify possible problems and solutions, share related information/knowledge and control the progress and quality of the service when they developed these fundamental functions. For example, Company E, in particular, often used coordinated development (system partnership) with its group companies when it contributed to developing a new service framework. Companies F, H and O also used a high degree of intensity in their collaboration to prepare major IT system designs with external companies. The case companies also adopted a lower degree of intensity (e.g. contract development) in their inter-firm collaboration with some suppliers, such as e-shops and some of the service content companies. This is because the task of these suppliers can have been simply to define their object, provision and restrictions and separate them from the case companies' development activities. In addition, the case companies do not have enough resources/knowledge available to perform these tasks. Case companies used only coordination meetings with their suppliers to define the task to be done and the regulations to follow; they formed a contract with them in order to expand the scope of their services to the consumers. According to the above discussion, this present study can claim empirical evidence that the intensity of inter-firm collaboration with suppliers in the process of developing new services (in particular online shopping with pick-up at store service development) depends on the degree of task complexity in different functional developments. The degree of task complexity is often determined by the number of different actors or functions which must mesh together in the functional development of a new service/product. Both the service developments considered here belonged to e-commerce services and involved different functions for information transfer between

different actors. The development of the online shopping with pick-up at store service is the more complex of the two in the matter of integrating information transfer among the IT systems of different functional actors, e.g. distribution companies (logistic function), convenience store chains (marketing) and channel role and e-shops (product provider) and coordinating the existing operation procedures of the different functional actors to advance this service development. For example, the case companies have a higher intensity of inter-firm collaboration with the IT system suppliers because the latter often coordinate an IT system of related actors, such as a self-owned distribution company, third party distribution company, convenience store chain and e-shop, on the basis of different requirements and the restrictions of the actors' IT system in the development of the online shopping with pick-up at store service. According to previous studies, the relationship between intensity and task complexity in inter-firm collaboration has been initially identified: the intensity of inter-firm collaboration is high when a task is more complex (Nylen, 2007). Her research used different terms to define this intensity, including coordination, co-operation and integration, which focused on the degree of involvement and interaction among parties. This present study further used different forms of inter-firm collaboration to identify the intensity between cooperative firms. Different forms of inter-firm collaboration can help to distinguish more clearly the different firms' responsibilities and decision making in inter-firm collaboration.

Moreover, this present study further found that the degree of newness may also influence the adoption of intense inter-firm collaboration when the case companies cooperate with the service content companies in the development of the MMK service. This is because the convenience store chains provided an IT platform (kiosk) and identified different business modules to cooperate with the various service content companies in order to expand the scope of the MMK service. Some service content companies may provide similar service content in each business module. This service development mainly focused on the IT connection between the convenience store chains and the service content companies and promoted a new business module in the kiosk. According to the different degrees of newness in different business modules, the case companies used a higher intensity of inter-firm collaboration (grey-box cooperation) with some of the service content companies when they mutually adjusted the two IT systems for connection or developed a new business module in the kiosk. Case companies often cooperate more closely with suppliers to identify their IT requirements and potential problems and share the related knowledge/resource in order to construct a new business module. In addition, case companies developed a service contract and signed it with some of service content companies on the basis of the existing IT systems of case companies or developed a business module for the kiosk. The contract terms include the IT requirements, restrictions and

financial regulation to be followed and the operation procedure to be coordinated. According to previous studies, in developing new products the degree of project newness traditionally defines how much of the existing product must be changed or adjusted (Clark and Fujimoto, 1991; Griffin, 1997). The different degrees of project newness often involved different degrees of technological uncertainty in the process of developing new products. In order to reduce the technological uncertainty of a new product, previous studies suggested that focal firms can seek a closer relationship with the supplier and pool their technological information in developing a new product (Auster, 1992; Hagedoorn and Narula, 1996). This present study provides insight in identifying the relationship between supplier integration and project newness when focal firms develop non-fundamental functions and quickly expand the scope of the existing business module. Focal firms can adopt a lower degree of intensity of inter-firm collaboration with the supplier when the degree of project newness is relatively low (e.g. based on the existing operation of the focal firm). Additionally, the focal firm may use more intense inter-firm collaboration with the first entrant to identify potential problems and reduce its technological uncertainty to contribute to a new business module. A lower degree of inter-firm collaboration appears between the focal firm and the second entrant because of the lower technological uncertainty of the existing business module.

CONCLUSIONS AND MANAGERIAL IMPLICATIONS

The main focus of this study was to identify how the intensity of inter-firm collaboration varies across four cases and two selected service developments. This present study found that the degree of intensity of inter-firm collaboration is influenced by the different degrees of task complexity and of project newness in different service developments. Because the characteristics of the task are complex and associated with the focal firm's development activities in the functional development of developing new services, case companies often use very intense inter-firm collaboration with suppliers in order to integrate different actors' requirements, reduce technological uncertainty and further improve service quality. When a task is simpler and can be separated from the focal firm's development activities, case companies may use a lower degree of inter-firm collaboration with suppliers. Additionally, the degree of project newness may influence the intensity of the inter-firm collaboration in terms of different degrees of technological uncertainty. Focal firms adopt more intense inter-firm collaboration with the first entrant to identify its IT requirements and problems and share the related knowledge to reduce the technological uncertainty of a new business module. Once the requirements and restrictions of the new business module have been clearly defined, the focal firm adopts a lower degree of inter-firm collaboration with the second entrant, in order to quickly expand the scope of the existing business module.

This research offers some managerial insights. First, firms can cooperate more intensively with fundamental suppliers (e.g. IT system supplier and logistics) to lay the foundation of a new service. This close collaboration allows a focal firm to identify functional requirements and integration problem with its suppliers to contribute fundamental functions of a new service. Second, it may be more appropriate for firms to cooperate less intensively with non-fundamental suppliers when a project is not relatively new, as these suppliers have fewer essential resources and some market alternatives to contribute to the new service development. Focal firm can modulize the development activities of non-fundamental suppliers and keep many alternatives, to improve external sourcing. A lower level of interaction between firms may reduce the time and cost to administer arrangements with these suppliers.

ABSTRACT

The increasing amount of product data is creating more and more challenges for companies, not the least whit data management and data quality practices. Defining and assigning product data ownerships and its related functions, practices and processes, enterprises can enhance their product data quality. The purpose of this study is to introduce and review the concept of product data ownership network (PDON). Furthermore the current roles, practices and processes that PDON includes were defined from enterprise practice. The results point out enterprise-wide definitions, policies and guidelines, product data management activities, product data owners, roles and responsibilities, and enterprise's business functions to be the key elements and enablers of PDON. PDON is built around product data owners, who in the end have the responsibility over the product data. Besides product data owners, the supporting network needs to be built around them in order to enable their tasks towards product data. This network consists of other roles, different practices, and various functions. Implementation of PDON and Product data Maintenance related functions requires resources, investments and approval from the upper level management. Both empirical and theoretical researches revealed that poor data quality affects both the operational and the strategic sides of business. Therefore PDON takes a strategic importance which needs to be validated by the participation of the management.

Key words: Product data, data ownership, ownership network

INTRODUCTION

Modern companies are dependent on information systems and most business processes are supported by information systems (Lagerström and Johnson, 2008). Functionality of these systems is dependent heavily on data concerning products. Efficient product data management practices have become one of the key aspects for business efficiency. At the same time enterprises are lacking the understanding how to manage data integrity and availability in daily operations (Reid et al., 2007). At the same time collaboration network has extended to cover partners, suppliers and contractors. As a result of the IT systems, collaboration network extension, the amount of data created and handled over products' lifecycles has become very extensive, which has led to realization of the importance of effective data management. (Stark, 2005; Saaksvuori and Immonen, 2008)

In companies a large number of stakeholders are involved during product lifecycle (PLC). As the number of individuals and organizations grows larger, it brings many kinds of challenges, not least with the product data. Companies, which are not able to control their product data, will face major challenges on getting their products under control (Stark, 2005). Typically companies do not know what product data they have, how critical it is, the sources that exist for critical product data, or the degree of redundancy of their product data assets (Khatri and Brown, 2010).

One way to handle the growing amount of product related data are PLM and PDM systems (product life cycle/data management). These systems help to organize, store, maintain and utilize product related data. Furthermore, PDM helps enterprises to manage their operations electronically (Stark, 2005). Because PDM systems do not clearly represent the linkage of product management through lifecycle, the wider managerial view, product lifecycle management (PLM), has been arisen. But even with PLM, the focus of data management is strongly focusing on engineering data management only in product design and manufacturing operations, letting the key point of the concept, lifecycle, rather untouched (Kropsu-Vehkapera et al., 2010).

Enterprise architecture (EA) model can be seen as a tool to define and develop enterprise's data related functions further. Although EA model is used to develop the whole enterprise, this research focuses on the information architecture discipline. The scope of information architecture is to define the enterprise's essential product data, assign the ownerships of product data and to describe the exchange of product data between different stakeholders. The results occurring from the work of information architecture work can be used as basis when defining and building PDON – product data ownership network.

Enterprises have also other systems (e.g. ERP, sales configurators) and applications (e.g. CAD-tools, CRM-tools) that use product related data (Loshin, 2001) creating even more challenges on managing product data effectively. Therefore, a set of enterprise-wide guidelines, policies and functions are needed to ensure functional product data management and quality of product data. Product data responsibilities are usually allocated according to organizational

units and related business process responsibilities. It is common that the person who creates the data is also the owners of the data or in some cases there might be an organization carrying the responsibility over data ownership. (Kropsu-Vehkapera et al., 2010.) Undefined data ownerships are fatal for business processes. Gaps and flaws in product data ownerships may complicate the whole order-delivery process and cause major business losses. The responsibility of product data cannot be left just for data owners, there has to be defined and implemented guidelines and policies for them to follow as well as a supporting network. This network's responsibility is to help and support data owners to outperform their tasks (Stark, 2005; Saaksvuori and Immonen, 2008).

Towards former background, this research aims to introduce and review the concept of product data ownership network (PDON). The concept of PDON is studied from the product data management, data governance and data quality point of view. The increasing amount of product data is creating more and more challenges for enterprises, not the least whit data management and data quality practices. Defining and assigning product data ownerships and its related functions, practices and processes, enterprises can enhance their product data quality. Product data ownership network also enables better and more efficient product data management practices. Research problem is divided on the following three research questions:

RQ1: What are the elements of PDON?
RQ2: What kind of roles, practices and processes should PDON include?
RQ3: What are the requirements for enterprise to create and implement PDON?

RESEARCH PROCESS

Figure 1 illustrates the research process applied in this study. First, a literature review strives for defining the key elements of PDON. Second, company representatives and specialists were interviewed on defining roles and responsibilities, working practices, processes and functions that are currently thought to be the key PDON practices in modern enterprises. In addition, the interviews were conducted to clarify what are the requirements of PDON implementation for an organization and enterprise. This study compiles all the essential parts and elements of a PDON and presents generic guidelines for building it.

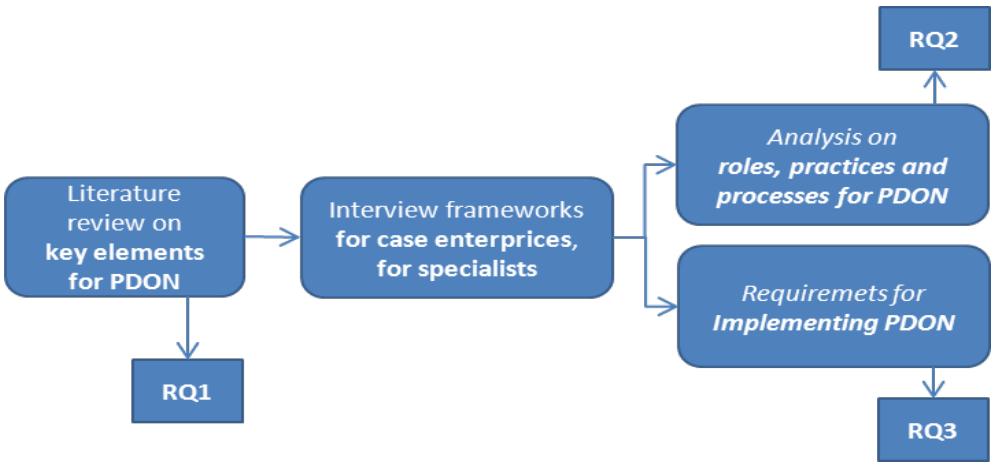

Figure 1: Research process.

The empirical data was collected by interviewing responsible data managers of companies and specialists with extensive experience consulting companies on product data management. In addition, the empirical material included documentation handed over by interviewees. The goal of interviews was to find out the current PDON definitions and functions in nowadays business processes from two different viewpoints. The study consisted of total 13 interviews. Although the number of interviews is not statistically sufficient for qualitative analysis, it is irrelevant according to Alasuutari (2004). It's rarely possible to achieve sufficient number of interviews in order to be statistically important when doing qualitative analysis and research. The amount of interviews made were left short from intended due to the fact that PDON was lacking in many enterprises, the maturity level of product data management was very low or the selected interviewee felt that one didn't have enough competence in order to answer the questions.

Interviews were done face to face at interviewee's place of employment or by phone. The scope of the interviews was to gather information about current definitions and functions of PDON. Interviewees were divided into separate groups; to the interviewees from case enterprises and to specialists. Thus, two distinct question frameworks were built for these groups (see Appendix 1). Question frameworks were based on the synthesis of the theoretical section and then modified to be suitable for both of the groups to be interviewed. The question frameworks were still slightly modified during the interviews in order to maximize the coverage of gathered research data and in order to leave room every interviewee to explain the subject freely. The questionnaire directed enterprises focused more on the actual working with PDON as the questionnaire for the specialists focused more on the requirements, challenges and benefits of PDON.

All the individual interviews were analysed separately in order to find the current roles, practices and processes that PDON includeswere defined. Also the challenges, benefits, and PDON implementation requirements were summarised. As a conclusion, the requirements that PDON creation and implementation sets for an enterprise was presented.

ELEMENTS OF PDON

Product data and ownership

In context of product lifecycle management product data is widely understood to covering all the information related to the product (Saaksvuori and Immonen, 2008). Product data can be divided for product master data and product related data. Master data describes the business-oriented properties of data objects that is used in diverse applications across the organization in multiple business processes (Loshin, 2001) and should be managed over company in an integrated fashion. There should be only one truth of data available when speaking on master data (Berson and Duboc, 2007). Product master data contains static data like product description, item code, weight, price, and suppliers (e.g. Nagi, 2001) as well as include configuration options and operation instructions (Yang et al., 2007).

From product data maintenance view,Van Alstyne et al. (1995) define data ownership as the right to determine usage rights to others. By usage rights they refer to ability to access, create, standardize and modify data. Duerr et al. (2004) state that data ownership should be connected to data preservation in order to ensure the future accessibility of the data. Berson and Dubov (2007) see data owners as individuals or stakeholders within the organization that has status to obtain and create data and have major role in distribution, access and controlling the content of the data.

Product Life cycle

Product related business functions trough out the product lifecycle (PLC), that create and/or use product data, can be divided into four major categories; product development, production, sales and marketing, and maintenance (after sales). It is important to understand that all these business functions need to be included and involved in PDON because they all have needs, requests and effects towards product data during the product lifecycle. All these functions also create product data, which needs to have assigned ownerships and made available for other business functions for their usage. (Stark, 2005; Sudarsan et al., 2005; Svensson and Malmqvist, 2002).

Because there are several actors (roles) from different business units working in PDON, it is important that they all have the same understanding of how the product data is created, distributed and maintained throughout the product lifecycle. Equally important is to have one single version of truth of product and its related data between business functions and between different actors. Policies and guidelines defined in PDON should be seen as enterprise-wide manner and those should standardize product data creation, distribution and maintenance related activities and processes between business units. Through standardization of procedures, business units can work more efficiently in co-operation with other business units and the consensus of product data related activities, processes and functions rises. (Levitt, 1965; Saaksvuori and Immonen, 2008)

In the early stages of product lifecycle, there is obviously product development function involved. Product development includes concept creation, product definition and designing of the new product. It is important to notice that in the early phases of PLC, the sales and marketing function is also active. This is not highlighted commonly in literature. During the product development, sales and marketing is creating sales brochures and developing promotion and launch materials. Even though it seems that sales and marketing has functions in all the phases during the time line of PLC, there can be found hardly any literature to support this. This makes it hard to place sales and marketing to the time line of PLC. After the product and its sales and promotion material has been created, the production and sales of the product can begin. Maintenance and services related to the product begins usually also at this point. Sales and marketing promotes the product during the production phase. After the product has reached its peak sales, the enterprise starts to decline the production and finally kills the product. Even though the production is concluded, the maintenance of the product can still remain for several years, in some cases even decades. Sales and marketing usually ends the promotion of the product not later that when the production ends, but it still may have some functions related to the product also during its maintenance phase. Depending on the product, at some point the maintenance function is also concluded and the lifecycle of the product comes to an end. (Andreasen et al., 1996; Svensson and Malmqvist, 2002; Shu and Wang, 2004, Saaksvuori and Immonen, 2008)

Product data ownership layers

There are several actors working with product data. All these actors have their own functions, effects and requirements towards product data ownership. The ownership can be categorized in different layers based on their hierarchy level (Figure 2).

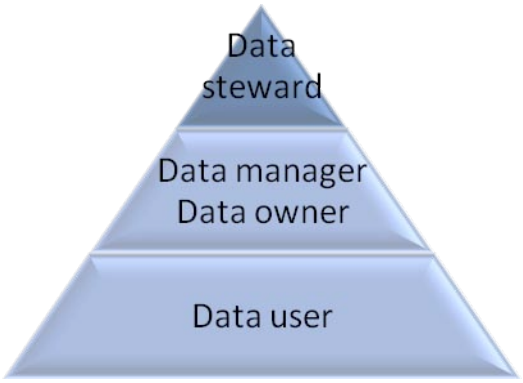

Figure 2: Product data ownership layers.

On the top of data ownership layers are data stewards. Their task is to define and help implementing product data ownership policies, requirements and functions according to the guidelines set up by enterprise and to improve the data flow throughout the enterprise.

The implementation of policies, requirements and functions is the responsibility of data managers, who are categorized in the next layer. It can be said that data managers are also

responsible of capturing, storing, retaining and disposing the product data, in other words, they are responsible of everything that concerns delivering and handling information. Data owners are typically also the creators of the certain product data they own. Their responsibility is to provide consistent product data that meets the quality standards and are always available for its users. Shortly said that data owners create and provide consistent product data, by using IT systems which provide the needed infrastructure for information delivery purposes. (Loshin, 2001; Becker, 2006; Berson and Dubov, 2007)

The lowest hierarchy level is data user. Data users must comply with the information management policies when they select the best information source to meet their needs. They must have applied authorities to the product data their using. Nevertheless data users mostly utilize product data in their tasks, they still must provide assistance to other stakeholders in order to improve product data ownership functions. Table 1 presents data ownership layers and responsibilities in RACI-chart. (Wende, 2007; Weber et al., 2009)

Table 1: Data ownership layers and responsibilities (Wende, 2007; Weber et al., 2009).

Task\Layer	Data Steward	Data Owner	Data Manager	Data User
Defining PDON policies, requirements and functions	R	I	C	I
Implementation of PDON policies, requirements and functions	R	I	A	I
Delivering and handling product data	C	A	R	I
Creation of data	C	A	I	C
Data quality ensuring	C	A	R	I

R - Responsible, A - Accountable, C - Consulted, I - Informed

Compiling key elements of PDON

Data governance is an essential part of PDON. It can be seen as a kind of enabling and supporting process operating behind the actual PDON function. Data governance is used to organize and implement roles, guidelines, policies, procedures, and standards for building up and maintaining PDON. (Cohen, 2006; Winter et al., 2001)

Like earlier presented, there are four major *business functions* that use PLC. There has to be information sharing and distributing between these functions in order to have the single version of truth concerning the product and data related to it. Under these disciplines are many roles and responsibilities that need to be fulfilled according to definitions made in data governance. Firstly, new product data needs to have owner. *Product data owners* (PDOs) primary responsibilities are to ensure the data quality, maintain the data and make it available

for other users needing it. Product data is created in every business function of an enterprise and therefore product data owners have to be found from all of these disciplines. (Andreasen et al., 1996; Svensson and Malmqvist, 2002; Shu and Wang, 2004, Saaksvuori and Immonen, 2008)

Besides product data owners, different business functions also include other *roles and responsibilities* concerning PDON. These commonly include e.g. making product data available for other disciplines, storing the product data or implementing and monitoring policies and guidelines defined by data governance. PDOs cannot operate product data by themselves; they need assistance from other roles in order to fulfill the demand set for the product data by the enterprise. To have a fully working co-operation a virtual network is needed and this can be called to fully operational PDON. Although literature defines the four business functions, it presents hardly any specific information about the roles and responsibilities under them or how are these related to each other concerning PDON. Therefore those cannot be unambiguously defined based on literature.

Information flow between business functions, from data owner (or creator) to data base and further to data user, must be organized and monitored. *Product data management* with policies and guidelines defined by data governance forms the foundation for data storage and distribution. Effective data distribution is vital for enterprises' business processes. Information gaps and delays can be costly. PDOs can ensure that the product data is in right form, at right time, at right place through product data management processes and protocols. Product data management integrates enterprise's disciplines and their data flows to an effective network. (Saaksvuori and Immonen, 2008; Loshin, 2001)

When constructed and maintained right, PDON can be huge benefit for an enterprise. But this doesn't happen by itself, it requires precise planning of functions and processes, following guidelines and policies as well as dedicated workforce to operate with it. Constructing PDON is heavily enterprise-specific manner and cannot therefore be unambiguously defined to fit in every enterprise or business area through literature. But still, the key elements that form the basis of PDON and data flows inside PDON can be presented (Table 2).

Table 2: Key elements of PDON.

Key element of PDON	Focus
Data governance	• Data governance is used to define, organize and implement guidelines, policies, procedures, standards, roles and responsibilities for building and maintaining PDON.
Product data management	• Is based on policies and guidelines defined in data governance. • Forms the foundation for data maintenance, distribution and storage. • Ensures that product data is in right form, at right place, at right time. • Integrates business functions and their product data flows to a single network.
Product data owner (PDO)	• Primary responsibility is to ensure data quality, maintain product data and make it available for other users. • PDOs have to be found from every business unit that creates product data and every part of product data needs to be owned.
Roles and responsibilities	• There has to be also other roles and responsibilities than PDOs involved in PDON. • These are to support and enable PDOs' activities in order to have functional PDON. • These roles and responsibilities cannot be unambiguously defined based on literature.
Business functions	• All the business functions are needed and have to be involved in PDON. • Product data is created and/or used in every business functions and therefore it has affects towards them. • There has to be single version of truth of the product and its related data. • Product data has to be made available for those needing it throughout the enterprise. Therefore product data sharing and distribution have to be established according to product data management guidelines and policies and it has to be implemented as an enterprise-wide manner.

Product data management and quality issues aren't solved by themselves. PDON can be used to ensure product data quality and distribution as well as making product data available for those needing it. Functional PDON requires hard work, dedication, comprehension, and most of all planning and defining. Enterprises must create visions and concepts and define that what is the data they want to manage and what are the processes, functions and systems to support the product data. These concept visions should support and be tied to the enterprises strategy and made as enterprise-wide manner.

KEY SUCCESS CRITERIA'S BASED ON THE INTERVIEWS AND LITERATURE

The scope of the interviews was to gather information about current definitions and functions of PDON. The amount of interviews made for case enterprises and specialists were left short from intended due to the fact that PDON was lacking in many enterprises, the maturity level of product data management was very low or the selected interviewee felt that one didn't have enough competence in order to answer the questions. Totally of 13 interviews were made for the case enterprises and specialists. Although the number of interviews is not statistically sufficient for qualitative analysis, it is irrelevant according to Alasuutari (2004). He states that it's rarely possible to achieve sufficient number of interviews in order to be statistically

important when doing qualitative analysis and research. The goal of interviews was to find out the current PDON definitions and functions in nowadays business processes from two different point of views. Summary of the results is in the table 3. Interviewees were divided into separate groups; to the interviewees from case enterprises and to specialists. Two distinct question frameworks were built for these groups. Question frameworks were based on the synthesis of the theoretical section and then modified to be suitable for both of the groups to be interviewed. Both of these frameworks were still slightly modified during the interviews in order to maximize the coverage of gathered research data.

Table 3. Collection of the essential answers from PDON point of view.

Role	Data ownership model	Key Elements of PDON	Data in scope
Enterprises	1. PLM directs the ownership 2. Corporate data ownership according to the enterprise structure 3. Ensure top management buy in.	1. Enterprise size 2. Organisation structures 3. Product Structure 4. Architecture and other guidelines	1. Guidelines and policies of the company define the data to be owned by PDON
Specialists	1. Implementing data ownership is difficult 2. Managing changes to ownership is difficult 3. Centralized data ownership and maintenance makes it easier	1. Product structure 2. Company structure 3. Existing roles and responsibilities 4. Guidelines and working instructions	1. Critical data (master data). 2. Other data to be considered case by case.

Roles, responsibilities and process

When creating and defining the concept of PDON, one of the challenges is to define the essential roles that it includes. Table 4 syntheses the finding from interviews and combines those according to literature review. Role-based approach to PDON is important for its functionality. These roles and their functions have to be defined enterprise-specific due to the differences between enterprises and business areas (table 3). What is common to all of these roles is that they must support the functions operated by data owners and create the supporting network around them.

Table 4: General roles and responsibilities that PDON should include and cover.

Examples of definition areas	Examples of content
Roles	What are the needed roles that PDON requires? • Data owner • Data administrator • Change manager
Responsibilities	What are the responsibilities of the roles? • Who distributes the product data? • Who is responsible of change management? • Who ensures data quality? • Who owns the product data?
Functions	What functions and activities are needed in PDON? • How is the data distributed and stored? • How is traceability organized? • How is data quality monitored? • What systems do we need? • How is support organized?
Data principles	What is the data we manage? • What are the uses of product data for the business? • How is the data defined and modeled? • How is the product structure constructed?

Starting point for role definition should be that roles represent the functions of the enterprise. This is to ensure that all data users and their view to the product data are covered. Some of these roles may include overlapping tasks due to the generalization.

Before defining any roles, it is important to highlight that PDON roles are not supposed to be main tasks for employees. Nobody should work only e.g. as product data owner. These roles has to be operated along with employees other duties due to the fact that PDON is supposed to be empowering background process for product data and quality management processes. It is also important to emphasize that individuals or organizations might have one or more roles assigned concerning PDON or there can be several actors operating under same role. This is depended on competence level that different actors have and should be decided as each case individually. It should also be pointed out that individuals or organizations operating these roles may also change during the different lifecycle phases of the product but the roles must move alongside with it throughout the lifecycle and be always assigned. Table 5 shows examples of responsibilities and potential roles.

Table 5: Example who should have responsibility to define the data owner roles.

Responsibility	Examples of potential roles
Definition of roles and responsiblities of PDON	• Enterprise data committee / council • Data steward
Implementation and monitoring of policies and guidelines	• Enterprise data committee / council • Data steward •Product data manager
Data delivery actions	• Product data manager • Data delivery specialist • Data owner
Overall responsibility of product, product data and product structure	• Product manager • Product data architecture • Product technical owner • Enterprise data modeler
Data quality	• Data owner • Data administrator • Data quality team • Data quality manager
Product change management	• Data owner • Change manager • Product change team
Support	• All the roles

There should also be a role, e.g. *product manager*, which has the overall responsibility of the product and product data over the lifecycle of the product. Product manager's responsibility is to ensure that all the needed information, product data, roles and functions concerning product are done or fulfilled before the product data can be released to the IT systems. One of the key responsibilities is to ensure that the product content meets the defined data model requirements which are based to EA. This means that essential product structure levels with right content is been ensured to guarantee smooth product launch and use in enterprise business processes. This type of structure levels are for example: sales structure, configuring structure, engineering structure etc. Also, the entire product related information, which is not included in enterprise's definition of product master data, has to be handled and ensured by this role.

Product data in the IT systems should also be maintained and its validity be ensured. This is administrative role, e.g. *data administrator* role. The data administrator role can be assigned for the one also having the ownership of certain part of product data, if not already included to the data owner's role. If enterprise chooses to have centralized ownership of product data, this role should be assigned to separate quarter, e.g. *data quality team*, which is responsible for all the product data quality related manners. This role may also include delivering the product data to the target systems and giving usage rights concerning product data.

During the product lifecycle, there are usually many changes made to the product and its related data. These changes must be handled with care in order to keep the data and product structure correct in IT systems. Enterprises can set up a specific role, *change manager*, to handle product changes or it can be included in data owner's role. When a product change is requested, the responsible for that part of the product needs to be informed and change management process started. The responsible one needs to analyze the change, implement and verify it, and follow-up that the change is done to the product and especially to the product data and structure.

Empirical research revealed also that PDON needs a supporting role and network to ease up and enhance the tasks of different PDON roles and players. Supporting role should be included in all the other roles in PDON but there should also be dedicated players that can be asked for assistance in the end. If someone has difficulties to do one's tasks, there should always be a way to get help fast and easily. For example data owner in R&D might be responsible of data that has low value for his/hers work. Actual user of the data is in operations or logistics.

Empirical material of this study emphasized the significance of product structure's effect on PDON, especially towards data ownerships. Product structure can be defined through data elements, which describes a certain products component, element, module, subsystem or assembly which all needs to be handled and owned through PDON.

In every enterprise, there has to be an unambiguous specific quarter, which defines and leads the building and monitoring of PDON. These manners don't just happen by themselves. Enterprise has to set up a dedicated group that works in closely with different business, operation and technology groups in order to successfully implement PDON. This quarter has to ensure that all the roles, functions and processes of PDON are commensurate as enterprise-wide wholeness. Figure 3 presents a simplified illustration of PDON's definition process.

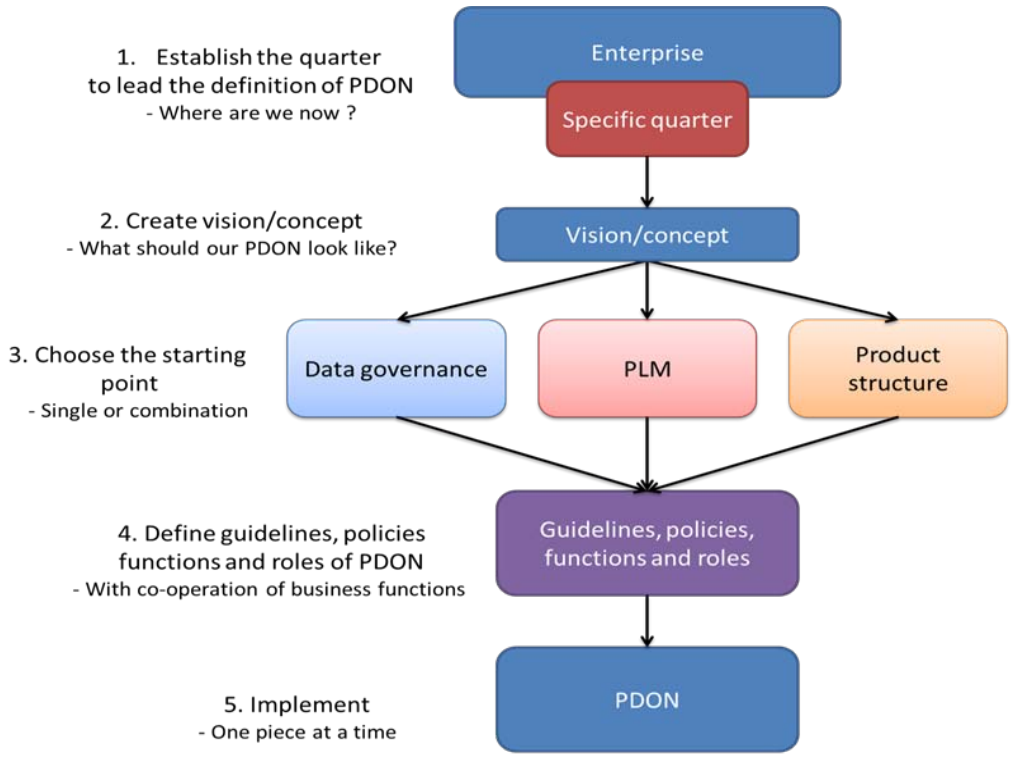

Figure 3: A Simplified PDON definition process.

Implementing PDON

Enterprise architecture model can be seen as a tool to define and develop enterprise's data related functions further. Although EA model is used to develop the whole enterprise, this research focuses on the information architecture discipline. The scope of information architecture is to define the enterprise's essential product data, assign the ownerships of product data and to describe the exchange of product data between different stakeholders. The results occurring from the work of information architecture work can be used as basis when defining and building PDON.

PDON model proposed in this paper is general and should be used as guideline when implementing in enterprises. It should also be mentioned that enterprise-specific customization of this model to meet the enterprises demands is recommended.

The biggest challenge concerning the building and implementation of PDON is the upper level management. Getting upper level management excited about product data and further about PDON is crucial. Without given resources and investments (financial and manpower) in product data and related functions, the efforts for building PDON are pointless. Because poor product data quality affects both the operational and the strategic sides of business, addressing PDON takes a strategic importance that must be validated by the participation of the management of the business. Easiest way of getting upper level management excited about product data is to present facts of financial losses from enterprise's history that were caused by data problems.

It has to be mentioned here that establishing PDON, ensuring data quality and making product data management functional is not done by overnight. These manners have to be seen as long-term processes, which are divided into intermediate goals. Changes and development in processes, protocols and functions always confront resistance that needs to be persuaded to approve changes in the long run. Developing these manners little by little eases this workload.

CONCLUSIONS

Eventough enterprises invest in IT, the return of the investment does not meet the expectations. This can be seen as higher operational costs. It is very often that IT projects go over their budgets or after the go live there are serious operational challenges within the enterprise. All these are caused by the fact that systems are getting more complicated with automation and this adds the need of high quality data. Data is used to master the functionalities within the systems. Data is owned by the business organisations and specially data owners. This job is often additional task to perform and one can only meet the expected quality level if the role descriptions are instructions are in place, trained and maintained.

Product data is the most complex master data element and was selected because of that. Making the data ownership visible within the enterprise, makes the cross-functional co-operation easier. To identify how this should be done in practise, this research focuses to discover the key elements and requirements of PDON.

Product data needs to be distributed, maintained and its quality ensured. PDON includes several practices and processes to support and operate these activities. Besides the actual *definition of PDON*, which includes definitions of guidelines, policies, roles, responsibilities and all the product data related functions, the main function of PDON is the *ensuring data quality*. The responsibility of product data quality is assigned to the data owners in the end but other roles and functions has also the responsibility to support data owners by monitoring and making corrective actions towards product data.

Making product data available for those needing it is crucial. Lack of critical part of product data can intercept enterprises' business processes. Therefore product data needs to be made available for those needing it through product data sharing and distribution practices. There are also commonly made changes to the product and its related data during the product lifecycle. There have to be effective *change management process* which is based on *traceability* of the responsible data owners and other responsible concerning those certain parts of the product. PDON should also be used as *supporting network.* As people always will confront difficulties in their daily tasks, there should be a quick way to receive support and assistance.

Clearly an area that needs to be further studied is how much the product type (tangible vs. intangible product or mixture of these) has influence to the functions and structure of PDON. This research was mainly concentrating on tangible products and PDON build around those. The product structure of tangible product can be constructed straightforward and as this study

pointed out, it has major effect towards PDON's structure. Product structure of intangible products is not relatively different from tangible product but the data content and product lifecycle are making the difference. Furthermore managing intangible product through PLM and PDM and intangible product's productization are still quite untouched topics in the literature. Therefore its effects to usefulness towards PDON should be studied.

During the interviews made for the empirical research part of this study, two further research topics came up and are opened here as they clearly are elements that have a big impact on PDON implementation.

1. Terminology of PDM, PLM and PDON area is still quite a mess. Many of the specialists emphasized that the terminology of these manners should be generalized in order to have common understanding between enterprises and specialists. The terminology is not competitive advantage of any enterprise and therefore the basis of it could be generalized.
2. Biggest bottleneck concerning the establishment of PDON was the upper level management and their ignorance and lack of understanding of product data related issues. In other words, business change management practices have to be understood within the enterprise. This is to be able to provide unambiguous proof about the benefits (financial and efficiency) of PDON and the product data management related functions, establishing and driving PDON and other data related functions would be much easier in enterprises.

Both topics raised here do require real life pilots of the PDON in different scale of companies and product categories (tangible vs. intangible). Biggest challenge of all is the tendency of enterprises to require fast results and lack of the business change management.. The Importance of good data is rising as the need of business intelligence demand increases. Also new starting IT projects in enterprises seems to have dedicated data management parts where PDON and related issues are been considered. Social media applications provide good supporting tools to manage PDON networks after they have been implemented beside of the product process management.

ABSTRACT

This paper discusses about the data quality dimensions and is related to general field of product data management research. Data quality dimensions are metrics, which can be set to measure data quality characteristics more precisely. In this research, data quality dimensions are investigated from the organisational point of view; how organisational function affects on the experienced importance of data quality dimensions. The results reveal that the most important data quality dimensions are "accuracy" and "accessibility", when viewing summarized results from each organisation function. But when results are viewed individually at organisation function level, we can see that there are differencies. The purpose of the data usage in organisational unit affect on the importance of different dimensions. The results founded here fortify the earlier research data quality needs to be considered together with the data usage. Also, this study provides new information as similar research concentrating on data quality in organizational functions has not been conducted before. What these results mean in practise is that data quality, and how it will be evaluated, need to be considered together with the data users, as they understood the actual use of the data. Data quality measurement alone can be meaningless if not tied up with the real data usage.

Keywords: Data quality, product data, product data management

INTRODUCTION

The amount of data is growing increasingly fast forcing organizations to invest on different technologies to collect, store and process the data (Madnic and Wang, 2009). Organization databases can grow up to 50% per year meaning more information to manage business (Valentine, 2010). However, the data needs to be high quality to benefit the business; otherwise data turns to pollution that may harm the company and its environment.

Therefore, data quality is gaining more attention when organizations are realizing that data quality issues cause losses in money, time and in missed business opportunities (Olson, 2003). According to Piprani and Ernst (2008), the reasons behind the overall poor data quality can be pinpointed to a lack of supporting business processes, insufficient analysis techniques, and methods of assessing incoming data quality. To improve these aspects the area of data quality management has absorbed practices from the product quality

management, from Six Sigma and Total Quality Management (Wang, 1998; Redman, 2001). Typical statement for these quality methods is that "you can't manage what you can't measure." This is also true for data quality management.

Measuring data quality is more difficult than a measuring product quality since the data is more abstract concept (Wang, 1998). To define what data quality is and how to measure it, academic researchers have divided data quality into smaller sub-sections; data quality dimensions. Depending on the research, there are typically 4-20 dimensions to be used for data quality measurements (e.g. Wand and Wang, 1996; Freiden et al., 1998; Wang, 1998; Kahn et al. 2002; Piprani and Ernst, 2008; Herzog et al., 2007; Batini et al., 2009; Herrala et al., 2010; Cappiello et al., 2010).

Data quality has been studied widely and in different point of views during the last decades. Massachusetts Institute of Technology (MIT) has been a pioneer on data quality research since Total Data Quality Management (TDQM) program was started 1992. (Madnick and Wang, 2009.) Despite the significant amount of research, there is still no accurate and unanimous definition what data quality exactly is. In general, data quality is understood as "fitness-for-use", meaning how well data can be used for different purposes. (Wand and Wang, 1996; Madnick and Wang, 2009). There are no commonly agreed definitions for data quality dimensions either.

In the earlier research, data quality dimensions are handled as general indicators without considering the actual use of the data. This study approach the product data quality from the organization functions point of view and investigates how the importance of product data quality dimensions is perceived in different organization's functions (product development, manufacturing, sales & marketing, service & maintenance and product data management). Product data is referred as data broadly related to a product and it is a very significant research topic since it ensures that a company manufactures, delivers, sells, and maintains correct products. This research can be summarized into the following research questions:

RQ1. What are the most important product data quality dimensions during the order-delivery process?

RQ2. Does the organisation affect on the importance of the data quality dimensions?

In context of data quality, there are two terms which are generally used; data and information. Data means raw data, such as results from measurements, and information is understood as processed data. Data quality might also refer to technical aspects and information quality to nontechnical aspects (Madnick and Wang, 2009). In many cases these two terms are used as interchangeably and if not mention separately, the same applies also for this paper.

DATA QUALITY: DATA TYPES AND DIMENSIONS

Different data types

In general, data can be classified in three types: 1. Structured data (e.g. statistical data, tables), 2. Unstructured data (e.g. generic sequence of symbols, free text) and 3. Semi structured data (e.g. XML mark-up language). As data loses structure the data quality techniques becomes more complex. The quality dimensions may have different metrics depending of the types of data. (Batini et al., 2009).

Product data, which is generated during product development, is often unstructured. According to Contero et al. (2002), typical PDM (product data management) system contains two kinds of data: product data (geometry, digital mock-up, analysis and simulation results, materials, reports) and process data (manufacturing engineering data, planning and machining data, plant layouts). Quality of product data is very important especially in concurrent engineering.

General definition for product data is often linked to product design or development. Phelps (1998) defines product data quality as "Product data quality is a measure of the accuracy and appropriateness of product data combined with the timeliness with which those data are provided to all the people who need it". Contero et al. (2002) presents three levels of product data quality:

1. *Morphological – relates the geometrical and topological correctness of the CAD model*
2. *Syntactic – evaluates the use of the proper modelling conventions*
3. *Semantic/pragmatic – considers the CAD model capability for reusing and modification*

ERP data is logical continuum for product data. Haug et al. (2009) claim that ERP systems handle two kinds of data: master data and transactional data. Master data contains the basic instances of business entities and transactional data describes the relevant events in a company. They discuss the different definitions of data quality dimensions and conclude that for ERP data, quality dimensions are:

1. *Intrinsic data quality dimensions: completeness, unambiguousness, meaningfulness, and correctness*
2. *Data accessibility dimensions: access rights, storage in ERP system, representation barriers.*
3. *Data usefulness dimensions: relevance, value adding*.

Xu et al. (2002) state that "data quality problems are one of the major reasons organizations implement an ERP". ERP systems integrate separate sub-systems, which caused intrinsic, accessibility and contextual data quality problems. However, ERP system may also worsen the data quality issues since the same data is used in different modules. To sum up the previous chapters, it can be concluded that data type and structure needs to be considered when planning data quality measurement.

Measuring data quality

Data quality can be categorised and measured with different dimensions and metrics. Wang and Strong (1996) have defined data quality dimensions as "a set of data quality attributes that represent a single aspect or construct of data quality". Dimension, such as accuracy, reliability or completeness, may contain several metrics. For example, dimension accessibility is measured with metrics: is data easily retrievable, is data easily accessible, is data easily obtainable and is data quickly accessible when needed (Lee et al., 2002). There are no common definitions and companies are creating dimensions and metrics for ad-hoc needs.

Most data quality dimensions and metrics refer to data values, such as customer data (name, address or date of birth). Dimensions can refer also to data schemas but those are rarely used. (Batini et al., 2009.) Many authors have presented different data quality dimensions lists. According to Wand and Wang (1996), dimensions are selected and created based on intuitive understanding, industrial experience or literature reviews. Table 1 summarises data quality dimensions and definitions gathered from the literature review (Wand and Wang, 1996; Freiden et al., 1998; Wang, 1998; Kahn et al. 2002; Piprani and Ernst, 2008; Herzog et al., 2007; Batini et al., 2009; Herrala et al., 2010; Cappiello et al., 2010).

According to Piprani and Ernst (2008) it is essential to be able to assess data quality across both the earlier and later stages of the product development lifecycle from any given point. The data quality cannot be evaluated independent of the people who use the data (Strong et al., 1997) and the way how stakeholders perceive the data quality affects their behaviour and decisions (Pipino et al., 2002).

Table 1: Data quality dimensions and definitions.

Dimensions & metrics	**Definitions**
Accessibility	The extent to which data is available, or easily and quickly retrievable
Accuracy	Inaccuracy represents a real-world state different from the one that should have been represented
Applicability	Number of orphaned pages
Appropriate amount of data	The extent to which the volume of data is appropriate for the task at hand
Availability	Refers to possible access limitations, such as component licences define
Believability	The extent to which data is regarded as true and credible
Comparability	How two or more databases can be compared
Completeness	The extent to which data is not missing and is of sufficient breadth and depth for the task at hand
Concise representation	The extent to which data is compactly represented
Consistent representation	The extent to which data is presented in the same format
Consistency	Refers to values and the representation of data
Contents	How attractive content is to the user
Convenience	Difficult navigation paths: number of lost/interrupted navigation trails
Credibility	Number of tuples with default values
Currency	The time data item was stored
Derivation integrity	Percentage of correct calculations of derived data according to the derivation formula or calculation definition
Ease of manipulation	The extent which data is easy to manipulate and apply for different tasks
Effectiveness	Effectiveness means the effect information has on the user
Form	Refers how information is made available to the user
Free-of-error	The extent to which data is correct and reliable
Functionality	Aggregation of interoperability, compliance, and security
Interpretability	The extent to which data is appropriate languages, symbols, and units, and the definitions are clear
Maintainability	Number of pages with missing meta-information
Objectivity	The extent to which data is unbiased, unprejudiced, and impartial
Precision	Lack of precision is typically viewed as inaccuracy
Presentation usability	The usability of presentation mechanism
Relevancy	The extent to which data is applicable and helpful for the task at hand
Reliability	Correctness of data in our systems
Reputation	The extent to which data is highly regarded in terms of its source or content
Security	The extent to which access to data is restricted appropriately to maintain its security
Speed	Server and network response time
Temporal relatability	Meanings and semantics that can change over time
Timeliness	The extent to which the data is sufficiently up-to-date for the task at hand
Understandability	The extent to which data is easily comprehended
Uniqueness	Data values that are constrained to a set of distinct entries - each values being the only one of its kind
Validity	Conformance of data values that are edited for acceptability - reducing the probability of error
Value-added	The extent to which data is beneficial and provides advantages from its use

Volatility	Time length for which data remains valid

Although Table 1 lists over thirty differently named dimensions, they are partly overlapping. For this research, the following dimensions have been selected: Accuracy, Completeness, Timeliness, Accessibility, Validity and Relevance. The selection is based on how often the dimensions are mentioned in the literature, and then how well the dimensions illustrate the different data quality properties for data handled in different organisation's functions (e.g. Piprani and Ernst, 2008; Herzog et al., 2007; Ravn and Hoedholt, 2009; Wang and Strong, 1996; Lucas, 2010).

RESEARCH PROCESS

Figure 1 illustrates the research process applied in this study. This study addresses the research questions in a qualitative and quantitative manner, through literature review and industry questionnaire. At first, literature review was made to gain proper understanding over current data quality research. The main focus was on data quality dimensions. Based on literature review, the most significant dimensions were selected for the study and the questionnaire was created.

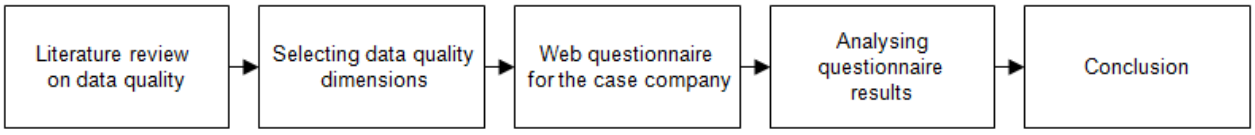

Figure 1: Research process.

The interview questionnaire included open ended questions and pairwise comparisons section. A pairwise comparison is a part of analytical hierarchy process -method, which can be used to rank a set of alternatives (in this case, the importance of data quality dimensions). Pair-wise comparison gives more accurate results, as only 2 items are compared at time (e.g. which one is more important dimension: accuracy or completeness, instead of listing all the dimensions and asking the person to rank all the listed items in descending order of importance).

The interview questionnaire was implemented as a web-application. The invitation letter and link to the web questionnaire was sent to the contact person from the case company, and the person was asked to forward the research to the data consumers from different organisations. Large companies are interesting research targets for data management and data quality research, as the challenges are more complex but also the benefits gained are more meaningful. The case company in this study is one of the leaders of its industry (large machining products and solutions), working globally and had billion class net sales in 2010. Employees from the departments (i.e. functions) of product development, manufacturing, sales & marketing, after sales, product data management and participated the research. Also, there were some answers, which could not be categorized under mentioned organisations. In the next chapter, the results are presented in more detail.

RESULTS AND DISCUSSION

Results from the case company

Altogether 27 answers were received from the case company. The answers were sorted into groups of "Product development", "Manufacturing", "Sales & Marketing", "Service & Maintenance" and "Product data management", based on what kind of product data the answerers need in their daily work or in which organizational department they work in. The results represented here are summarized from the open ended questions and pairwise comparisons.

Bar charts (Figures 2, 3, 4, 5 and 6) represent the importance factors of different data quality dimensions. The importance order of the different dimensions can be read from the charts but it also reveals the respective relations between different dimensions.

Product development

The data needed in product development organisation is very technical in general but also customer requirements data is needed. The leading manager of the technical product development concluded "*Product data that genuinely serves the organization or customer in some phase of the product lifecycle is the most important. Everything else is unnecessary and loads the employees for nothing*". It was said that "*Quality product data is easily readable and can be trusted. Employees are interest of it.* High quality product data "*makes daily work faster and easier, and increases work convenience*". In the product development organisation the downsides of poor data quality was clear seen: "*Bad or incomplete product data slows out work and decreases the overall reliability of product development*". The figure 2 presents the results of the data quality importance questionnaire from the product development organization.

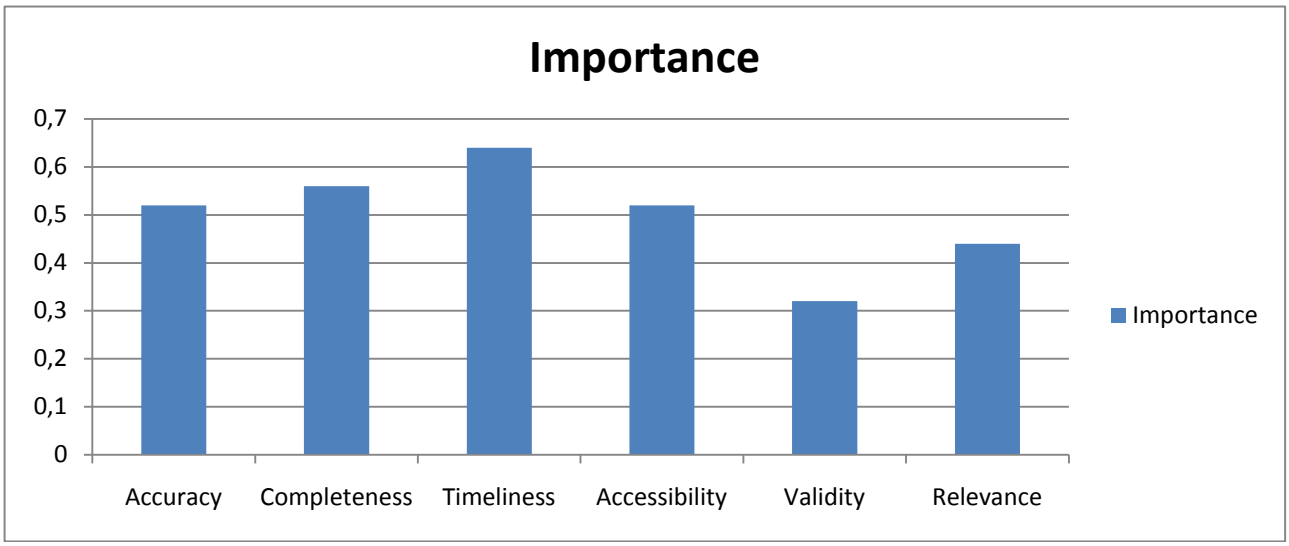

Figure 2: Importance of data quality dimensions in product development organisation.

Manufacturing

The manufacturing organisation needs product data for manufacturing products. The most important types of product data are: manufacturing documents and guidelines, drawings, traceability data, test data and change management data. Data quality means that data is "*correct and accurate, and available when needed". "The data needs to be easily accessible, in exact form and easily shared forward".* Figure 3 presents the result from the manufacturing organisation.

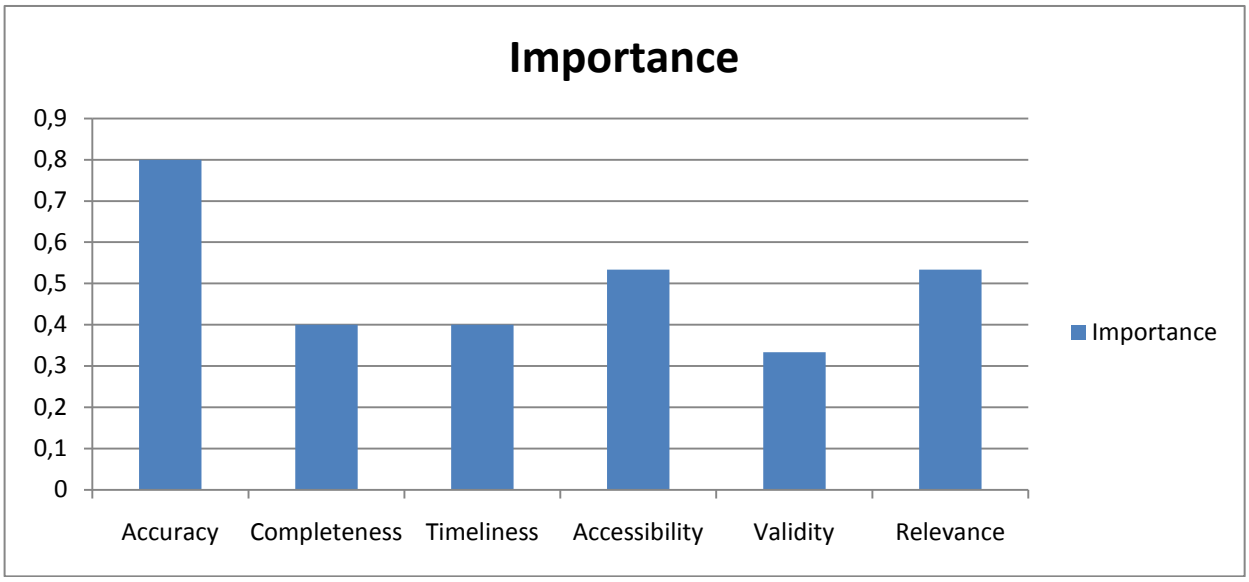

Figure 3: Importance of data quality dimensions in manufacturing organisation.

Sales & Marketing

The product data needed in sales & marketing organization is general on its nature, varying from customer data to technical information. Drawings, quality documents and product certifications are also often needed product data in sales & marketing. The quality of product data is understood as "*accuracy, in a way, that sales and purchasing pass through the systems without difficulties*". It was also said that *"data needs to be consistent – the data and the drawings need to tell the same information".* Another important dimension for the data quality seems to be the accessibility: "*The product data needs to be available all the time, also when working out of office, for example in customer's office*". Accessibility is important dimensions for the customers also, "*From the customer perspective, the data quality needs to high level, that data is easily founded and it has no errors".* The results from the S&M pair-wise comparisons are presented in figure 4.

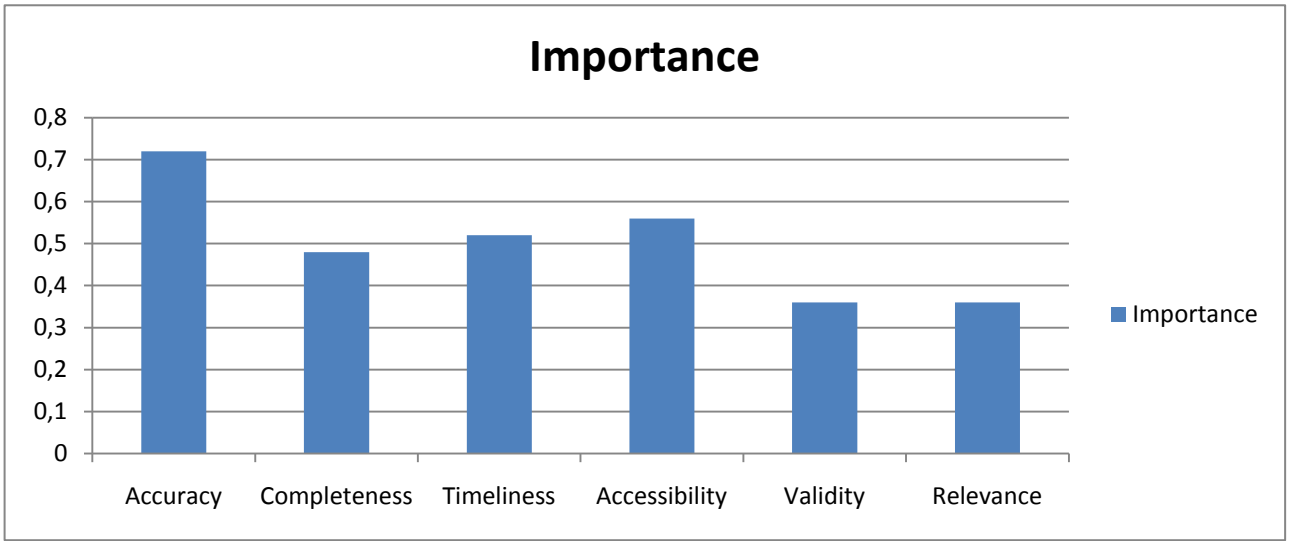

Figure 4: Importance of data quality dimensions in Sales & Marketing organisation.

Service & Maintenance

Service and Maintenance needs the product data to manage the spare parts information and the service business. Therefore, the most important product data are product related master data and technical data, such as product's technical properties, type markings, and what parts are used in which assembly. In sense of data quality, this means that data needs to be accurate. It is also needed that "*data is correct, up-to-date, and saved in correct fields*". "*The data needs to be accurate and in correct form*". In Service & Maintenance organisation, it was stated many times that data needs to up-to-date. The results from the Service & Maintenance pair-wise comparisons are presented in figure 5.

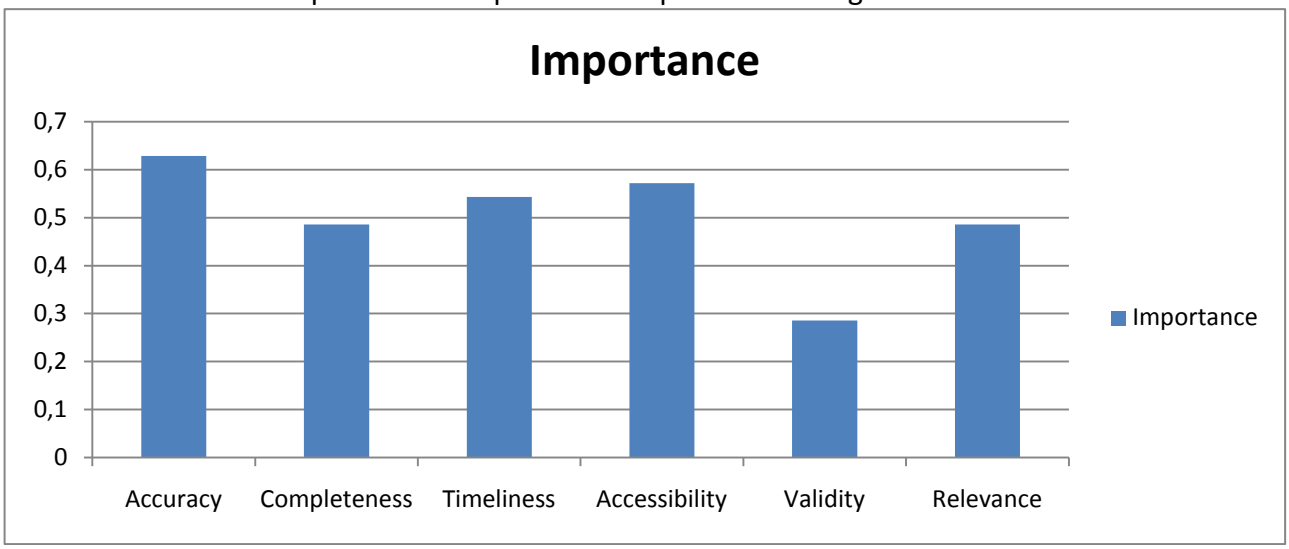

Figure 5: Importance of data quality dimensions in Service & Maintenance organisation.

Product data management

Product data management organisation is more supporting organisation than a traditional order-delivery organisation. However, people from the product data organisation may have the best view over product data as a whole, as they need view it more than one perspective, making it interesting research target.

Representative tasks of product data management are management of wide entities, such as product structure or combining different product data from many sources. They are also involved, when defining data management practices.

In PDM organisation, all product data in general was considered as equally important. "*The importance of data quality dimensions is defined by the business needs*". Accessibility dimension stood up as a most important data quality dimension and it was said that "*The data must be: easily accessed and divided into logical entities, no unnecessary data, data is in understandable form for its user and no special administrator rights are needed to use the data*". "*It is important to create and maintain correct data, which is relevant for business*", "*correct products with relevant product data in right place at right time*". The results from the Product data management organisations are presented in figure 6.

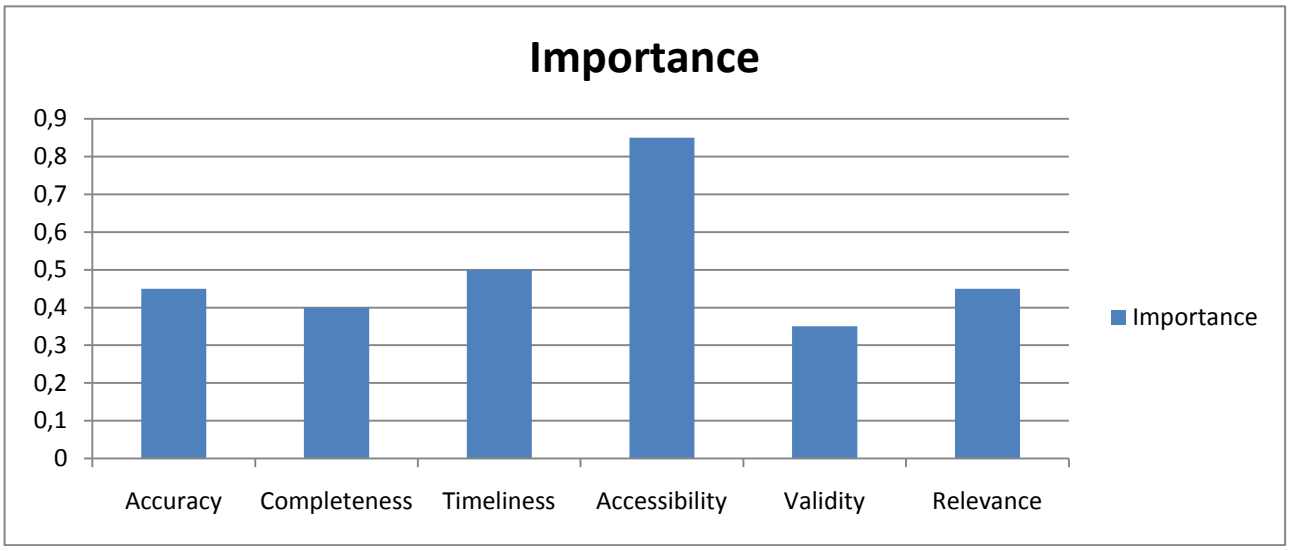

Figure 6: Importance of data quality dimensions in Documentation & PDM organisation.

Entire organisation

Figure 7 presents combined results from the entire company. It includes the results presented in earlier sections but also the results that could not be categorized under those organisations. These results are presented for comparing purposes.

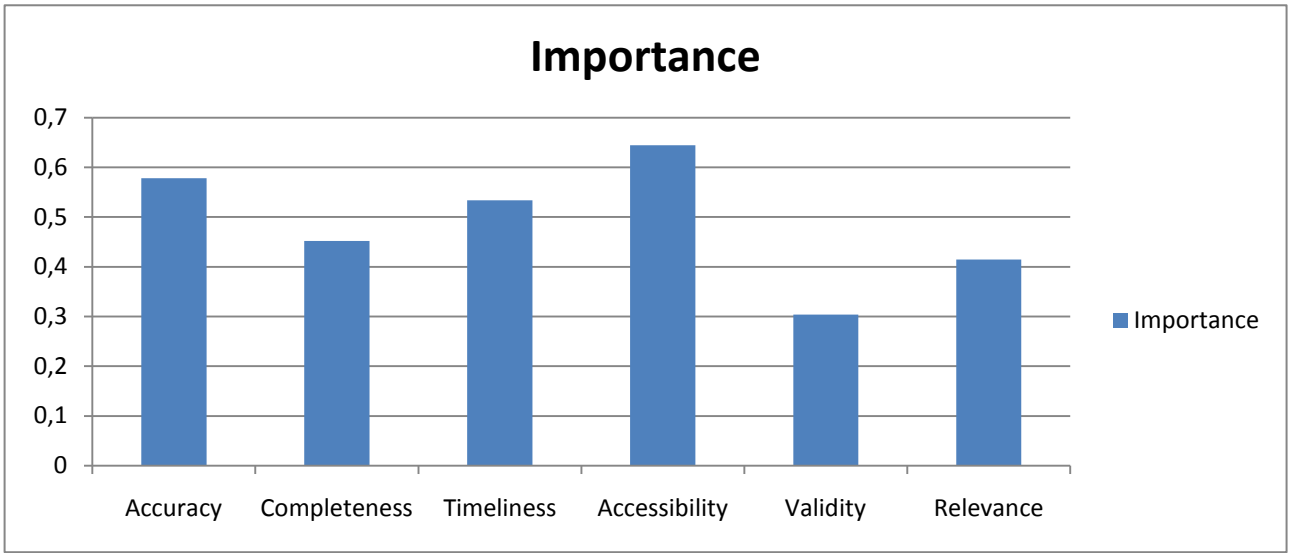

Figure 7: Importance of data quality dimensions in entire organisation.

Discussion

The results indicates that different organisation have different needs for data quality. For example, data users from product development prioritized "timeliness" as the most important data quality dimension for them. It can be explained with the need for the latest customer requirements, which is vital for successful product development.

Manufacturing organisation assigned "accuracy" as the most important dimension, which can be explained with the need for unambiguous manufacturing documents and guidelines. Also, the "accuracy" was considered almost twice as important as the next important dimensions "accessibility" and "relevance". This highlights the importance of "accuracy" for the manufacturing organisation.

In Sales & marketing, the "accuracy" dimensions stood up as the most important dimensions. "Completeness", "timeliness" and "accessibility" were the next important dimensions. Typically, S&M needs accurate and up-to-date information about products to market the up-coming products.

In Service & Maintenance, the importance of the different dimensions were most equal, expect the "validity", which was considered as the least important dimension. Also, there were no stereotypical statements to explain any differences.

Product management organisation considered all data equally important, which suits for the role commonly set upon PDM, as a supervisor of all data. In that sense "accessibility" as a most important dimension is a reasonable result.

Although the result represented here points out that different organisations have different needs for data quality, the sample size per each organisation is too small to be statistically significant. However, this study verifies the earlier research which state that importance of data quality depends on the data user and data usage. It also strengthens the view of data

quality as “fitness-for-use”, meaning that the data needs to be understood first, before any meaningful data quality measurement can be placed.

CONCLUSIONS

Data quality dimensions are metrics, which can be set to measure data quality characteristics more precisely. The most often used dimensions are “accuracy”, “completeness”, “timeliness” and “accessibility”. Companies can also set up their own dimensions for their needs. In this research, it was studied: *(RQ1) What are the most important product data quality dimensions during the order-delivery process?* and *(RQ2) Does the organisation affect on the importance of the data quality dimensions?*.

The results reveal that “accuracy” and “accessibility” are the two most important dimensions during the order-delivery process. However, the importance of the dimensions varies depending of the organisation. It seems that the purpose of which data is used have an effect on the importance of the dimensions. Typically, if organisation needs exact data (such as manufacturing documents in manufacturing organisation) then the accuracy is considered as most important dimensions.

What these results can mean in practise is that data quality needs to be considered together with the data users, as they understood the actual use of the data. Data quality measurement alone can be meaningless if not tied up with the real data usage. Therefore, it is not wise to build data quality capability from the outside of the organisation, since the data and its purpose need to be understood. This is especially in case of product data, which is often semi- or unstructured, and can be very technical requiring specific expertise to able to validate the data.

These result offer interesting view on data quality dimensions in different organisation’s functions, revealing what are the data quality dimensions that matter the most in different phases of product lifecycle. This is also new information as corresponding research has not been made earlier.

This research included results only from one company. It would be beneficial to conduct the study in several companies and see how it affects to the results. Additionally, this research studied a company, which produces tangible products. Another part of the research could study what are the most important data quality dimensions when dealing with services or software products.

ABSTRACT

Increased competition in many markets has forced firms to adopt new business models. One way to differentiate from the competition is to develop products based on implicit consumer needs that may be sold at a premium price. This research uses case study methodology to investigate a Swedish furniture wholesaler, and how their shift to a consumer driven business model has affected sourcing and inventory. The research reveals that the high focus on the demand-side of the company has had detrimental effect on the supply-side. Between 2004 and 2009 the number of stock keeping units increased dramatically, and the sales increased with 22%. Sourcing was affected since the order quantities became smaller, which lead to longer lead times in manufacturing. The inventory levels also increased, as did the average inventory turnover. As the market dropped in 2008 due to the economical situation, the case company was not able to respond to the changes in demand. The main theoretical implication is that the management of the demand- and the supply-side of the firm have to be coordinated on macro level, the main practical implication is that managers needs to devote time to both management directions, and the main social implication is that differentiated supply chain strategies may employ people closer to the consumption market.

Keywords: Consumer driven, sourcing, inventory, furniture,

INTRODUCTION

During recent decades a new market has evolved to co-exist with the conventional low-cost market. The new market is characterized by rapid and volatile demand changes, short product life cycles, and a high degree of customized products. Companies that want to be competitive in this market need to focus on the needs of the consumers rather than the technology of their products (Christopher et al., 2004). As a result of increased consumer sensitivity consumers have gained power to influence supply chain activities (Leonard and Sesser, 1982; Takuechi et al., 1982). One example of consumers' impact is found in the drug industry as consumer networks' word of mouth became more important than the claimed benefits of the drug (Prahalad and Ramaswamy, 2004). The quest for superior products, however, requires supply chain capabilities that can supply the products (Canever et al., 2008; Hilletofth, 2009; Jüttner et al., 2007; Walters, 2008).

Parallel to the evolution of the marketplace, globalization has changed worldwide business dynamics. Reduction of trade barriers, progress in information technology, and improved transportation infrastructure has facilitated a landscape for global operations (Hilletofth et

al., 2007). Countries are no longer isolated entities, but parts of a global trade system (Dreher, 2006). As an attempt to decrease costs and improve competitiveness companies outsource business areas to low-cost countries (Christopher, 2000). The result is complex, world spanning supply chains (Cavinato, 2004). Global supply chains do not only increase geographical distances, but also cultural distances, impairing collaboration (Lowson, 2001; Lowson, 2004, Warburton and Stratton, 2002).

Companies that enter into a consumer driven market environment needs to manage the new market, and the complexity of global sourcing. Activities dedicated to understanding, creating, and stimulating consumer demand is managed with demand chain management (DCM) (Charlebois, 2008; Hilletofth, 2011; Jüttner et al., 2007; Walters and Rainbird, 2004), and supply chain management (SCM) is a set of activities dedicated to the management of supply processes (Gibson et al., 2005; Lummus and Vokurka, 1999; Mentzer et al., 2001). Even though DCM and SCM are of vital importance to all organizations there is a tendency to manage them on micro level, often giving one priority over the other (Hilletofth el al., 2009).

This research investigates a small Swedish furniture wholesaler (Alpha) and how their consumer driven business model has impacted their sourcing, and inventory. In an attempt to differentiate from its competition, Alpha took a strategic decision in 2004 to change their business model. Alpha changed from competing on lowest price, to compete in a premium price range offering added value to their consumers, i.e. from cost driven, to demand driven. The change in business model was primarily focused on DCM capabilities, which has resulted in several innovative furniture solutions, but SCM was given equal attention. The purpose of this research is to investigate how a DCM focused business model affects SCM, more specific sourcing and inventory. The research question is: “How are sourcing and inventory affected by a demand led business model?” The question is investigated through a literature review, and a case study.

The remainder of this paper is organized as follows. In Section 2 a literature review is presented, in Section 3 the research methodology is presented, in Section 4 case study findings are presented, and Section 5 is a concluding discussion.

LITERATURE REVIEW

Since companies give DCM and SCM unequal attention, it is possible to distinguish demand led and supply led organizations in most industries (Jüttner et al., 2007; Lee, 2001; Piercy, 2002). DCM activities include market intelligence, new product development (NPD), branding, and marketing and sales, SCM activities include sourcing, manufacturing, and distribution (Hilletofth, 2011). Demand chain masters focus on product differentiation, and premium brands and products, and supply chain masters focus on cost reduction (Jüttner et al., 2007). If one management direction is over emphasized it may lead to major difficulties (Walters, 2008). Demand chain activities that not have supply chain support can result in increased costs, and inefficient product delivery, while supply chain activities that lack demand chain support can harm new product development (NPD), cause poor segmentation, and reduce efficiency in product delivery (Jüttner et al, 2007; Piercy, 2002).

It has been proposed that coordination between DCM and SCM should be assigned to either DCM or SCM (Mentzer el al., 2001; Srivastava et al., 1999; Williams et al., 2002), or that DCM and SCM should be coordinated on macro level (Canever et al., 2008; Hilletofth et al., 2009). The latter is called demand-supply chain management (Hilletofth, 2011) and strives to provide superior value, while minimizing costs (Hilletofth et al., 2009; Jüttner et al., 2007; Walters and Rainbird, 2004). DSCM suggests that DCM and SCM should be aligned, and that they require equal attention (Hilletofth et al., 2010; Jacobs, 2006; Jüttner et al., 2007, Rainbird, 2004). Management may be separated into three levels: long-term strategic decisions regarding structure and design of the chain, medium-term tactical decisions regarding planning of the chain, and short-term executional decisions regarding operation of the chain.

Demand and supply processes are closely related (Eriksson and Hilletofth, 2011; Hilletofth and Eriksson, 2011). Product design, for example, may have an impact on the supply chain performance, but the configuration of the supply chain may help to improve the NPD process (Van Hoek and Chapman, 2006). Cost-efficient creation of superior consumer value relies on: consumer focus in demand and supply processes (De Treville et al., 2004; Heikkilä, 2002; Hilletofth et al., 2009), coordinating value creation and delivery (Canever et al., 2008; Esper et al., 2010; Jüttner et al., 2007; Walters and Rainbird, 2004), a view that demand and supply processes are equally important and manage them in a coordinated manner (Hilletofth et al., 2009; Jacobs, 2006; Langabeer and Rose, 2004; Rainbird, 2004; Walters, 2008), and considering value creation in both demand and supply processes (Hilletofth et al., 2009; Vollmann and Cardon, 1998; Walters, 2008).

One of the most critical DCM processes is NPD, which includes all activities required to present a new or modified product to the market (Cooper et al., 2004; Rogers et al., 2004). The main objective on NPD is to develop products with new of different characteristics as quickly and cost-efficient as possible (Kotler et al., 2009). NPD may result in new products, or upgrades of existing products (Kärkkäinen et al., 2001; Perks et al., 2005). Successful companies develop a holistic NPD process that utilizes a stage gate system (Cooper, 1990). A stage gate system is a process consisting of several stages where the end of each stage is a gate or a checkpoint (Kotler et al., 2009). Empathic design is a technique that may be utilized during early stages of NPD. The goal is, with the use of observation of potential consumers, to identify areas for opportunity that consumers are unable to express (Leonard and Rayport, 1997).

Christopher (1972) was early to point out that differentiated supply chain configurations can make a product appealing to multiple consumer segments. Market intelligence involves activities devoted to collect, analyze and report data related to a certain market situation (Stone et al., 2004), which makes it closely linked to not only the product, but also the supply chain configuration. The importance to look past the product is stressed by MacMillan and McGrath (1997) who suggests that a company should map the consumption chain, i.e. the consumers' whole experience of the product from the time the consumer discovers the product, until it is disposed of. This includes delivery services, storage services, and payment options. The consumers, however, may not perceive the product, and services the same way as the companies intend them. It is thus important to focus on perceived

consumer value, and not only the specified value (Parasuraman et al., 1985; Parasuraman et al., 1991).

The most notable taxonomies for supply chain configurations are based on efficient, or responsive supply chains. Lean supply chains focus on removing waste across the supply chain. This includes reduced inventory levels, lead-times, and supplier base, as well as lean manufacturing and just-in-time techniques (Christopher and Towill, 2001; De Treville et al., 2004; Naylor et al., 1999). The agile supply chain focus on the ability to respond to changes in demand. Agility is increased through reduced lead-times, as well as coordinated planning, improved communication, and sharing of demand information (Christopher and Towill, 2001; De Treville et al., 2004; Mason-Jones and Towill, 1999; Naylor et al., 1999). Lean and agile approaches may be combined to a leagile approach using the Pareto rule (Goldsby et al., 2006), separating base and surge demand (Goldsby et al., 2006), or postponement separating lean and agile approaches in a decoupling point (Alderson, 1950; Buckling, 1965).

Fisher (1997) proposes a taxonomy matching fashion products with agile supply chains, and commodities with lean supply chains. Mason-Jones et al. (2000) suggest that order qualifiers and winners should dictate what supply chain configuration to use. If cost is the order winner, a lean approach should be used, if service level is the order winner, an agile approach should be used. Christopher (2000) proposes that if demanded volume, variety, and variability is stable, a lean supply chain is preferred, and an agile is preferred if the parameters are unstable. Christopher et al. (2006) have a taxonomy based on similar parameters, but add lead-time. If the lead-time is short, and demand is predictable a lean approach based on continuous replenishment is suggested, if the demand is predictable and the lead-time is long, a lean approach based on planning and execution is suggested, if demand is unpredictable and the lead-time is short, an agile approach based on quick response is suggested, and if demand is unpredictable and lead-time is long, a leagile approach based on postponement is suggested. The underlying idea of all models is that agile approaches should be utilized when demand is unpredictable, and lean approaches when demand is predictable.

METHODOLOGY

This research is devoted to investigating how a demand led business model affects sourcing and inventory. The issue is examined through a literature review combined with findings from an embedded single-case study. The research is explorative, and the researchers have no control over the contemporary events that are examined, which is a suitable setting for case study research (Yin, 2009). Data collection was initiated in 2009 with 60-90 minutes interviews with key informants representing senior and middle management. The interviews have been followed by brief interviews and meetings with all employees. Qualitative data has also been collected from over 20 supply chain partners including manufacturers in China, serving team in China, and retailers in Sweden. Over 600 documents of primary and secondary, qualitative and quantitative, data have been used to provide a broad and rich picture of the studied phenomenon. 96 yearly reports from Alpha and nine of its competitors are used for economical analysis.

The research has been an iterative process with the case company where findings have been discussed, and revisited continuously. Established theories have been used to explain the findings, and to spark new research questions. Several data sources, and theories have been used to triangulate findings and build a chain of evidence. The methods employed have helped to increase validity, and reliability. The generalizability has been increased due to a strong connection to theory (Yin, 2009).

CASE STUDY FINDINGS

Alpha is a Swedish wholesale furniture company. Its main business activities are design and distribution of furniture. Furniture manufacturing is outsourced to manufacturers in China, and about 400 retailers (customers) are responsible for consumer sales. The retailers are independent from the wholesalers, and each retailer displays furniture from several wholesalers. Alpha had a business model that focused on minimizing costs and prices, but faced fierce competition and decided to change business model to focus on consumer insight. The company defines consumer insight as a profound understanding for implicit and explicit consumer needs. Consumer insight is gathered during NPD projects and utilized in early stages of NPD when agents from Alpha have been observing and photo-documenting potential consumers in their homes. As a result, the company has developed several furniture collections that provide added consumer value, or cater to a need that was previously unknown.

Since the new business model was adopted in 2004 until 2009, the number of stock keeping units (SKUs) increased with 150%. Between 2007 and 2009 sales figures have dropped for Alpha and its competitors with 39%. The total sales volumes for 2004 and 2009 were almost the same for the investigated companies, while Alpha increased their sales with 22%. During the same time period sales per SKU dropped over 50% for Alpha as a result of the decline in the market place, and the increased amount of SKUs.

The life cycle of products in the furniture industry may span from the time it takes to sell one container, to over 50 years. Due to long life cycles of successful furniture, it is perceived to be more important to have an accurate NPD process, than a fast one. The volume value of furniture is rather low, so companies need to consider filling rates in transportation. Sofas, for example, are often sourced from European manufacturers to reduce transportation cost. The case company's product range includes most furniture for the home, except for office furniture and sofas.

The sourcing side of the case company's supply chain is shown in Figure 1. Alpha monitors its supply chain back to the manufacturer. Manufacturers have the responsibility to source raw material and hardware. However, materials and hardware are chosen in collaboration with the manufacturers to ensure stability in sourcing and to enable monitoring prices. A serving team in China is employed to bridge geographical and cultural distances. The serving team has close collaboration with Alpha. Their main tasks are to perform quality controls in manufacturing, monitor manufacturing facilities, and manage operational tasks with the sending ports. Due to the importance of filling rates in container, the serving team may consolidate products from factories within close proximity.

Containers are shipped from five ports in China to the port of Gothenburg. About 96 % of the containers are then transported by truck to Alpha's distribution center (DC) the rest is shipped directly to retailers. Products that are shipped directly to retailers are key account customers, where Alpha provides knowledge about the Chinese manufacturing market. These products have low contribution margins, but also lower risk since Alpha does not need to consider forecast error. The products that are shipped to the DC are stored there until a consumer places an order in a store, and distribution from the DC is initiated. This research is focused on the products shipped to Alphas DC.

The new business model has resulted in an increase of SKUs, which in combination with decline in sales and the global economical situation has had big impacts on sourcing. The high increase in SKUs compared to sales has made the order quantities smaller. This has had two impacts on manufacturing. Firstly, the orders are too small to fill up a production line, for example painting. Secondly it is troublesome for many manufacturers since they deal with large order sizes from their other customers. The manufacturing environment is not suitable for small order sizes. Some manufacturers have started to produce larger quantities than the actual order quantity and take the risk of inventory in anticipation on future orders. Other manufacturers have down prioritized Alphas orders. In some cases the purchasing manager has been forced to place orders that are larger than preferred to secure manufacturing, and to hedge against future uncertainty in manufacturing. The average lead-time in manufacturing has increased with 50%.

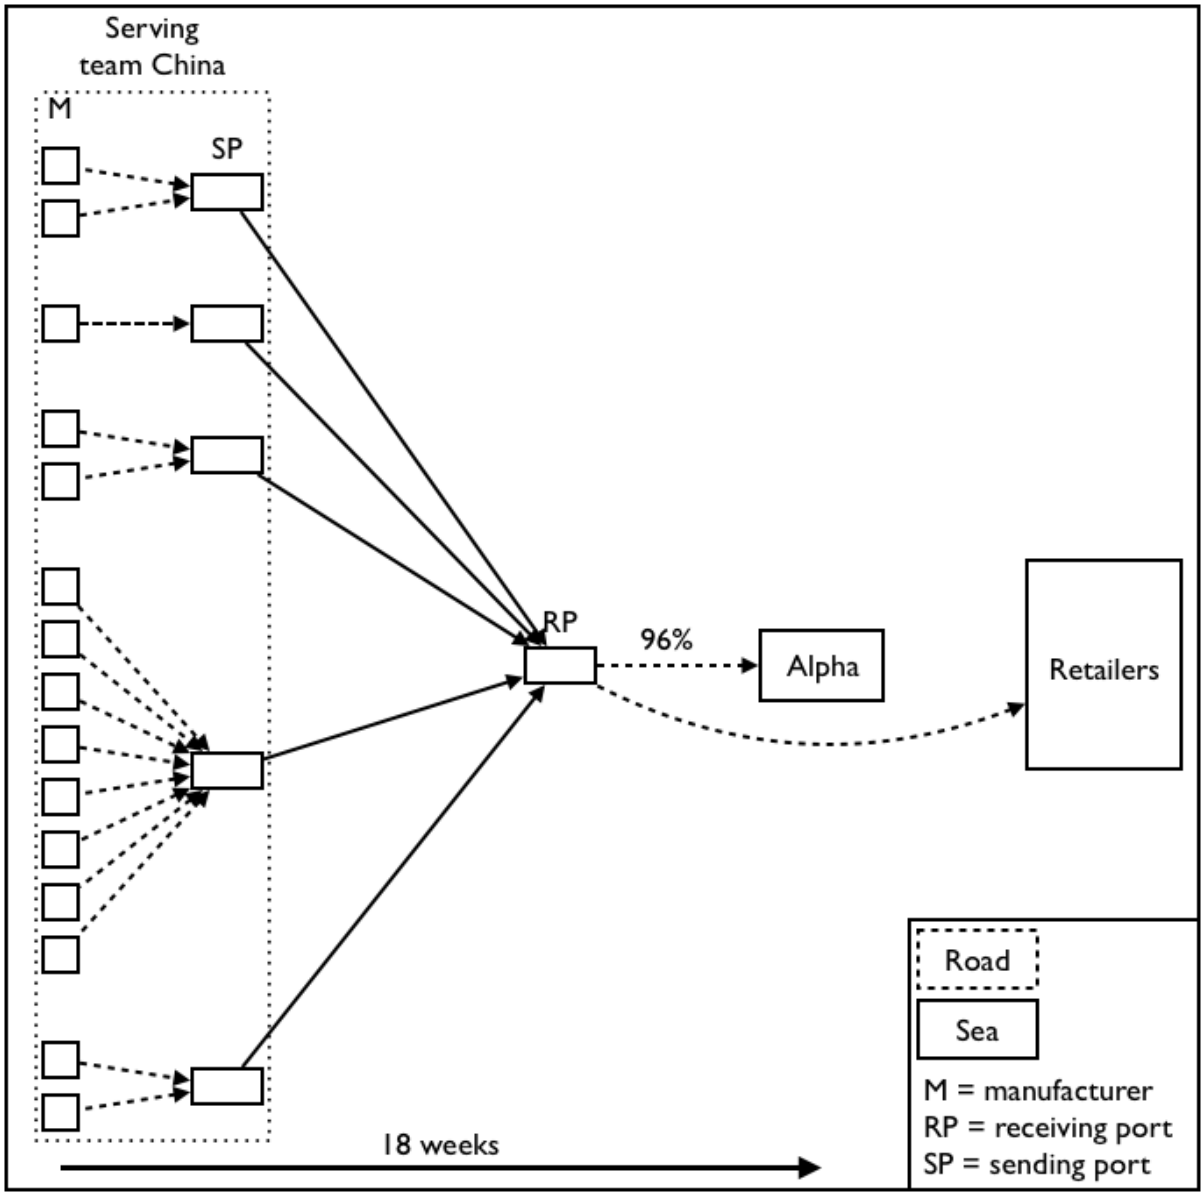

Figure 1: Alpha's sourcing system.

One issue with Chinese manufacturing is the quality of the furniture demanded by Swedish consumers. The Swedish market has a demand for furniture in a pristine white finish. In other countries, such as Norway, brown furniture has higher demand, and in the United States, there is big demand for furniture with a distressed look. Brown furniture is not as sensitive to a dirty manufacturing environment as white, and furniture with distressed look is treated with chemicals that produce a dirty finish. A dirty environment is not as expensive as a clean working environment, and since the Swedish market is small for Chinese manufacturers, the manufacturing plants are constructed with a dirty environment. Just before the end of 2010 the serving team called Alphas attention to two containers of furniture with dust grains in the lacquer, which were stopped before shipment.

The increased number of items and smaller order quantities have resulted in longer times to fill a container, and increased the need for consolidation. The result is not only longer lead-times, but has also increased the complexity with more SKUs per container. Furthermore, due to the global economical situation shippers have reduced the speed of their ships to

save fuel. The end result is that also shipping lead-times have increased with about 50%. The total lead-time has increased from about 12 weeks, to about 18 weeks.

The case company's inventory has increased with 67% between 2004 and 2009. During the same time period the inventory levels for Alpha and its competitors increased with 28% (Figure 2). Average turnover time in inventory for Alpha increased from 60 to 82 days, and from 52 to 65 days for Alpha and its competitors. The increased turnover time for Alpha is a result of the need to increase order sizes, and poor ability to adopt their business to the market decline.

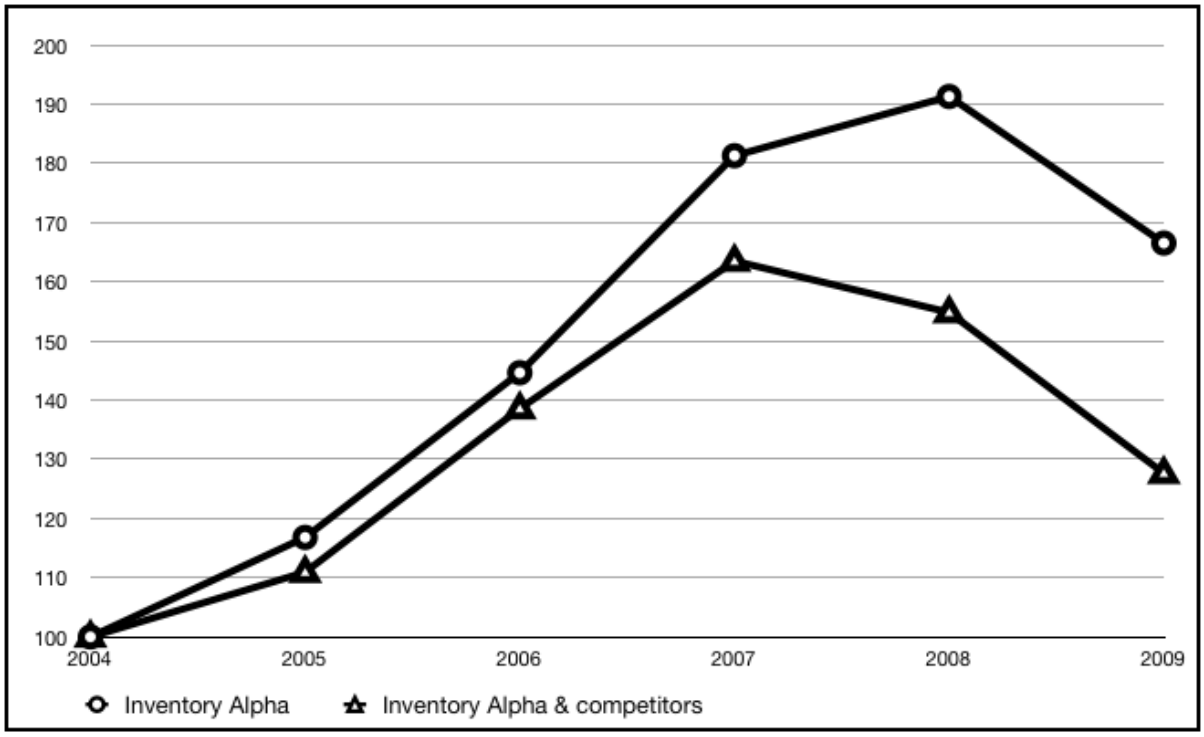

Figure 2: Inventory levels, 2004 indexed 100.

A one-year sales period starting in the summer of 2009 was compared with the inventory levels at the time (see Figure 3). To be able to compare the inventory with the sales 60% of the total article number had to be excluded due to discontinued products, and traceability in the data. Albeit a large piece of data is removed one finding is remarkable. 66% of the SKUs had one year or more of the demand in inventory, and the SKU with the longest inventory time would last over 52 years with current demand. In total there were 157 pieces of that particular SKU in stock and 3 were sold.

The case company has been focusing primarily on its demand chain processes, which has resulted in several new products offering added value. The technique for gathering consumer insight is very similar to the observation techniques of empathic design. However, the increase in article numbers, and the inability to adjust the business to changing market conditions have had detrimental effects on both sourcing and inventory. The sourcing strategy has a lean approach, but limitations and pressure from manufacturers have forced Alpha to place large orders.

The same sourcing strategy is utilized for all products, but the solution does not correspond well to the structure of the supply chain, nor the business model. In essence, there is bad fit between Alpha's DCM, SCM, and its ability to respond to changes in the market. Contrary to proposed models for supply chain configuration, fashionable products in the furniture do not have short product life cycles per se, and NPD does not need to be quick to respond to changes in demand.

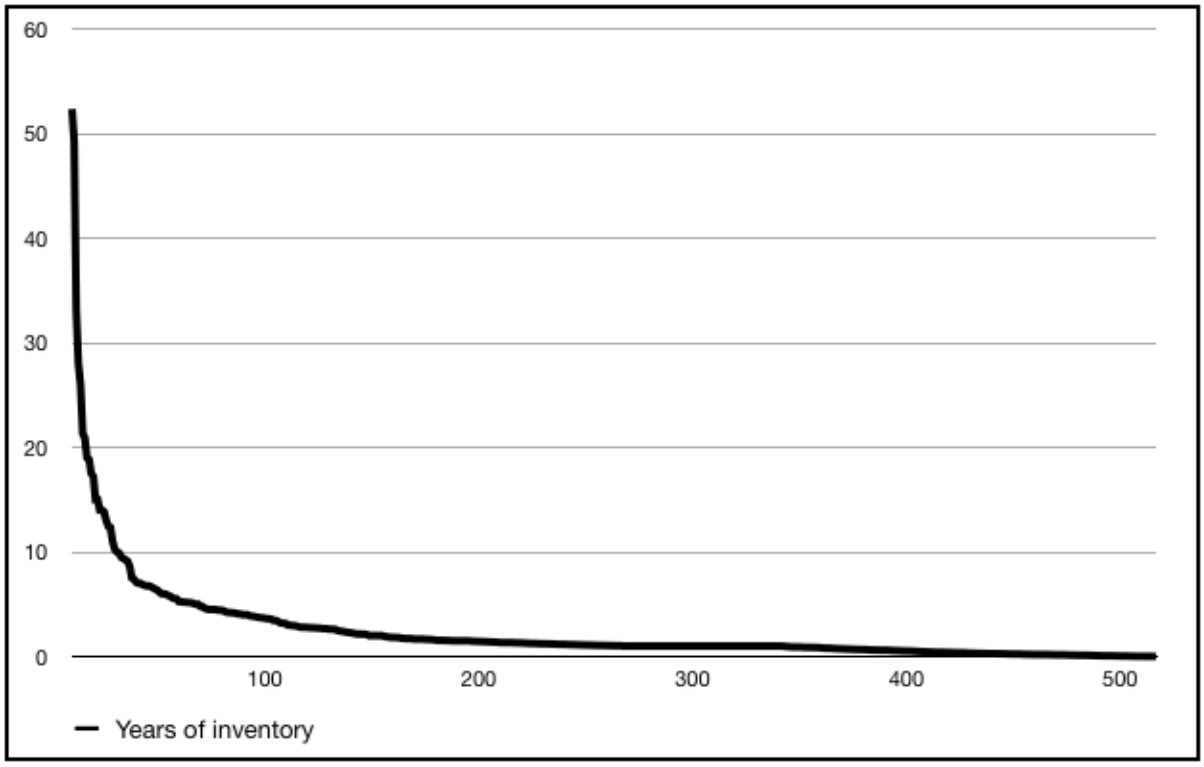

Figure 3: Years of inventory.

The connection between market intelligence, NPD, and sourcing is a good example of the close relation between DCM, and SCM. The case company has mainly focused on DCM processes, which has made the SCM processes inefficient. Moreover, the inability to respond to changes in the marketplace stresses the need to not only align processes internally, but in a way that enables them to change according to changes in the marketplace. The rigidity in Alpha's supply chain could be loosened up if leagile principles were adopted, such as using the Pareto rule to differentiate sourcing country based on predicted demand on the individual products.

CONCLUDING DISCUSSION

This research set out to investigate how sourcing and inventory are affected by a demand led business model. In this case the consumer oriented business approach has shown detrimental effects on both sourcing and inventory. Sourcing lead times has increased, sourcing complexity has increased, and the manufacturing country may not be suitable. Inventory levels has risen in comparison to sales, which has led to longer average turnover time in inventory. The case company is theoretically sampled, and it is not true to say that a consumer driven business model per default causes problems in SCM, but there is strong

support in theory that states that DCM, and SCM needs to be coordinated to create a competitive advantage. If DCM, and SCM were better managed on a macro level many of the problems may have been avoided. If, e.g. sourcing strategies were differentiated the higher cost of manufacturing might be acceptable due to increased responsiveness to changes in demand.

The main theoretical implication is that consumer driven business models needs to be coordinated according to DSCM theories, i.e. on macro level, to avoid sub-optimization of the management directions. The research also highlights that market orientation, or consumer insight as in this specific case, alone in not a path to success. The main practical implication is that managers need to devote time to align DCM, and SCM. Managers that want to pursue a premium market should not only focus on the elegance of their products, but also need to device a SCM strategy that is coordinated with the DCM strategy. The main social implication is that differentiated sourcing may move employments from low cost countries closer to the consumer market. The problems with manufacturing sofas in China is a good example of how supply chain strategy may have a social impact, as manufacturing has been moved to Europe.

Globalization and the quest for lower prices have caused manufacturing companies to outsource production activities to low cost countries. The move to global sourcing, however, may come at a cost that is larger than the cost savings in manufacturing. The case company suffers from several issues due to their sourcing strategy. The manufacturing industry in China is not suitable for the quality demands, nor the requested volumes. The result is poor efficiency in sourcing, and inventory. Alpha's consumer driven business model has increased the number of products, and the more the model is implemented the more it is likely to cause harm to the efficiency in the supply chain. Companies that device a business strategy similar to the one of the case company may need to reconsider the relentless quest for decreased manufacturing cost, and instead consider the total cost. Sourcing from countries closer to the consumption market may increase manufacturing cost, but if the supply chain strategy is differentiated based on the Pareto rule only products with low turnover will be affected.

It has only passed 6 years since Alpha changed their business direction. It is still not possible to say if the shift in business direction was a vise choice, and that the issues caused to SCM might just be an investment cost for the new business direction. However, if the change in business direction was undertaken with stronger theoretical support, it is likely that the investment cost would have been lower. This research has only investigated one company. Even though findings are in line with theory, more research is needed to truly understand how consumer driven business models affects SCM processes. Moreover, to fully understand the case company's situation would require that studies continue for several years.

DEVELOPMENT OF A DYNAMIC STRATEGIC PURCHASING MANAGEMENT MODEL FOR A PROJECT ORIENTED GLOBAL HIGH TECH COMPANY

Pirjo Janhunen*, University of Oulu, Finland
pirjo.janhunen@pp.inet.fi, *corresponding author

ABSTRACT

Goal of the research was to design a Dynamic Strategic Purchasing Model that meets the requirements of a global company operating in the global project environment.

The Case Company's Delivery Process (including designing, purchasing of materials and equipment, manufacturing, delivery, erection and start-up) is organized as customer specific Delivery Projects, which are complicated 1-2 years investment projects implemented by dozens of suppliers and subcontractors.

Case Company is able to manufacture and supply a complete Mill but as a Case Product in this research has been selected one essential part of it.

Though the basic construction of the Case Product is standardized, the real construction of the Product is different in every Delivery Project because of process requirements, customer requirements and local requirements of the Country where the Product will be delivered. The Project Country, the final destination of the Product, has a big impact to purchasing of the parts and subcontracting. Locality of the suppliers, location near the Project Site, where the Product will be delivered, is seen as a real advantage based on the empirical research.

On technological point of view, the most important suppliers for the Case Product are those who make the high pressure parts or otherwise technically complicated parts.

Supplier evaluation and selection is required to ensure that only reliable, competitive suppliers, which are able to supply products and services on needed quality level, are used.
A new supplier evaluation model was developed and has been used in the Case Company since that.

Main outcome of this research, a Dynamic Model for Strategic Purchasing Management, is based on two known, Kraljic's and Bensaou's, portfolio models but the combination and application principals are new, as well as the Supplier Evaluation and Selection principals included in the Model.

Keywords: Strategic Purchasing Management, Supply Chain Management,

INTRODUCTION

Supply Chain Management is one of the key interests in strategic planning and it has been one of the main objects for strategic changes in the Case Company. Purchasing as one of the most significant parts of Supply Chain Management in the Case Company has been selected as the research context of this study. In the Case Company cost of purchased materials, parts and subcontracting is 70-80% of the project costs.

There are common strategies, procedures and principles presented of Supply Chain Management and Purchasing Management in the studied literature. A lot of discussion for example of the portfolio models could be found, as well as criticism of their two-dimensional thinking and simplifying buyer-supplier relationships [4]. Network models have been popular during last years. One of the network models presented in last decade is the agile supply chain model. It stresses collaborative relationships as the supply chain strategy [14]. The presented models are more or less oriented in continuous, constant purchases and are not interested in changing, dynamic project environment.

The Case Company's Delivery Process (including designing, purchasing of materials and equipment, manufacturing, delivery, erection and start-up) is organized as customer specific Delivery Projects, which are complicated 1-2 years investment projects implemented by dozens of suppliers and subcontractors. Delivery Process as an element of the Business Processes of the Case Company is presented in Figure 1.

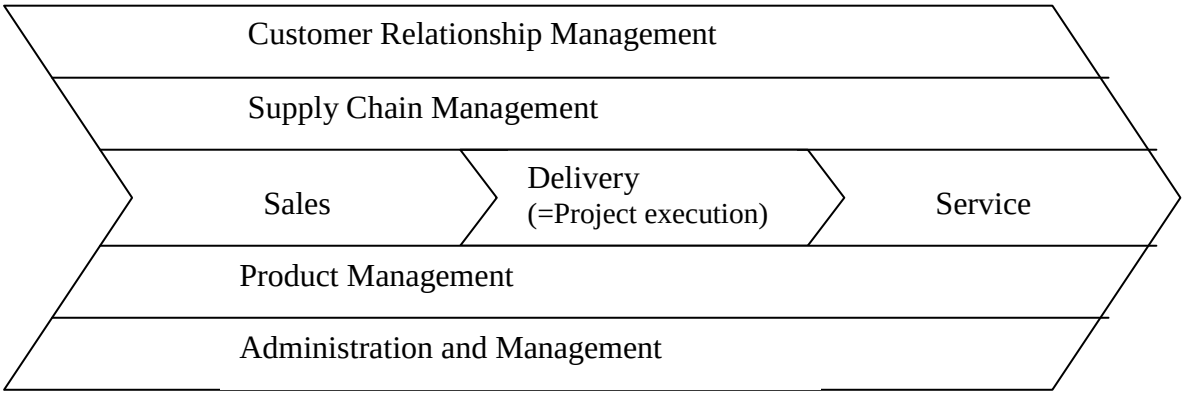

Figure 1: Case Company's Business Processes.

Industry, on which the Case Company operates, is growing fast in South-America, Asia and Russia. Those areas will be also destination areas for the Delivery Projects of the Case Company.

New market areas have generated in the Case Company need to manage global supplier network. Importance of global purchasing has increased and strategic purchasing planning is of great concern.

In this study it was tried to answer to question:

- What kind of purchasing management shall be used for strategic purchasing in dynamic global project environment?

Goal of the research was to design a Dynamic Strategic Purchasing Model that meets the requirements of a global company operating in the global project environment. Empirical background and logic of the development process is described in figure 2, which also is follows the reasoning in this paper.

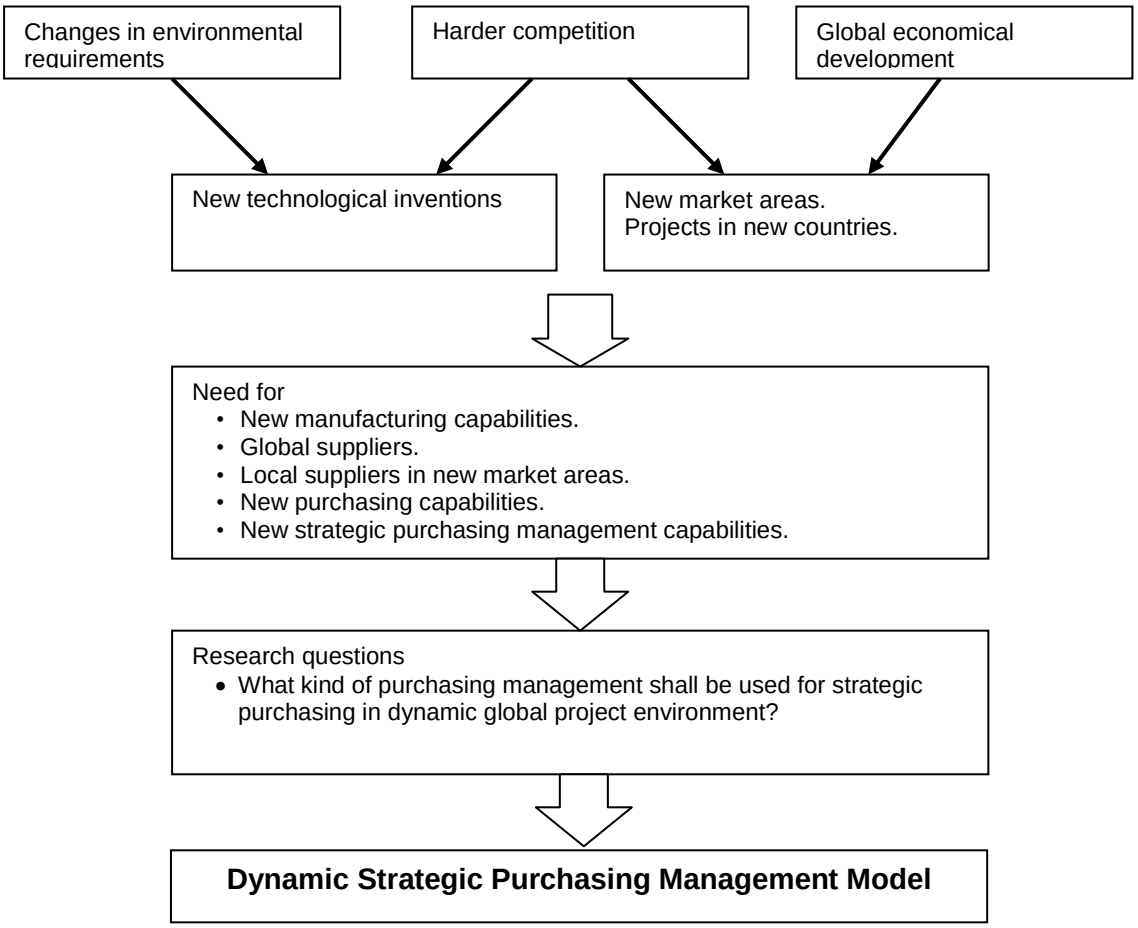

Figure 2: Development of a Dynamic Strategic Purchasing Management Model.

RESEARCH PROCESS

The empirical research for this study was conducted during five years as a Project Purchasing Manager in the Case Company.

The Case Company is able to manufacture and supply a complete Mill but as a Case Product in this research has been selected one essential part of the Mill.

Though the basic construction of the Case Product is standardized, the real construction of the Product is different in every Delivery Project because of process requirements, customer requirements and local requirements of the Country where the Product will be delivered. The final destination of the Product has a big impact to purchasing of the parts and subcontracting needed.

On technological point of view, the most important suppliers for the Case Product are those who make the most complicated high pressure parts or otherwise technically complicated parts.

Supplier evaluation and selection is required to ensure that only reliable, competitive suppliers and subcontractors, which are able to supply products and services on needed quality level, are used.

It was noticed in the Case Company in 2005 that strategic purchasing procedures and tools shall be evaluated to be sure of their suitability for the expanded and changed business environment and this research was started for that purpose.

This research was conducted during five years for the Case Company, a Mill manufacturer. Conducting the Research is presented in Figure 3.

2005-2007	Analysis of the status of Supply Chain Management, Purchasing planning and operations in the Case Company by reviewing - Strategic Purchasing Management - Purchasing Planning - Supplier Evaluation and Selection Process Business Process Handbook and other instructions and by doing Interviews
2005-2008	Review of available tools and methods by - literature studies - participating lectures and seminars
2005-2010	Developing the Strategic Purchasing Management Model by - improving the Supplier Evaluation and Selection Process - defining the main features of the Model based on analysis of the current status of Purchasing planning and operations - testing the Model in a Delivery Project - finalizing the Model based on the results got during the test and future view and plans of the Case Organization

Figure 3: Conducting the Research.

Goal of the research was to find or design a Dynamic Strategic Purchasing Management Model that meets the requirements of a global company operating in the global project environment.

Qualitative and quantitative research: review of organizations procedures, instructions, management books and data, and interviews were done to be aware of the purchasing strategy, and plans and tools used and their suitability to the Case Company.

LEARNING BY DOING- DEVELOPING AND TESTING THE STRATEGIC PURCHASING MANAGEMENT MODEL IN A CASE PROJECT

Qualitative and quantitative research

- Review of procedures, instructions, management books and data
- Interviews: 8 purchasing and project responsible interviewees (total number of personnel in those operations was 23).

was made to be aware of the purchasing strategy, and plans and tools used in the Case Company, and suitability of those based on experience of the interviewees.

Main findings of the review of the organizations procedures, instructions and management books were:

- Some critical subjects from the Case Product's point of view were not evaluated when selecting suppliers and subcontractors.
- The supplier evaluation process and procedures did not cover needs of global purchasing environment of the Case Company.
- The auditors had lack of product knowledge and process knowledge for auditing Case Product's pressure part manufacturers.
- There was a company level purchasing strategy, and upper level instructions and principals defined for category purchases. (Company level categories were material groups of the A-level materials selected with ABC-analysis).
- The Supply Chain Management main principles were good and useful as well as linking of Supply Chain Management strategic focus to the Company business planning.
- Because purchasing volume of the main parts of the Case Product was not big enough (not on A-level) on whole Company point of view, the main parts of the Product were not included in the categories, and there were no strategic purchasing planning principals, procedures or instructions for purchasing of these parts => purchasing planning and purchasing was done more or less uncontrolled and in a different way in every Delivery Project.

Main findings of the interviews were:

- Important characteristics of the suppliers and subcontractors besides competitive pricing, on time deliveries and good product quality were
  - up-to-date knowledge
  - perseverance and trust
  - teamwork capability
  - good chemistry

- Interviewees pointed out the following questions:
  - How to evaluate new suppliers in new project countries far away with different kind of knowledge, procedures, culture etc.?
  - Will there be longer partnerships in the future? Or will there be only one time relationships with local suppliers in those countries where products are delivered to in the future?

It was obvious that Supplier Evaluation and Selection Process have to be improved to meet requirements of the new project and purchasing environment with new requirements.

Starting point for improving of the Supplier Evaluation and Selection Process was to renew the Supplier Evaluation form. Earlier developed but very seldom used Audit List and Supplier's Annual Performance Form were used as basis. The form and content of the Audit List was modified by adding new check points and questions, and by designing a form to be suitable for global use among suppliers operating in different countries and cultures.

The new Evaluation Form was tested by sending it to 20 suppliers. The suppliers which were selected as the objects of the test had not been evaluated earlier because those suppliers were used only for needs of the Case Product and on the point of view of the whole Company were too small (based on ABC analysis and 20/80 rule) to be evaluated.

The test was started by sending the Evaluation Form to suppliers by e-mail.

Suppliers were asked to fill in the Form and send it back to the purchaser who had sent the Form. After sending the Evaluation Form, purchasers called the suppliers and fixed up the return date for the Form and meeting date with the supplier.

Suppliers filled in the form and returned it back to the purchaser by e-mail.

Purchasers met the suppliers and reviewed the information given in the Form and compared it with supplier company's operations and analyzed reliability of supplier company's self assessment results presented by them in the returned Form.

It was also found important that evaluated suppliers shall be scored with clearly defined criteria. Result of the evaluation shall not be based only on opinions of the evaluator. For each factor and aspect important to the Case Company, there must be a quantitative, like on time delivery %, or qualitative criteria like willingness and ability to improve operations.

When making the final decision of the scoring and selection of the Supplier, also performance in earlier projects shall be taken in consideration very strongly, if that information is available.

Main interest in the purchasing operations of the Case Company point of view of the Case Product was before 2007 more on operational level than on strategic level. To be competitive on global markets real strategic thinking must be applied also in purchasing of the parts of the Case Product.

Research for Strategic Purchasing Management Model was started. As main characteristics for the Model to be developed were defined: The Model shall be able to be used in every Delivery Project with its own special features coming from performance and process technical requirements by the customer, the local laws and requirements, political climate, nature and climate etc of the project country, from the scope of the delivery, and from the financial targets of the Case Company itself.

The model shall answer to questions:

- What could be bought from one-time or some-time local suppliers and what must be bought from already known long- term partners (location independently)?
- How to select "right" suppliers?
- How to manage supplier relationships?

It was decided to test and find a method to categorize the parts of the Case Product to be able to prioritize purchasing planning and operational purchasing as well as supplier relationships. Parts of the Product were classified into four categories by using Kraljic's portfolio model [18].

According to Kraljic, a company should sort out all its purchased items into four categories: strategic products, bottleneck products, leverage products and non-critical (routine) products in terms of profit impact and supply risk. Analysis of profit impact of a given supply in terms of volume purchased, total purchase cost, impact on product quality and business growth shall be executed, as well as assessment of supply risk in terms of availability, number of suppliers, competitive demand, storage risks, substitution possibilities and make-or-buy opportunities [18].
Strategic items are those with high profit impact and high supply risk. Bottleneck items have low profit impact but high supply risk. Leverage items have high profit impact but supply risk is low. Non-critical items have low profit impact and low supply risk [18].

In the Case Product among strategic parts are e.g. high pressure parts, high pressure piping, steam drum and some other. Among strategic items are also "CORE" parts, which the Company wants to manufacture itself.

Simultaneously with the development of the Strategic Purchasing Management Model, the Model was tested step by step in a Case Project to Russia.

It was noticed during the Case Project execution, that Kraljic´s classification could be used as a basis in this global project environment but local aspects of the country and its culture and requirements of local norms and authorities had to be taken into account as well as the content and scope of the project.

As supply risks, besides those ones that Kraljic has introduced, were identified:

- local laws and requirements the parts are required to fulfil
- requirements for the parts coming from political environment (e.g. domestic content requirement versus know how of the suppliers in the project country)
- requirements for the parts coming from nature and climate of the project country (e.g. seismic requirements, freezing etc)

Logistics costs of the parts to or in the project country could have a big profit impact depending on the same factors that were recognized as supply risks. Local laws and requirements concerning transportation of parts with certain size or weight could require extra arrangements and cause extra costs, etc. Availability and condition of the roads and railway, weather conditions, differences in altitude etc are also important profit impact

factors to be taken into account when classifying parts of the Case Product for a certain project.
Classification model of the parts of the Case Product is presented in figure 4.

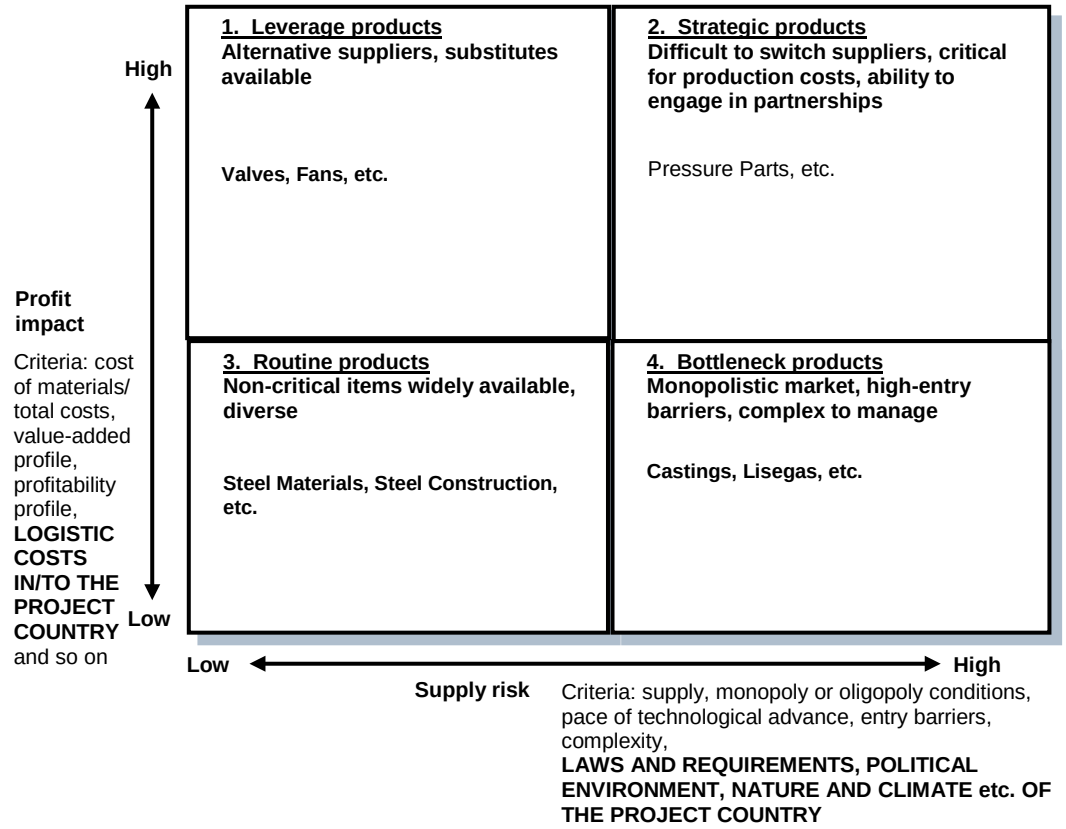

Figure 4: Classification model of the Case Product's parts. [18]

Kraljic´s Planning the Supply Management Strategy model with all steps:

- classification
- market analysis
- positioning
- action plans

was decided to take as a guideline for the development of the Strategic Purchasing Management Model for the Case Company.

To ensure also the flexibility and good chemistry (required by Case Company's interviewees), it was thought that there should be also in the future longer supplier relationships at least for delivery of strategic and bottleneck parts besides shorter local supplier relationships for other parts.

A model for supplier relationship management was also needed for the Case Company.

Professor Bensaou emphasizes companies to manage a portfolio of relationships instead of managing with only one design for all relationships. He offers a two-step framework; first identify which type of relationships matches the competitive conditions surrounding the product or services exchanged. And second, design the appropriate management model for

each type of relationship. If the design of each relationship matches to its external context, under-designed and over-designed relationships could be avoided [1]. Bensaou´s portfolio model is presented in figure 5.

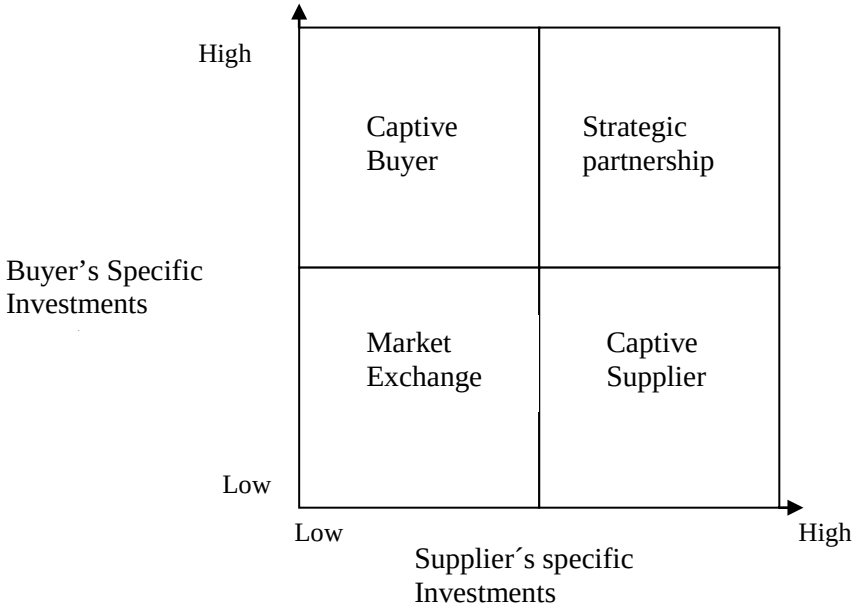

Figure 5: Bensaou's portfolio model. [1]

The Market Exchange cell represents a relationship in which neither party has developed specialized assets for cooperation and they can work together using general-purpose assets. Each party can turn to the marketplace and shift to another business partner at low cost and minimal damage [1].

Captive Supplier cell represents a relationship where supplier unilaterally makes investments to win the competition and keep the business with the customer [1].

Captive Buyer cell represents a relationship where buyer is held hostage by a supplier free to switch to another customer [1].

In Strategic Partnership cell both parties have posted high assets, both tangible and intangible investments, into the relationship [1].

The four cells differ along three sets of contextual factors: 1) the characteristics of the product exchanged and its underlying technology, 2) the level of competition in upstream market, and 3) the capabilities of the suppliers in the marketplace [1].

Bensaou found that management variables that make the relationship high or low performing were: 1) information sharing practices, 2) characteristics of boundary spanners' jobs, and 3) the social climate within the relationship [1].

Designing of relationships consists of three steps [1]:

1. the strategic selection of relational types to match the external conditions given by the product, the technology, and the market
2. the identification of an appropriate management profile for each type of relational design
3. matching design of relationship to the desired management model

It was decided use and test main principles of Bensaou's portfolio model to manage the Supplier Relationships in the Case Project.

To keep suppliers knowledge up-to-date, and to reach perseverance and trust and to have good teamwork and good chemistry during project execution as the interviewees required, supplier relationship management shall have similar characteristics as Bensaou has defined for the strategic partnership in his portfolio.

According to Bensaou, there are two kind of successful relationships: high requirements-high capabilities and low requirements-low capabilities. There are also two paths to failure, under-designed relationship and over-designed relationship [1].

Bensaou emphasizes companies to manage a portfolio of relationships instead of managing with only one design for all relationships. He offers a two-step framework; first identify which type of relationships matches the competitive conditions surrounding the product or services exchanged, and second, design the appropriate management model for each type of relationship. If the design of each relationship matches to its external context, under-designed and over-designed relationships could be avoided [1].

As a conclusion to reach the best possible relationship with every supplier, the supplier relationships shall at first analyzed and classified in every Delivery Project of the Case Company and after that the appropriate management model for each type of relationship shall be designed.

CONTRIBUTION

Supplier Evaluation and Selection Process of the Case Company was improved to meet requirements of the new project and purchasing environment.

Starting point for improving of the Supplier Evaluation and Selection Process was to renew the Supplier Evaluation Form.Main content/ main titles of the new developed form were as follows:

- General Supplier Information.
- Available delivery possibilities.
- Description of typical products or services.
- Volume per year, biggest customers etc.
- Capacity.
- Computer Systems.
- Quality System.
- Welding Qualifications.
- Available NDT-Methods.

- Other Testing Equipment .
- Fabrication.
- Welding.
- Machining.
- Heat Treatment.
- Surface Treatment.
- Transportation.
- Business Operations.
- Sales in euro.
- Sales price development +/- % during last 5 years.
- Cost development +/-% during last 5 years.
- Quality measures, e.g. % of faults found during manufacturing.
- Delivery reliability.
- Development Projects (Key projects (2-3 pc) during last and coming 5 years).
- General evaluation of the company with SWOT analysis (strengths, weaknesses, opportunities and threats) (Supplier's own opinion).
- Cooperation with Customers.
- Other comments and feedback.

The following Supplier Scoring and Selection criteria were also developed:

Good:

- Performance in earlier projects good, on time delivery % at least 9 %, price increase 0 % (or at least less than 2 % if material price increases) per year, faults during manufacturing less than 3 %, capacity big enough = at least three times the Case Company's needs, suitable IT infrastructure = MS Office, Adobe Acrobat, CAD, SAP or similar, Quality System in use for at least 3 years, financial situation good, regular customer need based development and improvement projects in progress, able to fulfill service needs of the Case Company.

Sufficient

- Performance in earlier projects acceptable, on time delivery % at least 95 %, price increase less than 3 % per year, faults during manufacturing less than 3-5 %, capacity big enough = at least two times Case Company's needs, suitable IT infrastructure= MS Office, Adobe Acrobat, CAD, SAP or similar, Quality System in use 0-3 years, financial situation good, able to fulfill service needs of the Case Company.

Rejected

- Performance in earlier projects bad or on time delivery % less than 95 % or price increase more than 6 % per year or faults during manufacturing more than 5 % or capacity not big enough = at least two times Case Company's needs or no Quality System in plans or financial situation not acceptable or not able to fulfill service needs of the Case Company.

The usage test of the new Form and Supplier Evaluation and Selection procedures was completed in two months by five purchasers.

The Form and Scoring and Selection Criteria were found suitable for needs of the Case Company and they were decided to take in continuous use and have been used since that.

Main outcome of this research is a Dynamic Model for Strategic Purchasing Management. Developed model is based on two known, Kraljic´s and Bensaous, portfolio models but the combination and application principals are new as well as the Supplier Evaluation principals included in the Model.

The developed Dynamic Strategic Purchasing Management Model is presented in figure 6.

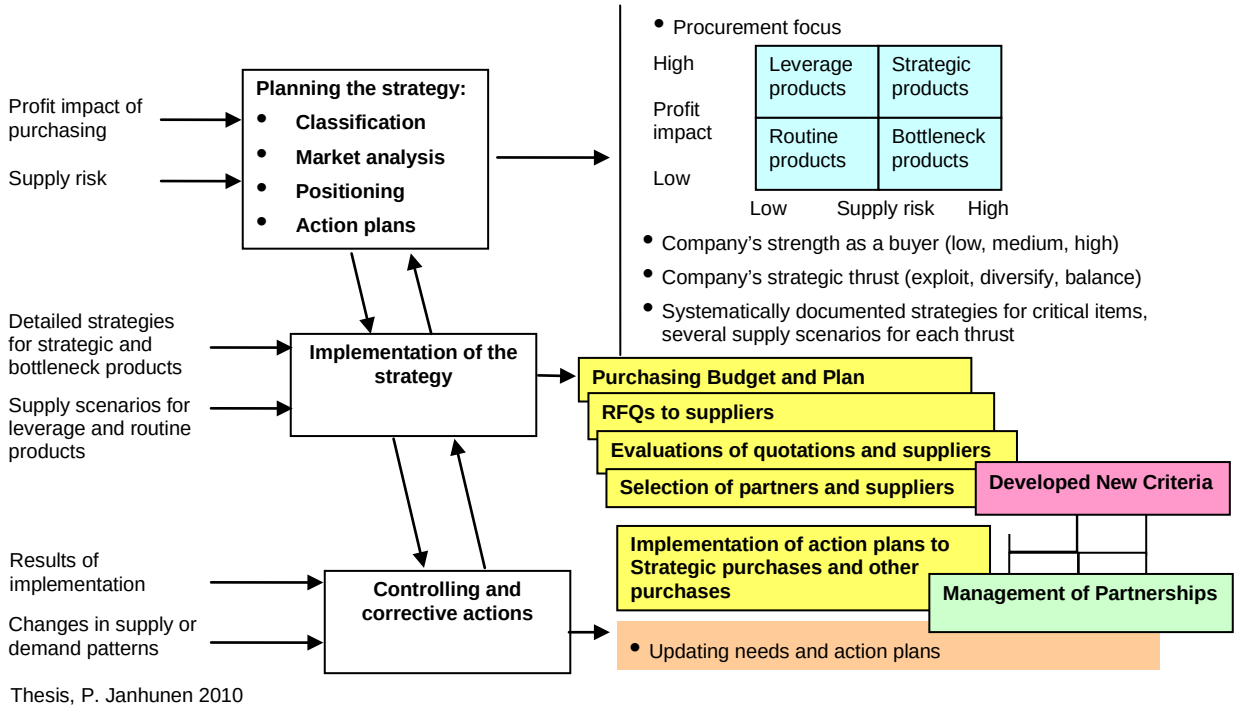

Figure 6: Dynamic Strategic Purchasing Management Model.

The usage of the Model in every project and updating of it after every usage makes the model dynamic and all the time up to date. The developed Model and usage of it are significant improvements on business and academic point of view and lead to better performance in a Project Oriented Global High Tech Company as testing in the Case Company proves.

Based on the Research and test of the Model during Case Project following thesis should be followed:

1. Material classification by using modified Kraljic's portfolio model has to be done for every project on the sales phase (or at the latest in the beginning of the project). Local aspects of the project country and its culture and requirements of local norms and authorities have to be taken into account when assessing profit impact and supply risk.
2. Purchasing market analysis of the project country has to be done to find best potential suppliers.

3. Strategic positioning (exploit, balance, diversify) of materials in each category has to be done.
4. Several strategic supply scenarios, action plans, have to be developed for each item category. And for the critical (strategic and bottleneck) purchasing materials, the outcome has to be a set of systematically documented strategies for them.
5. Suppliers have to be evaluated and the best possible ones selected according to the Classification model and developed Supplier Evaluation and Selection Process.
6. Detailed strategies for strategic and bottleneck products and supply scenarios for leverage and routine products have to be implemented.
7. Managing of the supplier relationships must be a key interest. To manage Supplier Relationships successfully modified Bensaou's portfolio model shall be used as guidance.

DISCUSSION

Developed model is a combination of two old, Kraljic´s and Bensaous portfolio models but new features added to the models, makes the developed model new.

Innovation was tested in a real delivery project. Criteria were project's financial results.

The developed model and method are significant improvements and use of them leads to better performance in a project oriented global high tech company as the test in a real project proves. Results (availability/delivery time of the materials, material costs, quality of materials and services) and financial results of the Case Project are better than in average.

The Case Project has been completed. Mill is in operation and acceptance of the Project Delivery has been got by the customer and authorities in 2010.
Presented proposal to use the Model in every project (for every different project country and for every different customer) and update it after every usage, makes the model dynamic and all the time up to date.

Results got, also other than financial ones, by using the Model in new delivery projects, must be collected and analyzed to be able to improve the Model.

This research proves that old models and methods could be used successfully also in different kind of business environment than they actually have been developed.

To ensure usage of the developed Model, next research step should be to define, what kind of tools are needed to make the usage easy and quick.

Another important Research Question could be: what kind of supplier relationships there will be in the future in the possible new purchasing market areas? Will there be suppliers or supplier networks? How the supplier relationships shall be managed?

It could be also interesting to research in the Case Company, how to combine purchasing categories and developed model to get the advances of the combined purchasing volumes

and at the same time take into account the special requirements of the dynamic global project environment.

CONCLUSION

This research was conducted during five years in Mill manufacturer's organization.

Goal of the research was to design a Dynamic Strategic Purchasing Management Model that meets the requirements of a global company operating in the global project environment.

Qualitative and quantitative research: review of organizations procedures, instructions, management books and data, and interviews were done to be aware of the purchasing strategy, and plans and tools used in the Case Company and suitability of those based on experience of the interviewees.

Main outcome of this research is a Dynamic Model for Strategic Purchasing Management. Developed model s based on two known, Kraljic's and Bensaou's, portfolio models but the combination and application principals are new as well as the Supplier Evaluation and Selection principals included in the Model.

Strategic Purchasing Planning shall be done for each project on the sales phase or at the latest in the beginning of the project.

Usage of the Model in every project and updating of it after every usage makes the model dynamic and all the time up to date. The developed Model and usage of it are significant improvements and lead to better performance in a Project Oriented Global High Tech Company as testing in the Case Company proves.

ABSTRACT

Business growth is usually strongly sought issue for SMEs. Since the size of domestic market in Finland is relatively small, internationalisation is an issue worth to consider for many SMEs. Internationalisation as a research topic is studied widely, and on several approaches. A route to internationalisation is determined by factors that are emphasized differently depending on the approach. The purpose of the study is to find out how trade fairs affect the factors in practice and how scarce resources should be allocated to gain an efficient trade fair outcome.

Research is conducted as a case study with four Finnish SMEs. The companies joined a delegation that participated in a trade fair held in Chengdu, China. The empirical data is collected by documentation, in-depth interviews, and by direct observation and participant-observation. The literature review aims to discover how trade fairs advance SME internationalisation. The first research question analyses the results gained from the fair activities. Finally, the second research question seeks solutions to improve the whole participation process.

The major factors advancing internationalisation are listed in the literature review. The most common theme among trade fairs, SME internationalisation and China is associated with networking. The empirical data indicates that the fair yielded plenty of significant information needed in internationalisation. However, the analysis of different participation phases revealed that trade fair outcome could have been remarkably improved with certain target actions such as creating clear guidelines for follow-up and finishing the façade of participating companies.

Keywords: SME internationalisation, trade fairs, China, networking

INTRODUCTION

Business growth, leading for example to increased profit or economies of scale, is usually strongly sought issue for start-up companies and SMEs (Small and Medium sized Enterprises). Since the size of the domestic market in Finland is relatively small, internationalisation is a topic worth to consider for many Finnish SMEs. The target market has huge impact for the internationalisation process since the business environment can clearly differentiate from a country to another (Johanson & Vahlne 1990). Current economical growth occurs especially in China that has been pulling the whole global economy during the recession. Growth combined e.g. with large domestic market and infinite labour force makes China conspicuous destination for companies to expand their business.

Johanson and Vahlne (1990) refer to the psychical distance, when considering differences in business environment. It can eventually emerge as a lack of understanding of laws, language, business practices, etc. (Oviatt & McDougall 1994). Consequently, before the actual business can start in a new market area, companies should gain knowledge of the business environment. When completing the groundwork properly, barrier to enter the foreign market gets significantly lower. (Johanson & Mattsson 1988.) A potential way to reach all of these preconditions and make groundwork is participating in trade fairs. They could also offer significant information for SMEs of preferred policies and actions when operating in the international business field. What really separates trade fairs out of other ways of marketing is that they enable inexpensive face-to-face contacts and fluent information exchange between different trade fair participants (Bellizzi & Lipps 1984, Kerin & Cron 1987).

This paper studies how SMEs could utilise trade fairs to advance their internationalisation process. The study investigates four case companies and their participation in a trade fair held in Chengdu, China. The study focuses especially on the companies' actions during the trade fair and the results generated by the fair. The whole participation process was arranged by the Department of Industrial Engineering and Management (DIEM) in the University of Oulu. Research questions are defined below.

RQ1: What kind of results was gained from the fair activities?
RQ2: How the participation could have been improved?

The first research question is based on interviews with the case company representatives and on the researchers' observations during the fair. The actions are compared with the companies' purposes to participate in the trade fair. Only short-term results can be studied, but the results are discussed whether they can yield any long-lasting effects on companies' international business operations. The second question is a comparison of the theoretical analysis and the empirical part based on the researchers' views how the participation could have been more effective and yield more significant results.

The paper starts with presenting theoretical background, which consists of three different themes: internationalisation, trade fairs and Chinese business environment. The next chapter introduces the empirical cases and the participation phases in general. After the

empirical part the discussion chapter answers the research questions and especially reflects the results of the case study to the theoretical background simultaneously attempting to find improvement actions for the case companies.

THEORETICAL BACKGROUND

The approaches of internationalisation

Literature distinguishes three main internationalisation approaches for SMEs. The oldest model, the stage approach, sees internationalisation process proceeding step by step. Foreign market entry is expected to start from markets that have the shortest psychical distance for the company. International appearance can thus be seen expanding like rings in the water. The mechanism for internationalisation is a dynamic process in which market commitment of the company and the experiential knowledge of the managers define the commitment decisions and current activities of the company. As every loop of the process increases learning in the company, so is the internationalisation enhanced as well. (Johanson & Vahlne, 1977.)

The network approach suggests that business relationships facilitate internationalisation hence enabling market entry also to psychically distant countries. Relationships are valuable intangible assets for companies, and they affect the companies' marketing strategies and how industrial markets function. Success of internationalisation is dependable on a company's positions in the networks, its ability to coordinate internal resources and ability to exploit its relationships to have access on external resources. Four different situations are separated based on the degree of internationalisation of the market and on the degree of internationalisation of the company: the early starter, the late starter, the lonely international and the international among others. (Johanson & Mattsson, 1988.)

International new venture or born-global approach is developed on the notion that more and more companies have gone through a rapid internationalisation process (Oviatt & McDougall, 1994). Technological developments especially in transportation and communication have increased globalisation, which, in turn, has affected the number of people involved in international business (Oviatt & McDougall, 1994; Madsen & Servais, 1997). A precondition for rapid internationalisation is an experienced manager that has desire and vision for rapid international market penetration (Johnson, 2004). Other necessary elements for sustainable international new ventures are alternatives for limited resources, i.e. having access to external resources, and finding foreign location advantages when combining domestic mobile resources with foreign less mobile resources. Unique knowledge of the mobile resources has the greatest influence on rapid internationalisation. Finally, unique resources are needed to protect and renew knowledge, which maintains the competitive edge and keeps the company sustainable. However, this is one of the major difficulties for SMEs, since they are usually lacking of resources. (Oviatt & McDougall, 1994.)

The role of and practicalities in trade fairs

Trade fairs are the second theme of the theoretical part. Exhibitors use trade fairs mostly for selling, promotion and networking activities (Rosson & Seringhaus, 1995). Trade fairs are a highly effective way to gather visitors in one place during a short period of time (Bertrand, 1989). Before choosing which fair to participate, companies should determine the objectives for the participation. Based on the objectives and companies marketing and selling strategies they can choose a fair which has the most appropriate market and geographical appeal. (Tanner & Chonko, 1995; Dallmeyer, 2010.) However, it should be noted that trade fairs have networking aspect as well which actually can be the most important reason to participate especially for SMEs (Evers & Knight, 2008).

Part of the pre-fair analysis is studying the participant list from the previous years after which some kind of understanding is received about attendee behaviour. Pre-fair actions also include plans how to be visible during the fair and how to attract the right kind of visitors. (Cavanaugh, 1976.) Particularly booth space and location, and a wide variety of product mix are means to get visibility also in the case of SME (Williams et al., 1993). Targeting the right audience should start with pre-fair promotion activities. Attendees are highly sensitive for such activities since they make effort to participate the fair and most of them use some kind previews to plan their visit. (Kerin & Cron, 1987.) In case of the most important attendees, it is suggested to send free tickets for the participation (Dallmeyer, 2010).

The booth should be staffed with social and enthusiastic employees with a high level of communication skills. Moreover, they should be given tailored training in addition to general boothmanship education. (Dallmeyer, 2010.) Training helps exhibitors to meet visitors' needs and recognise the role and hierarchical level of a visitor. By estimating these factors the exhibitors are able to adjust their interaction fitting best for the attendees' interests. Attendees in production roles call for different kind of personnel and support material than attendees in managerial roles. (Bello & Lohtia, 1993.) Training can increase only objective knowledge, so experienced personnel is still required in the booth (Bello & Barksdale, 1986).

Classifying the attendees helps also during the follow-up process (Herbig et al., 1998). The easiest way to evaluate attendees is based on time, i.e. how long it takes to conduct a first purchase, and value, i.e. what is the expected value of the first and following purchases (Dallmeyer, 2010). Based on the classification only the most important attendees are contacted immediately, for example in form of e-mail or a sales call (Herbig et al., 1998). If there is no current need for a purchase, the exhibitor should still stay in touch with the prospect and inform it about the latest changes in products and services. In general, the follow-up process is relevant part of the fair participation since most of the sales are concluded after the fair. (Konopacki, 1991.)

Trade fairs are an excellent infrastructure for developing networks (Evers & Knight, 2008). Besides utilising networks for internationalisation in general, they can have a more specific effect on relationship learning during trade fairs. This kind of information sharing within the network can create competitive advantage as collaboration aims to meet the customer's

needs thus strengthening the relationship. Variety of factors influence differently on the sub-processes of relationship learning; information sharing, joint sense-making and developing relationship-specific memories should be recognised as different processes to be able to actively manage them. Relationship-specific memories have the most significant effect for the overall relationship performance outcomes. (Li, 2006.) The relationship management should first consider which relationships to commit scarce resources. Once the decision about the most important relationships is made, efforts should be conducted to change experience, uncertainty, distance and commitment factors of relationships to direction which favours long-term relationships. (Ford, 1980.)

The special features of the Chinese business environment

There are some remarkable differences between Western and Chinese business environments. Being aware of the differences in these cultures is essential for avoiding problems with Chinese companies, labour and public sector. (Hutchings & Weir, 2006.) Cultural habits and business practices, for example, should be known by foreign businessmen aiming to establish business in China (Kettunen et al., 2008). One of the most important issues is guanxi which is deeply rooted in the Chinese culture, and thus reflects its influence also on business environment. Some of the features of guanxi are trust, commitment and reciprocity, concepts that cannot be ignored in relationships with Chinese partners. (Su & Littlefield, 2001.) Guanxi has also influence on choosing between different market entry strategies in China. Regardless of the choice of the entry mode, Chinese partners are needed either in sales, marketing and distribution activities or in the form of JV. (Kettunen et al., 2008.) Foreign companies should somehow be able to denote commitment for their partners but keeping the entry mode as low cost and low risk choice at the same time may turn out to be problematic (Su & Littlefield, 2001).

Synthesis of the theoretical background

The theoretical part listed numerous of factors that influence on SME internationalisation. The degree of the existence of the factors varies from a company to a company. As a result, all the approaches are valid, and different approaches just emphasise different factors. Figure 1 depicts an integrated model of the major factors determining a route to internationalisation. Product or service capabilities, for example, could also be included but the focus is now on these key factors. Discussion about the relation of the factors and trade fairs is quite marginal, although literature provides also some other models about the same topic (cf. Crick & Jones 2000).

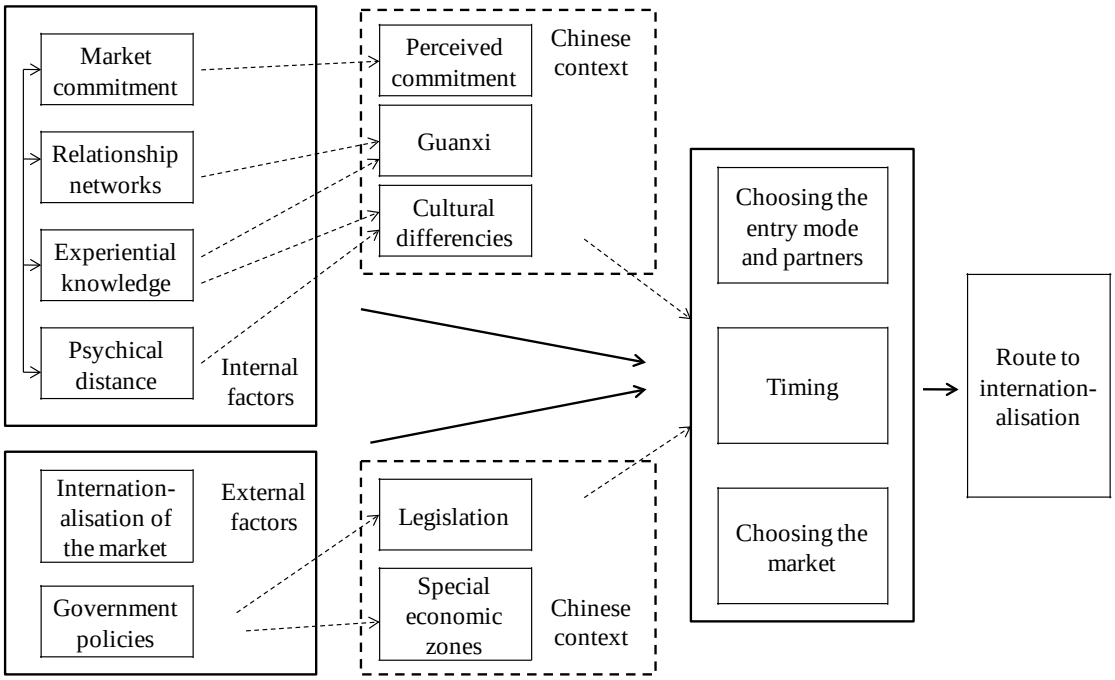

Figure 1: An integrated model of key factors influencing SME internationalisation.

In general, companies decide their internationalisation based on factors that are internal or external to them. The factors affect the choosing of entry mode and partners, the timing of the internationalisation intents and choosing the market. Both internal and external factors are a summary from the literature review, but they are modified by the researchers' own perceptions and understanding. As Chinese business environment is relevant in this case study, it is rational to review the factors from the Chinese point of view as well.

RESEARCH METHODOLOGY

DIEM decided to participate in EU-China Technology and Business Cooperation Fair organised by EUPIC (EU project innovation centre) in China with a delegation including SMEs in the Oulu region. Altogether four companies were involved and they are the case companies in this research. The research is qualitative and uses a case study method. Data is collected through documentation, in-depth interviews in the case companies, direct observation and participant-observation. Analysis and findings about the case companies are influenced by the researchers' perceptions. It leads to having a hermeneutic understanding of the research problem thus ignoring the quantitative methods of research.

Documentation is utilised in the study for example in forms of agendas or letters. Interviews, in turn, are the most significant source of evidence for the study. They are conducted as focused interviews, i.e. interviewer follows certain set of questions, but the situation is still more of an open-ended nature. In addition to the documentation and interviews, also direct observation and participant-observation are used in the study, because the researchers are part of the delegation. Whereas direct observation enables gaining knowledge of some behaviours or environmental conditions, participant-observation allows the researchers also to influence on the previously mentioned matters.

When considering the participant-observation as a source, there is a major problem concerning the close connection between the case organisation and the researchers, which may cause biases affecting the execution of the study. (Yin 2003.) The participant-observation method was utilised only in case companies 1 and 3.

Yin (2003) suggests following three principles for data collection. Using multiple sources is one of the guidelines that assure the evidence to be valid. Second principle is creating a case study data base, which clearly separates the original data by organising and documenting it from the analysed data. And third, maintaining the chain of evidence is necessary when processing the data into a new form of evidence. Consequently, an external observer should be able to trace the path used for processing the data. A case study analysis is considered as the most difficult stage of the whole case study. Problems can be reduced if the researcher develops strategy for analysing the data. Some options are pointed out for high-quality case studies. Pattern-matching compares the predicted pattern with the empirically based pattern. Such a matching would help strengthening the internal validity of the study. The second option, an explanation-building strategy, forms a kind of explanation about the case and aims to discover the causal links related to the case. Strategies should be replicated similarly for all the cases. (Yin 2003.)

EMPIRICAL CASES

Trade fair introduction

The fair was held for the fifth time and DIEM joined the event for the second time. The EUPIC event brings together European and Chinese companies, Europeans mainly as exhibitors and Chinese as trade fair attendees. The participation cost was significantly lower for the case companies than the actual cost was, since the project, which arranged the trip, got funding e.g. from governmental sources. The delegation intended to participate also in other trade fair at the same time at the same place, and it would have included different kind of visitors than the EUPIC event had. However, due to the last moment retiming arrangements of local organisers, the participation had to be cancelled.

The event is not clearly vertical trade fair but it does have clear industrial focus areas, which are IT, new energy, biopharmaceuticals and emerging industries. Altogether two days of exhibiting was included. The fair provided a gala dinner, a cocktail party and several seminars related to industrial focus areas during the six days it lasted. Moreover, the EUPIC organisation introduced the local business environment for example by visiting the chamber of commerce -type of organisation and the Chengdu Hi-Tech zone, and arranged also on-site visits to local Chinese and foreign companies. The event got also attention from the local press due to the international atmosphere of the fair.

The case companies made only few preparations for the fair. In general, DIEM made all the preparations and acted as a link between the companies and the organiser. As such a big delegation, DIEM negotiated itself a large booth with a central location. Requirements of the booth were discussed beforehand. Before the fair, the EUPIC organisation published a book consisting of all the companies and organisations participating in the fair. This was one

of the means to promote European companies to Chinese ones. EUPIC also organised numerous of match-making meetings for each participant. Chinese companies were selected based on European companies' specifications of their expected partner. A database provided by EUPIC consisting of local Chinese companies was to be utilised to find potential companies for the meetings.

Case descriptions

Case 1: Akkuser

Akkuser recycles hazardous batteries and accumulators in an environmentally sustainable manner. The company has full market share of the Finnish battery and accumulator recycling markets and receives material also from the Estonian, Swedish and Norwegian markets. The domestic market yields more than half of its revenues although the share is decreasing all the time. China is a natural target for Akkuser due to the appeal of the market area. Before the fair the company had a few contacts in the country but had not made any business with them. Akkuser has no intents to establish business units to China at least for a few years, though. Currently they are seeking for partners that could ship batteries and accumulators to Finland for further processing.

The company could not send a representative to the fair; therefore DIEM took care of representing Akkuser. Both the discussions at the booth and the match-making meetings were carried out in a way that a Chinese skilled person, i.e. the Chinese employee of DIEM or an interpreter, was present during the discussions. Five long discussions were held at the booth in the first day of exhibiting. Some of the discussions were continued in the next day during the match-making meetings. In general, the value creation model and how the Chinese could benefit from the possible cooperation were the most asked issues during the meetings. The CEO was briefed about all the met companies and Akkuser plans to take the discussions even further.

Case 2: Flowman

Flowman offers solutions that consolidate, streamline and automate business processes in print media industry. The company has strong hold of its domestic market, which constitutes approximately 50 % of its revenues. The rest of the revenue comes mainly from China, where it has two major customers in Southern China in the Pearl River delta area. The company participated in four trade fairs in Central Europe a few years back, but participation was decided to stop. Besides the managerial time they took, the trade fairs were not reaching the appropriate managers within the potential customers; trade fair visitors were mainly technical managers although Flowman would have wanted to contact more CEOs and other executive officers. This time Flowman ignored the short-term sales effect as an objective and instead aimed to get known to the business environment in Western China and establish some relationships in the area.

The company's booth did not have many visitors probably due to its niche industry. The main attention was therefore in the match-making meetings which Flowman had five. The meetings were not believed to completely fulfil the company's objectives, though. Part of

the plan was thus to find a local company that gives on-site visit for Flowman. It was found to be very difficult task because of the special features of Chinese print media industry. One of the local companies in match-making meetings, however, was finally willing to give a short on-site presentation of their operations. As a software company it was able to enlighten the software business in China in general, but Flowman's urge to visit a company from the print media industry still remained. Flowman found three somewhat significant contacts that could be of a long-term interest for the company. The contacts fulfilled only partially Flowman's needs to establish relationship, but the whole event gave insight information about the market area. Nevertheless, the CEO's belief about trade fair usefulness in general was not changed.

Case 3: Hitmedia

The company provides a full platform, i.e. different kind of players, for mobile audio/visual content. Their focus is currently in domestic market, although the company aims immediately for international markets as well. The company's CEO could participate in the trade fair only during the two last days. Decision to participate was a natural choice because of the extensive base of Chinese consumers and low costs of the participation. The goal was to find at least one content provider among producers, copyright owners and artists. Reaching the consumers was thus completely out of scope. Hitmedia targets Chinese consumers primarily outside China and providing content for consumers in China is only part of a long-term plan.
