INTERNAL POLICIES	Objectives for internal policies, standards, processes and practices e.g. policies and internal standards definition and deployment, best practices dissemination, harmonization of practices, agility and adaptability of technology creation.
INDUSTRY RELATIONS	Objectives for industry relations e.g. compliancy to regulations, standards, de-facto standards, standardization strategy and policy, IPR, licensing, supplier strategy, extend of supplier base, publications, collaboration with institutes, creation and support of technology ecosystems.

Properties of product technologies must satisfy qualitatively and quantitatively the product offering objectives of a company. Company's business model defines technology related objectives concerning revenue logic, business scope and scale, value chain aspects and supplier base. For example technology selections affect on potential technology supply, supplier lock-in and change costs. Furthermore decisions and objectives on technology assets' lifecycle, proprietary ness, standards compliancy, scope and scale reflect product offering targets and aspects of value chain objectives. Technology asset base determines also productivity of a company in terms of product development speed, cost, competence and resource needs, and lifetime costs due reusability and maintainability. Productivity is influenced by existence of internal policies, commonality of operational processes and practices, and agility of technology creation and use enabled by technology. Also objectives for industry relations concerning standardization, regulation, intellectual property management and collaboration with industry eco-systems, suppliers, competitors and institutes are needed.

Impacts category of the framework

In the *impacts* category the main elements are tangible outcomes, business model, knowledge based, transitional and dynamic, socio-economic and environmental impacts. The *impacts* category of the framework is presented in Table 4.

Technology embedded in products and services cause tangible impacts when delivered by a company. Management of technology has a significant consequential effect on the company's business model which is enabled by technology, investments and position of the company in value chains and industry eco-systems. A company also creates and accumulates knowledge through its activities that are directed by strategic technology management. On the other hand tangible outcomes and company's business model cause impacts in the market place, diffusion of innovations, technology and industry evolution which can be observed over technology lifecycles and trajectories. Finally, technology management causes social, economic and environmental impacts through utilization of technology in tangible outcomes.

Table 4: Impacts category of strategic technology management framework (Sahlman and Haapasalo 2011a, published by permission of Inderscience).

Main element	Definition
TANGIBLE OUTCOMES	Impacts of technology management by technology manifested in delivered products and services.
BUSINESS MODEL IMPACTS	Impacts of technology management to the company's offering, value creation system, industry clusters, revenue logic, value creation and productivity.
KNOWLEDGE BASED IMPACTS	Impacts of technology management on skills, competence, data, information, knowledge and wisdom embodied in people and enterprise capabilities.
TRANSITIONAL AND DYNAMIC IMPACTS	Impacts of technology management that can be observed as phenomena in the market and environment.
SOCIO-ECONOMIC IMPACTS	Impacts of technology management on social welfare and people's behavior.
ENVIRONMENTAL IMPACTS	Impacts of technology management to natural resources consumption, materials exploitation and waste.

Validation of the framework

The entire framework was validated after completion of the categories by interviewing five experienced industry practitioners who all had at least 25 years of experience in high-technology companies. The validation was conducted as evaluation of the relevance and current state of the framework elements in scale from 1 to 10. Evaluation results are presented in Appendix 1.

Relevance of the elements was evaluated on average from 8.0 to 9.4. Methods, tools and IT systems element scored 7.0 being seen as least relevant in structures category, and socio-economic and environmental impacts in impacts category scored 7.2 and 6.0. Nevertheless methods and tools were stated to be relevant in large companies and role socio-economic and environmental impacts were seen to be increasing. The current state of the elements was evaluated by the interviewees on average from 6.2 to 7.6 indicating that the practices are not systematic in companies, especially artifacts element in structures category scored 5.2. Collaboration networks got the highest score at 8.0, reflecting the necessity of networked mode of operation in global high-technology companies.

On average all the elements were seen relevant and their substance was understood by the interviewees. They also were able to associate and link the elements with business management and enterprise strategy. Interviewees stated that it is important to see the whole picture related to strategic technology management for which the framework was seen to provide a logical structure. Also positioning technology management in strategic dimension was seen right. Distinguishing strategic technology management clearly from R&D management was seen beneficial to improve visibility to technology matters, decision making and to technology strategy execution.

THEORETICAL CONTRIBUTION

The research problem i.e. lack of comprehensive frame of reference for strategic technology management was approached by developing a conceptual framework that describes the elements of strategic technology management in strategic dimension. The main theoretical contribution of this paper is the synthesized logical framework model for strategic technology management. Thus, knowledge of strategic technology management school (see Drejer, 2004; Phaal et al., 2004; Lichtenthaler, 2008) is enhanced.

The framework is built on the integrated management theory of Bleicher (2004) and enhances previous technology management models (e.g. Gregory, 1995; Luggen and Tschirky, 1991) that are typically focusing on specific aspects of technology management like processes, functions, routines or methods and tools (see Table 1). In the framework, Gregory's (1995) five process model, *identification, selection, acquisition, exploitation, protection*, is suggested to be enhanced by *strategic planning, technology development* and *technology disposal*. Cetindamar et al. (2009) suggests that *learning* should also be included in the process framework for technology management.

In addition, contemporary thinking on challenges of strategy execution high lights management of strategic initiatives and objective setting for organizational entities (e.g.

Kaplan and Norton, 2005; Mankins and Steele, 2006). Instead, for applying the framework, transformation of business objectives into strategic objectives for technology is proposed. The framework also connects aspects of the company's internal and external influence of strategic technology management with socio-economic environment.

For the creation of the framework, organizational management, technology management and strategic management theories were applied. The framework unites socio-economic and environmental context with enterprise management concerning technology aspects, which is useful for theoretical consideration of technology management as an own managerial discipline in a multifunctional organization.

MANAGERIAL IMPLICATIONS

The purpose of this research was to outline a conceptual framework on strategic technology management to assist practitioners in definition and development of the practices in enterprises. The substance of the framework is reflecting conceptions of scholars and practitioners in the field. The framework presents essential topics, viewpoints and interrelations of strategic technology management issues in enterprises. It also considers technology management in larger socio-economic context, thus increasing awareness of the impacts of strategic technology management.

Enterprises should consider technology management as an own managerial discipline in strategic dimension together with e.g. business and product portfolio management. Typically technology management is seen as an implicit function, most often embedded in R&D management. For the purpose of developing strategic technology management as an explicit practice the framework provides a frame of reference for the necessary structures i.e. artifacts, processes, methods, organizational functions and governance, and collaboration networks.

The framework also highlights importance of strategic objectives setting for technology. Typically, strategic objectives are related to business topics and they are targeted for organizational functions and activities, market positioning and key performance indicators of the business. Instead, strategic technology management objectives should be directed on properties and attributes of technologies used in a company. Therefore a transformation of business objectives to technology objectives is needed through strategic technology management activities. In this respect, the main considerations are related to managing technology over product life-cycles and assessing technology gaps versus business objectives. Thus creation, deployment, maintenance, reconfiguration and fusion of technological capabilities of a firm are in the focus as industries, markets, products and technologies evolve over time.

Along the logic of the framework model, the objectives of strategic technology management to technology are related to product offering, value chain, technology assets, productivity, internal policies and industry relations. When the objectives are realized in industry and socio-economic context of the company through structures and operational activities, the activities influence on technology infrastructure of the company and create external impacts and have an influence on technological capabilities. Consequently, the generated

capabilities and impacts cause technology and industry evolution, and creates wealth and social change.

The developed framework is intended to assist practitioners for identification, discussion, communication and presentation the complex managerial field of strategic technology management.

CONCLUSIONS

In this paper, the results of the four research phases are concluded as synthesized framework for strategic technology management in high-technology enterprise context. In an increasingly complex and dynamic environment practitioners in enterprises are facing a challenge how to strategically manage technology to sustain the company's competitiveness. While companies have evolved to multifunctional strategic orientation where technology has a significant role, there still is no comprehensive frame of reference for strategic technology management. The synthesized framework for strategic technology management answers to the **RQ** 'What are the elements of strategic technology management in high-technology enterprise context'.

The research was conducted in large and small to medium-sized enterprise high-technology enterprise context. The framework was developed based on literature findings and using questionnaires and documents to acquire data for analysis and abductive reasoning to describe a possible solution to the research problem. The entire framework was validated by interviewing experienced practitioners in high-technology companies.

The framework for strategic technology management consist categories of *structures, objectives* and *impacts* in strategic dimension. The categories are formed from six main elements each containing several sub-classes.

The main theoretical contribution of the research is the framework that provides a logical structure to elements of strategic technology management. The framework unites strategic management, organizational management and technology management viewpoints to enterprise management, and enhances knowledge in strategic technology management.

As the main managerial implication it is proposed that companies should define systematic practices for strategic technology management, and integrate it with other managerial disciplines as an own managerial function. For practitioners the framework provides a frame of reference for conceptualization and organizational development of strategic technology management.

ABSTRACT

In the globalization and competition situation, merger and acquisition become a popular way to acquire technology and realize enterprise expansion. However, most merger and acquisition evaluations focus on finance indices, but few studies explored production efficiency of technology-oriented business in fast changeable environment. This study proposed an effective method to assist bio-tech industries to evaluate the production efficiency and find the candidate priority of merger and acquisition under the price of merger and acquisition. To do this, we develop an approach by combining with Data Envelopment Analysis and heuristic technique to efficiently find the merger and acquisition candidate in complicatedly technology conditions. Numerical exercises based on U.S. 11 bio-tech industry realistic data are conducted. We selected the capital expenditure, the sum of employees and R & D expense as input variables, and the net income and the patent value as output variables in 2008. The results demonstrate that our method can help the bio-tech companies effective explore the best efficient candidates of merger and acquisition to expand their business strategy. Moreover, this method can help firms in simulating the results to predict the success of future merger and acquisition.

Keywords: Merger and Acquisition; Efficiency evaluation; Data Envelopment Analysis; Candidate

INTRODUCTION

Over the last decades, because of the globalization and information circulation, business merger and acquisition (M&A) has emerged as important. Therefore, many businesses try to adjust their developmental strategies to cope with the global economic changes by M&A. M&A refers to the process of merging or acquiring all or parts of other companies' property rights under certain conditions in order to have the controlling rights (Song and Chu, 2006).

In fact, business M&A seems to be the best way for industries to maintain their competitive edge in today's competitive market and for businesses achieve reinvigorate their vitality, providing for a sustainable existence (Cristina et al., 2010). Hence, M&A is a convenient method for hastening business growth (King, Slotegraaf, and Kesner, 2008; Louis and Harjeet, 2008; Hagedoorn and Duysters, 2002). Generally speaking, the main strategy for business production is to reduce cost and increase output. A company can reach their strategic goal faster and at a lower cost through buying another company or integrating with another organization (Baars and Kemper, 2008; Myriam et al., 2006).

M&A has not only been considered as the quickest route for expansion, but it also changes the competitive environment by reducing the number of competitors in an industry (Santomero and Seater, 2000). Therefore, to increase the success of M&A activities, the critical step for a bidder company is to identify suitable target companies that have better synergy to those of the bidder company. It is the critical step of an M&A activity because an inappropriate selection likely leads to the failure of this M&A activity. To choose better candidate of M&A is also important from the perspective of possible target companies. Hence, this study proposes a prediction method that can decide the best candidate company of M&A. Such method will facilitate companies to develop appropriate strategies for improving their possibility of M&A and increasing economic benefits from future M&A activities.

Bio-tech industry is an industry based on knowledge and intensive technology, which invests a high proportion of R & D in investment. The products in a high tech industry are high-risk and can yield large profits (Lee, Yang, Chen and Chen, 2010; Vanderbyl and Kobelak, 2007). Bio-tech industry generally fluctuates rapidly, but has huge market and economic influences on other industries (Coombs, Mudambi and Deeds, 2006; Michael and Shankar, 2009; Tsai and Erickson, 2006). Thus, in the U.S., industries keep their dominant economic position in the world. We take well-known enterprises in U.S. bio-tech industry as research targets to explore its optimal candidate through M&A.

In the bio-tech industry, patent data is the most representative indicator in research and development capabilities. Previously, patent data has been used for quantifying and understanding the process of technological development, and evaluating its relationship to innovation performance in various countries, regions and companies (Verbeek and Debackere, 2006). The creation of patents, which is the major output of research and development, could capture innovation that is the result of knowledge transfer and organizational learning through inter-firm R&D agreements (Li et al., 2009; Franz and Patrick, 2009). Furthermore, patents have received so much attention as the most important output indicators of innovation activities because they contain standardized and detailed

information as well as being continuously available across time (Andrea and Josep, 2008; Lee et al., 2009; Deepak, 2008). In addition, patent analysis is the only formally and publicly verified output measure that can empirically explain most aspects of inventive activities in developed countries (Ma and Lee, 2008; Cong and Tong, 2008). Therefore, patents and patent analysis are nowadays widely used as the measures of innovation and inventive activities. There are many indicators representing the strength of patent data, and among them, we chose the patent value as the output of DEA. Patent value should indicate a firm's inventive prowess, and should reduce capital costs as they inform external investors' about the abilities of the firm to successfully engage in the invention process, as well as the likelihood of achieving cash flows from the technology. Thus, the efficiency value through DEA is more representative for the actual R & D status of a bio-tech industry. Moreover, we use the multiple efficient frontiers to determine different level group of the efficiency, and each level represented the difference of goodwill, which can determine the M&A price. In addition, the sensitivity of DEA (Jahanshahloo et al., 2005; Sharma and Thomas, 2008) is used to get the policy of the most efficient candidate.

The rest of the paper is organized as follows: Section 2 develops the construction of the choosing candidate method. Section 3 describes the data and empirical methods used. Finally, Section 4 presents concluding remarks.

CONSTRUCTION OF OPTIMUM CANDIDATE METHOD

The multiple production efficient frontiers

The relative efficiency value of Decision Making Unit (DMU) can be divided into four levels: super- efficient units, the efficient edge units, the non-efficient edge units, and significant non-efficient units (Norman and Stocker, 1991; James, 2009). We use the selection methods of multiple production efficient frontiers (Mithun and Song, 2009) to rank the non-efficient units to reduce time for unnecessary integration status in our model.

The selected method of multiple efficient frontiers is to remove the units of super-efficient frontier from all units, and re-rank second efficient frontier from the non-efficient units. And it would continue until the number of non-efficient frontier units is smaller than the number of input variables＋number of output variables / 2.

Sensitivity Analysis

This study mainly explored the M&A price by the sensitive of post-M&A efficiency, which get changes in a single variable. Therefore, this section describes the sensitivity analysis of DEA

(Adler et al., 2002; Valter, 2006; Jie et al., 2009).

Sensitivity analysis discovers how the changes in input and output variables influence the relative efficiency value. In brief, sensitivity analysis means that "reducing the output will reduce efficiency of the target unit, however, to what extent the output reduce, the target unit can still maintain efficiency = 1. The post-M&A efficiency may be efficient or non-efficient. If non- efficient, we can change the input to be smaller or output to be larger, and can get the sensitivity of single variable for achieving efficient. Otherwise, if efficient, this study will use the sensitivity analysis of data excluding method (Andersen and Petersen, 1993) to get the efficiency value that be greater than 1, which can be adjusted to go back to efficiency =1. Hence, we can get the sensitivity of single variable.

The Optimum Candidate Method

This study focuses on a specific company executing the horizontal M&A. The decision of selecting candidate is based on remaining efficient after M&A, therefore, this study uses M&A price as the key point. In brief, M&A must pay the price, which will increase the company's capital expenditure might affect its efficiency after M&A. Therefore, this study explores how much the M&A price is, which still allows post- M&A's company to maintain efficient. Moreover, we can get the relative M&A price of each candidate using the way of multiple production efficient frontiers, and obtain the ratio, which can get better candidate. Hence, this study proposes the optimum candidate method, and better candidate using relative ratio, as following:

Relative ratio = relative price/price of variables maintaining (promoting) efficient

SAMPLE STUDY

Sample and patent data

The sample of this study selected 11 bio-tech companies in U.S. We selected capital expenditures, sum of employees, and R & D expenses in 2008 as input variables, and net income and patent value in 2008 as output variables. This study constructs the data set from two databases: Standard & Poor's (S&P) COMPUSTAT database and United States Patent and Trademark Office (USPTO) database. We collected data on capital expenditures, sum of employees, and R & D expenses from the COMPUSTAT database. These data are shown in Table 1.

Table 1: Data of input and output.

	Input			Output	
	Capital Expenditure (millions of dollars)	Employees (thousands)	R&D Expense (millions of dollars)	Net Income (millions of dollars)	Patent Value
DMU	I(x1)	I(x2)	I(x3)	O(y1)	O(y2)
Abbott Laboratories (A)	1287.724	69.000	2786.067	6917.719	222.7427
Amgen Inc (B)	672.000	16.900	3030.000	6233.000	123.5981
Bristol-Myers Squibb Co (C)	941.000	35.000	3617.000	7284.000	650.6048
Cardinal Health Inc (D)	376.100	47.600	152.900	3337.600	23.53819
Johnson &Johnson (E)	3066.000	118.700	7758.000	14986.000	108.5411
Kimberly-Clark Corp (F)	906.000	53.000	297.000	3727.000	698.2427
Merck & Co (G)	1298.300	55.200	4805.300	9845.400	406.6093
Monsanto Co (H)	918.000	26.400	1144.000	4061.000	633.5535
Pfizer Inc (I)	1701.000	81.800	8578.000	10141.000	415.3648
Schering-Plough (J)	747.000	51.000	3529.000	3940.000	2.333333
Wyeth (K)	1408.999	47.426	3373.213	6454.833	249.8254

Implementation procedure of method and the result

After collecting data, we began the process of choosing candidate in 11 bio-tech firms using the optimum candidate method. Since choosing the candidate, from 11 bio-tech companies, this study randomly selected a company that would merger other company. Therefore, we would select Kimberly-Clark Corp (F) that assumed M&A's motive as the target company. First, we must carry out the multiple production efficient frontiers to determine the levels of different efficiency. Therefore, we got the first and the last efficient frontiers using multiple efficient frontiers as shown in Table 2. From this, we discovered that the first efficient frontier were B, C, D, F and H, and G and A were the second efficient frontier, and the third efficient frontier were K, E and I, and J was the last efficient frontier. Each DMU of same level both represented the same goodwill, which was a basis of M&A price for mergering different candidates. Moreover, this study would use the difference goodwill as the basic of M&A's price, called the relative price. Therefore, the relative price is that the capital expenditure of candidate multiplied by its coefficient of efficiency level that is 1, 0.95, 0.9 or 0.85. For example, if A was acquired, its relative price was 1223.3378 (=1287.724*0.95).

Table 2: multiple efficient frontiers before M&A.

1	**F**	1									
1	**H**	1									
6	G	0.880489	2	**G**	1						
7	A	0.735097	2	**A**	1						
8	K	0.705487	8	K	0.89713	3	**K**	1			
9	E	0.698005	9	E	0.88873	3	**E**	1			
10	I	0.681505	10	I	0.78617	3	**I**	1			
11	J	0.568653	11	J	0.69553	11	J	0.905393	4	**J**	1

The target company, F, respectively carried out M&A with other 10 companies and got the post-M&A's efficiency as shown in Table 3. From this, we discovered that the efficient DMUs were F+B, F+C, F+D and F+H, and others combinations were the non-efficient DMUs. Therefore, we can explore the difference situation with efficient and non-efficient. We can get the sensitivity of capital expenditure of individual candidate, which was the price of maintaining efficient. Then, we could get the relative ratio according to the optimum candidate method as shown in Table 4. If post-M&A's efficiency was non-efficient, we could change the capital expenditure to be smaller and get the sensitivity of capital expenditure for achieving efficient as shown in Table 5. From Table 4, F can choose to merger D, because its relative ratio was smaller than others. If post-M&A's efficiency was non-efficient, F can choose to merger G, because its relative ratio was bigger than others.

Table 3: efficiency after M&A.

State	Efficiency
F+A	0.81860682
F+B	1
F+C	1
F+D	1
F+E	0.73307224
F+G	0.91804878
F+H	1
F+I	0.72310459
F+J	0.74295567
F+K	0.78637421

Table 4: Post-M&A's efficiency = 1.

State	relative price (capital expenditure * coefficient of level)	price of maintaining efficient	Relative ratio (relative price / price of maintaining efficient)
F+B	672	93.42	7.19332
F+C	941	321.7	2.92508
F+D	376.1	377.47	0.99637
F+H	918	456	2.01315

Table 5: Post-M&A's efficiency < 1.

State	relative price (capital expenditure * coefficient of level)	price of promoting efficient	Relative ratio (relative price / price of promoting efficient)
F+G	1233.385	246.68	5.00004
F+A	1223.337	466.71	2.62117
F+K	1268.099	621.15	2.04152
F+E	2759.400	1491.64	1.84991
F+I	1530.900	683.80	2.23880
F+J	634.950	537.64	1.18098

CONCLUSIONS

In the globalization and competition situation, M&A become a popular strategy for many bio-tech companies to extend their business roadmap, and companies usually conduct M&A to pursue complementarities from other companies for preserving and/or extending their competitive advantages. M&A is an important strategy within the enterprise but, and it cannot endure any decision-making mistake. In addition, appropriate selection of M&A candidates for a given bidder company is a critical first step to the success of the M&A activity. Therefore, this study provides an effective search for the most suitable candidate when a company implementing M&A, as well as the analysis of the operational efficiency after the forming of the M&A. We develop an approach by combining with DEA and heuristic technique to efficiently find the M&A candidate with the methods of multiple production efficient frontiers, the sensitivity analysis, and the optimum candidate method in complicatedly technology conditions. Its focuses are on the realization of operation efficiency and evaluate the capital expenditure.

According our proposed method, we can easily separate target candidates to different priority and assist bio-tech companies to evaluate the operation efficiency and find the candidate priority of M&A under different M&A's price. This method can help firms to simulate the M&A's results for planning future M&A. It also allows companies to choose the appropriate candidate for M&A, which can cause the post-M&A's firms to have the most stable efficient under a more reasonable M&A's price. More importantly, this application

design might help top managers for decision making in business extension.

ABSTRACT

As advancement in information technology makes work more efficient, computer and internet have become an essential tool for corporations. Information ethical issues has become the urgent topic of modern Corporations. In order to prevent staff's illegal or immoral behavior which may damage the corporation's image, implementation of information ethics policy should be more thoroughly considered.

The purpose of this study was to construct indicators of measuring corporate fulfillment of information ethics in Taiwan. This study reviewed related literatures and interviewed corporate executives and academic scholars to establish the structure of indicators. The indicators were organized into four categories, namely, corporate executives' cognition and supports in information ethics, information ethics policy, control mechanism on information ethics, and information ethics education.

Delphi method and Analytic Hierarchy Process (AHP) were employed to collect and analyze data in this study. The 13 panelists represented both academic scholars who have specialized in the field of information ethics and corporate executives who are responsible for information ethics policies. Three rounds of Delphi questionnaires surveys were first conducted to evaluate the adequacy of indicators. Based on the results of Delphi surveys, indicators were categorized into four purpose levels, 13 basic levels and 60 measuring items. Then, the AHP was used to calculate the weights of the indicators at both purpose and basic levels.

Finally, a reliable and valid tool for evaluating corporate practices on the information ethics was presented based on the findings of the study.

Keywords: Information ethics, corporate information ethics, indicators of information ethics

INTRODUCTION

The Executive Yuan of the Republic of China convened 26th technical consultant council in April, 2006. In the meeting, deliberation was made to make a preliminary decision “the Basic Law of High Quality Network Society”, hoping that through the ordinance to achieve the goal of the communication ethics, and then promote the development of information-related policies into a higher level of information society. In addition to construct the hardware of high-quality network society and to promote the application of the information-related services and industries, how to build "information ethics" has become one of the high-profile issues (iThome, 2007.）

World Summit on the Information Society (WSIS) in Geneva proposed that more people have come to recognize the need to prevent the misuse of information and communication technology based on society values. It pointed out that the establishment of information ethics is not only to enjoy the convenience of the information and communications technology, but to avoid possible negative effects and to promote positive values such as peace, freedom, equality, and solidarity awareness to wake the concepts of information ethics and moral connotations（iThome, 2007.）

According to the ETtoday reports in May 2007, As an e-mail fraud led the market value of Apple Inc. instantly evaporated in 2.8 billion U.S. dollars in just 6 minutes, at the same time, the stock price of Apple fell down 2%（ETtoday, 2007.）

From the above, it is believed that information technology is now widely integrated into business activities of a corporation's process. In this perspective, the company’s reputation and stakeholder’s equity are influenced directly by information ethics.

In order to prevent staffs’ illegal or immoral behavior which damages the corporation’s image, this study suggests that implementation of information ethics policy should be more fully considered. Therefore, this paper will construct the indicators which are concerned with the development and implementation of corporate information ethics. By using these indicators, managers can conduct self-inspection and refer to related information policies.

At present the related research about the corporate information ethics indicators is still rare and this paper will broaden the scope of information ethics. So the main research objectives of this study are as follows:

1. Review the related literature and results of case interviews to construct indicators of evaluating corporate information ethics.
2. Use the Delphi method to evaluate the indicators.
3. Provide practical reference indicators in the future when carrying out information ethics policies.

LITERATURE REVIEW

Information Ethics

The term of information ethics can be traced back to 1940, MIT Professor Norbert Wiener of computer studies, focusing on the computer ethics (Bynum, 2001). Owing to the advance of computer technology and internet, information can be effectively managed, utilized and transmitted, and that opened the ethical issues different from the past study. The so-called "information ethics", is to discuss the behavior of human use of information and is the question of right or wrong (Chuang, 1996). The scope of information ethics behaviors includes information collection, collation, use, storage and dissemination other than moral subject.

Facing the information era, Mason (1986) proposed four major ethical issues of information: information privacy (Privacy), information accuracy (Accuracy), intellectual property rights (Property) and information access (Accessibility). These summarized in an acronym – PAPA.

1. Information Privacy

What kind of individual or corporate information can a person reveal to others, under what conditions and with what safeguards? Which things can people keep as secrets and not be forced to reveal to others?

2. Accuracy

Who is responsible for the authenticity, fidelity and accuracy of information? Similarly, who is to be held accountable for errors in information and how is the injured party to be made whole?

3. Property

Who owns information? What are the fair prices for an exchange? Who owns the channels, especially the airways, through which information is transmitted? How to allocate scarce resource?

4. Accessibility

What information should one be required to divulge about one's self to others? Under which conditions? What information should one be able to keep strictly to one's self? These are some questions that related to privacy. Today more than ever cautious citizens must be asking these questions.

From the above information ethical issues, it is argued that information ethics has become a so important concept that is helpful to the advancement in moral connotations of applying information technology.

Corporate Cognition about Information Ethics

Traditional western philosophy holds that thinking comes before the motion (Liu, et al., 2004). Trevino (1986) believed that one's level of moral recognition, will affect his decision-making in the right/wrong judgment. So, people may make different decisions when they are at different stages of moral awareness. (Kohlberg, 1984)

Managers may enhance ethical behaviors within organizations through establishing and operating ethics policy (Hsu, 2005). The main purpose of ethics policy is to standardize the overall directions of ethics within organizations, and educate employee corporate ethics. Therefore, institutions, regulations, or approaches which can improve the quality of ethics in an organization are regarded as means of implementing ethics (Wu, et al., 2004; Hsu, 2005). Currently, there are many researches indicating that ethics rules are the solutions to ethical related issues among employees. And managers also deploy ethical rules as an appropriate approach to deal with ethical problems (Robin, et al., 1989).

Information ethics is in response to ethics issues arising from information technology. Information ethics education establishes the basis for information ethics literacy. Education can lead learners to change values and enhance ethical cognitive, and furthermore, emphasize the importance of information ethics issues (Wu, 2002). As well as to information system experts and managers, structural training courses can enhance sensitivity on the issues of information system and development (Heide & Hightower, 1983; Lin,, et al., 2001). In recent years, domestic institutions set up many information ethics courses. Although the topic of 'information ethics' is not numerous, moral education is an imperative issue in Taiwan (Wu, 2007).

When it comes to improving the right of privacy, property, accuracy, and access of information, the information security cannot be ignored. Liu (2004) argued that information security can protect knowledge assets, maintain the competitiveness for s, and avoid personal privacy from being usurped, modified, or known for public. Therefore, in order to put information ethics into practice, not only establishing the ethical standard but also placing importance on information security in corporations. It can prevent substantial loss caused by errors of information system, improper use, and negligence of information management.

CASE INTERVIEW

Basic Information of Cases

In this study, there are five different types of corporations in case interviews to understand the value and progress on information ethics issues of each company. This is a reference design for the subsequence of corporate information ethics indicator.

Table 1: Basic Information of Cases.

Industry	Number of Employees	Main Business
A. Electronics	**10,000**	**Manufacture of Communication Devices**
B. Bank	**6,000**	**Financial Affairs**
C. Technology	**2,000**	**Antivirus Software**
D. Hyper-media	**555**	**Broadband Internet Service**
E. Stock Company	**3,000**	**Stock Exchange Agency**

Results of Case Interview

There are several indicator assessments to identify the extent of the value and progress of corporate information ethics, as follow:

1. Setting up the regulations will help employees to understand the information ethical policy.

Corporations all consider that setting up the regulations for information ethics is a measuring perspective for assessing the extent of the value and progress of information ethics. When it comes to ordering the information ethics on employees, setting up regulations is the most important. It makes employees understanding the company policy, and provides criteria for facing ethical dilemma.

2. IT education develops information ethics within companies.

IT education is an important factor for developing correct concept of information ethics. However, in order to put relative courses or trainings into practice, plenty of cost is required for corporations. Therefore referring to carrying out the IT education, the larger scale a corporation has, the more it values IT education.

3. Corporations start to limit the use of instant messenger software.

According to the iThome survey of using instant messengers from top 300 corporations in Taiwan, most of the corporations allow the use of IM on certain conditions (iThome, 2006). From the case interviews of this study, it is found that most of the uses of IM are totally forbidden or opened on the conditions judging from the information security. This result was the same as iThome survey.

4. Applying the international standards to the concrete practices of information ethic issues in corporations.

Following the international standards is not equal to the quality of information ethics, but these international standards in the aspects of information data, software/hardware equipments, organization process, and human resource arrangement implicitly contained information ethics PAPA issues mostly. While a corporation adopts some standard of bill of an international organization, it shows great consideration and awareness on information ethics. Therefore, applying the international standards will promote the concrete practices of information ethic issues in corporations.

RESEARCH DESIGN

The aim of this study is to construct and develop an evaluation system of corporate information ethics indicators on the base of motives and expectations, literature review, and outcome of case interviews.

Framework of information ethics indicators for corporations

The outcome is shown as a hierarchical framework in Fig. 1.

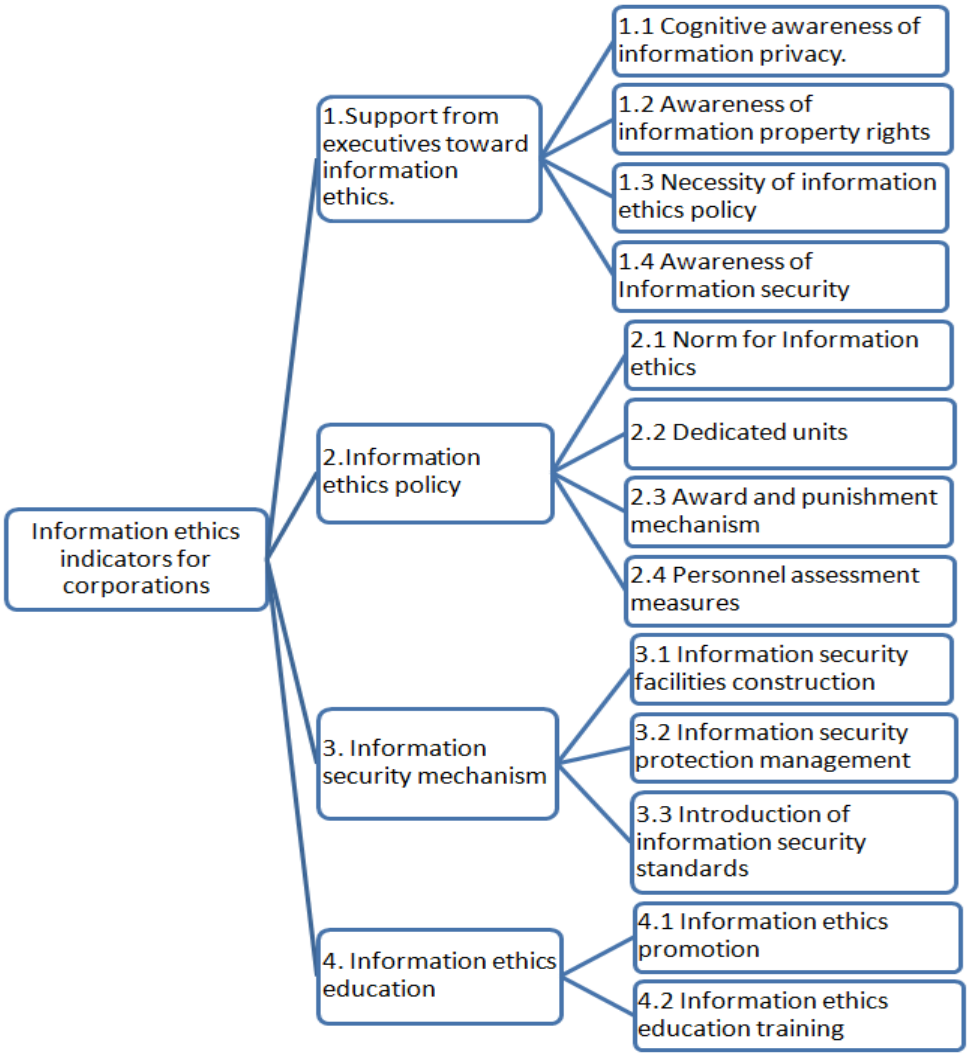

Figure 1: The framework of information ethics indicators for corporations.

Indicators Illustration

The whole framework consists of four main aspects: support from executives toward information ethics, information ethics policy, information security mechanism and information ethics education. The aspect of "support from executives toward information ethics" contains 4 main ideas: cognitive awareness of information privacy, awareness of information property rights, necessity of information ethics policy and awareness of information security. Detailed indicators are listed in Table 2.

Table2: The content of indicators about executive support toward information ethics.

No.	Content
1.	Executive support toward information ethics.
1.1	Cognitive awareness of information privacy.
1.1.1	The collection and usage of personal data is only limited in the relevant range.
1.1.2	The collection and possessing of personal data is obliged to inform the persons concerned.
1.1.3	In prevention to the occurrence of damage, the design of personal information privacy protection system is to avoid information abuse.
1.1.4	Business use of personal data in accordance to the purpose has the obligation to maintain informaiton accuracy and completeness.
1.1.5	The personal data within corporations should be well-protected. （Ex. unauthorized interception, usage, modification or disclosure of personal information unpermitted.）
1.2	Awareness of information property rights
1.2.1	The scope of information property rights includes copyright, patent, trademark right and trade secrets and so on.
1.2.2	Information usage may relate to the issues of privacy, trade secrets and copyright.
1.2.3	Any respect of information reproduction will relate to property issues(Ex. music, software programs）
1.2.4	To understand that personnel within the corporation using pirated software will cause corporations to cast the stigma of violations of property rights, or to bear the loss of money and goodwill.
1.3	Necessity of information ethics policy
1.3.1	Can information ethics policy effectively reduce the occurrence of information abuse?
1.3.2	Can information ethics policy do as guidelines when employees facing the ethical dilemma?
1.3.3	Can information ethics policy enhance corporate ethical issues?
1.3.4	Do positive effects reflect on the corporate image when businesses execute information ethics policy?
1.4	Awareness of Information security
1.4.1	Firms have the obligation to protect information confidentiality.
1.4.2	The accuracy and availability of information must be managed efficiently.
1.4.3	Unauthorized organization staff should not access the resources of the computer and communication service.
1.4.4	Information security system is established to ensure legal access of the information resources and sustain the operation of commercial activities.

There are four main ideas under information ethics policy aspect: information ethics, corresponding sectors, award and punishment mechanisms, and personnel assessment measures. Detailed indicators are shown in table 3.

Table3: The content of information ethics policy indicators.

No.	Content
2.	**Information ethics policy**
2.1	**Norms for Information ethics**
2.1.1	**Whether the organization maps out norms regarding information ethics or not?**
2.1.2	**Whether the content is compatible with the existing laws or not?**
2.1.3	**Whether ethical norms formulated by the organization include information abuse or not? (Ex. Computer/Internet use in non-work-related affairs)**
2.1.4	**Whether the ethical norms are clearly understandable or not?**
2.1.5	**Whether the ethical norms have real examples as references or not?**
2.1.6	**Whether the ethical norms are revised in response to business needs or not?**
2.1.7	**Whether members in the organization are informed or not?**
2.1.8	**Whether ethical norms vary among organizational hierarchies or not (Ex. the higher level is bound to stricter constraints.)**
2.1.9	**Whether reward and punishment approaches are drawn up in ethical norms or not?**
2.2	**Dedicated units**
2.2.1	**Are there any concerning sectors responsible for the implementation of information ethics?**
2.2.2	**Whether the information ethics sector implement according to the ethical norms set by the organization or not?**
2.2.3	**Whether the information ethics sector keeps monitoring and managing the implementation of ethical norms or not?**
2.2.4	**Whether the information ethics sector builds up ways of communication on the implementation of ethical norms or not (Ex. online message boards, e-mail or virtual communities, etc.)**
2.3	**Award and punishment mechanism**
2.3.1	**Whether the award and punishment mechanism is in accordance to the ethical norms set by the organization or not?**
2.3.2	**Whether the rule in the behavior of employee is clear or not?**
2.3.3	**Whether the rule in the behavior of employee is fair or not?**
2.3.4	**Whether the rule in the behavior of employee is appropriate or not?**
2.3.5	**Whether the rule in the behavior of employee is promptly or not?**
2.4	**Personnel assessment measures**
2.4.1	**Whether the promotion institution within the organization is associated with the employee ethical behavior or not?**
2.4.2	**Whether employee performance is linked to the behavior of his subordinate?**

There are three main points in the aspect of information security mechanism: information security facilities construction, information security protection management, and introduction of information security standards. Details are shown in table 4.

Table 4: Content of information security mechanism indicators.

No.	Content
3.	**Information security mechanism**
3.1	**Information security facilities construction**
3.1.1	**Is there any software tool for checking or diagnosing information security or not?**
3.1.2	**Whether systems of the organization use legal antivirus software and update virus codes all the time or not?**
3.1.3	**Whether there are any concrete security systems in the organization or not?**
3.1.4	**Are there Internet guarding systems or not? (Ex. Intrusion detection system /firewall.)**
3.2	**Information security protection management**
3.2.1	**Whether information access control policies conform to regulations in concerned laws and contracts for information protection or not?**
3.2.2	**Whether the organization maps out norms of management regarding storage devices or not? (Ex. Hard drive /magnetic tape / flash memory.)**
3.2.3	**Whether the organization has daily processing procedures sustaining information security or not? (Ex. Regular data backup/scanning for virus /operating environment monitoring.）**
3.2.4	**Is there an explicit regulation regarding e-mail delivery?**
3.2.5	**Is there an explicit regulation regarding staff's Internet usage? (Ex. Non-work-related upload /download.)**
3.2.6	**Is there any managing regulation especially regarding IM? (Ex. Authorized sectors /non-work-related chatting.)**
3.2.7	**Whether the organization sets up any personnel or sector solely responsible for information security or not?**
3.2.8	**Is there an authorization regulation for interior information assets? (Ex. Management of accounts / passwords.)**
3.2.9	**Is there any regulation regarding information access and authorization control to a**
3.3	**Introduction of information security standards**
3.3.1	**Whether the organization introduces any international standards regarding information security or not? (Ex. BS7799 or COBIT.)**
3.3.2	**Whether the organization introduces any international standards improving information system quality or not? (Ex. ITIL, ISO, etc.)**

Information ethics education aspect, which checks if a corporation implements information ethics education with concrete training and promoting measures, is divided into two parts: information ethics promotion and information ethics education training. Details are shown in table 5.

Table 5: Contents of information ethics education indicator.

No.	Content
4.	**Information ethics education**
4.1	**Information ethics promotion**
4.1.1	**Whether the organization makes regular promotions regarding regulations of information ethics or not?**
4.1.2	**Whether the orientation includes any illustrations regarding regulations of information ethics or not?**
4.1.3	**Whether the organization encourages staff take information ethics courses or not?**
4.1.4	**Are regulations regarding information ethics available for the staffs to browse or not?**
4.2	**Information ethics education training**
4.2.1	**Whether supervisors think highly of issues regarding information ethics education or not?**
4.2.2	**Whether the organization provides any courses regarding information ethics training or not?**
4.2.3	**Whether the organization encourages employees to join training courses or conferences regarding information ethics or not?**
4.2.4	**Whether the organization invites external people to give speeches on information ethics or not?**
4.2.5	**Whether the organization evaluates results of information ethics training or not? (Ex. ethics tests.)**

Consultation Samples and Methods

To effectively integrate academic and industrial opinions and to establish a proper structure of indicators, we consult some experts who possess actual experiences about information ethics in academies and corporations. This study conducted 13 interviewees, 8 of which are senior scholars having specialized in the field of information ethics, and 5 are corporate experts who have ever implemented information ethics activities.

In this research Delphi Method is used to receive collective opinion with repeated questionnaire surveys. According to Murry & Hammons（1995）, after consulting related literature and adjusting itself, a survey was developed a structural questionnaire to reduce the time of examining the questions. Therefore, in the first round a half-structural questionnaire is adopted, in which each answerer not only selects specific options but also gives additional responses (feedbacks, extra information, etc.)

Instruments for Statistics Analysis

Firstly the information ethics indicators are set up according to literature reviews and cases interviews, and then used Delphi questionnaires to consult with the experts in academies and corporations to reassure the completeness of the indicators in this study.

The first round questionnaires are evaluated by two parts. The first part concerns the appropriateness of the main constucts, and the second focuses on specific indicators of each

consturct. Likert six-point scale was adopted to judge the degree of appropriateness; larger numbers shows greater appropriateness.

Methods for Statistics Analysis

Standard deviation and average numbers are employed to comprehend and analyze the experts' opinions about the appropriateness of the indicators. When the average score of an indicator is higher than 4.0, this indicator is qualified; if the standard deviation of the score is less than 1, it means that the indicator is supported by the experts for a certain degree; ones regarded as inappropriate by 20% of the experts is delete.

RESULTS AND ANALYSIS

Backgrounds of experts

There were 13 experts invited to be consultants in this research. They received the Delphi questionnaires, evaluated the fitness of the information ethics indicators, and gave feedbacks. Among the experts in this study, 62% are from schools, and the rest are from business. Only one of them is engaged in information ethics studies or activities for less than 1 year, 4 for 1~3years, 3 for 3~5years, 5 for more than 5years.

Results of Modification

According to experts' suggestions, results of modification are listed below by the order of the four main aspects.

Support from executives toward information ethics.

23% of the experts consider that support toward information ethics is not equal to the concept of cognition. So, one of the items were changed to "support and cognition from executives toward information ethics." Three new ideas and three new indicators were added (seen in table 6). Former idea 1.4 "awareness of information security" was deleted and its indicator was reconstructed to other dimensions. After modification, there were 6 dimensions and 20 indicators in this aspect.

Table 6: New items in aspect 1.

No.	Content
1.3	**Awareness of information accuracy**
1.4	**Awareness of information accessibility**
1.6	**Degree of support toward information ethics**
1.6.2	**To know the importance of information property right to individuals and corporations and propose its well-arrange protection.**
1.6.3	**To know the necessity of information ethics policy and urge an implementation of it.**
1.6.4	**To work on establishing an information security management system, ensure legal access to information sources and sustain normal operation of business.**

Information ethics policy

In this aspect, indicator 2.1.9 and 2.4.2 were deleted due to 20% of experts' suggestion and a lower average score than 4, and 4 new indicators were added (seen in table 7). In the end, there were 4 dimensions and 22 indicators in information ethics policy aspect.

Table 7: New items in aspect 2.

No.	Content
2.2.5	**Whether information ethics sector provides consultant services about information ethics issues and legal problems or not?**
2.2.6	**Whether information ethics sector monitors and evaluates personnel and sectors that probably involved in information ethics problems or not?**
2.4.2	**Is there a positive correlation between information ethics on staff behavior and merit system in the organization?**
2.4.3	**Is there a positive correlation between staff information ethics behavior and bonus system in the organization?**

Information security mechanism

More than 23% of the experts thought that category of information ethics cannot fully cover information security, so after consulting experts and adviser of this research, the title of this aspect was rephrased as "information ethics control mechanism." Two new constructs, "information ethics techniques" and "information ethics management," are added, and the former constructs were deleted. Indicators originally under old three constructs were moved to under new ones, and a new indicator was suggested to be included. There were 2 dimensions and 16 indicators in the modified aspect.

Table 8: New items in aspect 3.

No.	Content
3.1.5	**Whether the organization set up an off-premise backup system to ensure normal operation of information access or not?**

Information ethics education

Indicator 4.1.3 was deleted according to 20% of experts' suggestion; indicator 4.2.2 and 4.2.4 are too similar to be combined; 4.1.2 was moved to 4.2 "Information ethics education training" because it was much more related to that construct. After modification, this aspect contains two dimensions and 10 indicators.

Table 9: New items in aspect 4.

No.	Content
4.2.6	**Annual number of personnel who attend information ethics education training in the organization.**
4.2.7	**Annual hours taken for information ethics education training in the organization.**
4.2.8	**Whether the organization give fortified information ethics education to personnel and sectors that probably involved in information ethics problems or not?**

CONCLUSIONS

The original framework of information ethics indicators has four aspects and 13 constructs and 61 indicators under. After the modification according to experts' advice, it contains 14 constructs and 68 indicators.

The result of this study can provide organizations with a reliable and valid tool for evaluating corporate practice on the information ethics. But practical research will alter with time and environment. The following researchers can refer to this framework and adjust the contents, to construct an more adaptable and profitable device.

ABSTRACT

The advantages of using a Public-Private Partnership (PPP) have been widely documented in contemporary literature. Traditionally, Public-Private Partnership (PPP) models are classified into Design-Build-Operate (DBO), Build-Operate-Transfer (BOT), Build-Own-Operate-Transfer (BOOT) and Build-Own-Operate (BOO). This paper proposes a new PPP Business Model, namely, PPP-WWW, as a novel approach to address the operational challenge to emergency services that arise from inadequate indoor radio coverage in the Hong Kong Special Administrative Region (HKSAR). On average the HK Police Force receives ten thousand 999/911 emergency calls daily. The HKPF performance pledge strives to respond to all genuine emergency calls within 9 minutes in the urban area and 15 minutes in the rural territory. A review of the challenges associated with the highly profiled HK Police Force project, a Third Generation Command and Control Communications System (CC3) in support of frontline beat patrol police officers, is examined. The new PPP-WWW pilot scheme was implemented successfully in 2009-2010 with the following key achievements: (1) A creative, innovative and sensible solution was evident with the new Public-private Partnerships (PPP) business model; (2) Timely services delivered, within budget and meeting all user requirements. The implementation period was shortened from 3 to 6 months with projected cost saving of around 40% in comparison with the other engineering solutions achieving similar results; (3) CC3 indoor radio coverage at pilot shopping had been enhanced covering over 640,000 sq. fleet of floor space; (4) Rental and electricity charges waivers were granted by the Shopping Mall and (5) Excellent feedback was received from the end-users.

INTRODUCTION

"The United States suffered a tremendous loss of lives in four separate and almost simultaneous attacks on September 11, 2001. One of the key lessons learned from the terrorist attacks of 9/11 is that adequate and reliable in-building public radio coverage is vital for the first responders to saving lives." (Private-public Sector Partnerships for Emergency Preparedness, 2003)

Figure 1: 911 Photos (Source: http://x9.org.tw/blog/img/thumb-911zn2.jpg).

The Hong Kong Police Force (HKPF) rolled out the Third Generation Command and Control

Communications System (CC3) in March 2006. CC3 was designed and developed to meet the challenges of a fast changing environment and advancing technology, as well as the ever-increasing expectation for better police services and faster emergency responses. It was primarily designed for outdoor radio communications during the initial rollout.

Reliable and efficient radio communications are essential for day-to-day policing duties. Seamless radio coverage, in particular indoor coverage, has always been a common challenge (Rappaport, 1996) to all mobile radio systems and police radio waves are of no exception, especially for beat police officers patrolling inside buildings such as shopping malls, basement floors, and carparks. Modern metropolis such as Hong Kong, London, and New York are commonly known as concrete jungles packed with skyscrapers.

To cope with the intensive metropolitan development in Hong Kong, developers are building more indoor shopping malls, thereby creating even bigger operational challenges for frontline patrolling officers in carrying out their police duties at these indoor areas. Hence, indoor radio communications are becoming an essential requirement to support daily police duties. Obviously, it is not practical to build a new comprehensive radio infrastructure inside all shopping malls in the constraints of time, cost and technicalities.

What are the problems?

In recent years the growth of public and private mobile radio communications has meant that the provision of seamless radio coverage has evolved from a desirable to an essential requirement. Especially, emergency services need clear and reliable radio communications for efficient incident management and personal safety. Imagine the case that police officers enter a building in response to a jewellery shop robbery incident, where some ladies and children are taken hostage. As the officers approach the crime site, they realize that the situation is beyond their capabilities. They definitely need additional assistance and equipments to handle the emergency. Next, the officers use the police radios to call their dispatch centre, requesting additional assistance and back up support. They wait for the dispatch centre to respond, but no reply is received. Then, they try to communicate through radio to other police teams in the street outside the building. Again, there is no reply. They try both methods repeatedly but still gain no reply. These officers know they cannot handle the incident without assistance, so they decide to make their way back outdoors, where there is a high chance of getting connected to the dispatch centre or other police teams who are nearby.

As a result, precious time is lost while trying to find a location where police radio

communications are possible. In many cases, officers need to travel completely outside the building before they can make use of their police radios to communicate. In a worst case, officers inside the building are trapped, injured or killed, and they cannot make contact with anyone. Indoor radio coverage is therefore essential for public-safety networks in tunnels, railway and subway stations, convention centres, hospitals, airports, and other special locations.

PROBLEM ANALYSIS

The Law of Physics

The poor indoor radio coverage is caused by both building losses and by interference from intentional or unintentional transmitters. The law of physics can explain the building losses. The signal waves from the radio normally start at the transmitter tower located on a hilltop or building-top. The waves are reduced as they travel to and from the radio. The amount of loss varies under different materials, and is diminished even over the air. This means that anything attenuates or reduces the radio waves. On the other hand, each radio has a minimum signal level that it must receive in order to work. The signal waves begin out high and are reduced along its path to the radio. Buildings and their construction materials, such as concrete, cinderblock, steel, brick and tinted glass, all reduce the radio waves. So buildings are not friends of the first responders. These construction materials, used in most large structures, absorb radio waves. The strong outside radio waves quickly become non-existence on the inside of the building. Path loss is a major component in the analysis and design of the link budget and signal loss of a radio system.

Problem Owners and Existing Solutions

Many public safety agencies believe that it is fair and reasonable to make the building developer or owner responsible for assuring a viable public safety radio signal, throughout his or her property. This is particularly true when the building itself greatly attenuates the public safety radio waves, plus activities inside the building warrant a genuine need of public safety response to the site. Some municipalities in the US and Europe have written building or fire codes to address the problem. The building developer or owner is required to comply with the code before a certificate of occupancy is issued. However, results are often undesirable because the code is usually not written in a language that is measurable or enforceable, or the problem is seemingly insurmountable because of legacy. The alternative is, therefore, to place the burden of adequate radio coverage on the community as a whole, or to settle for situations where public safety communications are not at all reliable.

Worldwide public safety agencies, including fire jurisdictions and police authorities, have adopted standards[1] for in-building public safety radio enhancement system (RES). These standards are developed to ensure adequate indoor radio coverage for fire fighters and police officers for emergency response. RES is better known in the industry as Distributed Antenna System (DAS), which is the typical solution to address the indoor radio coverage problem. DAS, as shown in Figure 2 that uses the pilot scheme in Telford Plaza as an example, is a network of components that distributes radio signals throughout the building from a central point. The system takes radio waves, amplifies and distributes them, by an off-air bi-directional amplifier (BDA) connected to an outside antenna which points to a donor site and a cabling structure[2]. Then, the BDA transmits the waves through remote antennas to provide adequate radio coverage. Apparently, DAS seems to give a solution to improve the in-building radio coverage for anyone who uses a cell phone, a police radio, or a wireless laptop. Using such traditional design of repeater systems, with distributed antennas or radiating coaxial feeders can obtain seamless internal radio coverage. A DAS solution does bear high installation costs and has a lengthy implementation time.

Another common solution is that Police deploy in-vehicle transportable repeaters to extend the range of police communications. Though the ad hoc repeater solution is not perfect, it has obvious advantages of easy and quick set up. And it can support limited internal coverage during emergency response.

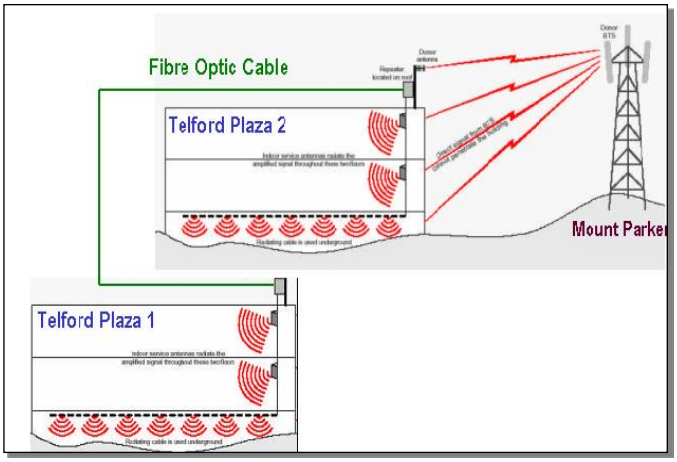

Figure 2: Distributed Antenna System at Telford Shopping Plaza.

[1] Section 510 of the International Fire Code (IFC), International Building Code, National Fire Protection Association (NFPA) Fire Code, and Recommendation 22 of the National Institute of Standards and Technology (NIST) are common industry standards.

[2] The cabling structure is normally made of coaxial cable or fibre optic (radio-over-fibre) depending on the length.

Concerns and Issues

The world is urbanizing at a rapid rate. In just a half century the world urban rate of population increase grew from about 30% to about 50% (Trzyna, 2007). There are growing police concerns and security problems associated with urbanization. Modern metropolis like New York, London, Tokyo, Dubai, Shanghai and Hong Kong are commonly known as digital cities. And ubiquitous wireless broadband connectivity is the key element for a digital city. These cities are concrete jungles packed with skyscrapers and underground cities. They are very dynamic and their infrastructure development will never stop. To cope with the extensive metropolitan development Hong Kong developers are building more indoor shopping malls, sport facilities, convention centers, hospitals, and warehouses. This trend poses even bigger operational and economical challenges to public safety in-building radio communications and emergency response.

It is seemingly mission impossible to refurbish all legacy buildings or to build a totally new comprehensive radio infrastructure for public safety inside all buildings, taking the constraints of time, cost and technicalities into consideration. On the other hand, real estate and public safety communities are challenged with providing full comprehensive radio coverage in parking garages, elevators, and open areas for both commercial devices like cell phones, smart phones, personal digital assistants (PDAs) and public safety radios. Building developers and owners now rate the ability to coordinate with local emergency responders as the most important public safety feature. Developers have a stronger motivation to meet building and fire codes involving safety. And they need better solutions that clear in-building radio coverage is made available for emergency personnel.

Likewise, first emergency responders are also nervous about switching from analogue to digital radio systems, where there is insufficient indoor coverage. This trend has accelerated during these years, with many discussions amongst all parties involved, and reflected as well as the conference program as a topic of increasing importance.

FINDINGS

Public Sector Reform

The Government is committed to providing the best services it can for the community. Its goal of enhancing public sector productivity and keeping down the public sector's share of the Gross Domestic Product (GDP) means that the police sector must examine new ways of providing services other than increasing the size of civil service. Private Sector Involvement

has been woven into the Government's reform measures, mainly in the form of outsourcing and public private partnership (PPP) (Grimsey and Lewis, 2004). In Hong Kong, PPP continues to be encouraged within the public sector as a means to improve coverage, effectiveness, efficiency and quality in the delivery of public services. With the few exceptions of Australia and Los Angeles, PPP has yet to be applied in emergency services worldwide. In fact, the Los Angeles County Police model has proved to provide a level of flexibility not achieved in a police officer–only model (but joined by private security resources). The authors were inspired to introduce a somewhat different application of the PPP model in a business case of providing reliable indoor police radio communications in a digital city like Hong Kong. Such model is depicted in Figure 3. The model allows the HKPF to use the spare communication bandwidth capacity of various mobile operators on-demand and in a just-in-time manner.

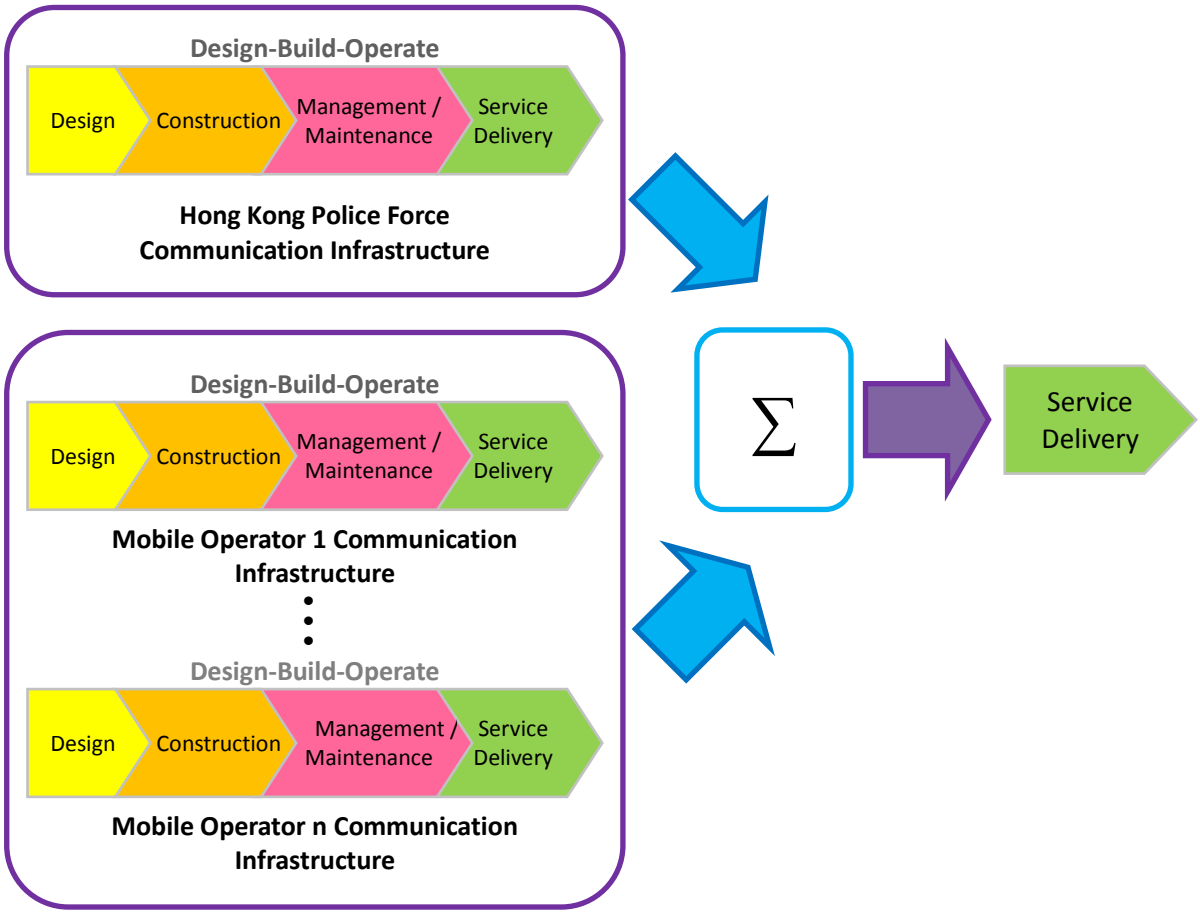

Figure 3: A Public-Private- Partnership-Win-Win-Win Business Model.

The Hong Kong public sector reform was originally conceived to provide focus for sustaining the integrity, efficiency and effectiveness of the public service during the transition in 1997. Through the development of the political accountability system it is now time to look forward to the tests that public service, including the police, will face in the next decade and

consider how the public service, as an institution, will rise to the 21st century challenges.

Change is Constant

Extensive criticism is frequently voiced against governments and bureaucracies worldwide, suggesting that the perceived rigid-red-tape nature, inefficiency, lack of flexibility, and negative attitudes towards change, will restrict social progress and economic growth in modern states. The Hong Kong civil service itself faces a huge social change, as the great "baby boomer" generation who built the new towns and other infrastructure projects of the last three decades retire and make way for a fresh influx of talent and ideas. The speed of change is increasing. This presents an opportunity to re-engineer and redeploy the public service to meet the needs of an evolving political system and an ageing, more socially diverse population, characterised by more rapidly changing ideas and opinions. Change is constant in today's world. Public service sustainability is therefore fundamental to the public security that individuals, families and business can enjoy in Hong Kong. Sustaining that framework with integrity, acumen and innovation is the responsibility of every public manager. And innovation is particularly relevant to increase the value delivered to stakeholders in a new environment.

Managing Changes by Innovation

Innovation is absolutely important in a public sector. Constant change requires constant innovation. In brief, there are three types of innovation: Technology Based Innovation, Design Based Innovation, and Business Model Based Innovation. In today's changing world it is imperative that public sector effectiveness and efficiency is constantly increased to deliver on constantly increasing value expectations made by the key stakeholders. In order to deliver on these expectations, it is essential to integrate the three types of innovation.

The Hong Kong Police Force has successfully rolled out the Third Generation Command and Control Communications System (CC3) in support of frontline beat patrol officers since 2006. Reliable and efficient radio communications are essential for their day-to-day policing duties. Seamless indoor radio coverage has always been a common challenge to all mobile radio systems and police radio waves are no exception, especially when beat officers are patrolling inside buildings such as shopping malls, basement floors, and carparks. The project work has a clear focus, about meeting the challenges of in-building police radio black-spots, by developing and deploying a novel and affordable technical design with an innovative business model, for the public safety sector to share the infrastructure facilities (in-building transmission and antennae systems) of the commercial mobile operators, with a view to

achieving win-win-win outcomes for stakeholders – police, commercial mobile operators, and members of the public.

PILOT SCHEME

Background

In 2008, police regions were invited to critically examine the locations where indoor coverage was absolutely essential according to the criteria laid down by the CC3 Operation Implementation Team. The criteria include: -

- Number of Incidents;
- Crime Reports;
- Pedestrian Average;
- Pedestrian Peak;
- High Risk Premises; and
- Public Events.

Based on some detailed analysis of the user requirement and factual statistical data submitted by police regions, 59 specific indoor locations were selected and endorsed by the HK Police Force Management for enhancement with CC3 indoor radio coverage.

To prove the PPP concept, the Telford Shopping Plaza was selected as a pilot site for the CC3 Indoor Coverage Enhancement Project. As the largest regional shopping and entertainment complex in East Kowloon, the Telford Plaza catchment area, as illustrated in Figure 4, will be both far and wide. In addition to the 560,000 East Kowloon residents and the 20,000 residents of Telford Gardens, the close proximity of the Kowloon Bay MTR station provides a steady flow of commuters averaging 150,000 per day.

Figure 4: Telford Shopping Plaza.

This service aligned with the HKPF's strategic direction for supporting frontline units. Such professional mobile radio services will empower frontline units with highly responsive and resilient communications capabilities to meet increasing safety and security needs, in particular patrol sub-units and criminal investigation teams. The frontline officers can respond to the public and solicit assistance in an effective and rapid manner.

Service Design

Efficient, User-friendly and Effective Service

Traditionally the frontline officers had to set-up a gateway repeater in proximity with fairly limited radio coverage to relay the outdoor CC3 signals into the indoor areas or by using the Direct Mode Operation (DMO) of CC3 radios for line-of-sight communications. In response to the operational needs from the frontline officers, this service design provides a quick-win deployment solution to the frontline officers. Officers can now rely on the enhanced radio coverage inside the Telford Plaza with seamless transition experience and without any communication interruptions or any manual interventions.

Innovation

Following the detailed survey, there are 76.3% (45) of locations with very good public mobile operator coverage at these 59 selected indoor locations. As such, HKPF can enjoy the radio coverage at such locations by riding CC3 radio on the public mobile operators' infrastructure. Currently, there are five public mobile operators in Hong Kong that deliver seamless mobile phone services inside the shopping malls with general radio penetration of over 95% at public areas. Three field trials were conducted with the mobile operators at Cheong Hing

Square, Yuen Long Neway Karaoke and Fu Chong Shopping Centre with encouraging results.

Taking the advantage of the technology, this enhancement project employed the wideband radio equipment (380MHz to 2100MHz) for CC3 radio signal riding on the current public mobile operators' infrastructure. The solution (riding on the public mobile operators' antenna and transmission infrastructure) is proven and the synergy effect has been evident during these field trials. Hence, the creative and innovative ideas were adopted for the delivery of the service.

Also, a new business model (Public-Private Partnership - PPP) between public and private sectors regarding the provision of public services over a private infrastructure is established. Purportedly, this is an effective means of bringing together social priorities with the managerial skills of the private sector, relieving the government from the burden of large capital expenditure, and transferring the risk of cost overruns. Rather than completely transferring public assets to the private sector, as with privatization, government and business work together to provide exceptional services.

Cost effectiveness

The aforesaid solution has been successfully delivered at Telford Plaza since August 2009. The project was commissioned by one of the public mobile operators in collaboration with Mass Transit Railway Corporation Limited (MTRCL) maintenance contractors, through competitive tendering, at an affordable cost. The cost saving is around 40% in comparison with the other engineering solutions but with an effective use of the existing resources inside the shopping mall. This initiative introduced minimal investment with maximum benefits to HKPF.

Service Implementation

Staff Communication

The Communications Branch of the HKPF played a leading role in providing close liaison with frontline officers to formulate the service strategy and implementation plan for the delivery of services. The disturbance to the end users was minimal.

Difficulties and Challenges

In the planning stage, it was anticipated that the following difficulties would happen during the implementation stage:

- Installation works at the shopping mall's public areas and inside the shop might affect the customer flows and be a high concern of the Management Office.
- The location of the outdoor antenna near the residential areas may cause inconvenience to the residents of Telford Garden.
- The selection criteria of the wideband radio component should consider the system scalability to Mobile 4G (Long Term Evolution, LTE) delivery in future.
- The appearance of the indoor antenna should match the indoor environment and not affect the corporate image of the Shopping Mall.

These inherent difficulties were factored into the design consideration during the detailed design stage. These challenges had been tackled and handled properly by a flexible and proactive approach:

- Night works were carried out at public areas after the closing of the shopping mall. In these locations, that did not allow for access for installation works, the antenna were relocated and diverted with detailed engineering prediction.
- Close liaison with the shopping mall management office to successfully install an outdoor antenna at the podium level of the commercial building and far away from residential areas was achieved.
- Wide band radio components were selected and will also fitted for the wideband Mobile delivery in future.
- The appearance and colour scheme of the antenna was approved by the shopping mall prior the installation.

End-users Early Buy-in

Upon the completion of works, the frontline officers were invited to take part in the User Acceptance Test at Telford Plaza. This ensured the services delivered would meet the user operational requirement in action.

Continuous Improvement

A project review was carried out by the senior management with post-implementation customer feedback. The lessons learned in the pilot scheme would be adopted for the full deployment works at remaining 58 locations. Under the new indoor premises, pre-provision of Radio Injection Ports for HKPF is to be considered with the policy support from Office of the Telecommunications Authority (OFTA). That will be beneficial and entail a minimal retrofit required for extending police radio coverage into the new indoor

premises.

RESULTS

On average the HKPF receives ten thousand 999 emergency calls daily. The performance pledge is to strive to respond to all genuine emergency calls within 9 minutes in the urban area and 15 minutes in the rural territory. As a continuous improvement initiative, the pilot scheme at Telford Plaza was implemented successfully in Aug 2009 with the following key achievements:

- A creative, innovative and sensible solution was evident with the new business model of Public-private Partnerships (PPP) (Grimsey and Lewis, 2004).
- Services delivered timely, within budget and meeting all user requirements. The implementation period was shortened from 3 to 6 months with projected cost saving of around 40% in comparison with the other engineering solutions achieving the same results.
- CC3 indoor radio coverage at Telford Plaza was enhanced, covering over 640,000 sq. fleet of floor space.
- Rental and electricity charges waivers were granted by the Shopping Mall.
- Excellent feedback was received from the end-users.

CONCLUSION

The operational challenge of extending radio communication support to frontline officers in the discharge of their duties at the indoor shopping malls has been met by this novel PPP approach. The operational efficiency and personal safety of frontline officers was achieved and the public safety to the community was enhanced.

Moreover, there are three perceived benefits of the “PPP Model” to both Government and Community. First, private sector resources, expertise and creativity, were exploited. Second, the commercial potential of government-held project (value-added commercial services are normally not government’s core-business), were maximized. Third, costs and risks have been managed in a proper manner and under strict control.

CC3 is a mission critical system for emergency response. Its productivity cannot be quantified but it enables the police to respond faster to emergencies. The time saved greatly enhances the chance of saving life in life and death situations. As a result of the innovation Hong Kong remains one of the safest and most stable cities in the world.

THE INVERTED U-SHAPED RELATIONSHIP BETWEEN BUSINESS UNITS' SLACK AND PERFORMANCE: THE CASE OF INDONESIA[1]

Fuad, Diponegoro University, Indonesia
fuad@undip.ac.id

ABSTRACT

This study reconciles the positive and negative views of behavioral theory of the firm and economists regarding slack. This study tested the non-linear effect of business units' slack to its performance outcome on 135 manufacturing business units in Indonesia. Using non-monotonic structural equations modeling, the study showed that corporate diversification positively affects the budgetary slack while it provides little evidence for the significant effect on financial slack. The study also indicated that both the financial and budgetary slack increased the financial and non-financial performance at some "peak" levels, and beyond them, they would hurt the business units performance.

Keywords: financial slack, budgetary slack, financial and non financial performance

INTRODUCTION

Slack that is defined as the excess of resources above the necessary minimum to produce a given level of organizational output has been an important and intriguing domain in management accounting literature. Particularly it is because of the opposing theoretical streams among economists and behavioral accountants on the true role of slack that have led confusions among the researchers to justify the conclusive, robust findings. Accounting "behaviorists" for instance, have evoked the use of idle resources that may act as a buffer from environmental pressures (Lin et al. 2008, Patzelt et al. 2008, Geiger & Makri 2006, George 2008, Stede, 2000; 2001a; Cyert & March, 1963), or as a shock absorber (Merchant 1985), and as a buffer to engage in risk taking/innovative behavior (Yang et al. 2009, Herold et al., 2006; Love & Nohria, 2005). These "idle resources" are, therefore, important in providing organizations capabilities to act in ways that are not possible for other organizations poorer in resources (Nohria & Gulati, 1996). George (2005) maintained that the presence of slack can be used as an enactment of strategies. Lawson (2001) urged that attempts to reduce slack may be ill-advised; and in a more provoking position, Martinez and Artz (2006) even argued that "it is not possible for a firm to survive long without the presence of resources above and beyond its immediate needs" (p.12)

On the other hand, economists such as Jensen (1986; 1993) and Jensen and Meckling (1986) argued that slack reduces incentives to innovate and promotes undisciplined investment in R&D activities. They further argued that this slack creation rarely yield economic benefits and reflects the self-serving interest of managers. Bourgeois (1981) and Yasai-Ardekani

[1] The paper is funded by Indonesian Higher Degree General Directorate, Ministry of Education, Indonesia , under scheme No 238/E5/LL/2011

(1986) documented that slack promotes the creation of suboptimal systems, processes, and structures that reduce a firm's aggressive explorations of new responses (e.g. innovation, creativity). In fact, as been noted by Cheng and Kesner (1997), the term slack itself conjures up a host of negative perceptions.

This study is not going to pick either side of this debate, but rather this study aims to provide a way out of this intractable debate by reconciling the views of economists and accountants. Particularly, this study proposes that there is a "curse" and at the same, "bless" for both approaches. In simpler words, current study maintains that there is an inverted U-shaped between slack and performance, in which the relationship is positive and may turn to negative when the extent of slack reaches its optimum peak.

Although the positive and negative impact of slack have been recognized in the literature, few research in management accounting has attempted to test whether slack is good or bad for business units performance. Bourgeois (1981), trying to reconcile economists and behaviorists, postulated a curvilinear relationship between slack and organizational performance in general. Recent studies by Nohria and Gulati (1996), Geiger and Cashen (2002) and Herold et al. (2006) have extended the non-linear argument between slack and R&D intensity. They argued that R&D activities cannot be carried out without any slack available; and on the other hand, too much slack may deteriorate the R&D due to wasted spending and careless innovation projects.

Furthermore, this study believes that lack of interpretable results between slack and its outcome may not be looked on the relationships, *per se*. but the focus of the study must also be directed to the slack conceptualization that we believe, is the source of those intractable, unsolved debate. Slack creation, that can be traced back to the behavioral theory of the firm (see seminal works of Cyert and March, 1963 and Bourgeois, 1980) is a multi-dimensional construct, and not as observed variable that can be traced directly to the budgeting process of a firm. The use of subjective measures *per se* raises some question about the accuracy in measuring budgetary slack. Organizational theorists (e.g. Bourgeouis, 1981; Cyert & March, 1963) proposed objective measures of slack in organization that rarely put into considerations in management accounting research, despite its flourishing use of its conceptualizations. Such objective measures were usually operationalized using financial indicators of slack such as absorbed and unabsorbed slack (Singh, 1986) and available (Ahuja, 2000, Combs & Ketchen, 1999), recoverable (Steensma & Corley, 2000) and potential slack (Simerly & Li, 2000, see also Daniel et al., 2004 for a meta analysis). Therefore, in order to provide a more meaningful result, this study looks at slack from the objective and subjective measures.

Therefore, this study aims to examine the non-linear pattern of multidimensional construct of organizational slack to its performance outcome. As a consequence, this study also contributes to the wide-array of accounting literature in several ways. First, this study is among the first to test the non-linear attributes regarding the relationship between slack and performance, in their higher order terms (multi-dimensional constructs). Second, this study provides a way out of the intractable debate between behaviorists and economists by reconciling those views. In particular, this study insists that there is "curse" in both "too few slack" and "too much slack". For instance, too few slack may inhibit the business units to

flexibly engage in their activities because there is no room to make maneuvers (as there is no idle resource). On the other hand, too much slack reveals inefficiency and pursues the business units to make insufficient, pet projects that may not yield economic benefits to the organizations.

This study is decomposed into several sections. The next part of this study explains in detail the literature review and hypotheses developments, while the methodology of the study is explained in the third part. The fourth and fifth parts of the study elaborate the findings and discussion, while the conclusion, limitations and avenues for further research are discussed in the last section.

LITERATURE REVIEW AND HYPOTHESES DEVELOPMENT

Nature of Organizational Slack

The leading view of financial (organizational) slack used in the literature is one based on Cyert and March (1963), in their seminal work entitled *A Behavioral Theory of the Firm*. They are credited and cited most often for their preconceived ideas on organizational slack. Their impressive essence conceptualization of slack was excess of payments over the minimum necessary required to maintain the organization that took an additional idea which is so-called "reserved resources". Thus, it is likely that members of the organization may have a different resource needs and different slack requirement depending upon environmental favorableness. Cyert and March (1963) suggest the need for slack as a buffer by proposing that

> …it seems to be useful in dealing with the adjustment of firms to gross shifts in the external environment…When the environment becomes less favorable, organizational slack represents a cushion. Resource scarcity brings on renewed bargaining and tends to cut heavily into the excess payments introduced during plush times…the cushion provided by organizational slack permits firms to survive in the face of adversity. (pp. 37-38)

A great deal of authors have then defined slack into diverse conceptualizations (kindly compare the works of Nohria & Gulati, 1996; George, 2005; Chattopadyay, 2001; Love & Nohria, 2005; Martinez & Artz, 2006, among others). These various conceptualizations also lead to the conflicting stands regarding the benefits and disadvantages of having slack in an organization (refer to table 1)

Table 1: Positive and negative impacts of organizational slack.

Positive impacts of organizational slack	Negative impacts of organizational slack
1. enhance the fit between strategy and structure (George 2005)	1. reflects organizational inefficiency (Bourgeois, 1981; Jensen and Meckling 1978)
2. influences ability of a firm to adapt to its environment (Bourgeois, 1981; Miller et. 1996)	2. encourages a lack of discipline
3. facilitates innovation (Cyert & March, 1963; Herold et al. 2006, Martinez & Artz 2006; Nohria & Gulati 1995)	3. Diminishes incentives to innovate (Jensen 1986)
4. Encourages increased risk-taking (Martinez & Artz, 2006; Singh 1986)	4. enhancing the non-optimizing behavior (Bourgeois 1981, Jensen & Meckling 1978)
5. Facilitates creative strategic behavior (Bourgeois 1981; McGratch & macMillan, 2000; George 2005)	5. Loosen the management control systems (Davis & Stout 1992)
6. Encourages experimentation (Bourgeois 1981)	6. leads to wasted resources and careless spending (McGrath & MacMillan 2000)
7. Encourages increased risk-taking (Singh 1986)	
8. Supports exploitation of opportunities (Bourgeois 1981)	

Financial Slack

Slack resources can be measured using several financial indicators. Most prior researches differentiate slack into three main typologies; which are available, recoverable, and potential slack resources (Bourgeois, 1981; Bourgeois & Singh, 1983; Sharfman et al, 1988; Singh, 1986). Available slack (that can also be referred as unobserved slack) describes the resources that are available but not yet committed for any particular allocation such as the funding for innovation activities or dividend payments to shareholders (Martinez & Artz, 2006). Recoverable slack (as it is sometimes referred as absorbed slack) represents resources that have been allocated and absorbed by the organization but can be easily recovered through cost-cutting and efficiency. One example of recoverable slack is the overhead costs for executive salary. Nevertheless, as pointed out by Herold et al. (2006) and Hendrick (2006), although recoverable slack is theoretically easy to recover, but in practice the recovery could be difficult and may bring out some strong negative consequences. Potential slack on the other hand is simply conceptualized as the organization's future

capability to earn resources. Usually potential slack is basically operationalized as the extent of equity capital owned by the company.

The presence of slack has been linked to the idle capacity of the firms. As company resources increase, the presence of slack in organization also increases, but in a faster rate (e.g. Cyert & March 1963). In contrary, when the company resources decrease, organizational slack decreases, also at a faster rate. The financial mechanism of slack over time is a function of sales growth, profitability, situational and behavioral factors. Leavins (1995) postulated that the slack in the highly performing firms inherently tend to increase, but firms can find many alternative ways to reduce the costs if they are forced to do so. This relationship was modeled by Wolf (1971) as:

$$\frac{\Delta E}{\Delta R} > 0, \frac{\Delta SGE}{\Delta E} > 0 \text{ , and } \frac{\Delta E}{\Delta R} < \frac{\Delta SGE}{\Delta R}$$

Use of resources in a slack building state

$$\frac{\Delta E}{\Delta R} < 0, \frac{\Delta SGE}{\Delta R} < 0 \text{ , and } \frac{\Delta E}{\Delta R} > \frac{\Delta SGE}{\Delta R}$$

Use of resources in a slack reduction state

ΔE indicates the change on profit on time t and t-1 while ΔR denotes the change on revenue, while ΔSGE denotes the change on selling and general expenses. The models obviously evoke the question why firms have lower change of profit while on the profitable situation, and they still can operate normally and earn above-average profit even in a very fierce situation, as is the case of some organizations in the crisis period.

Budgetary Slack

Earlier work defined budgetary slack as the result of management's consciousness and intentional behavior during the budgetary process as an outcome of rigid budgetary evaluation (Schiff and Lewin 1968). Recently, Douglas et al. (2007) defined budgetary slack as the variances of actual spending and budgeted spending and the difference between the expected and actual performance. Garrison et al. (2006) proposed budgetary slack as the consequence of self-imposed budget which might result in inefficiency and waste. On the other hand, Yuen (2004) conceptualized budgetary slack as the building of excess resources in a budget or understating productive capability and thus will make the budget easier to attain. Douglas and Wier (2000) claimed that budgetary biasing behavior is the difference between planned performance target and real performance capabilities. Leavin et al. (1995) insisted that budgetary slack exist due to the results of management conscious and intentional behavior during the budgetary process.

The non-linear relationship between slack and performance

Organizational slack which is the available resources above immediate, required needs is one possible source of funding for many activities. Therefore, several researchers have linked the needs of slack for innovation-lead performance activities. Nohria and Gulati (1996) insisted that slack may increase the undisciplined investment and thereby deteriorating the innovation activities.

A behavioral theory of the firm would maintain that slack to have some positive impacts on performance in several ways (Cyert & March, 1963; Bourgeois, 1981). First, the presence of slack may loosen the managerial controls rigidity of a particular organization (Cyert & March, 1963), allowing manages to embark on discretionary steps in pursuing new projects (Geiger & Makri, 2006). Second, the slack resources can be consumed during bad times and thus becoming less vulnerable to the uncertainty of experimental projects and thereby increasing the innovative cultures (Nohria & Gulati, 1996). Members of the organization are also less likely to worry about the risk of failure in embarking a particular project because they have resources as a buffer against the failure (Geiger & Makri, 2006).

On the other hand, slack has been argued to have some negative impacts on performance as the managers may utilize the slack resources for less risky activities thereby may decrease the experimentation and innovation activities (Denis et al., 1999; Jensen, 1986). Agency perspective also warned the use of slack not as to foster experimentation and innovation, rather as a resource to maximize their own personal wealth or interests. On the other hand, X-Efficiency theory of Leibenstein (1978) view slack as wasteful and incompetence of business units. These two views of theories would maintain that slack should be reduced and if possible eliminated.

Reconciling the behavioral theory of the firm and economics, it is interesting to note that slack can be a blessing and a curse, implying the presence of curvilinear relationship between slack and performance. The advocates of slack (a behavioral theory of the firm) maintained that slack as a resource facilitating proactive strategic actions and thereby increasing performance (Daniel et al., 2004). In contrary, those who assume slack as idle resources denotes for inefficiency (X-Efficiency (Leibenstein, 1966; theory of the firm of Jensen & Meckling, 1978) and diminish long term organizational performance. This inefficiency paradigm also posits that slack can encourage satisfying or self-serving behavior that hurt performance. For instance, Jensen and Meckling (1978) and Jensen (1986) maintained that the presence of excess resources may enhance the managers tendency to pursue self-serving projects.

It is therefore, interesting to figure out whether there is a “curse” in both the economics and behavioral perspectives. In this vein, organization must have excess resources to absorb for the unforeseen contingencies but not too much so that preventing the self-serving behavior of the managers.. Therefore, this study predicts that *the relationship between slack and performance is inverted U-Shaped*.

METHODOLOGY

The population frames of current study, where the source of data were gathered, were from several sources. Corporate parents' annual reports and Indonesian Capital Market Directory (ICMD) 2006 & 2007 were used to identify the number of business units being controlled and firms-specific financial attributes. ICMD periodically published a concise public firm's financial statements. Firm's annual reports were then utilized to identify the business units. Another set of directory that was used in this study is Indonesian Manufacturing Industry Directory (IMID) that is issued periodically. This directory was useful in identifying addresses, primary products and employment of business units. The total manufacturing companies per December 2006 is 20,890 companies.

In order to ensure the validity of the findings, the study restricts the sampling procedure into a subsidiary of a corporate with a 50% ownership minimum and must at least own two subsidiaries. Therefore, this study was conducted at the business units' level in order to understand the ways, effectiveness and appropriateness of control and monitoring activities placed by the corporate parents.

The cover letter involving questionnaires were sent via mail (in stamped addressed envelope) directly to the top and middle level manager in a respective business unit since they are the ones that have considerable contact with the corporate. The cover letters also assured that there would be no responses attributed to any individual or business unit, and only statistical, summary data from the total responses from several business units would be published.

The questionnaires were developed using 6 item Liker scale. The use of six items Likert scale has been commonly employed in social sciences and in fact, may result in greater efficiency and reliability (Chang 1994). A study conducted by Infosurv (2006) and CICIES (2007) indicates that some respondents prefer the 6-items Likert Scale because the respondents have to commit to either positive or negative values, without any neutral point.

Operationalization of Variables

Organizational Slack

Business units' slack, in this study, is conceptualized as the excess of actual or potential resources that could assist the organization to absorb the environmental pressures and shocks (Bourgeouis, 1980). This variable is a multidimensional constructs consist of two dimensions: financial (business units' slack and budgetary slack).

Financial slack represents the extent to which the organizations have the access to the resources to be further utilized during unexpected shocks or take immediate actions for the emergent opportunities (Martinez & Artz, 2006). With regard to this financial slack, agreement has been reached pertaining to its operationalizations. Usually, it consists of available slack, potential slack and recoverable slack. For these variables, two steps were employed. The study use archival, objective measures of business units slack generated from annually financial statements and/or annual report. If these data were not available,

survey method will be conducted. Business units managers will be asked to indicate the amount of slack (proxied by several financial ratios) in their business units. If both data are available, objective measures will be used since there is no social obligation from managers to report good results thereby increasing the validity of the data.

Financial slack is measured using three indicators: 1) available slack that is determined according to current ratio (i.e. current assets/current liabilities) which a reflection of organizations' resources availability on terms of liquid assets that can be used as a buffer from the negative implications of environmental shocks (Herold et al., 2006). Current assets in this study are simply defined as the assets that can be easily converted into cash within a short time. It consists of cash, marketable securities, receivables, inventories and other short term assets. Current reliabilities on the other hand is the financial obligations that have to be settled within a short period of time. 2) potential slack, that is defined as the firm's ability to have new capital resources through debt borrowings (Martinez & Artz, 2006). Following Palich et al. (2000) and Simerly and Li (2000) suggestions, this study measures potential slack as debt-equity ratio**.** 3) recoverable slack, that is also known as absorbed slack, is the extent to which resources are embedded in firms as excess costs but could be recovered through when firms experience financial difficulty (Singh, 1986). Following Geiger and Makri (2006), recoverable slack is measured by selling, general and administrative expenses divided by sales**.**

Budgetary slack, on the other hand, is defined as manager's likelihood to set the budgets lower by underestimating the budgeted revenues and overestimating the budgeted costs so that the budget targets becomes easier to achieve. (Lukka, 1988). This variable was measured by Dunk (1993) and Stede's (2000; 2001) measurement consists of 5 items (items 1-4, using 6 items Likert's scale from strongly disagree to strongly agree, and item 5 is fully anchored question asking whether the budget is very easy to attain until impossible to attain). Following Stede (2001, p. 41), the questionnaires include: 1. Succeed to submit budgets that are easily attainable; 2. Budget target induce high productivity in my business unit (reverse coded); 3. Budget target requires cost to be managed carefully in my business unit; 4. Budget target have not caused me to be particularly concerned with improving efficiency in my business unit; and 5. a fully anchored question: "My Business unit budget is…" from very easy to attain to impossible to attain

Performance

Current study adopted two widely used of financial performance, which are Return on Assets, Return on Equity, operating profit and sales growth. Moreover, subjective measures of business unit performance were also employed. Using financial, objective measures of performance will increase the likelihood the presence of 1 or more year lag relationship between slack and performance. For instance, slack resources may not affect the performance on its current year, but it probably affects performance on its 1 or more year a head. While subjective, non-quantitative measures of performance are created using the measurements of Birkinshaw et al. (2005). In this vein, the performance of business units managers are evaluated, relative to other business units, on the basis of their productivity, quality, supplier relationships, labor costs, productivity improvements, technology and

customer development on a six point scale, ranging from 1=significantly worse than competitors, and 6 = significantly better than competitors.

Data Analyses

Structural Equation Modeling (SEM) was employed in this study for several reasons. First, SEM allows the analysis of multiple relationships simultaneously that cannot be conducted by other conventional multiple regressions analyses. Thus, SEM accounts for the presence of structural errors. Ignoring these errors may lead to the specification errors affecting validity of the results. Second, SEM provides measures of overall model fit. These measures were important to figure whether the model is acceptable given a particular data. Third, and most importantly, SEM explains the significance of each relationship between the variables hypothesized. SEM also allows for testing the indirect effects between variables. Fourth, unlike regression models and path analysis, SEM may account for the effects of measurement errors in multi-item variables (constructs). Since constructs were measured using multiple indicators, it is unreasonable to assume that these constructs are error-free, and instead, there are potential errors in those indicators.

In testing the non-monotonic relationship of the hypothesis, this study adopts an approach suggested by Ping (2004, 1995) and Cohen et al. (2003) involving two steps. In the first step, the measurement model is evaluated by Confirmatory Factor Analysis. The measurement model assessed whether all items in a given scale represented the same latent factor. Second, the structural model then examined to ensure whether the variables hypothesized were fit. On the next step, an estimation technique is proposed for quadratic latent variables in structural equation modeling specifying these quadratic latent variables with a single indicator (Ghozali & Fuad, 2004). With regard to this single indicator approach, the quadratic product (*x:x*) of slack is specified as $[x_1 + x_2 + \ldots + x_n]^2$. The loadings ($\lambda_{x:x}$) are given by $[\lambda_{x1} + \lambda_{x2} + \ldots + \lambda_n]^2$ and measurement errors ($\theta_{x:x}$) are fixed by $[4(\lambda_{x1} + \lambda_{x2} + \ldots + \lambda_n)^2$. VAR(X). $(\theta_{\varepsilon.x1} + \theta_{\varepsilon.x2} + \ldots + \theta_{\varepsilon.xn})$. As been suggested by Anderson and Gerbing (1988), use of a measurement model must be separated from model structure issues. Therefore, besides using the measurement model to ensure unidimensionality of the constructs, parameter estimates from a linear-term measurement model can be used to compute the values of $\lambda_{x:x}$ and $\theta_{x:x}$ (fixed loadings and fixed errors, respectively). This approach may eliminate the substantial differences in the estimated parameters of measurement models and structural models (Ping, 1995).

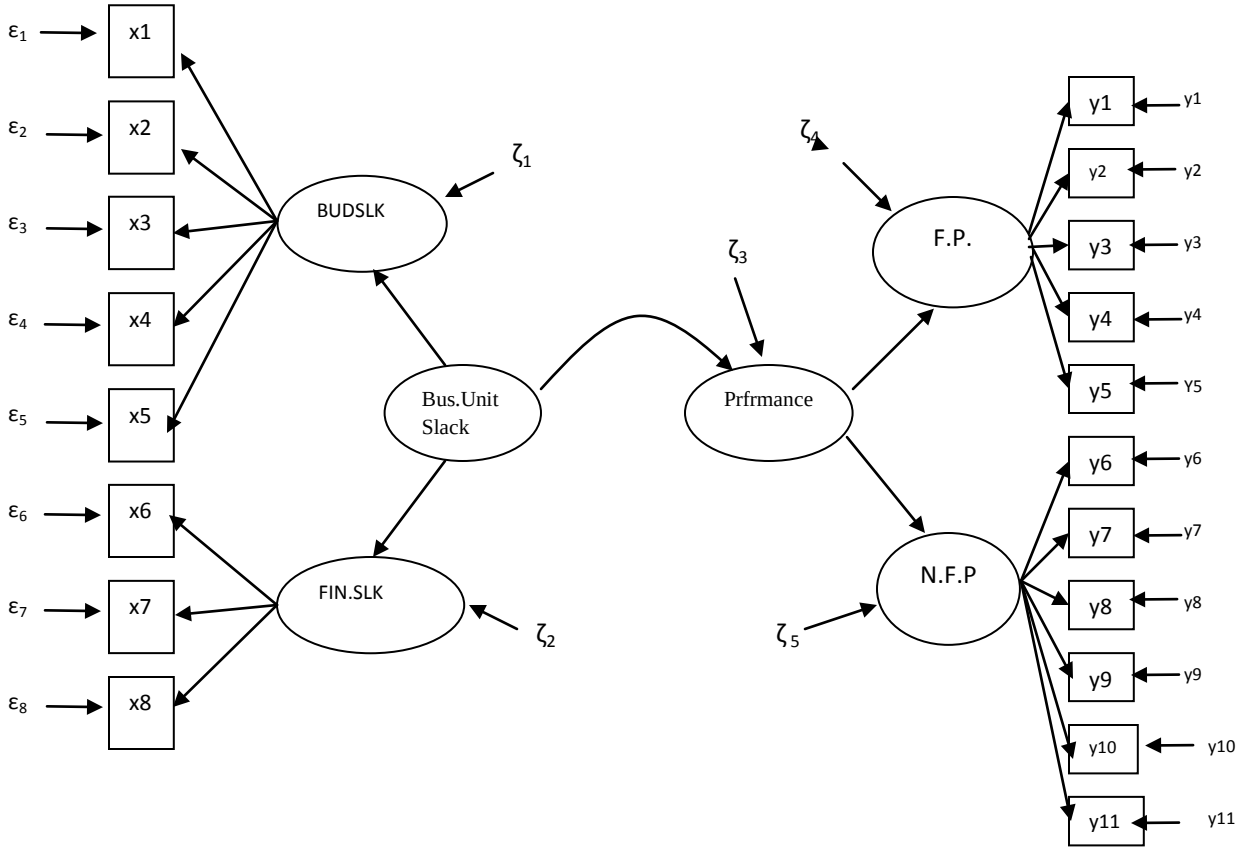

Figure 1: the structural model of second order performance outcome of business units' slack.

This model is estimated using this polynomial technique by (1) estimating the measurement model parameters, (2) calculating the equations above to generate the loading ($\lambda_{x:x}$) and error variances ($\theta_{x:x}$) for the quadratic latent variable, and (3) estimating the structural model with the fixed values of $\lambda_{x:x}$ and $\theta_{x:x}$. This method employed Linear Structural Relationship using Maximum Likelihood approach. This procedure requires mean-centered indicators for both exogenous and endogenous latent variables, which is created by subtracting the indicator's mean with its each value in the data set per case (i.e. $[x_i - \mu_x]$; where x_i denotes for observation *i-th* of *x* manifest variables and μ_x denotes for mean of a particular manifest variable *x*). the model fit was tested by several indices. Table 2 portrays important indices and their respective cut-offs.

RESULTS

The profile of business units are clearly portrayed in table 5.6. Business units with public-listed corporate parent comprise 55% of the sample while the remaining 45% are business units with non-public listed corporate parent. Regarding the size of the firm (in terms of average sales), sixty seven business units are considered large as they earn more than Rp 10 billion on sales, fifty one are considered medium as they make Rp.5-10 billion sales while seventeen are regard as small since their average sales are less than Rp 5 billion. Regarding the types of the business units, seventy five business units are local based-company seeing that their products are aimed for local markets, while sixty business units are multi-national company. Regarding the business units tenure, eighty one business units have been in operation for more than ten years, while fifty three business units have been in operation for 6-10 years.

Pertaining to the production type, fifty one business units engage in food and beverages industry, thirty one in textile mill products, twenty nine in lumber and wood products, and twenty three business units enroll in chemical and allied products. Regarding the focus of their market, forty five business units focus on local market and twenty one business units focus on export market. Sixty nine business units focus on both local and export market. All of the respondents reveal that they are involved in the budgeting process, but only sixty nine of one hundred thirty five receive full autonomy from the corporate parent, while the remaining sixty six business units hold no/partial autonomy.

Table 2: Business units' characteristics.

	Frequency	Percent
Corporate Status		
- Public Listed	74	54.8
- Non-public listed	61	45.2
Type of Business Units		
- Local based Company	75	55.6
- Multi-national Company	60	44.4
Business Units Tenure		
- 1-5 years	1	0.07
- 6-10 years	53	39.3
- More than 10 years	81	60
Production Type		
- Food and Beverage	51	37.8
- Textile Mill Products	31	23
- Lumber and Wood Products	29	21.5
- Chemical and Allied Products	23	17
- Others	1	0.07
Type of Products		
- Consumer products	77	57
- Industrial products	52	38.5
- Both or others	6	4.4
Autonomy		
- Full Autonomy	69	48.9
- Partial/No autonomy	66	51.1

The result of Confirmatory Factor Analysis (CFA) in the first step is conducted in order to calculate the fixed loadings and error variances for the second step are portrayed in table 3. The results below did not used for measurement models testing. Rather, this step is conducted in order to uncover the fixed and constrained values for the single indicator of quadratic latent variables of financial and budgetary slack.

Table 3: *First step of Ping (2004) approach in non-linear Structural Equations Modeling.*

Items	Loading	Errors	R^2
BUDSLK1	0.39	0.84	0.16
BUDSLK2	0.55	0.69	0.31
BUDSLK3	0.38	0.85	0.15
BUDSLK4	0.39	0.85	0.15
BUDSLK5	0.40	0.84	0.16
CRT	0.21	0.96	0.04
DERT	-0.31	0.90	0.1
SLEXT	0.38	0.86	0.14

Applying the generated loadings to $[\lambda_{x1} + \lambda_{x2} + \ldots + \lambda_n]^2$ yield the constrained loadings for budgetary slack of 2.01 and financial slack of 0.1296. Furthermore, applying the generated error variances to $[4(\lambda_{x1} + \lambda_{x2} + \ldots + \lambda_n)^2$. VAR(X). $(\theta_{\varepsilon.x1} + \theta_{\varepsilon.x2} + \ldots + \theta_{\varepsilon.xn})$ yield constrained error variance about 73.528 for budgetary slack and 1.399 for financial slack. Thus, the measurement model for non-linear outcome performance equation is:

$$\begin{Bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \\ x_6 \\ x_7 \\ x_8 \\ x_9 \\ x_{10} \end{Bmatrix} = \begin{Bmatrix} \lambda_{x1.1} & 0 & 0 & 0 \\ \lambda_{x2.1} & 0 & 0 & 0 \\ \lambda_{x3.1} & 0 & 0 & 0 \\ \lambda_{x4.1} & 0 & 0 & 0 \\ \lambda_{x5.1} & 0 & 0 & 0 \\ 0 & \lambda_{y1.2} & 0 & 0 \\ 0 & \lambda_{y2.2} & 0 & 0 \\ 0 & \lambda_{y3.2} & 0 & 0 \\ 0 & 0 & 4.4944 & 0 \\ 0 & 0 & 0 & 0.1296 \end{Bmatrix} \begin{Bmatrix} \xi_1 \\ \xi_2 \\ \xi_3 \\ \xi_4 \end{Bmatrix} + \begin{Bmatrix} \delta_1 \\ \delta_2 \\ \delta_3 \\ \delta_4 \\ \delta \\ \delta_6 \\ \delta_7 \\ \delta_8 \\ 73.528 \\ 1.399 \end{Bmatrix}$$

The constrained error variances and loadings generated then used to calculate the non-monotonic relationships hypothesized in this study. The results are depicted in table 4. The results indicate that there is an inverted U-shaped ($\cap$) relationship between financial slack and financial performance (γ = -0.027, t = -6.90). However, the proposed inverted relationship between financial slack and non-financial performance cannot be accepted (γ = -0.0035, t = -1.18).

Table 4: Results of Non-linear Structural Equations Modelings.

The Effect of…	To…	Estimates	t-values
Financial Slack	Financial Performance	0.73	7.37*
Budgetary Slack	Financial Performance	-0.25	-2.45*
Financial Slack^2	Financial Performance	-0.034	-6.96*
Budgetary Slack^2	Financial Performance	0.0082	1.02
Financial Slack	Non-Financial Performance	0.28	3.84*
Budgetary Slack	Non-Financial Performance	0.52	6.39*
Financial Slack^2	Non-Financial Performance	-0.0043	-1.15
Budgetary Slack^2	Non-Financial Performance	-0.0061	-7.90*

Interestingly, this study found that there is no quadratic effect of budgetary slack to financial performance (γ = 0.002, t = 1.10), but hinted the presence of non-linear relationship ($\cap$) between budgetary slack and non-financial performance (γ = -0.013, t = -7.90).

The results can also be elaborated to figure-out the optimum level of slack. For instance, the results above indicate that there is a non-linear relationship between financial slack and financial performance. For a simple non linear function of $Y = b_1 X + b_2X^2 + e$, the maximum value of vertex (peak value of the parabolic graph) would be $-b_1/2b_2$. Kindly recall that the non-linear structural equation function is FP = 0.73*FS + -0.034*FP+0.28 therefore, the maximum value of the vertex would be = 0.73/(2*-0.034). The graph below visualizes the non linear relationship between financial slack and financial performance.

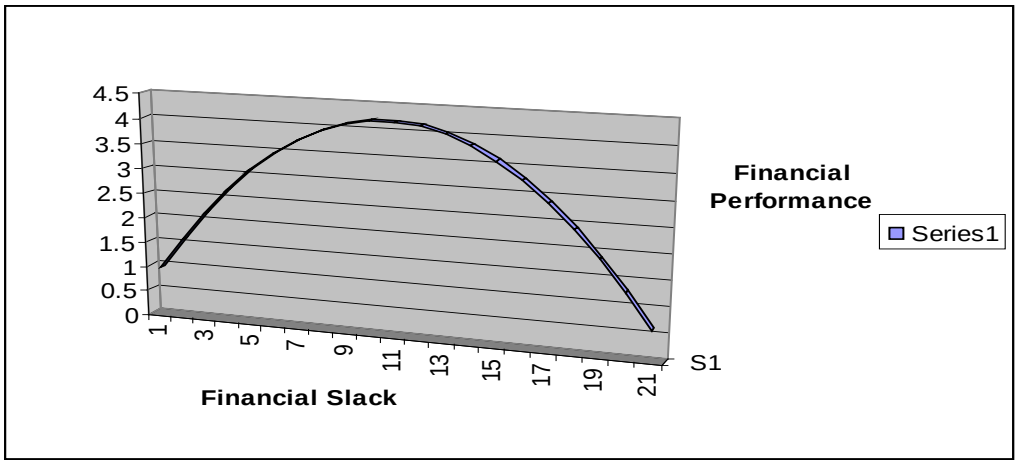

Figure 1: The non-linear relationship between financial slack and financial performance.

DISCUSSION

This study cannot test the effect of higher order business units' slack to higher order overall performance as the model did not fit well with the data. Rather, this study examines the non-

monotonic impacts of lower order exogenous variables of business units' slack (e.g. financial and budgetary slack) to lower order endogenous variables of performance (e.g. financial and non-financial performance). The acceptance or rejection of the hypothesis therefore, is based on this assumption.

This study found that there is a non-monotonic relationship between financial slack and financial performance. In particular, this study found that the relationship between financial slack and financial-performance is inverted U-Shaped. It means that the relationship between financial slack and financial performance is positive, until it reaches the peak point and then turn to negative. Hence, it signifies that there is a "curse" in both very few financial slack and too much financial slack pertaining to its effect with financial performance.

This non monotonic (∩) relationship implicitly concurs with several arguments on the slack-performance relationships (Latham & Braun 2008; George, 2005; Tan and Peng, 2003; Nohria and Gulati, 1996). This finding substantiates the joint roles of behavioral theory of the firm as well as economist perspectives. The behavioral theory of the firm argues that slack as good and may increase the innovative ideas and to absorb the shock of environmental turbulent and thus may increase the firm's financial performance. After some level, based upon the perspective of economist, too much slack may inhibit the innovative ideas as there is a great chance that the business units will be investing in pet-, non productive projects, and therefore may inhibit financial performance.

However, it is interesting to figure out that the alternative hypothesis of the non-linear effect of financial slack to non-financial performance cannot be accepted. One main possible explanation for this failure is probably due to the presence of lag effect financial slack to non-financial performance. In particular, the presence of financial slack may not directly affect the non-financial performance in a timely manner, rather, it is plausible that the effect can only be seen within the next few years a head. Or simply stated, current financial slack may impinge on future non-financial performance (e.g. productivity, product quality, supplier relationship, productivity improvement, technology, customer development and labor cost). However, this speculation cannot be further tested as this study is cross-sectional in nature and such longitudinal data are very hard to attain. The use of objective, pure quantitative data may also be blamed for such a finding.

Furthermore, the result of this study indicates the rejection of the alternative hypothesis regarding non-monotonic relationship between budgetary slack and financial performance. Rather, this study found the negative, linear effect of budgetary slack to financial performance. Several arguments are offered regarding the non-acceptance of non-linear effects of budgetary slack ton financial performance and acceptance of negative linear effect of budgetary slack to financial performance. First, the sample of this study is the business units that are held accountable on terms of the cost spent and revenues generated, or simply stated the samples were profit centers of the corporate parents. With this regards, the slack creation during the budgeting process implicitly means the flexibility, innovativeness and creativeness that are transformed into operating actions that shall yield in short-term profit or performance. Indeed,

there is a possibility that the positive effects of budgetary slack to financial performance may not be exist in the long-run, as they may in fact impair the long-term profitability. Nevertheless, this argument cannot be further tested in this particular finding as longitudinal or pooled, cross-series study should play a major approach for this type of study.

Furthermore, as expected, this study found the presence of non-monotonic relationship between budgetary slack and non-financial performance. This finding indicate that slack creation during the budgeting process yields the intangible performance, but again, too much budgetary slack may in fact impair the stability of the firms' particularly on terms of its intangible performance relative to business unit's performance. This finding apparently solve the intractable debate between "behavioral accountants" (Stede 2000; 2001, Davis et al., 2006; among others) and the economists (so called "theorists of the firm" such as Jensen, 1986; Jensen & Meckling, 1976 among others) regarding the non (discretionary) use of budgetary slack to the performance.

CONCLUSION

The findings of these studies need to be considered in light of several limitations. First, the research was confined to a manufacturing industry in Indonesia, and thus generalizations to other industries should be used with extra cautions. It is very plausible that the pattern of relationships between the slack and performance may be different than those found in this study.

In order to provide fruitful findings, as well as robust generalizations of the estimated parameters, further study should consider other industries, particularly in Indonesia. Martinez and Artz (2006), Hendrick (2006), Combs and Ketchen (1999), Hitt et al. (1991), and many others argued that slack requirement may be different among different industries, and thus the reasons and its outcome may be different from one industry to another.

Second, it is necessary to acknowledge the limitation of cross sectional based survey research, as such this study design prevent any test on causal statement on the time series basis. Besides, slack creation can be an accumulation of several periods phenomenon. In particular, the slack creation may not affect the performance in the timely manner, but they may be transformed and require time period to show its real effect. For instance, slack may affect future performance, instead of current performance. With this regard, future research should also consider the time series properties of the data, particularly on the contextual variables affecting business units' slack and slack outcome to performance.

ABSTRACT

Technology-based service encounter (TBSE) is an important role in service industry especially in the area of marketing and consumer behavior. Prior research have mostly focused on the interaction of organization and end-user. This study aimed to examine TBSE adopted by the hospital and validate the moderating effect of technology readiness on the relationships among TBSE towards service quality and perceived value. With paper-based questionnaire, the quality and value of TBSE were evaluated by the clinical staff to understand whether it could meet their needs and desires when serving the patients. Statistical methods such as structural modeling equation (SEM) and hierarchical regression analysis were conducted for data analysis. The results revealed that TBSE has direct effect on both service quality and perceived value; and both of them also have direct effect on satisfaction of using TBSE. Technology readiness was showed to have moderating effect on the relationship between TBSE and service quality but not on TBSE and perceived value. The additional analysis revealed a direct and significant effect on both TBSE and perceived value. From the managerial perspective, staff opinions are important for making decision of implementing or upgrading new technologies. The management should encourage staffs continue learning and exchange their knowledge to use TBSE more completely, ultimately, enhancing the service quality. Manufacturer or provider should pay more attention to the feedback from institutes and establishing a tight relationship to develop good impression and enhance satisfaction of the staffs.

Keywords: Technology-based service encounters (TBSE); service quality; perceived value; technology readiness

INTRODUCTION

Service encounters are very important and crucial for all industries, including those that have not been traditionally defined as service industries such as health care or manufacturing industries (Bitner, Brown and Meuter, 2000). The increasing development of technology is changing the essence of service encounters; hence, many companies or

institutes put an emphasis on how these encounters can be improved through the effective use of technology.

Several studies (e.g., Bitner et al., 2000; Froehle and Roth, 2004; Schumann, Keller, Wangenheim and Holzmuller, 2007) have stressed on the importance of technology and the critical role of technology-based service encounter (TBSE) in service industries. However, studies that indicating TBSE from the viewpoint of healthcare industry is rare. Many scholars have mentioned that service quality is the key of continued improvement in service industry such as healthcare industry (Aga and Safakli, 2007; Piligrimiene, 2008; Yang and Peterson, 2004). Parasurman (2000) indicated technology readiness as a main effect of measuring how much people love technology.

This study aimed to understand the influence of TBSE towards service quality and perceived value, subsequently explored the satisfaction of clinical staff that have experienced technology-based encounters. Technology readiness of clinical staff was considered as a moderator in the study. Therefore, the main objectives of the study was (1) to examine the direct effect of TBSE on service quality, and the perceived value; (2) to further examined the direct effect of service quality and perceived value on satisfaction of clinical staff who have experienced technology-based service encounter; and (3) to examined the moderating effect of technology readiness on the relationships among TBSE, service quality, and perceived value.

THEORETICAL BACKGROUND

Technology-based Service Encounter

Nowadays, TBSE plays an important role in miscellaneous fields, especially in service industries. Froehle and Roth (2004) define TBSE as service providers delivering information to receivers via a technological interface in order to allow for an immediate information exchange between receivers. Technology-based service, can be restored, customized, served long distance, and provided automatically (Schumann et al., 2007), brings changes to record keeping process for both clinical staff and the patients in health care institutes. Abdolrasulnia, Menachemi, Shewchuk, Giner, Duncan and Brook (2008) indicated that the medical quality of doctors will improve when hospitals have well installed technology-based equipment. Meanwhile, other researchers believe that suitable technology-based products such as electronic medical records (EMRs) can reduce paperwork and medical errors (Li, Bahensky, Jaana and Ward, 2008). Schumann et al. (2007) stated that TBSE allow the provision of consulting services in a technology-mediated interaction process between clinical staff and the patients in hospitals.

The usefulness, easiness to use of the technology product/service will be evaluated by the clinical staff to determine whether it is useful, accessible, controllable, and beneficial to them. They will also assess whether the EMR system can save time as well as storing the correct consultation record (Froehle and Roth, 2004). Technology undoubtedly brings advantages to the users; however, the complexity and compatibility of the technology are always the issue (Menachemi, Chukmaitov, Saunders and Brooks, 2008). User attitude and technology readiness toward new technology are the determinants of implementing information system in healthcare setting (DelliFraine, Dansky and Rumberger, 2006). As

above, the study defines technology-based service encounters (TBSE) as "the clinical staff perceived the technologies are useful, accessible, and beneficial service via technological interface which allows for immediate exchanges of medical information between all clinical staffs and patients through modern communication and medical IT."

Service Quality

Service quality is consisted of several dimensions by scholars such as the two-dimensional models: technical and functional quality (Grönroos, 1984), process and outcome quality, including physical, interactive, and corporate quality (Lehtinen and Lehtinen, 1991); the three dimensional model: interaction, physical environment, and outcome quality (Brady and Cronin, 2001); the SERVQUAL model: tangible, reliability, responsiveness, assurance, and empathy (Parasuraman, Zeithaml and Berry, 1985), and etc.. However, these dimensions are overlapping with each others in some ways.

Parasuraman et al. (1998) argued that service quality is an elusive and indistinct construct that not easy for customers to define. According to Shonk and Chelladurai (2008), service quality can be defined as the differences between what is expected from each of the service dimensions and what a user perceives he or she receives from them. In hospital, quality is regarded as something related to benefits, mostly concerns with how much patients gain or loss from the hospitals, but do not mention about the gain or loss of clinical staff from the new technological equipment. Evaluated health care service quality from the patient's perspective, Piligrimienė and Bučiūnienė, (2008) indicated that many efforts have been made for developing a thorough and generally applicable definition of health care service quality. Dabholkar (2000) defined health care service quality as "the kind of care which is expected to maximize an inclusive measure of patient welfare, after one has taken account of the balance of expected gains and losses that attend the process of care in all its parts." However, clinical staffs also evaluate the real service quality of the latest TBSE with regard to themselves and the patients' concerns.

The American Medical Association identify that some specific attributes of care such as health promotion and disease prevention should be included in the examination quality. Those are the criteria help clinical staff to evaluate service quality of a new technology-based product/service by assessing its stability and improvability. Health care quality is to reach the desired objectives using a legitimate means, where the desired objectives imply the achievable level of health (Piligrimienė and Bučiūnienė, 2008). Thus, health care quality is attained when a physician helps the patient to reach an achievable level of health properly. The service quality of a technology-based product is the key factor influencing patient's needs, as well as an evaluation factor for hospital staff.

The SERVQUAL model by Parasuraman et al. (1985) is adopted for measuring the service quality of hospital in this study. The five dimensions are: "tangibles of technology-based service encounters", which means physical facilities, equipment, and appearance of personnel; "reliability of technology-based service encounters" is defined as the ability to perform the promised service dependably and accurately; "responsiveness of technology-based service encounters" is regarded as the willingness of manufacturers to provide prompt services for the customers; "assurance in technology-based service encounters"

means the knowledge level and courtesy of manufacturers' employees; and "empathy of technology-based service encounters" is the caring, individualized attention that the manufacturers provide to its customers.

Accordingly, this study defined service quality as the belief on the part of clinical staff that the provision of TBSE for the hospital is tangible, reliable, responsive, and has assurance and empathy.

Perceived Value

Cengiz and Kirhbir (2007) pointed out two important characteristics of hospital perceived value by the receivers (e.g., doctors, nurses, or other clinical staff). At first, the use of equipment, such as a technology-based product (e.g., X-ray machine) which differentiates it from personal or organizational values, is inherent. Second, it is perceived by receivers, and cannot be determined objectively by the manufacturers (Cengiz and Kirhbir, 2007). Only the clinical staffs in hospitals are able to perceive the actual value of the products or services offered. This value has been variously conceptualized as customer utility, perceived benefits relative to sacrifice, psychological price, worth and quality (Woodruff, 1997). Furthermore, perceived value varies depending on the types of technology-based products or services and on the personal characteristics of clinical staff in hospitals. Healthcare industries should make an effort to detect the most value perceived attributes that could attract and retain customers.

Zeithaml (1988) defined perceived value as the customers overall assessment of the utility of a product, based on perceptions of what is received and what is given (p.14). Woodruff (1997) also indicated that receivers may perceive value differently at different time such as the stage of purchasing and during or after using a product or service. With this notion, Woodruff developed a customer value hierarchy model; consumers may desire a certain value (desired value), and may evaluate a product or service after they have experienced it (received value). Perceived value has its root in the equity theory, which takes the ratio of a receiver's outcome/input to that of the service provider's outcome/input into consideration (Cengiz and Kirhbir, 2007). As a consequence, this study defined perceived value as the clinical staff overall assessment of using technology-based product adopted by the hospital based on their perceptions of what they benefit from the system and what they could give to the patients via the technical service.

Satisfaction

Satisfaction is the critical outcome to a service encounter because a high level of satisfaction can bring positive word-of-mouth (Wixom and Todd, 2005) and relationship quality. In hospitals, when clinical staffs have higher satisfaction of using a new technology-based product/service, they will have positive perception about the manufacturer. Meanwhile, Customer satisfaction is an emotional response that resulted from a cognitive process of evaluating the service received against the costs of obtaining the service (Tam, 2004). Aga and Safakli (2007) define satisfaction as "the receivers judge that a product or service feature, or the product or service itself, provides a pleasurable level of consumption-related fulfilment, including levels of under or over-fulfilment." In a service context, overall

satisfaction is similar to overall evaluations of service quality (Gustafsson, Johnson and Toos, 2005). As a performance measure, satisfaction is considered an important outcome in healthcare industries. Service quality and satisfaction are in common in many ways, but they can still be distinguished. Satisfaction is generally viewed as a broader concept, while service quality assessment focuses on dimensions of service (Akter, Upal and Hani, 2008).

According to Zviran and Erlich (2003), receiver satisfaction is an important criterion for measuring the success of technology-based products/systems; they define satisfaction as the degree to which receivers believe the new technology-based system at their disposal is fulfilling their needs. An exploratory study on the correlation of receiver satisfaction with computing conducted by Chang (2010) found that there are significant and positive relationships between receiver satisfaction and hardware or software accessibility and availability, the receivers' computer background, attitudes toward computing, and system utilization. Besides, the studies such as Lin and Shao (2000), Staples, Wang, and Seddon (2002) mentioned that customer participation, attitude, involvement as well as expectation of TBSE show a significant relationship with customer satisfaction. Zviran and Erlich (2003) pointed out customer satisfaction is an important elements of measuring technology product/ service success.

Chakrabarty, Whitten, and Green (2007) defined satisfaction as the sum of feelings resulting from receivers' beliefs regarding the extent to which a technology meets their requirements. This study adopted three scales: time information product, knowledge, and involvement to evaluate receiver satisfaction in the hospitals. The "time" scale measures the degree to which the administrators can wait for developing a new system in a hospital. The "information product" scale measures the reliability, relevancy, accuracy, precision, and completeness of the output information. And the "knowledge and Involvement" scale measures the degree of technical training provided to receivers in the hospital, the degree to which receivers understand and have positive or negative participating feeling on the systems (Chakrabarty et al., 2007).

As a consequence, this study defined satisfaction as a sum of feelings of the clinical staff about using a technology product / service adopted by the hospital and evaluated by the time, product information, knowledge and involvement scales."

Technology Readiness

Technology readiness has been applied in a variety of fields such as consumer marketing, online service, educational fields, and health care industries. Parasuraman (2000) stated that technology readiness is the degree to which people love or embrace a new technology to achieve their goals. He also claimed that people who have adopted advanced technologies earlier than others will take using cutting-edge technology-based products for a normal thing. In other words, these people usually demonstrate a strong desire to absorb new technological products into their lifestyles.

Several studies suggested that as the differences in the psychographic profiles of technology adopters are discovered, hospitals need to determine the different levels of technology readiness within the staff and divided the low level into four groups – displaying optimism,

innovativeness, discomfort, and insecurity (Lin and Hsieh, 2006; Parasuraman, 2000). Displaying optimism means the people who have positive attitudes toward new technology and believe in the benefits will come along with new technology. Therefore, in the case of TBSE, this group is made up of positive individuals who can see it as a fresh experience. Innovativeness as the clinical staffs in hospitals have willingness to learn new technology due to the decrease of administrative errors and time consuming reduction for paperwork, regarding themselves as innovators and leaders who will head up the trend to try new technology as a fad. Discomfort is individuals who have negative attitudes towards new technology and avoid using it in a workplace full of technology-based equipments. They perceive these equipments as unnecessary and inappropriate for junior members to use. Insecurity is those who totally dislike new technology and believe that it have made their daily life more complicated and more troublesome. As to the connection between TBSE and technology readiness, Parasuraman (2000) pointed out that people generally have positive or negative attitudes toward technology-based services or products based upon their need, evaluation or acceptance. This study defined technology readiness as the degree of preparation of the clinical staff for the technology-based products/services adopted by the hospital.

Conceptual Framework

Figure 1 below illustrated the conceptual framework. The model represented that TBSE had direct effect on service quality and perceived value, and both service quality and perceived value subsequently affected satisfaction. The dimensions of service quality were labelled as tangible, reliable, responsiveness, assurance, and empathy. And satisfaction included three dimensions: time, product information, and knowledge and involvement. Technology readiness was adopted as a moderating role that moderated the relationship between TBSE and both service quality and perceived value.

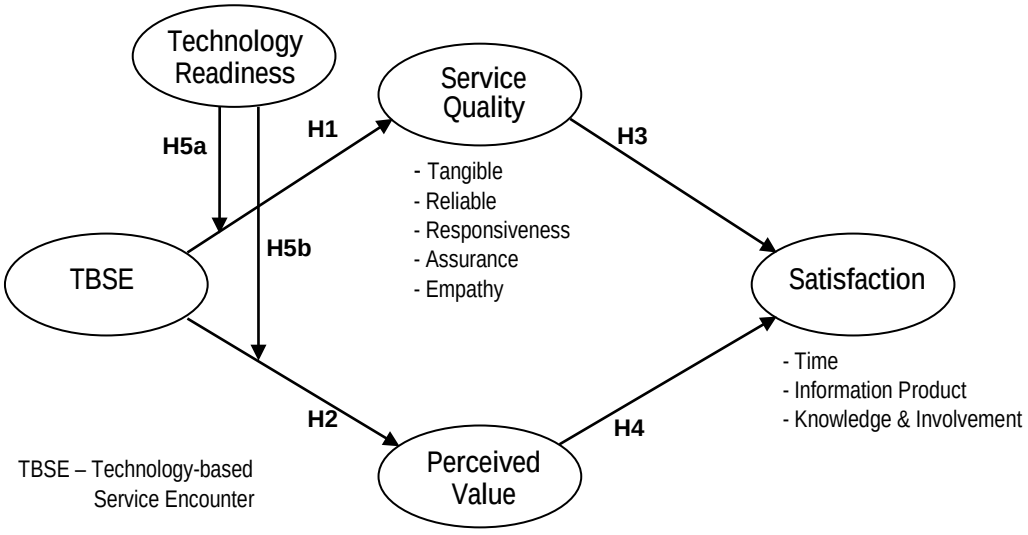

Figure 1: Conceptual Framework.

Hypotheses Development

Technology-based Service Encounters and Service Quality

Parasuraman et al. (1998) indicated two different service styles, personal and technological services, which people would judge them by their own expectations and evaluations of service experiences. According to Bitner et al. (2000), infusing technology into the service encounter would generate a high level of a great satisfaction, such as customization, spontaneous delight, and service recovery. It infers that there is a positive relationship between TBSE and higher degrees of satisfaction.

Chang and Chang (2008) conducted a study on the receivers' preferences and evaluations of TBSE in hospitals and found that different receivers held different opinions and perceptions about the TBSE. They also indicated that the overall evaluation of the TBSE quality was based on the receiver attitudes toward the technology-based service and the demands for interaction between the receivers and providers. It reveals that when clinical staff in a hospital that had a positive attitude toward TBSE (equipment) would have optimistic attitude about receiving it. Parasuraman (2000) pointed out that the positive influence on TBSE towards service quality of hospital was building higher entry barriers, enhancing of productivity, and an increase in profits. Therefore, in most of service industries, TBSE plays an important role in remaining competitive. Following the above discussion, the study proposed the hypothesis 1 as below:

H1: The adoption of technology-based service encounters designed to serve patients can positively increase the service quality of clinical staff.

Technology-based Service Encounter and Perceived Value

Perceived value on TBSE (equipments) was regarded as a personal experience and judged by the TBSE (equipments) using experience by the clinical staff. The positive or negative perception of the TBSE (equipments) is likely depending on the clinical staff attitude and experience toward it.

Additionally, perceived value of the attitude toward the use of new TBSE (product/service) would bring high or low satisfaction with the facilities involved. Tam (2004) defined perceived value as the degree of service quality from the clinical staff in hospital or health care centre. It revealed that the clinical staff of hospital or health care centre staff care about the service quality provided to their patients, when the perceived value toward a technology-based product/service is positive, they will have more satisfaction. Hence, this study proposed the following hypothesis:

H2: The adoption of technology-based service encounters designed to serve patients can increase positive perceived value of clinical staff toward the technology.

Service Quality and Satisfaction

In recognition of the expanded role of the technology-based system department and the importance of technology-based products/services, researchers have begun to include service quality as a measure of satisfaction or success in recent years (Zhu, Wymer and Chen, 2002; Brown and Chin, 2004). Oliver (1980) stated that service quality can influence receiver satisfaction not only directly via receiver observation, but also indirectly via an input to the disconfirmation comparison (e.g., discrepancy between performance and expectation). Parasuraman et al. (1985) proposed that a higher level of service quality can increase receiver satisfaction. Several studies have also acknowledged receiver satisfaction is positively connected with the level of service quality that delivered by the service providers (Host and Andersen, 2004; Saravanan and Pao, 2007). Accordingly, it can presume that service quality is significantly related to receiver satisfaction.

McDougall and Levesque (2000) studied the service domains of dentists and other industries in Canada and concluded that core service quality will drive receiver satisfaction. When clinical staff satisfy the modern software or hardware with the technology-based equipments, they are more likely to accept the waiting time of adopting the new system. Moreover, clinical staff will be more satisfied when the manufacturers show a sincere interest in solving problems, perform professionally with necessary knowledge, as well as customize necessary technology for the hospital. These can enhance the clinical staffs' confidence and perception on the manufacturers, and ultimately facilitate their satisfaction. Based on the discussions above, it can be asserted that there are positive relationships between service quality and satisfaction. Hence, this study made the following hypothesis:

H3: The increase in service quality can positively increase clinical staffs' satisfaction toward technology.

Perceived Value and Satisfaction

Fornell and Larcker (1981) identified perceived value is the main driver of overall receiver satisfaction. Meanwhile, McDougall and Levesque (2000) concluded that perceived value is a significant factor and has impact on work loyalty entirely through receiver satisfaction. According to Yang and Peterson (2004), perceived value is the ratio of the benefits received from providers relative to the costs sacrificed by receivers. Tam (2004) indicated that the value of the technology-based equipment which perceived by the clinical staffs in hospitals or health care industries is the pivotal determinant of their satisfaction. Once the clinical staffs perceive greater value than the actual cost of the TBSE (equipments), such as it brings more benefit to the patients, which in turn results in higher satisfaction.

On the basis of the behavioural model toward perceived value and satisfaction, the perceived value effect is significantly influenced by the cognition of the clinical staff in hospitals. According to Tam (2004), received-perceived value in health care industries has a positive effect on receiver satisfaction. Based on the discussion above, the study infers there is a positive relationship between perceived value and satisfaction. Therefore, the following hypothesis was purposed:

H4: The increase in perceived value can positively increase the satisfaction of clinical staff toward technology.

Moderating Effect of Technology Readiness

From the perspective of TBSE, Mick and Fournier (1998) mentioned that people sometimes hold two conflicting thinking in their mind, they pointed out eight technology paradoxes (control vs. chaos, freedom vs. enslavement, new vs. obsolete, competence vs. incompetence, efficiency vs. inefficiency, fulfilling vs. creates needs, assimilation vs. isolation, and engaging vs. disengaging) to explain different values, needs and acceptance are the keys to determine or affect a person's thinking. DelliFraine et al (2006) claimed that some of the nurses regard technology as an additional task but some regard it as a positive benefit. It is obvious that different level of technology perception and the ways people work will affect the quality of TBSE.

In addition, different background of clinical staff including doctors, nurses, and medical administrators have different perception as well as technology readiness on new technology, which in turn affecting the attitude and satisfaction with such new technology when applying it. According to Cengiz and Kirkbir (2007), perceived value has been variously conceptualized as receiver utility, which is related to the psychological price, worth and quality. As above, technology readiness can be regarded as an overall thought of individual to determine whether he or she is eager to use a new technology (Parasuraman, 2000). For instance, when the clinical staff in hospitals are ready for the technology-based service adopted by the hospital and perceived it as easy, useful, and beneficial, they will have a positive attitude towards the service quality. Thus, there may have a positive or negative relationship between TBSE and service quality in certain level. As a consequence, this study proposed two hypotheses as following:

H5a. Technology readiness of clinical staff has a moderating effect on their use of TBSEs and the service quality toward technology.

H5b. Technology readiness of clinical staff has a moderating effect on their use of TBSEs and the perceived value toward technology.

RESEARCH DESIGN

A quantitative research design was adopted by this study. The questionnaire was based upon seven-point Likert style which ranged from "Strongly Agree" to Strongly Disagree". A total of 45 measurements were modified from the previous studies with the relevant definitions. The definitions of each constructs and dimensions were illustrated in Table 1. There were five major constructs as TBSE, service quality, perceived value, satisfaction, and technology readiness to measure the implicit and explicit knowledge of the clinical staff in hospitals.

Table 1: Summary of Overall Model Constructs.

Construct	Description of This Study	Key Citations
Technology-based service encounter (TBSE)	The clinical staffs provide service via technological interface to the patients, which allows for an immediate exchange of medical information between the clinical staffs and the patients through modern communication and medical information technology.	Froehle & Roth (2004), Schuman et al. (2007), Li et al. (2008)
Service quality (SQ)	The belief of clinical staff in the providers of technology product (service) for the hospital is tangible, reliability, responsiveness, assurance, and empathy.	Parasuraman et al., (1998), Aga & Safakli (2007), Sohail et al. (2007), Shonk (2008)
Perceived value (PV)	The clinical staff overall assessment of the utility of the technology-based product adopted by the hospital, based on perceptions of what is received and what is given	Yang & Peterson (2004), DelliFraine et al., (2006); Ekrem & Fazil (2007),
Satisfaction (SAT)	The clinical staffs' sum of feeling on using technology product/service which is adopted by the hospital and evaluated by time, information product, and knowledge & involvement scales.	Chakrabarty et al. (2007), Wixom & Todd (2005), Tam (2004), Akter et al. (2008)
Technology readiness (TR)	The preparation degree of the clinical staff for the technology-based product/service adopted by the hospital.	Parasuraman (2000)

A pilot study was conducted before the formal survey for ensuring the scales' reliability. Cronbach's alpha coefficient was adopted for assessing the interrelationship and internal consistency for each items; the threshold must be greater than 0.70 (Nunnally, 1978). Besides, the assessment of item-to-total coefficient is the Pearson correlation coefficient between the score on the individual item and the sum of the scores on the remaining items. This indicates the degree of an item's relationship to the total score. Item-to-total lowered than 0.50 was subjected to deletion (Weise, 1975). A computer-based questionnaire was distributed via e-mail in mid October 2008. Thirty-two participants responded, two were invalid and the rest were retained for pilot test analysis. As result, Cronbach's alphas of all scales were greater than 0.70, and item-to-total of all items were greater than 0.30. It revealed all measurement scales had steady internal consistency, and all measurement items indicated high degree of item relationship with each constructs.

RESULTS OF DATA ANALYSES

The objective of this study was to examine the attitude toward TBSE of the clinical staff in the hospital. The formal questionnaire was distributed to the health care industries such as clinics, private and public hospitals which providing stable and high quality services. Staff in the hospital are the objects for answering the survey including nurses, doctors, clinical administrators, and etc.. A confirmatory factor analysis (CFA) was conducted for assessing measurement model, structural equation modelling (SEM) for full model; a one-way ANOVA post-hoc Scheffé test analysis was applied for the demographic variables.

Sample Characteristics

The data was collected via paper-based questionnaire, which distributed to the clinics and hospitals including National University Hospital, Presbyterian Church Hospital, the Private Dental Clinic, and etc. in Taiwan from early January 2008 to late February 2009. There were 241 responses to the survey with thirty-five were found invalid. At last, 206 questionnaires were valid for further analysis.

Table 2 illustrated the characteristic of respondents' demographic. It revealed majority of the responses were female (73.8%) and the age was among 20 to 29 (55.3%); most respondents were nurses (51.9%) and had a bachelor's degree (86.4%); 23.3% were from internal medicine department; x-ray machine was the most frequent used technology-based products (16.5%). And lastly, the clinical staff commented that they usually used the technology-based products in the hospitals about 2-5 times each day (33%).

Table 2: Demographic statistics of respondent (N=206).

Measurement Model Analysis

Confirmatory factor analysis (CFA) is assessing measurement model to test convergent validity for all the variables. In arriving at the final set of items, the study deleted certain items from the initial pool of questionnaire based on the criteria of item-to-total and factor loading coefficients. The final results showed all item-to-total were above the threshold of 0.30; however, there were three items' factor loading below the threshold of 0.50. These items were deleted for further analyses.

To determine the good model fit of measurement model, the study adopted the model fit indices that recommended by Hair et al. (2006). Not only the χ^2/df must not be greater than 3.0, but also other criterions such as goodness of fit index (GFI) and adjusted goodness of fit index (AGFI) should be greater than 0.80, comparative fit index (CIF), and normed fit index (NFI) should be greater than 0.90, as well as root mean square residual (RMR), and the root mean square error of approximation (RMSEA) should not be greater than 0.05 and 0.08. The results were showed as followings: χ^2/df = 2.297; GFI= 0.856; AGFI= 0.808; CFI= 0.946; NFI = 0.908; RMSEA= 0.080; and RMR = 0.056. All indices were within the recommended value except for RMR. As the RMR was very close to the criterion, the study considered the measurement model had good fit.

Convergent analysis was assessed by computing the factor loading coefficients. Convergent validity was demonstrated by the high average variance extracted (AVE) for all constructs which greater than 0.40 were considered adequate (Verhoef and Hoekstra, 2002). Table 3 illustrated the AVE of all constructs were from the range of 0.669 (service quality) to 0.869 (perceived value) except for technology readiness (0.381) which was very close to the criterion of 0.40. Hence, the study considered all constructs had convergent validity. Besides, all Cronbach's alpha coefficient and composite reliability (CR) also had exceeded the criterion of 0.70, revealing that all constructs had high internal consistency and reliability.

Discriminant validity was assessed by computing AVE for all pairs of constructs and comparing the square root value to the correlation between two constructs of interest (Fornell and Larcker, 1981). Table 4 illustrated the results of discriminant validity analysis. It revealed all square root of the AVE (diagonal value) were larger than the correlation value between the two constructs. Therefore, the study determined that the discriminant validity was satisfied.

Table 3: Convergent Validity and Reliability Analysis.

Variable	Cronbach's Alpha	Variance Extracted	Composite Reliability
Technology-based Service Encounter	0.926	0.714	0.967
Service Quality	0.976	0.669	0.950
Perceived Value	0.951	0.869	0.994
Satisfaction	0.939	0.703	0.954
Technology Readiness	0.750	0.381	0.700

Table 4: Discriminant Validity Analysis.

Construct	TBSE	SQ	PV	SAT	TR
Technology-based Service Encounter (TBSE)	**0.845[a]**				
Service Quality (SQ)	0.602	**0.817[a]**			
Perceived Value (PV)	0.668	0.561	**0.932[a]**		
Satisfactions (SAT)	0.519	0.517	0.547	**0.838[a]**	
Technology Readiness (TR)	0.525	0.420	0.508	0.393	**0.617[a]**

Note: [a]Diagonal elements represent square root of AVE for that construct.

Path Analysis of Full model

The model parameters were the regression estimation coefficients of constructs. For accessing the model fit of full model, the same criteria were adopted as the measurement model fit indices. The path diagram and the results of full model were illustrated in Figure 2 which revealed $\chi 2 / df = 2.735$ ($p = 0.000$), GFI = 0.953, AGFI = 0.816, CFI = 0.953, NFI = 0.929, RMR = 0.069, and RMSEA = 0.092. The study determined the model had acceptable fit for further analysis.

The results of path analysis revealed the parameter estimation of TBSE towards service quality and perceived value were positive and reached statistical significance at 0.001 level ($\beta = 0.702$, $p = 0.000$; $\beta = 0.752$, $p = 0.000$). It revealed TBSE had a positive effect on service quality and perceived value; hence, the finding supported H1 and H2. Services quality and perceived value toward satisfaction also revealed positive and reached statistical significance at 0.001 level ($\beta = 0.441$, $p = 0.000$; $\beta = 0.494$, $p = 0.000$). The finding supported H3 and H4 as both service quality and perceived value positively affected satisfaction.

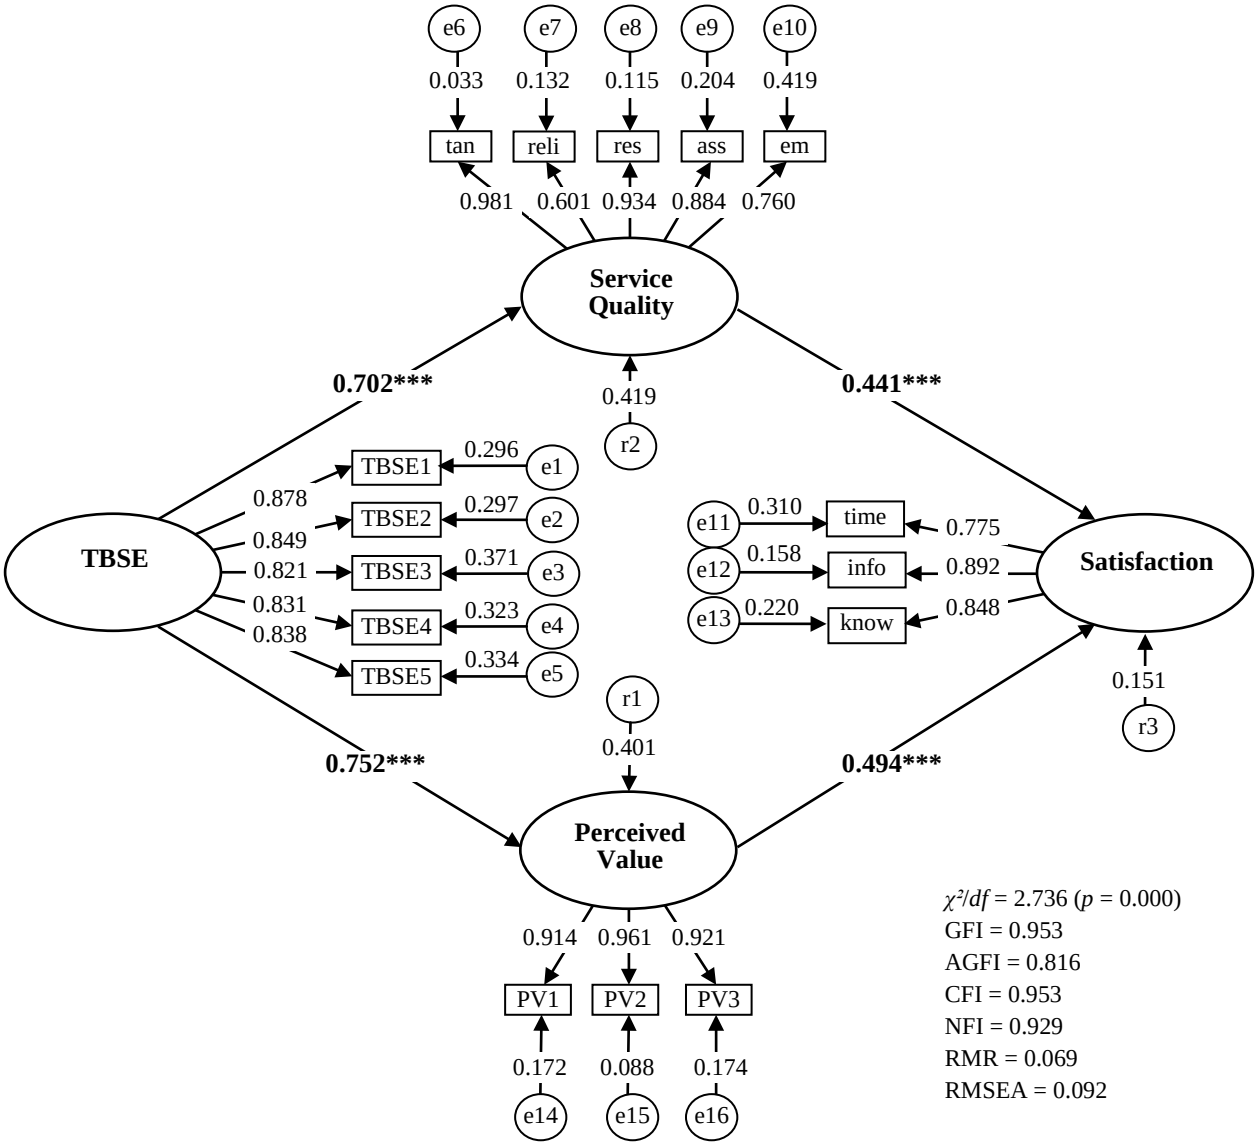

Figure 2: Path Diagram of Structural Equation Model Analysis.

Hierarchical Regression Analysis – Moderating Effect

This study adopted hierarchical regression analysis for assessing the two moderating effects of technology readiness: on the relationship between TBSE and service quality as well as perceived value. The constructs with multi-items was measured through a single index by averaging the item scores. Mean centre were computed for each constructs and interaction terms were formed. Three Models were tested for both dependent variables (service quality and perceived value) and the results of hierarchical regression analysis were illustrated in Table 5. Model 1 and Model 2 tested the direct effects of predictor variables (TBSE and technology readiness). The results revealed a significantly direct effect on both dependent variables. Model 3 tested the direct effects and the interaction term (TBSE × technology readiness). The study found that technology readiness had a positive and significant effect on service quality (β = 0.183, p < 0.01) but had not significant effect on perceived value (β = 0.103, p > 0.05). To conclude, technology readiness had a moderating effect on the

relationship between TBSE and service quality, but had not significant moderating effect on the relationship between TBSE and perceived value. Therefore, the finding supported hypothesis 5a and did not support hypothesis 5b.

Table 5: Results of Hierarchical Regression Analysis.

Dependent Variable	**Service Quality: H5a**			**Perceived Value: H5b**		
Predictor Variable	**Model 1 (*β*)**	**Model 2 (*β*)**	**Model 3 (*β*)**	**Model 1 (*β*)**	**Model 2 (*β*)**	**Model 3 (*β*)**

Notes: **p<0.01; ***p<0.001

t-Test and ANOVA Analysis

A one-way ANOVA analysis was conducted for assessing the difference in all constructs across demographic variables such as age, education, position and department. *t*-Test was adopted for the assessment of gender As the results, there was no statistical difference between groups of these demographic variables for all constructs. Therefore, the study deduced that different groups of demographic variables had no differences to all constructs.

DISCUSSION AND IMPLICATIONS

Using technology-based service encounter (TBSE) as an antecedent, the objective of the study was to examine the relationships between service quality and perceived value towards satisfaction. Technology readiness was adopted as a moderator to examine its moderating effect on TBSE towards service quality and perceived value.

The results supported H1. H2, H3, and H4. Nurse is one of the most heavy loading and stressful position in the hospital. Therefore, hospital should advocate and promote a positive attitude towards launching new technological systems to reduce clinical staffs' workload and provide better treatment services quality to the patients. However, the hospital should take staffs' opinions into account when choosing a provider (brand, supplier or manufacturer) of TBSE (equipment). As the staffs use the equipment every day, they have better understanding about what functions are needed, convenient, and beneficial the most to the patients. In this line, service quality of the provider and staffs perceived value of the TBSE are also important reference for making purchase decision. When the providers are reliable and responsible to provide a tangible TBSE with assured and emphatic service, the clinical staffs would be more likely to have positive attitude towards the TBSE. Moreover, if the existing TBSE are easy, convenient, and practical to use for serving patient satisfyingly,

the staffs will definitely give their support to the management for applying TBSE widely in the future, which also can help to enhance the staffs perceived value towards the TBSE. Therefore, when the TBSE providers provide high service quality to the hospital and the clinical staffs perceive the TBSE have high value, they are more likely to have positive attitudes and satisfaction towards the TBSE.

H5a was supported but H5b was unsupported in the moderating effects test. According to Parasuraman (2000), people have strong desire for adopting new IT when they are well trained. As these people (the staffs) have higher sense of technology, they will require more or better services quality to fulfil their duties from the provider. However, the staffs will consider the TBSE has poor service quality when the providers fail to meet their needs. Some respondents comment that regardless of the staffs' high or low technology readiness, TBSE is perceived as valuable. It is because they believe IT not only can reduce paper-work, easily transfer patients' medical report from one division to another, and reduce examination steps, but also can provide complete diagnosis results to the patients. Therefore, the staffs perceived TBSE as high value. Some respondents point out that no matter they are conservative or innovative, IT is an indispensable tool in their workplace; in fact, IT bring them convenience and reduce workload.

Theoretical Implication

Prior research generally used the quality-satisfaction relationship to discuss the topic of marketing in service industry, such as Lin and Hsieh (2006), Saravanan and Pao (2007), Snellman and Vihtkari (2003), and etc. This study contributes an overall understanding on the research model is actually suitable for applying to the healthcare institute.

This study, focusing on the practitioners (e.g., the clinical staffs) who use the TBSE instead of the patients, is different from the prior research (e.g., Eriksson and Nilsson, 2007; Lin and Hsieh, 2006; Snellman and Vihtkari, 2003) which mostly emphasize on the perceptions of consumers or the people receive the services. The overall model is discussed from the viewpoint of services instead of marketing. The moderator (technology readiness) also plays a critical role in the model based upon the statistical analysis. Prior studies mostly discuss the degree of technology readiness has influence on perceived value and satisfaction of the end users (the consumers). The findings of this study imply that technology readiness not only has influence upon end users, but also the mediums (the clinical staffs) that provide services.

Managerial Implication

From the managerial perspective, the technology readiness of staffs in the healthcare institute is generally high because technological proficiencies are prerequisite for the occupation. Therefore, the staffs tend to be keen on supporting the decision of implementing new technology when it is needed (Yang and Peterson, 2004), and they could gain professional knowledge of particular technology from day-to-day experience of serving the patients. Hence, a routine meeting must be conducted to collect opinions in terms of the patients needs, and modify the working procedure to promote their effectiveness. And,

the staff opinions are also important for making decision of implementing or upgrading new technologies.

As technology changes rapidly, the management should encourage staffs to attend seminars, symposiums, conferences or exhibitions related to new technology to upgrade themselves. Different technology system certification should also be encouraged to enable cross-sectional cooperation. Accordingly, the staffs should continue their learning and exchange their knowledge to use TBSE more completely, ultimately, enhancing the service quality.

Manufacturer or provider should pay more attention to the feedback from institutes and establishing a tight relationship with them to provide better and in-time services. It not only can establish good impression to the provider, but also can enhance satisfaction of staffs' as well as patients by reducing waiting time.

Limitations and Future Research

There are several limitations to the study. Firstly, the research data are collected from institutes at different size such as private and public hospitals, or even small clinics. Secondly, it is not possible to make a comparison between different departments and different divisions in clinical institutes as the respondents are too few to divide into groups. The study believes the results may be different with other research methods.

Lastly, other constructs such as leadership style (Neufeld, Dong and Higgins, 2007) or organizational culture (Leidner and Kayworth, 2006) may play an important role in affecting staffs to use technology. These constructs are worth exploring and discussing from the organizational perspective, especially from the healthcare institute in future.

CHALLENGES OF LAUNCHING INNOVATIVE TECHNOLOGY APPLICATIONS THROUGH CUSTOMER PROJECTS

Tuula Lehtimäki, University of Oulu, Finland
tuula.lehtimaki@oulu.fi

ABSTRACT

This study explores what kinds of launch challenges can be identified from marketing perspective when launching innovative technology applications through customer projects. The literature review identified seven launch challenge categories including, for example, launch timing decisions and sales force management. Launch challenges were further examined through a case study involving an innovative technology application developed, implemented and introduced within a customer project. In the studied empirical context the challenges differ remarkably from the literature review findings. In general, a major challenge for getting the innovative application introduced and for promoting its future sales was related to acquiring and succeeding in the first customer project, which is later utilized as a reference. That is, the launch happens through the phases of an introduction bond to the first customer project, and a possible re-launch followed by the application's further development. The study findings can be partly explained by the strategy of the examined firm and the characteristics of its business field, which are not typical in the general launch literature. This study contributes to the launch literature by extending the scope of different types of contexts where launch is researched and by discussing the implications of the context characteristics for the perceived launch challenges. The findings support the notion that launch is a context-dependent phenomenon. Therefore further studies on launch and its challenges in different types of business contexts are suggested.

Keywords: launch, challenges, innovation, technology, project business

INTRODUCTION

This study examines launch challenges in case of innovative technology applications that are developed within customer projects. Launch is the process of introducing a new product into the market for initial sale [11,59]. Its purpose is to maximize the chances of achieving the desired demand outcomes [25], and it has a significant effect on the new product's overall success [12]. Accordingly, a great deal of launch literature examines the elements of launch that contribute to new product success [9,22,25,31,33,34,38]. However, launch challenges, the other side of the coin, have been largely ignored. In addition, launch is said to be often poorly managed [33], and the launch process to be unstructured [7,24]. Therefore, it is suggested here that in order to develop a more organized approach on launch it would be important to understand the challenges of it. Because the marketing function is a focal function during launch [26,55], marketing perspective is considered suitable for examining these challenges. That means that for example production ramp-up issues are not of interest here as such, but perhaps their effects on the timing of the new product launch.

Typically launch is described as the last step of a firm's new product development (NPD) project [12]. The majority of launch research does not pinpoint the product categories and when it does, the division is made between consumer and industrial products [33]. Here the focus is on industrial product launch. New products are not always developed within internal NPD projects, but also within customer projects, after which the products are introduced for initial sale after the project. That is often the case in technology firms which match their technological capabilities with the buyers' needs, and sometimes innovative solutions are required. Hence, a launch of an innovative industrial product that has been developed within a customer project is of interest, because the project business, a customized industrial product, and launch through the first customer reference are aspects that are rarely included in launch research. This choice of context offers a possibility to further refine understanding on industrial launch.

That leads to the research question of this study: *What kinds of launch challenges can be identified from marketing perspective when launching technology applications through customer projects?* The research question is answered through a topical literature and an in-depth case study. The paper concludes with a discussion on the findings and linking them to the existing launch literature. In addition, managerial implications and ideas for further research are presented.

LITERATURE REVIEW ON LAUNCH CHALLENGES AND THE IMPLICATIONS OF THE CONTEXT CHARACTERISTICS FOR LAUNCH

Launch process includes phases such as launch planning, market testing, marketing communications planning, launch implementation and evaluation [15,44]. Launch challenges have not been systematically linked to launch process phases in the existing launch literature so the examination of launch challenges covers the whole launch process. For example pricing and distribution decisions have their own research streams, and they are not reviewed here because the focus has been on how these challenges have been discussed in the literature, where launch is the main topic of interest. Next, a review on launch challenges is presented, followed by a discussion on the characteristics of the examined launch context and their implications for launch.

The launch challenges identified in the literature

Launch timing decisions

One of the most important success factors and biggest challenges related to launch is timing [36,61]. Often the problem is delay instead of launching too early, even though that also might be an issue for example if the market is not ready for a radical innovation. Technical, engineering and development problems are often the reasons for delays [29,36], as well as deficiencies in the proficiency in executing new product development activities [10]. Delays compared to the announced launch date can have a negative effect on sales [36,9] and decrease the market value of a firm [29], even though the correlation between staying in schedule and good business results is not always existent [38]. Timing can be viewed also in relation to competitors' acts [38]. An entry too early might be risky if the technology is immature, and being too late might sacrifice the sales [36]. Timing related to firm's other

own product launches entails a question of cannibalization [42]. Cannibalization, i.e. new product harming the success of another own product of the firm, is a relevant timing problem when looking at launch at a product family level or higher [56].

Global and local launch timings are increasingly important launch issues in global markets [9,8]. An important timing question then is a choice between sequential and simultaneous launch across different markets. Simultaneous launch strategy is supported in the literature, because it is considered to lower the risks [10,37]. Sequential launches are more often delayed than simultaneous launches, which is seen to depend on the deficiencies on the sufficiency of marketing and technological resources (e.g. to train sales staff, provide after-sales service), and communication between the headquarters and local organizations [9]. Delays in sequential introductions resulted in lower-than-expected product sales and profitability [10]. Geographically dispersed virtual multicultural teams are suggested for taking care of the coordination between the headquarters and local organizations [27]. When operating in a business, where product technology customization is needed to different markets, delays are common [9]. Also the schedule of the local channel owners and customization of marketing communications might cause delays [6]. Hence, realistic schedules for marketing and R&D with sufficient resources should help to achieve a timely launch with a ready product [9].

Effects of product innovativeness on marketing

The meaning of innovativeness for launch is discussed occasionally in the NPD and the launch literature. The efficient launch process is found to be important for the success of less innovative products [54]. That implies that the launch of a more innovative product is not just about the efficiency. Innovativeness of a new product can lead to higher adoption barriers of the sales force [4,60] and the customers [1,43]. That has implications both for internal and external communications during launch. Salespeople are often more reluctant to sell innovative products than their companies expect them to be [4,60]. For sales the new product might first translate into more effort with more uncertain profits. Thus, more innovative product launches may face challenges in educating and motivating the sales force. Rackham [45] sees that the problem lies in the product-centric approach used when introducing highly innovative products to the sales force, which leads to product-centric sales approach, which eventually makes the customer interest to fade. Hence, customer-oriented communication should be utilized in launch communications, both for internal and external audiences [45].

For a buyer, innovative products are more difficult to compare with other products and the benefits might be difficult to understand, which requires learning effort and means higher perceived risk [1]. If there is no longitudinal performance data available, the perceived risk increases. For industrial firms being adventurous when buying capital goods might be costly if the risks of adopting new innovative products or technologies are realized. The buyer might not have enough resources to evaluate a complex technology and instead chooses a simpler technology [43]. Overcoming these adoption barriers successfully takes a lot of effort to educate the customer from the selling firm. Another way to affect the customer adoption barrier is to acquire the first customer reference for an innovative product, which

is essential for creating future sales opportunities [23,51]. The reference is utilized in promoting the product in order to increase seller's and the product's creditability [35].

Development of a launch strategy

Several studies point out the importance of having a well justified launch strategy with clearly defined objectives [34,31,33]. At the same time the formulation of such a strategy is perceived challenging [25]. The launch decisions most frequently made by firms are not well in line with the elements that are linked to higher new product success [33]. Unclear segmentation and positioning can lead to new product failure [52].

Sales force management

As superior skills of sales force are important for launch success, sales force management is an often discussed launch challenge [4,45]. Sales force carries out product positioning. The effect of sales force adoption of the new product on selling performance is stronger when the firm provides information on the background of the new product to salespeople through internal marketing. Marketing managers should treat sales force as a front end to customer base and put effort on presenting the new product to them in a motivating manner [4].

Promotion decisions

The own sales force and direct customers are important target groups for promotional activities, but also distribution channels should be motivated to promote and sell the new product preferably relative to competitors' products [6]. Industrial firms often use agents and brokers when introducing new products to new markets, but if the product is complex and difficult to sell, those middlemen might prefer easier to sell products, if there are no contractual or other incentives [33]. One question repeatedly presented in the launch literature is how much should be put emphasis on targeting the majority versus the innovators**,** and the conclusion is that if the effect of the innovators on the majority stays the same when the product's market penetration increases, the effort put on targeting the innovators pays off [40].

Distribution decisions

Even though integrating logistics early on in launch planning is related to launch success, the practices of doing so could be remarkably improved [15]. In addition, utilization of new distribution channels is related to unsuccessful industrial new product launches, and spending less than competitors on distribution is not the amount related to successful launches, but still industrial firms often make those decisions [33].

Launch process management

Despite of these challenges, launch is often poorly managed [33]. Taking a systematic and well-defined approach on launch process management is not a common practice [7], and unstructured launch process itself has been presented by several authors to be one notable launch challenge [7,24].

Summary of the presented launch challenges

Table 1 presents a summary of the launch challenges identified in the literature review. Launch is often examined in the launch literature through the strategic launch decisions made early in the NPD process and the tactic launch decisions which are made later in the process [32]. Launch strategy, product innovativeness, and timing can be considered to relate to strategic decisions whereas promotion, distribution, sales force management and launch process management are more tactical [32,33]. Nonetheless, the context of the studies reviewed here is typically a product-focused firm. Therefore, the applicability of the challenges identified in the existing launch literature to the context of this study is further examined through examining the scope of the reviewed literature and an empirical inquiry.

Table 1: Summary of the presented launch challenges based on the literature review.

Challenge	Explanation for the challenges and their possible consequences
Launch timing decisions	Delays related to the announced launch date caused by 1) technical, engineering and development problems, 2) customization of product or marketing communications for different markets, 3) schedules of local channel owners ▸ Negative effect on sales, decreased market value of the firm Delays related to competitors' acts ▸ Inferior position for the product, lost sales Timing not optimal related to firm's other own product launches ▸ Cannibalization Sequential launches delayed due to insufficient marketing and technological resources and deficiencies in communication between the headquarters and local organizations ▸ Lower-than-expected product sales and profitability
Effects of product innovativeness on marketing	Innovative products might raise the adoption barriers of the sales force ▸ Special requirements for internal promotion, customer-centric approach suggested Innovative products might raise the adoption barriers of the customers ▸ Special requirements for promotion to inform and to educate the customer, especially in conservative industries and when capital goods in question ▸ Important to get the first customer reference for an innovative product Product-centric approach used when introducing innovative products to the sales force ▸ Can lead customer interest to fade
Development of a launch strategy	Difficult to formulate a well justified launch strategy with clear objectives. Common combinations of launch strategy decisions not aligned with strategic decisions linked to higher new product success. ▸ Unclear positioning and segmenting can lead to new product failure
Sales force management	Motivating and informing the sales force. Assuring that the sales force carries out product positioning as intended. ▸ Unclear/unintended positioning can lead to decreased sales
Promotion decisions	All targeted customer groups, sales force and other channels should be motivated to promote and sell the new product preferably relative to competitors' products. ▸ If not successful, inferior new product sales Balancing the emphasis on targeting the majority versus the innovators ▸ If not successful, inferior new product sales
Distribution decisions	Industrial firms often use new distribution channels when entering new markets and to spend less than competitors on distribution. Logistics not integrated to launch planning. ▸ Inferior launch success
Launch process management	Unstructured launch process and poor launch management ▸ Inferior launch success

Launch of an innovative technology application by firm delivering customized integrated solutions for project customers

Launch strategy is formulated on the basis of firm strategy. As the industrial project business is the broader context of this study, the role of an application launch in such a business needs to be discussed. "*Project business is the part of business that relates directly or indirectly to projects, with a purpose to achieve objectives of a firm or several firms*." [3]. Firm strategy is aligned with performing in delivering projects, and individual applications are less central in the firm strategy, even though they are units in the offered solutions. Project refers here to the delivery of integrated solutions, which are unique combinations of products and services that address a customer's specific business problems [5]. NPD relationships for customized products require considerable buyer-seller interaction [57]. In the project business the interaction between the buyer and the seller is in a key role throughout the project and relationship marketing plays an important part in sustaining and getting customers.

Firms offering integrated solutions can move from the first bid or project of its kind in a new domain of business and aim to achieve economies of repetition [13]. Hence, a customer project can introduce an innovative technology or an application that brings new business. The first project where a particular application is implemented can be utilized as a reference, and the application can then be included in future projects [51]. The first reference is a source of learning, a technology test bench and a powerful promotional tool for reference selling and credibility, and if a reference fails, it can be decisive in the success of a new technology [23]. Literature suggests that technical verification should be conducted before the first customer project and instead the project should be utilized in forming the sales arguments [49,50]. But that is not always possible if an innovative product is developed within the project. Also firms delivering customized integrated solutions for project customers are encouraged to develop modular products and services, even though it is a complex task, in order to gain benefits of scale economies while maintaining the customer orientation [28]. Table 2 summarizes these context characteristics and their assumed implications for launch.

Table 2: Context of the study and its implications for launch.

The context elements	Implications
Project business, customized integrated solutions, importance of references	Products are less central in the firm strategy Buyer-seller interaction in an important role as well as relationship marketing Need to develop modular solutions to gain benefits of scale economies ▸ Launch through the first customer project, which is later utilized as a reference ▸ The solution is further developed after the launch

Hence, in this context launch can be considered to refer to the first project where the application is implemented, because after that the application is usually released for sales in other projects. If considering the launch definition utilized in this study, it is not a launch if the new application is communicated randomly to the customers via personal contacts but not to the broader market via some type of public announcement or introduction.

Compared to the traditional approach on new product launch, this type of launch might not be as systematic and as coordinated a process followed by intensive promotional activities.

METHODOLOGY

The in-depth, qualitative and explorative single-case study [62] concerns an industrial customer project, during which an innovative technology application was developed, implemented and introduced, and the followed promotional activities. The case is chosen in order to explore whether the challenges in the particular case context are covered by the current launch literature. The qualitative research methods are used, because it is not purposeful here to examine the subject in terms of quantity, amount intensity, or frequency [14]. Qualitative research studies phenomena in their natural setting in order to make sense of them through the meanings people bring to them [14]. Therefore, launch challenges are examined in an industrial firm through personal interviews. The 22 semi-structured interviews [2] with managers from marketing, sales, and R&D form the main data (see Table 3). The first seven interviews were conducted with the key people involved in the examined customer project. In order to link the data on the project to a broader understanding of the marketing practices of the firm, 15 interviews were conducted among marketing, communication and sales managers. The interview data is complemented by observation memos from firm workshops and meetings, where recording was not an option, and related firm documentation, which makes data triangulation possible. Data on the project, the application and its introduction, and the firm was collected also from public sources.

Table 3: The qualitative data from the case study.

Data source	Duration	References*
The seven interviews on a customer project including an innovative technology application in a chronological order:	**13,5 h**	**376**
Technology Director & VP R&D, Senior Technology Specialist, VP New Business Solutions, VP Sales I, Technology Specialist, Project Manager, VP Sales II	c.a. 2h each	
The 15 interviews on marketing practices of the firm in a chronological order:	**12 h**	**174**

Other materials		**144**
Meeting and observation memos, internal documents e.g. presentations and emails		94
Materials from public sources, such as press releases, annual reports, news, brochures		50

*) One coded reference includes typically ca. five to ten sentences.

The research problem is answered through systematic combining of theory and empirical data with abductive logic [16]. Analysis is based on the phases of data reduction, data display and conclusion drawing [41]. Interviews were recorded and transcribed word-to-word. QSR NVivo software was utilized for coding in order to make the data reduction more organized. Coded references from the data were first categorized based on the launch challenge categories presented in the literature review. Categories were added inductively when a challenge not covered by theory-based categories was identified. The contents of the categories were divided into sub-categories inductively in order to display the

condensed contents of the data. Several iterations of analysis were made to clarify the categories. The sub-categories from the analysis were compared to the theory-based sub-categories. Conclusions were drawn on the nature of the challenges in the examined context and to what degree the reviewed topical literature covers them.

LAUNCH CHALLENGES IN THE EXAMINED CASE

Firm introduction

As the firm strategy affects the launch strategy, a short general introduction to the examined firm is needed. The firm offers a broad range of advanced customized technology solutions with an over-the-average investment cost and lower operating costs. The targeted scale is between turn-key projects and application sales, and for the broader scale solutions the firm offers good warranties. The firm has a strong market position, reputation as a knowledgeable technology provider for challenging projects, and well known proprietary technologies and applications of which many have scantly competitive alternatives. The importance of application sales varies between business divisions offering different technologies, but in general at the time of examination the trend in the firm's marketing has been away from emphasizing individual applications. Even though customization is practically needed in every customer project, the firm has been working on to develop modular solutions. Against this brief introduction, the identified application launch challenges are discussed next.

Identified launch challenges in the examined case

Vagueness of a launch strategy

Products were perceived to have a lesser role than technologies in the firm strategy. The concept of product was not perceived unequivocal in the firm, as it can refer to different types of offerings. However, the concept of product was used by the interviewees and in the firm's marketing communications materials. The interviewees perceived that distinctive for a product is that it has a certain degree of repeating or fixed elements, even though those elements can and typically need to be customized to specific customer needs. From the marketing perspective, a product has a name and marketing materials such as brochures. Applications are often developed in customer projects whereas technologies that the applications are based on are result from the R&D.

> *"- Well, I mean a traditional product. We can't... In our firm a product, it is not...it is a piece of equipment or a process or a service or some other added value that is offered. But if we have a unique episode like in [the name of the examined project], partly unique, (...) we don't start to do brochures on the project.*
> *- No, but on this process we developed, for instance. I think that is a product.*
> *- Right. That you can do. (...) So you can think we have this case, which then brings new commercialization tasks." (Technology Director & VP R&D.)*

Thus, in the examined firm products have a less central role and a more unstable form than in firms delivering standardized products, and all this makes the concept of launch also vague, and the concept of launch strategy was barely mentioned in the interviews.

Effects of product innovativeness on marketing

According to the interviews, an innovative application is typically a result of incremental improvements realized in customer projects, which happen when designing the best possible solution for a certain customer. In some projects the existing applications are not functional and a natural need for improvements emerges. For the customer innovative applications mean potential improvements in performance, but first and foremost, risks. For the seller technological innovativeness means new business potential, but usually also compromises in project price and contract terms so that the buyer's risks are compensated. Innovative applications put special requirements for marketing communications due to their technical uncertainty, especially in conservative industries. The interviewees emphasize repeatedly that if there is no comparable reference for an innovative application, the benefits of the innovative application must be argued solely through other means, which is challenging, because references play such a central role in the marketing in this business. The functionality and performance of the application must be communicated for the customer with other illustrative manners, such as scale models, 3D models, simulations and calculations.

> *"So we showed to this fellow [a consult hired by the customer] that we have calculated it like this and take a look at that piece of equipment; the results were alike. Your thing here in you model looks very different than this physical scale model. So we agreed that let's forget about it. After that we didn't discuss it". (Technology Director.)*

When an innovative application is developed, implemented and introduced through a customer project, it means usually a challenging sales project. The first customer project where an innovative application is implemented has a high marketing communications value and the firm needs to succeed with the project in order to assure the future sales opportunities for the application. The first reference project is utilized in marketing communications of the application and it is a proof of the performance of the application, creating an image of its reliability and credibility.

> *"Well, yes, because the references mean everything in our field of business. So if you don't have a functioning reference, it will be a remarkably lot more difficult to sell the project." (VP Sales I.)*

The technical uncertainty included in an innovative application is not, however, always the only reason for customer adoption barriers. For example, the customer might have contacts to other technology providers who could potentially offer an alternative solution. Lack of trust to the seller might make the buyer to question the offered innovative solution especially when the buyer is less knowledgeable of the applied technology.

> *"I have never participated in a project with so many consults. On the other hand, they are experienced fellows, but…maybe the buyer acknowledged that they do not have enough technical know-hot to evaluate it [i.e. the solution], so they need someone. But how many and how broad commissions they made shows that they must have lacked the general*

trust towards us. The basic assumption was that we're wrong, instead of 'let's see if they are wrong'." (Technology Specialist.)

According to the interviews, if the buyer and the seller have a strong existing relationship, the innovativeness of the application might not raise customer's adoption barriers in a similar manner as when the relationship is weak or nonexistent. Trust entwined in a good relationship helps to overcome the adoption barriers and interlinked challenges along the project. Relationship marketing plays a role in how the innovative applications eventually surmount the customer's adoption barriers and assure the first reference for the application.

Promotion decisions

Promotional activities were not emphasised at the time when the innovative application was first introduced to the market, not at least in a similar manner as is typically done in a firms operating in product business. The application introduction, for example via a press release, was linked to an introduction of a particular customer project, where the application was sold and implemented for the first time. Marketing communication materials such as brochures were prepared later, such as brochures, magazine articles, white papers, and conference presentations. The contents of the marketing communication are technical, because the customers need fairly detailed information on the applications in order to know whether they are suitable for their needs. Depending on the business potential of the application, the application can be technically developed into repeatable modules and later perhaps into a product family. Then, a product family usually has several types of marketing communications materials and a new introduction might follow for the family.

"Well this piece of equipment is now developed into a product in a way, because we have produced this marketing material plus then the design is now developed into a form that we define how it will be done, measures are fixed, and how it is implemented. And I don't know if there is much else we can do about it." (Senior Technology Specialist.)

In industrial project business relationship marketing has a crucial role and other marketing activities or visibility elsewhere than at the customer has a lesser role. Relationships bring business, the realized projects and the customer network build firm credibility, and because the solutions need to be customized, in any case the personal contact to the customer and mutual trust evolved over time are important. Hence, relationship marketing and a personal contact to the customer had a dominating role in firm's marketing communications. Advertising in mass media was not practically utilized at all when considering application introductions. Printed and internet-based materials were considered appropriate along with face-to-face communications with customers during customer visits, conferences, congresses, seminars, exhibitions and fairs.

"Personal selling and personal engineering work, whatever you call it, is the key. Then probably the Internet is the next most important, then printed materials, brochures and leaflets and white papers and such. These are the most important that we need. And all these brochures and materials must be supporting the people on the field in their activities. We leave them to the customers to remember us by." (Corporate Communications Coordinator.)

Some interviewees considered this emphasis of the importance of personal contacts to undermine the role of other means of marketing communications.

"People here have this 'whatever' mentality towards communications and marketing, all units and organizations do not see it as an important activity. (...) It's not merely seen as a cost, but its potential is not seen, people don't know how to utilize it and don't understand the value it could offer to the organization." (Corporate Communications Coordinator.)

Sales force management

Sales force management was not a launch challenge in terms of sales adoption barriers. Quite the contrary, sales force sometimes sold solutions that were still under development, difficult to implement, or financially suboptimal. Therefore, it can be said that aligning the sales with the aim to offer solutions that are based on existing solutions whenever possible was not always fulfilled. Engineering personnel responsible for the detailed design perceived that if sales had consulted them, they would have been able to optimize the design. After the project is sold, customers are reluctant to accept changes. However, ad hoc developments or improvements are often done at the implementation phase, perhaps due to this issue between the sales and the engineering.

"A comment from a firm representative 'The sales has no problem as it puts the problem downwards in the chain.' The sales sells something that might not exist, and engineering tries then design what sales has promised and what customer does not want to change, because it has been already promised, even though the changes might be considered essential by the engineers." (An observation memo from a firm workshop.)

Sales force has a strong technical knowledge and the personnel are prepared to listen to the customer and to work closely with them. The sales approach is problem solving, and the personnel easily end up with unique solutions instead of offering the existing ones. The firm has a broad knowledge base, which could be utilized more efficiently.

"I think that we've rarely had a ready-made [solution]. And why should we have?" (Technology Director.)

"Actually, it [designing the solution] did not start from a scratch. Several existing units have been utilized. It is just about how to apply the existing units. (...) We have loads of expertise in this firm, but it is scattered. The challenge is how to bring it out at the right time." (Senior Technology Specialist.)

"This internal efficiency, it is linked to this development of products, so that everything would not start from a scratch, and you would have ready-made materials for calls for bids and such (…). But that is still a challenge." (VP Sales I)

Considering implications of this for launch, if the sales force does not put emphasis on promoting the existing, introduced solutions, it undermines also the effort increase the sales of the modular solutions, since no one is promoting them to the customers. Accordingly, it makes sense not to put effort on promoting new applications at the time of introduction if the life-cycle of the application remains short and new applications are developed instead.

Launch process management

The idea of launch was perceived to be vaguer than in firms that deliver standardized products. Several interviews mentioned that the concept of launch, or even product development, is complex in the firm, because the path from an idea to a commercialized product is long, and all the versions of the product along the path are unique as are the projects in which they are implemented. Launch was not perceived as a process that culminates in one event that introduces an application but the interviewees discussed a longer time-span during which the application evolves through customer projects in an unorganized manner.

> *"If you consider the normal idea-to-product, to a commercial product, this is not the same. (…) Behind a commercial product, normally, a piece of equipment or such, there are hundreds of ideas (…) based on the experience, history, re-engineering, and know-how. Those ideas have been put together, physically, so we have ended up with this product. So the number of ideas might be the same, but they come together differently, it is not this traditional…it is a different time span." (VP R&D.)*
>
> *"There are no general rules, the projects are always unique. We do not sell bread over the counter." (VP Sales I.)*

The concept of launch was, however, utilized in firm's marketing communications, but it did not refer only to the new application. For example, in press releases where they introduced the new application, launch was linked to the announcement of the related new customer project. The phenomenon of introducing something new to the market is discussed also through concepts such as introduction, bringing to market, and commercialization. All in all, the concept of launch process is rarely mentioned in the interviews and the launch process does not have a similar meaning as in product-focused firms introducing novelties to the market after internal NPD projects. As the examined firm aims to offer more modular and fixed, though customizable, applications, it is possible that application launch and new application marketing will have a different role in the future.

Pricing decisions

The price of an application was discussed in context of pricing a new, innovative technology application. An innovative application does not typically allow an excess price in the project where it is developed. The price for the project must be reasonable in order to get the project or even to get into negotiations with the customer. Usually innovativeness means compromised price due to the technological risk perceived by the customer. On the other hand, if the application is successful, the customer might gain benefits e.g. in form of improved performance. Interviewees considered that if the relationship with the customer is strong, price plays a less significant role, because the trust compensates the risk. The customer thinks that if there will be problems with the innovative application, they will be solved together.

> *"A comment from a firm representative: 'the customer might go to a competitor, if a better price is offered, even though the solution would not be as suitable and the customer might have to adapt the solution afterwards and even end up with a higher end price what we offered.' A following comment: 'Then the customer relationship has an*

important role, to make the customer stay and to prioritize other things than price'." (An observation memo from a firm workshop.)

For the seller innovative applications developed within a customer project can mean both positive and negative surprises. Sometimes the application performs better than expected, but the development and testing costs are difficult to estimate in the early phases of the project when the price is negotiated. The negotiated price is difficult to change afterwards. Therefore customers are often responsible at least part of the testing costs. The seller's price risk is compensated by the reference value of the project, if the first project including the innovative application is successful. All in all, when an innovative application is introduced, the price is more likely to be moderate than high, because the risks affect the price. When there are functioning references the price might be increased.

DISCUSSION OF THE FINDINGS

Next, the identified challenges in the examined case (see Table 4) are discussed in relation to the existing launch literature. *Launch timing* challenges were discussed in the launch literature in a number of studies, but they were not identified in the empirical data. This might be related to the firm strategy, where launch of individual applications have a lesser role. The launch is not emphasized as an individual phase on an application's long and ragged path from an idea to a salable product. Launch happens along the way, introduces the application, but a lot of can be done after the first customer project. Relationship marketing has such an established position in the field of business that it also might overrun the advantage right timing can provide. But perhaps the major explanation is that the developments in this field of business do not happen overnight. Applications include the know-how cumulated over the decades. An efficient launch process is important for the success of less innovative products [54], but in the examined context that has a lesser role, because the developments in the examined field of business are generally slow-paced. Hence, timing appears not to be as crucial in the examined context as on markets where new products are introduced continuously, relationships are less important, it is possible to acquire the knowledge the products are based on in a shorter time, and the competition is fierce.

Distribution was another launch challenge identified in the literature review, even though through a limited set of references, but not in the empirical data. The examined firm sells customized solutions directly to its limited number of customers it already knows well, and distribution channel choices are not that relevant compared to a firm that sells standardized products via multiple channels. The only challenge that was discussed in the empirical data but not in the literature review was *pricing*. Pricing issues should be carefully considered with the risks of the project when the firm wants to get the first reference customer for its innovative application. Pricing was discussed in the empirical data as another decision to make, not an especially challenging area of launch. That is, neither pricing nor distribution can be considered as major launch challenges in the examined context. The reason, why they were not presented as important launch challenges in the launch literature either, could be that distribution and pricing choices have their own research streams which have not been strongly immersed with the launch research.

Table 4: Summary of the identified challenges of an innovative technology application launch.

Challenge	Explanation for the challenge and their possible consequences
Vagueness of the concept of product and launch strategy	The concept of product somewhat ambiguous in the firm and the role of a product less central in the firm strategy ▸ The concept of launch vague ▸ Launch strategy not a central concept in the firm
Effects of product innovativeness on marketing	The first customer project has a high pressure to be a success because of its reference value. Customer adoption barrier due to the perceived risks. ▸ A challenging sales project, compromises in price and contract terms, strong warranties ▸ The benefits and functioning of the application must be illustrated to the customer ▸ A strong relationship can lower the adoption barrier as the customer trusts the seller
Promotion decisions	Promotional activities were not emphasized when introducing a new application. A typical way of introducing a new application for the first time was through a press release at the same time the related customer project was published. Relationship marketing and personal contact to the customer have a central role in marketing communications. ▸ The potential benefits of more versatile utilization of means of marketing communications are lost The content of the marketing communication is technical due to the information needs of the customers. ▸ Instead of bringing out the technical details of applications, the benefits for the customer could be emphasized
Sales force management	Coordination issues between the engineering and the sales. The sales personnel aim to solve customer problems with unique solutions. ▸ The strategy to sell more modular solutions based on existing solutions is not supported ▸ New innovative applications do not reach their sales potential after the introduction
Launch process management	The idea of a launch process is vague. Launch process is unorganized and evolves through customer projects. Launch can refer to introduction of new applications, new application generations, and new customer projects. ▸ The application is developed and launched as a part of a customer project
Pricing decisions	Innovative technology applications mean high risks and potential benefits perceived both by the customer and the seller, which are accommodated to the price. ▸ Compromised price in order to get the project and possibly the first reference

Challenges related to launch strategy, effects of product innovativeness on marketing, promotion decisions, sales force management, and launch process management were identified both in the literature review and in the empirical data, but the elaborated contents of those challenges are different.

The concept of *launch strategy* was not strongly present in the empirical data. The main reason for this appears to be the firm strategy focused on technologies, which resulted in the vagueness of the concepts of product and launch, and the launch process. This study supports the perception that firm strategy has a central role in launch strategy [31]. The firm strategy affects launch strategy, which then is the basis for launch tactics. Also the market characteristics, such as market growth and competitiveness, are relevant for launch strategy decisions [30]. Because the launch decision sets are found to be extremely sensitive to

environmental or competitive context, launch strategy research should be done in a much narrower context [32]. If the launch tactics are also strongly context dependent, it can be assumed that launch challenges are too. Perhaps the existing launch literature focuses too often to firms where the firm strategy is based on selling stand-alone non-customizable products in competitive markets. The closest studies to the launch context of this study discuss how to bring high technology or high-technology products to market [19,20,21]. In addition, service launch has also received scarcely research attention (an exception [44]).

Product innovativeness affected strongly the customer adoption barrier in the examined case but not the sales adoption barrier, even though innovative application meant challenges for sales force in convincing the customer. Promotion was strongly based on the personal contact and the importance of the reference was clear for further promoting the application after the initial introduction. The findings support the study by Dunn et al. [17] who state that personal selling is a suitable strategy for marketing high technology products whereas advertising, sales promotion, and other pull strategies are effective in marketing low technology products. The promotion strategy reminds the "lower adoption barriers" launch strategy applied by high technology companies [18].

Sales force management was linked in the literature and in the examined case to the challenges of supporting the sales strategy. The literature discussed how sales force might need motivation and education to encourage them to sell new innovative products [4], but in the examined case the challenge was reversed: how to encourage the sales of existing solutions instead of offering new, unique, not-yet-developed solutions.

Launch process was even vaguer in the examined case than discussed in the launch literature, because the role and nature of launch was different in the firm per se, not only that it would have been poorly managed. On the other hand, the path from an idea to a salable product goes through same phases of ideation, development and introduction, but they happen in a customer project or in the course of several projects, and therefore the path towards launch becomes more unpredictable. The launched product is often improved afterwards and re-launched. The lice-cycle model suggested for hi-tech products, which starts with a launch, is followed by the development of the whole product, and a re-launch [19], appears to be appropriate for the studied context. Actually, the introduction of new product features, which is a common product development activity for any firm [58], is not far from the idea of re-launch. It takes time to get the conservative customers reassured of innovations and it is not necessarily meaningful to emphasize promotional activities when an innovative application is launched for the first time. As Easingwood and Harrington [19] put it, "*It is not generally worthwhile investing hugely in the launch stage (unless you are Microsoft and are launching Windows!) because a period of time in the "chasm" is to be expected and the subsequent re-launch will provide the opportunity for a major programme of execution strategies*."

CONCLUSIONS

This study explored what kinds of launch challenges can be identified from marketing perspective when launching technology applications through customer projects. The main phases of launch are similar for launch of a product and of an innovative technology

application through a customer project, but the time scale and the launch activities differ, as well as the major challenges. With the help of the in-depth case study, the vagueness of the concept of product and launch strategy, effects of product innovativeness on marketing, promotion decisions, sales force management, and the vague launch process were identified as challenging areas of launch in the studied context.

The differences between the launch challenges identified in the literature review and in the examined case can be largely explained by the strategy of the examined firm and the characteristics of its business field, which are not included to the general launch literature examining firms offering standardized products through several distribution channels in competitive markets where relationship marketing is not in a dominating role. The firm having a firm strategy based on succeeding in technology delivery *projects* means that product has a less central role in the firm strategy, and the concept of product can be vague, and therefore the concept of launch is vague. The need for *product customization* is one reason for the vagueness of the concept of product. Products support the overall firm strategy and are developed and introduced via customer projects. Innovative applications initially introduced in customer projects are the first ever implemented versions of the application. Identified effect of *the moderate competition and importance of relationship marketing* is that advertising and other means of traditional push marketing communications are less important when initially introducing new applications. Instead, launch challenges are related to getting the first customer to buy the application that is not yet even developed. Succeeding in the first customer project is crucial due to the reference value of the first project, if the application has a high business potential. The first customer reference can be considered as the first step in a process of launching the application for a broader market. Later the perhaps a more promotional re-launch introduces a product family suited for different needs, where an application is both modular and customizable.

Theoretical implications

This study contributes to the existing launch literature; *first*, by identifying the launch challenges relevant for the particular context and illustrating in detail how they differ from the challenges identified in the existing launch literature. These challenges are only partly discussed in the existing industrial marketing or innovation literature, and only marginally in the launch literature. For example, the importance of references for launching industrial innovations [46,47,48], the meaning of the first reference for technology start-ups [49,50,51], and the challenges of choosing the first reference customer for high technology products [23] touch the launch challenges identified in this study, but they focus on references, not on launch. *Second*, the study extends the scope of different types of contexts included in launch research and discusses the effects of the context characteristics to the perceived launch challenges. With the help of the case examination it was possible to incorporate the presented context characteristics, such as customization and project business, and the challenges related to them to the launch research. In the literature review these issues were discussed through e.g. project marketing, high technology marketing, and reference marketing research. Even though launch is an established research stream, it has focused on a limited set of contexts. *Third*, the study brings empirical support for the previously mostly theoretically justified concept of re-launch [19].

Managerial implications

This study offers implications for managers responsible for new product introductions in firms operating in high technology project business. Especially the study provides an insight into the specific launch challenges they might face. The challenges are different depending on the launch context, and therefore the general wisdom of launch research might not apply to every firm. Similarly, no generic launch strategies are found [32]. All in all, the path from an idea to a modular application can be seen to go through the first customer reference, further development and a re-launch. References have such an important role in selling and marketing the innovative applications that reference management deserves special attention after the first customer project has been successfully implemented. The situation at the each reference facility should be monitored, the reference lists should be continuously updated and relationship with the reference customers nurtured [35]. Systematically thinking the application life cycle and planning marketing communication activities to the phases of launch and re-launch could help to enhance marketing communications. Even though personal contact to the customer might be the major channel for marketing communications, other means to inform the potential customers could be perhaps utilized more actively in order to support new product sales also in project business. Based on this study, Internet appears to be a good communication channel, where the information is easy to find, customers are present, and also interaction with the customers is possible, or at least the contact information is available for further inquiries.

Even though an application launch might not appear relevant for a firm focused on the delivery of customized integrated solutions, the current research encourages development of modular solutions [28], mostly in order to gain cost efficiencies and to release resources from inventing the wheel again. It is challenging to encourage innovativeness and keep the modules compatible [39], and to cut the costs and to meet the customer needs at the same time. Technologically advanced and modular applications could be considered as the core around which the customized solutions are built. So the applications are, however, important in this type of business, too.

Evaluation of the study

A single-case research design offered a possibility to build a rich description of a customer project including an innovative technology application and the marketing practices of the firm. The study offers a starting point for further studies on the topic. At the same time the limitations by exploring a single case are acknowledged. The findings of the study can be considered applicable to similar contexts, referring to application launches of firms with a strong position in relationship-based industrial project business and which compete with advanced technology. Nevertheless, the research design was built on the existing general launch literature and the theoretical generalization was conducted by linking the findings to the general launch discussion. In order to enhance the reliability of the findings the data sources and the analysis process were explained, and quotations from the interviews were presented [62]. The iterative and a stepped analysis process aimed to strengthen the internal validity of the findings so that the categorization would represent the contents of the data as literally as possible. Utilization of the case data from firm interviews and documents, researcher's memos, and public sources gave a possibility to do data

triangulation in order to support the validity of the findings [62]. No remarkable differences (i.e. how the degree of innovativeness of the introduced application was described) were identified between the data sources. It can be considered whether the concept of launch is valid in the examined firm where the concepts of product and launch were ambiguous. However, both concepts were used in the data and, even though an application launch was not in a central role compared to project marketing efforts and technology marketing, data from both the interviews and public sources contained evidence, that an application launch is an identifiable activity in the firm. Even though the concept of launch was not defined or brought up by the interviewer in the interviews so that the perceptions of the interviewees on launch would not be affected, launch referred in the empirical data to the same phenomenon as in the literature.

Avenues for future research

The findings are applicable only with caution to other contexts than specified in this study, and therefore more research is needed on the topic with broader sets of data in order to strengthen the external validity of the findings. In general, the literature on launch challenges is scattered and scarcer than the research on launch success factors. Launch challenges were not the main focus of any of the reviewed launch studies. This study does not commit on evaluating and comparing the importance of the different launch challenges, which could be another topic for future studies. The concept of re-launch was relevant in the studied context, but it fits poorly to the current launch literature which often presents launch as the last phase of a NPD process [12,24,53]. Perhaps more research effort is needed in order to understand launch and re-launch as parts of the product life cycle. This study suggests that launch could be studied in a broader set of firms than the current launch literature does, because the phenomenon of launch appears to have context-dependent characteristics. The role of product launch could be also examined in firms where the strategy is not built around products, because innovative repeatable modules, products or applications are often important parts of broader offerings, but this type of launch research is missing.

ABSTRACT

At present, the Website evaluation of Government websites are starting point for general public and focus on people's convenience, data correctness, and Aesthetics, lack of customer locality and intention on return. From the Web of Industrial Development Bureau in Ministry of Economic (MOE) at Taiwan, we found that the web customers are not general people, they are special require in skill, biological, or VC. Therefore, we need a new method to evaluate the website effectiveness. Lin and Lu (2004) proposed website accepted model, this model can use to evaluate the consumer's intention of website. By using website accepted model, we adopt functional service quality, computer system quality, perceived usefulness and perceived ease of use to estimate a new model to evaluate consumer's intention to return the MOE Website in Taiwan.

The study collected 259 government web users, and got some founding as followed: 1. In functional service quality of MOE website, customer agree it they can got correct information, and full information about project related law, police of government; 2. In computer system quality, User hope that when need to use, they can connect the MOE website successfully at anytime, anywhere, and don't happen website closed or shutdown; 3. Tthe responders feel that the MOE website is usefulness and easy to use; 4. If website has all the above functions, they will like to intention on return to the government website on Industrial Development Bureau in Ministry of Economic.

Keywords: Electronic government, website user's satisfaction, intention to return, Industrial Development Bureau in Ministry of Economic.

INTRODUCTION

As technology advances and information technology advances, the portal of Internet and web site integration and promote the development of information and links. In order to reduce the distance of people, enterprises can use the Internet and websites to interact with partner companies and customers around the world. As the Internet information is completely transparent, customer loyalty lower than in the past weak, so revisit the site loyalty and willingness to greater significance. If you can maintain the loyalty of site users, the users continue to come back to the original site to use various services, it will to ensure the site's competitive advantage. Revisiting the site on behalf of customers are willing to accept a service or product means the higher degree of Internet users revisit the site and the higher degree of the Internet use.

Ministry of Economic Affairs commissioned for a variety of project are set to an entry site for people or business to check or to bid the cases. The site offered network service and retrieval service, but it lack of the function of evaluation the customer loyalty and willingness to revisit. Industrial Development Bureau Ministry of Economic Affairs, for example, offering the site of commissioned project plan is not public, but for those with special needs such as technology, biotechnology, venture capital, etc., so it is necessary to establish a new assessment models to evaluate the sites effectiveness of these sites.

LITERATURES REVIEW

E-Government

e-Government (short for electronic government, also known as e-gov, digital government, online government, or connected government) is digital interaction between a government and citizens (G2C), government and businesses/commerce/eCommerce (G2B). This digital interaction consists of governance, information and communication technology, business process re-engineering (BPR), and e-citizen at all levels of government (city, state/provence, national, and international). Essentially, the term e-Government or also known as Digital Government, refers to 'How government utilized IT, ICT and other telecommunication technologies, to enhance the efficiency and effectiveness in the public sector (Jeong, 2006).

E-Government should enable anyone visiting a city website to communicate and interact with city employees via the Internet with graphical user interfaces (GUI), instant-messaging (IM), audio/video presentations, and in any way more sophisticated than a simple email letter to the address provided at the site (Kaylor et al., 2001), the use of technology to

enhance the access to and delivery of government services to benefit citizens, business partners and employees (Deloitte Research, 2000). The focus should be on:

- The use of Information and communication technologies, and particularly the Internet, as a tool to achieve better government (OECD, 2003).
- The use of information and communication technologies in all facets of the operations of a government organization (Koh and Prybutok, 2003).
- The continuous optimization of service delivery, constituency participation and governance by transforming internal and external relationships through technology, the Internet and new media (Gartner Group, 2000).

While e-Government has traditionally been understood as being centered around the operations of government, e-Governance is understood to extend the scope by including citizen engagement and participation in governance. As such, following in line with the OECD definition of e-Government, e-Governance can be defined as the use of ICTs as a tool to achieve better governance.

E-government portals and platforms

The primary delivery models of e-Government are classified depending on who benefits. In the development of public sector or private sector portals and platforms, a system is created that benefits all constituents. Citizens needing to renew their vehicle registration have a convenient way to accomplish it while already engaged in meeting the regulatory inspection requirement. On behalf of a government partner, business provides what has traditionally, and solely, managed by government and can use this service to generate profit or attract new customers. Government agencies are relieved of the cost and complexity of having to process the transactions (Jeong, 2006).

To develop these public sector portals or platforms, governments have the choice to internally develop and manage, outsource, or sign a self-funding contract. The self-funding model creates portals that pay for themselves through convenience fees for certain e-government transactions, known as self-funding portals.

Technology Acceptance Model

David et al.(1989) originally formulated the Technology Acceptance Model (TAM) in an attempt to understand why people accept or reject information systems. Davis adapted and Ajzen and Fishbein's (1980) Theory of Reasoned Action (TRA) to intentions to accept the information technology. The original TAM explained the causal links between beliefs

(usefulness of an IS and easy of using the IS) and users' attitudes, intentions and "actual computer adoption behavior" (Davis et al. 1989). The purpose of the TMA was to explain and predict user acceptance of IS from measures taken after a brief period of interaction with the system. A person's acceptance of an IS is hypothesized to be determined by his or her intention to accept it. The intention, in turn, is determined by the person's attitude toward the IS and his/her perceptions concerning its usefulness. Attitudes are formed from beliefs a person hold about the IS (Szajna, 1996). Lin and Lu (2000) proposed website accepted model, this model can use to evaluate the consumer's intention of website. By using website accepted model, we adopt functional service quality, computer system quality, perceived usefulness and perceived ease of use to estimate a new model to evaluate consumer's intention to return the MOE Website in Taiwan.

The Portal of Project Plan Industrial Development Bureau, MOE Taiwan

The concept of electronic government was first proposed in United States in 1997, the other countries started later, but gradually mastered over the Internet to provide services to the people and interact with the public. Taiwan promoted the e-Government for more than 10 years, successful completion of the Government of network infrastructure and other medium-range plan of Internet applications. Ministry of Economic Affairs in charge of the national industrial development, to assist industrial innovation and transformation and upgrading, comprehensive counseling and assistance manufacturers in investment, strengthen the operating structure to enhance their competitiveness ability. The Industrial Development Bureau(IDB), not only to promote the various project plans, but also through the aerospace industry, rail vehicle industry, precision machinery, biotechnology and pharmaceutical industry, communications industry to helping improve the building industry, hardware and software environment, promote foreign investment, technology transfer and the introduction of industrial cooperation and capacity learn cooperation, to create a good environment for sustainable industry development.

The policy of IDB is to promote the industrial development of new and key industries, high-value industry and new services. Also to help Taiwan industrial R & D, enhance the international operations, shaping the sustainable development of a quality environment and the strengthening of industrial human resources training. The current project plan commissioned a total of 79 sites. Technology to achieve the policy objectives of the Industrial Development Bureau, commissioned the Foundation, corporation aggregate, academic research institutions, tertiary institutions and industry associations and other organizations to promote and implement the project plan to implement the policy direction of Taiwan's industrial development, a total of 4,231 counseling firms, the overall increase in firms of more than US$4.17 billion output value, the overall lower cost manufacturers up to

more than US$780 million dollars. Commissioned projects are set to have an import site plans, please refer to Figure 1.

Figure1: The Portal of Project Plan Industrial Development Bureau, Ministry of Economic Affairs.

Evaluation the Website of Government

The features of website of government can be divided into several categories: based portal, providing convenient service categories and types of information-based. RDEC of Taiwan in From year 2007, RDEC began to promote and improve government service quality, continued the year 2005 conducted executive appraisal, assessment indicators are six main items: Web site is correct, sufficient and appropriate, Site restoration, Site structure and navigation, interactive bidding function, layout and multimedia design and Website promotion and management (Development and Evaluation Commission, Taiwan, 2005).

From year 2007, RDEC began to promote and improve government service quality, continued to promote the public satisfied with the service, to ensure the public's right to know and the right to use information and to encourage agencies to provide creative integration services as the three core objectives, the creation of the Government Service Quality Award, as the evaluation of service quality to promote the people, of which government website evaluation by the Government Service Quality Award operations manual, the flow of information services dimension, including the two are assessed to provide information and retrieval services and online services and e-participation (Development and Evaluation Commission, 2008). The computer user satisfaction is the

organization provided by means of computer-based information and services, the user feeling and emotion generated by the integrated response (Pearson, 1997). Mckinney et al. (2002) research focuses on different types of user satisfaction in IS: system satisfaction, process satisfaction, and outcome satisfaction; and explores interrelationships among them. Web site information quality is whether the information provided could satisfied user demand, like the relevance of information, practical and easy to understand, accuracy, reliability, timeliness and completeness of the presentation as a judge.

Consumer intention to return the Web

Corporations spend millions of dollars a year creating and maintaining corporate websites, yet many of these sites fail to reach the organization's goals (Freemantle, 2002);. Recent research suggests that these failures reflect poor website design, yet this research lacks the specificity necessary to provide practical recommendations for improving site performance (Rosen and Purinton , 2004). Hausman and Siekpe (2009) proposed the way to fill that gap by providing specific recommendations regarding website design elements that generate positive managerial outcomes. First, he test a wide range of design elements to determine those that providing human elements and computer elements. Next, these elements are linked through intermediaries using the uses and gratifications theory, technology acceptance model, and the concept of flow to explain purchase intentions and intentions to revisit the site. Lin and LU (2004) consider the information system success model is proposed information quality, response time, system accessibility for the external technology acceptance model variables to verify the user intention to accept the use of the Internet.

RESEARCH METHODOLOGY

This study focuses on the project commissioned site of Industrial Development Bureau Ministry of Economic Affairs, to understand the site quality and site acceptance model to measure the user willing to reuse the site, the tendency, the research framework as figure 2.

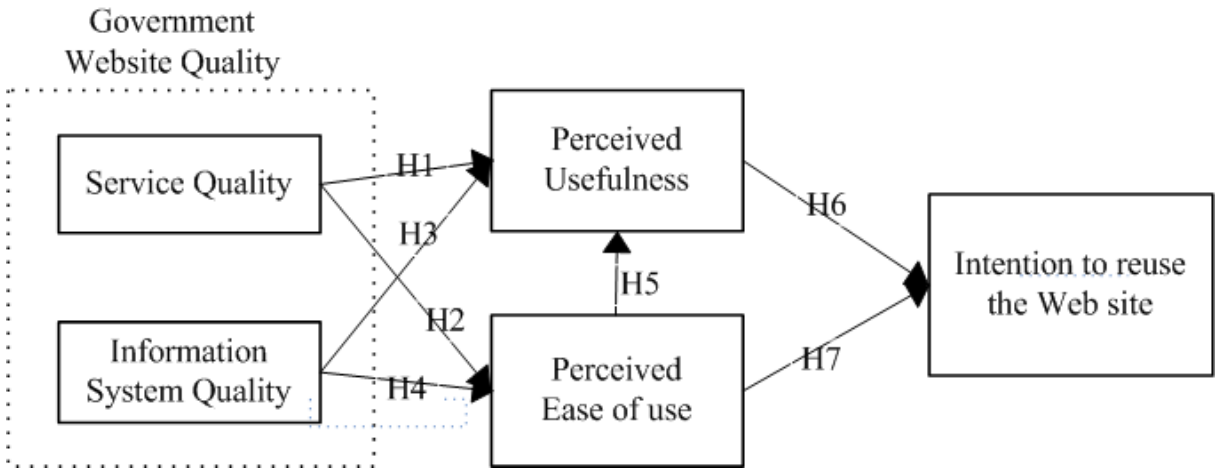

Figure 2: Framework

The Government commissioned this study to the quality of web information systems, the two parts of the affected users feel the satisfaction of Internet use, its contents and definitions are as follows; government commissioned site quality into functional service quality and the quality of the computer system, function quality of service whether to use the site to meet the needs of the user's work, including energy-related businesses on the site by public law, policy and full, accurate information, website design Category clear layout beautiful art, the site use the operating smoothly. The quality of the computer system platform for the site quality of the computer system, including Web site information to search or enter the action, the implementation of the results can be smooth and normal display, do not experience unknown site or no site is off the page to read often lead to an error occurs on this page not found. Feel part of the user: the user's knowledge and attitude on the system easy to use, or usefulness of such can be expected that the behavior of the user after use. For example, in using the Web site, whether they find easy to use, using the Internet, whether they find this site useful. The Hypothesis of this study as followed:

H1：Government Web sites Service Quality has positive correction with Perceived Usefulness
H2：Government Web sites Service Quality has positive correction with Perceived Ease of use
H3：Government Web sites Information System Quality has positive correction with Perceived Usefulness
H4：Government Web sites Information System Quality has positive correction with Perceived Ease of use
H5：Perceived Ease of use has positive correction with Perceived Usefulness
H6：Perceived Usefulness has positive correction with Intention to reuse the Web site
H7：Perceived Ease of use has positive correction with Intention to reuse the Web site

The study sample was 60 Ministry of Economic Affairs commissioned the site users, so the sample by sample surveys, site selection 5 users each commissioned to conduct a questionnaire survey sampled a total of 300 samples. And pre-test questionnaires at the 15 test the questionnaire, collect test suggested that, for some ambiguous place after the final adjustment and modification. Asked five-point Likert scale mining securities (Likert Scale), from strongly agree to strongly disagree is divided into five levels for subjects respondents. Using SPSS 12.0 Windows professional software as the statistical analysis tools. The analysis is based on descriptive statistics of the basic characteristics of the sample analysis, factor analysis to the validity analysis, and Cronbach's α for reliability analysis, regression testing with the hypothesis of this study is established.

DATA ANALYSIS

Sample Description

This study to investigate from 12/01/2010 to 12/31/2010, totally 259 valid questionnaires were collected, the analysis based on the demographic variables of gender, age, education, occupation, browser frequency. We use distribution statistics to analysis the frequent of commissioned sites, in order to understand the structure of the samples. On gender, the proportion of women slightly more, 57.14%; in the age distribution, 30 to 40 years more, accounting for 42.85%, Proportion of the age under 20 are none; to educational attainment, the university and Master degree are the largest proportion, the two combined ratio is 96.13%; in the occupation, the proportion of the general services the most, accounting for 24.71%, followed by the electronic information industry, the percentage ratio was 23.55%.

The intention of the questionnaire of users were divided into five parts, dimensions, features a total of seven parts of the service quality items, the quality of some computer systems include eight items, users feel a useful part of the total of six items , users feel easy to use part of a total of six items, intention to use the site part of a total of five dimensions of items. Respondents in the functional service quality dimensions of the answer to the results of the various items mean and standard deviation shown in Table 1, most respondents agree that the Industrial Development Bureau website to provide relevant information to the right, followed by image classification of items that the site is Clearly, the site also conforms to the image of the project design.

Table 1: Question of Service Quality.

No	Question	Mean	Standard Deviation
SQ1.	**I can get from the website of government the business plan related to public laws, policies and adequate information.**	**4.02**	**0.838**
SQ2	**It's hard to find the information provided by the website from other sites.**	**3.52**	**1.001**
SQ3.	**I think the website can provide correct information.**	**4.17**	**0.787**
SQ4.	**I think the classified projects is very clear.**	**4.05**	**0.787**
SQ5.	**The image design of the site is adequate for the project.**	**4.05**	**0.809**
SQ6.	**The layout and graphic design of the site looks good.**	**3.87**	**0.850**
SQ7.	**Operation and layout of the site is very smooth.**	**3.92**	**0.806**

Respondents in the computer system the results of quality dimensions of the answer, all items of the mean and standard deviation shown in Table 2, respondents in the quality of the most requested is smooth anywhere when needed to connect to this website, do not experience this site or unexplained construction site is off, followed by request rapidly turn smoothly site's home page in the site search or input actions, the implementation of the results can be smooth and normal display.

Table 2: Question of Information System Quality.

No	Question	Mean	S.D.
ISQ1.	**Web site links invalid, page errors or can not found won't happened.**	**4.01**	**0.934**
ISQ2.	**When I need a smooth connection anytime, and anywhere when browsing this site, the web site is under construction or unexplained close will not happened.**	**4.13**	**0.920**
ISQ3.	**When I entered this site or the information search actions, the implementation of the results can be smooth and normal.**	**4.03**	**0.882**
ISQ4.	**I think the home page opens quickly and smoothly.**	**4.05**	**0.857**
ISQ5.	**I think the site's pages reads fast.**	**3.97**	**0.877**
ISQ6.	**I think the website information text and picture is easy to understand.**	**3.97**	**0.866**
ISQ7.	**Site have a privacy policy or information security policy statement**	**3.86**	**0.937**
ISQ8.	**Personal data privacy protection can be trusted.**	**3.95**	**0.913**

Respondents feel useful to the user to answer the result dimension, the items of the mean and standard deviation shown in Table 3, respondents felt the site useful, feel that this site as a whole, the website of the respondents Very useful and practical help.

Table 3: Question of Perceived Ease of use.

No	Question	Mean	S. D.
PEU1.	**Learn to use this web site is very easy.**	**4.11**	**0.808**
PEU2.	**When Using this site will not be confused.**	**4.03**	**0.837**
PEU3.	**Using this site will not have unexpected error messages.**	**4.05**	**0.886**
PEU4.	**Get the information from this site is easy.**	**4.09**	**0.808**
PEU5.	**It is easy to familiar with the website.**	**4.15**	**0.827**
PEU6.	**Overall, I think this site is easy to use.**	**4.16**	**0.813**

Respondents felt use dimensions in the user answers, the results of the various items mean and standard deviation as shown in Table 4, respondents felt the site easy to use, think of this site as a whole, the website by respondents very easy to use and easy to learn, easy to proficiency.

Table 4: Question of Perceived Usefulness.

No	Question	Mean	S.D.
PU1.	**Without this site, will make me feel bad.**	**3.79**	**0.904**
PU2.	**This site is actually helpful to me.**	**4.03**	**0.828**
PU3	**Use of this site will improve my efficiency.**	**3.92**	**0.802**
PU4	**Use of this Web site can save lots of time for me.**	**3.95**	**0.856**
PU5.	**This website enhance the quality of deal with things.**	**3.88**	**0.866**
PU6.	**Overall, I think this site is useful to me.**	**4.04**	**0.835**

Intention of the respondents in the use of the website to answer the result dimension, all items of the mean and standard deviation shown in Table 5, respondents intention in the use of websites, find this site were satisfied and considerable like to use this site..

Table 5: Question of Intention to reuse the Web site.

No	Question	Mean	S.D.
ITR1.	**Overall, I like to use this site a lot.**	**4.00**	**0.849**
ITR2.	**I think it is a very good choice to use the site.**	**4.04**	**0.794**
ITR3.	**I am satisfied with this site.**	**4.04**	**0.806**
ITR4.	**If use such government websites in the future, I will think of this web site.**	**4.12**	**0.843**
ITR5.	**If need use such government web sites, I will definitely use this site.**	**4.11**	**0.859**

Reliability and Validity

In this study, using factor analysis to reduce or inductive dimension variables, using principal component analysis (Principal Components Analysis) for each dimension of scale, structure factors were extracted, and the orthogonal axis method (Orthogonal Rotation) of the maximum variation Method (Varimax) for the shaft to obtain the rotation matrix load, while using Cronbach's α coefficient to detect the dimensions of the questionnaire reliability.
Functional service quality dimensions are 7 questions asked were designed items, the principal component analysis to factor analysis, variance explained 59.230%, KMO value is 0.859, P-value is 0.000, see Table 6.

Table 6: Factors analysis for Service Quality.

	Content of factors	Factor loadings Component 1
SQ4.	**I think the classified projects is very clear.**	**0.860**
SQ5.	**The image design of the site is adequate for the project.**	**0.836**
SQ7.	**Operation and layout of the site is very smooth.**	**0.836**
SQ3.	**I think the website can provide correct information.**	**0.780**
SQ6.	**The layout and graphic design of the site looks good.**	**0.778**
SQ1.	**I can get from the website of government the business plan related to public laws, policies and adequate information.**	**0.726**
SQ2.	**It's hard to find the information provided by the website from other sites.**	**0.517**

Hypothesis test and discussion

The Government commissioned site features a useful sense of service quality for users (H1) and the users feel easy to use (H2) of the hypothesis of the regression analysis are shown in Table 12 and Table 13 shows, the hypotheses H1 and H2's not been significant. The results support that the Government commissioned website features a useful sense of service quality for users feel easy to use and user does not exist significant positive correlation.

Table 12: The Regression Model of Government Web sites Service Quality to Perceived Usefulness.

Regression	**Dependent：Perceived Usefulness**			
Independent	**Std. Error of the Estimate**	**Standardized Coefficients Beta**	**t**	**Sig.**
Service Quality	**0.9799**	**-0.208**	**-3.415**	**0.01**
Test Value	**R Square = 0.043**		**Adjusted R Square = 0.040**	
	F= 11.664		**P= 0.01**	
	Durbin-Watson= 1.574			

Table 13: The Regression Model of Government Web sites Service Quality to Perceived Ease of use.

Regression	Dependent：Perceived Ease of use			
Independent	**Std. Error of the Estimate**	**Standardized Coefficients Beta**	**t**	**Sig.**
Service Quality	**0.9887**	**-0.162**	**-2.629**	**0.09**
Test Value	**R Square = 0.026** **F= 6.911** **Durbin-Watson= 1.474**		**Adjusted R Square = 0.022** **P= 0.09**	

Hypothesis H3, the results of regression analysis in Table 14, shows the results of this study support the hypothesis H3, that the Government commissioned site computer system useful for the quality of the user has a positive correlation between sensation. Hypothesis H4 regression analysis in Table 15, shows the results of this study support the hypothesis H4, that the Government commissioned the quality of the user computer system site easy to use has a positive correlation between sensation.

Table 14: The Regression Model of Government Web sites Information System Quality to Perceived Usefulness.

Regression	Dependent：Perceived Usefulness			
Independent	**Std. Error of the Estimate**	**Standardized Coefficients Beta**	**t**	**Sig.**

CONCLUSION

This study was to explore the effectiveness of the Website of the Government commissioned project. After Web survey, we got several important results: (1) functional service quality level, respondents believed that they can get correct information from the

website, to get Ministry of Economic Affairs commissioned the business plan related to public laws, policies and full information. (2) The computer system quality, Users hope that when need to use, they can connect the MOE website successfully at anytime, anywhere, and don't happen website closed or shutdown; (3) The responders feel that the MOE website is usefulness and easy to use; (4) If website has all the above functions, they will like to intention on return to the government website on Industrial Development Bureau in Ministry of Economic, they will like to use this site definitely.

MANUFACTURING CAPABILITIES PRIORITIZATION TO ACHIEVE CUSTOMER FOCUS IN KNOWLEDGE-INTENSIVE ENVIRONMENTS

Ajmal, Mian M., Abu Dhabi University, United Arab Emirates
mian.ajmal@adu.ac.ae

Sandhu, Maqsood, UAE University, United Arab Emirates

ABSTRACT

This paper explores the significance of knowledge attributes to establish a competitive manufacturing capability by further developing an understanding of knowledge and manufacturing strategies in small and large companies. A theoretical framework is developed initially. Later on an intensive survey of small and large manufacturing companies leads to the design of a process to prioritize manufacturing capabilities. Results show that large manufacturing companies putting higher demand for know-why knowledge attribute by considering all manufacturing capabilities to achieve customer focus. On the other hand, small size manufacturing companies putting higher demand for know-what knowledge attribute just by considering two manufacturing capabilities like quality and delivery. Results are derived from a limited number of empirical data only in one country, therefore these cannot be generalized. Future research with larger samples of small and large manufacturing firms from other countries is needed. To be competitive, manufacturing companies must reshuffle their production strategies to allow the company to play a part in global knowledge-intensive competition. Therefore, they should incorporate knowledge attributes as a way to achieve higher levels of firm performance. This study is among the first and most exhaustive studies carried out in the small and large size firms operating in the manufacturing sector. It provides a conceptual model of how four manufacturing capabilities are being exploited to achieve customer focus by being specific in three knowledge attributes like: know-what, who-how and know-why.

Keywords: Knowledge management, knowledge intensive environments, manufacturing capabilities, manufacturing companies, production, and customer focus

INTRODUCTION

In recent years, there has been an escalating concentration on the knowledge-based organization (Robertson and Swan, 2004) since the world shifts from an industrial age to an information-based era (Teo et al., 2008). In order to survive and remain competitive, small and large manufacturing firms, require creating and restoring knowledge continuously (Valkokari and Helander, 2007). Knowledge has become an essential source of value generation and sustainable competitive advantage (Teece, 2005; Ajmal et al., 2009). The ability of manufacturing firms to create knowledge persistently and manage it strategically is viewed as critical to organizational success and survival (Nonaka and Teece, 2001; Desouza and Awazu, 2006).

Organizations that build up and leverage knowledge resources attain greater success than firms who are more reliant on tangible resources (Autio et al., 2000). Knowledge

management is ever more becoming an primary business function for many firms as well as for individual projects (Ajmal et al., 2010), as they realize that organizational competitiveness pivot on the effective management and creation of knowledge (Randeree, 2006).

On the other hand, competition in the manufacturing sector has increased as globalization and customer requirements have evolved. Manufacturing companies are increasingly influenced by intense foreign competition, rapid technological change, shorter product life-cycles and customers ever more unwilling to settle for mass-produced items or services with limited value (Krause et al., 1998; Hitt et al., 1998; Zhang et al., 2003). Customers are having full fledged knowledge demand greater responsiveness to a dynamic set of requirements. Now, organizations are competing not only with their external capabilities but also on their abilities to leverage manufacturing capabilities.

Increased customer requirements coupled with competitive pressure from globalization have forced managers to ensure that their organization's resources are well aligned not only across all functional areas but also throughout the entire supply chain. This alignment is the key in developing and maintaining manufacturing capabilities required in meeting evolving customer demands in knowledge-intensive environments.

The primary goal of this paper is to assess the significance of knowledge attributes for achieving customer focus goal by taking into account the manufacturing capabilities in small and large manufacturing companies. The paper is structured as follow. First it portraits theoretical background of the concepts used in the study. Second it describes research methodology and preliminary findings. Finally, it comes with the conclusions and future research directions.

LITERATURE REVIEW

Manufacturing capabilities

The major theme of manufacturing capabilities is the manufacturers' choice of emphasis among key tasks. These capabilities or competitive priorities include cost efficiency, high quality, fast and reliable delivery, and product/process flexibility (Hayes and Wheelwright, 1984; Hill, 1994; Krajewski and Ritzman, 1996). Recent studies suggested that manufacturing capabilities are built sequentially over time. First, a solid foundation of quality; second, delivery; followed by low cost and flexibility capabilities. Four competitive priorities, the dimensions on which a firm's operations have elected to compete in the marketplace (Hayes and Wheelwright, 1984), have been generally accepted in the literature. They are (i) cost (ii) quality (iii) flexibility; and (iv) delivery.

Cost

Competing in the marketplace on the basis of cost efficiency requires striving for low cost production. In order to keep manufacturing costs competitive, managers must address materials, labor, overhead, and other costs. Inventories have long been the focus of cost reduction in factories and are one of the justifications of the JIT system. Therefore, inventory and inventory-related items, such as improving vendor's quality, reducing waste of purchased materials, are considered as the indicators of the cost capability. Realizing low inventory level, decreasing labor cost, and reducing machine time are all positive factors of the cost efficiency construct.

Quality

Quality has been identified as a manufacturer's capability to compete in the world market (Hill, 1994; Krajewski and Ritzman, 1996). Quality was defined as process quality and pre-sale, transactional, and post-sale services. Quality means superior features and close tolerance of the product. The strength of the quality control/assurance function in the plant is the indicator of quality emphasis (Evans and Lindsay, 1996). Quality also means helpfulness, courteousness, availability of service employees, and convenience of access to service. Pre-sale service enables manufacturers to get information about their customers' needs and provide what the customers want. Transactional service includes good description, documentation, and training. Post-sale service includes installation, warranty, alterations, and repair.

Flexibility

Flexibility is the ability to respond to changes. In this study, the construct was defined primarily in terms of increasing and/or decreasing of product mix, volume, and product design. Flexibility is the ability to accommodate the unique needs of each customer and typically implies that the production operating system must be flexible to handle specific customer needs and changes in design. Product mix flexibility is measured by the frequency of occurrence of product mix changes. Volume flexibility is, on the other hand, to accelerate or decelerate the rate of production quickly to handle large fluctuations in demand.

Manufacturing flexibility was originally defined as the ability of a manufacturing firm to respond to environmental changes (Mandelbaum, 1978; Li, 2000). Research by Upton (1995) defined manufacturing flexibility as the capability to react to market changes within a shorter time and at less cost. Other researchers have suggested that manufacturing flexibility is a multi-dimensional construct that could be measured in many different ways (Sethi and Sethi, 1990; Gerwin, 1993; Duclos et al., 2003; Dreyer and Gronhaug, 2004). Recent studies have categorized manufacturing flexibility into internal and external flexibility (Upton, 1995; Chang et al., 2003). The internal manufacturing flexibility is relative to the need to meet customer requirements efficiently and not directly related to market demand and environmental uncertainties. Examples of internal manufacturing flexibility are machine, component, material, and routing flexibilities.

Conversely, external manufacturing flexibility is relative to the need of customer requirements. It is usually recognized well by customers since it directly affects a firm's competitiveness. Examples of external manufacturing flexibility include new product flexibility, product mix flexibility, and volume flexibility. Sethi and Sethi (1990) and Gerwin (1993) defined new product flexibility as the ability to develop new product models quickly and product mix flexibility as the ability to provide product variety in the market. Volume flexibility permits the manufacturers to increase or decrease in the aggregate production level without incurred transition penalties. In regards to delivery, we could talk about speed of delivery or delivery dependability. It is clear that delivery reliability deals with the ability to meet quoted (make-to-order environment) and/or anticipated (make-to-stock environment) dates and quantities. In terms of quality, we could talk about quality of conformance specifications or quality of features of products, and so on.

Swamidass (1988) distinguishes machine-level flexibility from plant-level flexibility. The former being "predominantly technology based" and the latter being derived from a combination of technology, infrastructure, design and engineering capabilities, and the competitive goals and objectives of a firm. Upton (1994) defines internal flexibility as the operations strategy and the set of capabilities a firm nurtures to respond to its environment, and external flexibility as capabilities possessed by the firm and used to accommodate sources of variability to which the firm must respond and which are seen as flexible by the market. This external dimension fits the two major strategies proposed by Hyun and Ahn (1992) for using flexibility: reactive and proactive. In the same vein, Gerwin (1993) also suggests two major strategies for using flexibility: adaptive and redefinition. The adaptive strategy refers to the defensive or reactive use of flexible competencies to accommodate unknown uncertainty, while the redefinition strategy refers to the proactive use of flexible competencies to raise customer expectations, increase uncertainty for rivals and gain competitive edge.

Delivery

Delivery capability is a time issue. Delivery is usually defined in a number of aspects of an organization's operations. One is how quickly a product or service is delivered to a customer. Another is how reliably the products or services are developed and brought to the market. The third is the rate at which improvements in products and process are made (Krajewski and Ritzman, 1996). Many companies seek to maintain or increase their customer base by focusing on the competitive priorities of development speed, and fast and reliable delivery. With time-based competition managers need to carefully identify the steps and time needed to deliver a product or service and then analyze the trade-off between time and cost, and between time and quality.

Customer focus

Customer focus can be defined as the degree to which an organization always fulfils customer requirements and expectations (Philips Quality, 1995). A winning organization must be proverbial with the need to consign the customer as the first priority in every decision taken (Zhang, 2000). The key purpose of an organization is to keep up an invariable association with the customer. Such as, counting customers' proposals in knowledge creation activities, storing knowledge that is valuable to customers, reviewing

customer complaints and applying that knowledge to fulfill customer needs and enhance customer satisfaction (Ju et al., 2006). Bassi and Van Buren (1999) emphasize that the intellectual assets of an organization are not just employees' know-how, but also business process and customers' knowledge as well. Liao (2006) explicates that sharing the information and knowledge about customer needs among co-workers or leaders could proceed as a competitive advantage to the business. Fast learning and knowledge transfer from an individual to another is what an organization must do extremely well in order to retain the products and services in front of the needs and anticipation of customers (Pfister, 2002).

Stankosky (2001) signifies that organizations must comprehend that their customer's problems and needs are absolute and that they are the major inputs of incessant progress and novelty. The customer-focused knowledge strategy focuses on incarcerating knowledge about customers, understanding of customers' needs and bringing the knowledge of the organization to put up with customer problems (O'Dell et al., 1999). Thus, we compose the following section to elaborate the significance of knowledge for manufacturing organizations.

Knowledge and manufacturing

Knowledge is vibrant, relational and based on human action (Davenport and Prusak, 1998; Nonaka and Takeuchi, 1995). There are two kinds of knowledge, explicit and tacit (Polanyi, 1967; Nonaka and Takeuchi, 1995). Explicit knowledge refers to codified knowledge, which is effortlessly transmitted in a formal, explicit and systematic language. Tacit knowledge refers to knowledge that remains much harder to transfer, formalize or codify, due to its individual superiority. Tacit knowledge as divergent to explicit is profoundly rooted in action, commitment and involvement in a specific situation or context (Tsoukas and Vladimirou, 2001) and involves cognitive and procedural components.

The next generation of manufacturing businesses must be in a position to make use of information and extract knowledge from information system and the competitive environment to maximize their return (Davenport and Prusak, 1998) and reuse knowledge for innovation (Hung et al., 2005). This approach converts data to information and transforms information to knowledge (Ajmal and Koskinen, 2008) so that business intelligence can be devised and used in the decision-making process. Nonaka (1994) distinguished knowledge into explicit and tacit. Explicit knowledge is precisely and formally articulated and codified in documents and databases of corporate procedures and best practices (Alter, 2002). Tacit knowledge is the practical wisdom possessed by experts that is difficult to capture, yet repeatedly demonstrated in contexts as varied as factory floors, research laboratories, army basis, and corporate board rooms (Crowley, 2000). Knowledge management has been applied in manufacturing (Paiva et al., 2002; Wang et al., 2004), new product development (Ding and Peters, 2000), production management (Wagner et al., 2000), continuous improvement system (Beckett et al., 2000), customer relationships management (Xu and Walton, 2005), supply chain management (Fan et al., 2000); and online procurement (Hsieh et al., 2002).

However, little research can be found on the application of knowledge management dimensions for prioritization of manufacturing capabilities in highly knowledge-intensive environments. Acquiring knowledge is often associated to learning (Argote, 1999). In manufacturing, there are in-process learning and off-line learning (Upton and Kim, 1998). Lapre and Wassenhove (2002) distinguished these methods as operational learning (yields know-how) and conceptual learning (yields know-why). Following table 1 has elaborated know-what, know-how, and know-why concepts which can be also called as knowledge dimensions (Ajmal et al., 2009a).

Table 1: Knowledge Attributes.

Knowledge Attributes	Features	Practical Examples
'know-what' It specifies what action to take when presented with a set of stimuli. For instance, a salesperson who has been trained to know which product is best suited for various situations.	Least sophisticated variety Easy to apply Incorporated in many computer-systems	In the insurance and banking industries customer service representatives who use database systems to address customer questions about products ranging from dishwashers to latest digital TV sets.
'**know-how'** It is, knowing how to decide on an appropriate response based on a diagnostic process, whether in sales, medicine or any other area. It permits a professional to determine which treatment or action is best.	Sophisticated variety Not easy to apply	In the above mentioned example when customer service representatives suggest the appropriate available option that is most suitable/appropriate for the customers according to their requirements.
'**know-why'** It involves an understanding of underlying theory and/or a range of experience that includes many instances of interactions and exceptions to the norms and conventional wisdom of a profession.	Most Sophisticated variety Complicate to apply	Knowing that an unusually high level of sales might be due to an interactive effect – an influence of one factor that only operates at certain levels of another factor would also represent such 'know-why' knowledge.

Knowledge is debatably the most vital resource of organizations (Grant, 1996). More specifically, know-what corresponds to an understanding of the specific system configurations that different customer groups may want and the different uses they may put these systems to (Garud, 1997). Consequently, learning takes place through interactions between suppliers and customers (Garud, 1997; Von Hippel and Tyre, 1993)

and requires the incorporation of knowledge from different knowledge domains (Newell et al., 2005; Okhuysen and Eisenhardt, 2002).

Know-how symbolizes an understanding of procedures required to manufacture each component and an understanding of how components should be put together to perform as a system (Garud, 1997; Lundvall, 1996). From a management perspective, the capability of producing a particular product and the modification and enhancement of manufacturing processes are enabled through this type of knowledge (Matheus, 2009). Furthermore, the sharing and integration of know-what and know-why knowledge into manufacturing processes is an imperative management deliberation (Newell et al., 2005).

Know-why stands for an understanding of the principles underlying the structure of each component and the interactions between them (Garud, 1997). Know-why reflects the theoretical understanding of why the components of a particular product work together to allow a general purpose of a product, i.e. research and development (Sanchez, 1996). Know-why knowledge exists if an organization is able to modify a product design or to build up an innovative product design to make new product substitutes (Sanchez, 1996).

Many studies have focused knowledge at the technological level (Prencipe, 2005; Sapolsky, 2005). This study has considered knowledge more specifically in relation to manufacturing capabilities. Next section shed light on the methodological approach of this study.

Research Methodology

The purpose of the research is to refine current theory on the attributes of knowledge and to propose a process for competitive manufacturing capability development. Thus, this research is designed by composing multi criteria decision making of KM attributes so as to find their contributions to customer focus strategy through manufacturing competitive priorities. The decision making process follows Analytical Hierarchy Process (AHP) by seeking experts' choices on KM attributes and manufacturing competitive priorities as Figure 1 below.

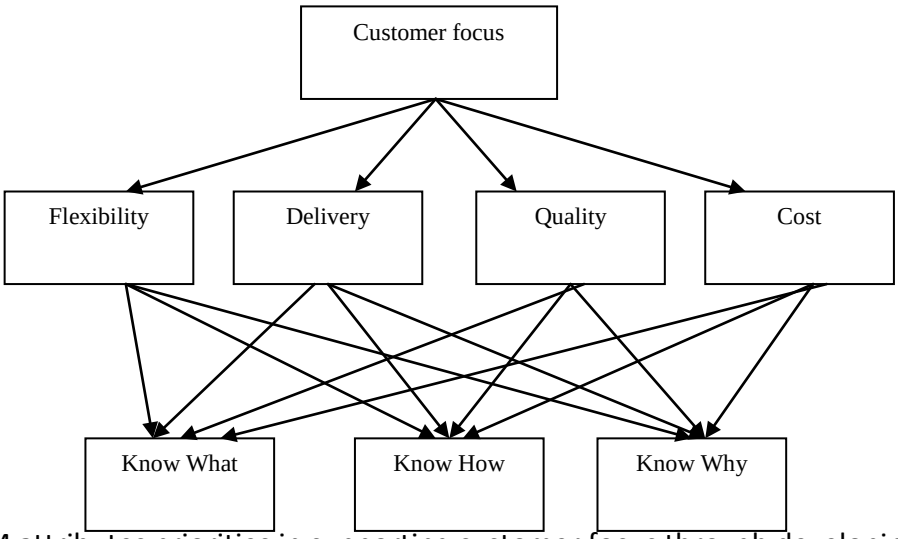

Figure 1: KM attributes priorities in supporting customer focus through developing manufacturing competitive priorities.

Data collection

Particulars of the manufacturing capabilities and knowledge attributes were collected from six manufacturing companies, three of those were small and three were large manufacturing companies situated in Finland. The size of the companies was determined by the number of employees. As explained by the European Commission (see Table 2). Small manufacturing companies were with less than 50 employees and large manufacturing companies were with more than 250 employees. Sample was taken by using same criteria for instance, the similarity of the operations, industrial sectors and corporate cultures of the small and large companies. Operation is defined as their daily manufacturing characteristic here.

The collected data were further analyzed by using AHP. The justification to use AHP is that it requires judgment from senior managers or directors of the companies. Thus, the clear understanding of the questions is strongly important to guarantee the reliabilities of the data. In addition, since the respondents are the key persons in the case companies so that we are confident about its validity.

Table 2: Company categorization (source: the new SME definition: user guide and model declaration, European Commission).

Enterprise category	Headcount: Annual work unit (AWU)	Annual turnover
Large	≥250	≥€ 50 million
Medium	<250	≤€ 50 million
Small	<50	≤€ 10 million

FINDINGS

Analysis is conducted by grouping companies into two categories, small and large size manufacturing companies and we get the results as follows.

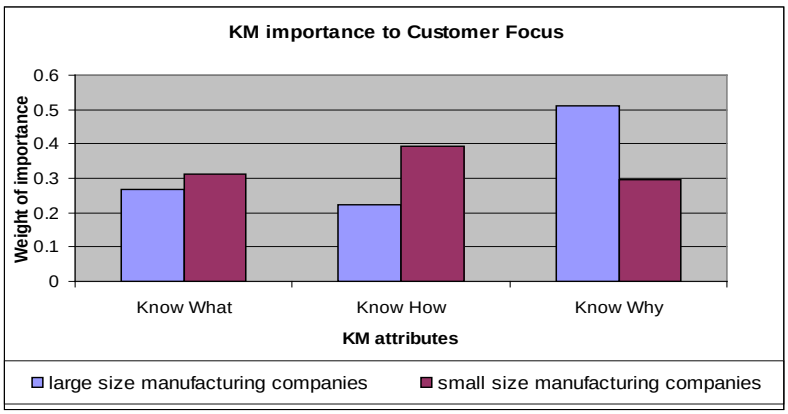

Figure 2: KM attributes priorities in large and small sizes manufacturing companies.

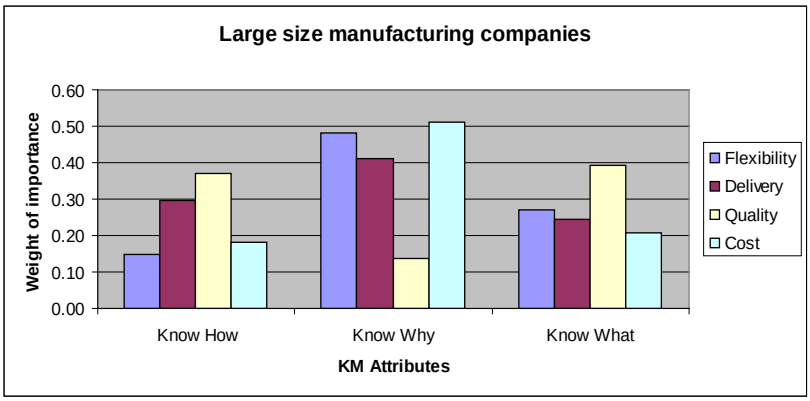

Figure 3: KM attributes priorities in large size manufacturing companies.

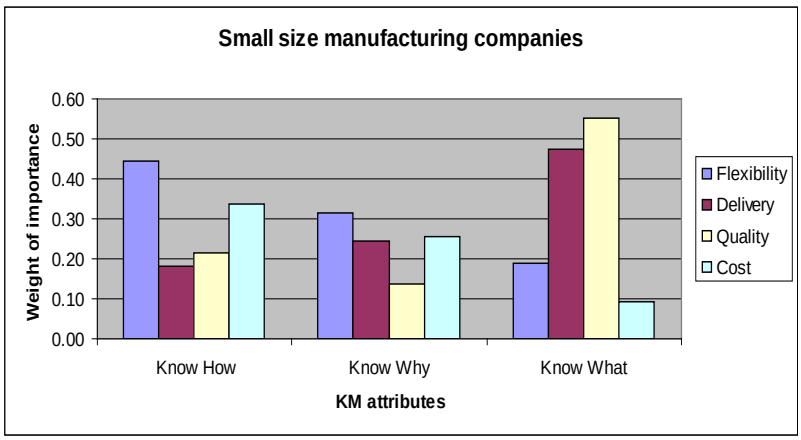

Figure 4: KM attributes priorities in small size manufacturing companies.

Above results show that large size manufacturing companies emphasize on Know-Why and Know-How for small size manufacturing companies as the most important KM attributes for supporting customer focus. Furthermore, this research found that large manufacturing companies putting higher know-why in all manufacturing capabilities as compared to small size companies. On the other hand, small size manufacturing companies putting higher know what in quality and delivery. This suggests that small companies KM is emphasized on routines for keeping their daily activities on the predetermined quality level while large size companies move further by finding the ways to achieve customer focus at the most efficient way.

Finally, this research also found that the both of small and large size manufacturing companies putting flexibility and cost as two most important manufacturing capabilities for supporting customer focus (Figure 5). This suggests that the both manufacturing companies sizes support leagile manufacturing strategy by meeting lean (cost) and agility (flexibility) as competitive advantage over competitors (Shariffi et al, 2006).

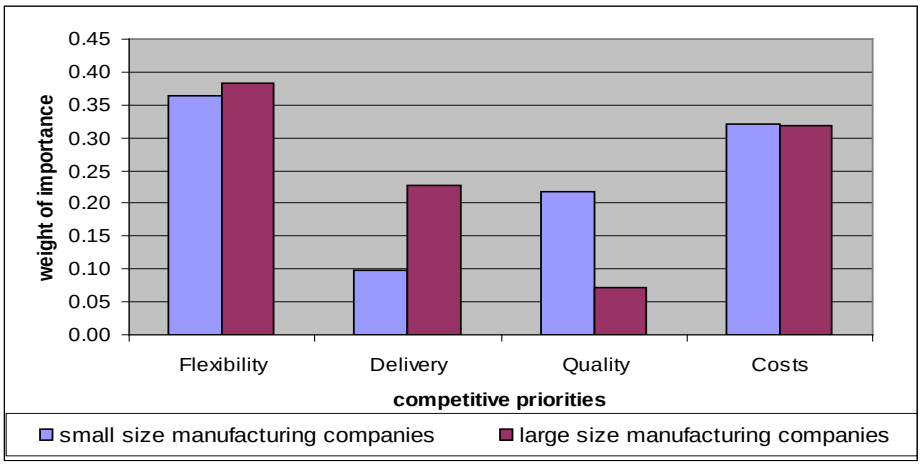

Figure 5: Competitive priorities of large and small sizes manufacturing companies.

CONCLUSION AND FUTURE RESEARCH

This research summarizes conclusions according to previous discussion:

1. Know-what knowledge attribute is for small size manufacturing companies and Know-why knowledge attribute is for large size manufacturing companies.
2. Cost and flexibility are two most important manufacturing capabilities for small and large size manufacturing companies.
3. Small manufacturing companies more emphasize on routine activities while large companies more emphasize on cost efficiency in achieving customer focus.

In terms of future research, it is important to extract further data from small and large manufacturing companies according to their order decoupling point in order to investigate knowledge attributes for different decoupling points. Furthermore, extending this research to service industry is also important to find competitive service strategy.

ABSTRACT

This paper discusses the structure and meaning of business ecosystem in business development, especially in value creation and offering development. The literature is reviewed for describing business ecosystem. Ecosystem metaphor emphasizes symbiotic relationships and dynamic nature of business network members. As a result semiconductor business ecosystem case is described based on information available in public. Companies need to understand their position and role in the ecosystem they are involved. Business ecosystem described through actors' business models defines the structure of the ecosystem and increases understanding of the ecosystem dynamics. Based on ecosystem description actors can analyze potential business development paths concerning company's offering and ecosystem value creation.

Keywords: Business ecosystem, business model, value network, semiconductor industry

INTRODUCTION

Networked business is the reality for most companies in any industry. Business ecosystems are composed of hundreds of and even thousands of organizations globally. (Dittrich and Duysters 2007; Iansiti and Levien 2004b) Individual companies are dependent on success of the whole aggregate and thus face a vast challenge in their business development. To thrive sustainably inside an ecosystem and in competition between rival ecosystems, development and innovation efforts of companies must benefit the ecosystem as a whole.

The metaphor of business ecosystem is derived from biology and used to describe business network originally by Moore (1993). The metaphor provides a vivid view on the nature of business network regardless of the fact that biology and business have not very congruent scientific basis (Corallo et al. 2007). This paper is built on idea that business ecosystem consists of interdependent business actors and "species" of each actor is based on its business model. Thus, business ecosystem can be described through actors' business models.

This paper contributes academic discussion of business networks by studying value creation and offering structures in a business ecosystem. Practical part of the study focuses on actors in semiconductor industry such as foundries, device manufacturers and design houses. The research focuses on business development in an ecosystem and answers to the research question: **How do the business models of actors describe a business ecosystem?**

This study reviews literature for the background. As a main theoretical contribution, a business ecosystem is described as composition of business models of actors. Theoretical background is reflected to practice with a case of semiconductor business ecosystem. The case is built on actors of semiconductor industry based on information available in public. Discussion is focused on business development in an ecosystem and conclusions are drawn against meaning of business ecosystem. The actors can utilize the study for creation and analysis of potential development paths within the ecosystem they are involved.

THEORETICAL BACKGROUND

Business ecosystem is largely overlapping concept with value chain and especially with value network. In general, all those concepts define how organizations are connected to each other to provide value to customers.

The idea of value chains is introduced as industry level approach where each actor, or a firm, adds value to the product (Porter 1985). In a value chain, organizations are horizontally linked to each other and each provides products or services to the next operator in the chain (Porter 1985). Value chain can be considered as a group of sequential activities, which can be connected through information and resource flows. The ultimate goal of a value chain is to provide value to the end customer of the value chain.

In contrast to value chains, in value networks the value created is not only for the customer, but also for firms and societies participating in the network (e.g. Parolini 1999; Bovet and Martha 2000). In value networks, resource and information flows can run vertically and horizontally. These flows can be simultaneous and multidirectional. Therefore, the value network could be rather described as a web than a funnel like value chain. The value network can be considered as a network structure where actors are linked, vertically and/or horizontally, to each other through value exchange activities. The ultimate goal of a value network is to provide value to the end customer and actors participating in the network.

In a business ecosystem it is always possible to identify value network or chain, the structure where actors are linked to each other through value exchange activities. However, ecosystem metaphor emphasizes network members' symbiotic, co-evolving relationships and dynamic nature of business network. Henceforth, business ecosystem is used to define business network in this study and business model is used to define actors of business ecosystem. Business model describes how a firm is creating and capturing value.

Business model elements and components

Business models are actively discussed topic in literature during last fifteen years. As a consequence, dozens of various business model concepts and frameworks exists including

up to fifty different business model components (Morris et al. 2005; Mäkinen and Seppänen 2007; Shafer et al. 2005). For this study couple of various and comparable business model definitions and frameworks is chosen for review. Those frameworks form a representative sample of literature since the origin and purpose of them are different.

Afuah (2004) defines a business model of a firm as a framework for money-making and explains business models as a strategic management approach. This framework is conceptualized through five main elements and embodies money-making aspects of strategies. According Osterwalder and Pigneur (2009) a business model describes the rationale of how an organization creates, delivers and captures value. Furthermore, Osterwalder and Pigneur (2009) explain the business model being like a blueprint for a strategy to be implemented through organizational structures, processes, and systems. It is broadly used model that is conceptualized through four main elements and nine building blocks. Shafer et al. (2005) define business model as a representation of a firm's underlying core logic and strategic choices for creating and capturing value within a value network. This descriptive study is an example of many attempts to define business model by integrating and synthesizing earlier literature. According Suikki et al. (2006) business model describes the offering, the value chain or network, and revenue model of a firm. Suikki et al. (2006) designed their framework for describing and building business models in telecommunications industry. It provides an example of using business model for research purpose in industry settings. Frameworks are presented in Table 1 in terms of main elements and components.

Table 1: Business model elements and components in literature.

Author	**Main elements**	**Components**
Afuah (2004)	Positions	Customer value, market segments, revenue sources, price, relative position (vis-à-vis competitive forces)
	Industry factors	Competitive and macro forces, co-operative forces and industry value drivers
	Activities	Decisions of: Which activities to perform and which not, how to perform activities and when to perform activities?
	Resources	Resources (or assets: tangible, intangible and human), competences (or capabilities)
	Costs	Cost drivers of: industry, resource, activity and position
Osterwalder and Pigneur (2009); *Osterwalder* (2004)	Offer	Value proposition
	Customers	Customer segments, channels and customer relationships
	Infrastructure	Key resources, key activities and key partnerships
	Financial viability	Cost structure and revenue streams
Shafer et al. (2005)	Strategic choices	Customer, value proposition, capabilities/competences, revenue/pricing, competitors, output (offering), strategy, branding, differentiation and mission
	Create value	Resources/assets and processes/activities
	Value network	Suppliers, customer information, customer relationship, information flows and product/service flows
	Capture value	Cost, financial aspects and profit
Suikki et al. (2006)	Offering	Composition, customer and sales approach
	Value creation	Structure, players and size

	system	
	Revenue model	Basic logic, cost and pricing structure, market and share of value

Mäkinen & Seppänen (2007) concluded that literature of business models is diverse and lacks unified taxonomy and conceptual groundings. Besides differences in naming and in hierarchical classification, there is divergence also in actual content of business models. Inside a firm, business model concept is linked with and somehow positioned between strategy and operational level in which activities and processes are carried out (e.g. Osterwalder 2004). It is being argumented whether business model includes competitive strategy, value capture aspects of strategy or is like a blueprint of strategy (Afuah 2004, Chesbrough and Rosenbloom 2002, Osterwalder and Pigneur 2009). Furthermore, Osterwalder and Pigneur (2009) and Suikki et al. (2006) exclude strategy from business model itself. Relations to external environment and actors outside a firm are variously described and included in business models. Besides customers, perception varies which actors should be included in business model by default. In addition, approach to value creation varies from value network to be based on resources and activities. Relation to environment is overextended in Afuah's (2004) business model framework compared to others. Especially, the main element of industry factors and its components are not built into others' business model frameworks. This study distinguishes industry factors from business model because those factors are not describing how an organization creating and capturing value.

Description of business ecosystem

Moore (1996) defines business ecosystem as *"an economic community supported by a foundation of interacting organizations and individuals - the organisms of the business world."* In a business ecosystem, companies co-evolve capabilities around new innovations by working cooperatively and competitively to support new offerings, satisfy customer needs and eventually discover innovations (Moore 1993). Iansiti and Levien (2004b) define business ecosystem as "*loose networks – of suppliers, distributors, outsourcing firms, makers of related products or services, technology providers, and a host of other organization – that affect and are affected by the creation and delivery of a company's own offerings*." Originating from biology, an ecosystem provides a rich analogy for understanding business networks and symbiotic relationships of ecosystem members. Both business and biological ecosystems are characterized by a large number of loosely interconnected participants who depend on each other for their mutual effectiveness and survival (Iansiti and Levien 2004a).

Ecosystems have some specific features: the structure, the relationship among members, the kind of connections among members, and the differing roles played by their members (Iansiti and Levien 2004a). According Moore (1993) business ecosystem members can be classified as leaders, followers and business partners. The leader plays a role of central ecological contributor, and the role is valued by the rest. Followers need a leader and appreciate the leader because of its grip on customers (Moore 1993). Iansiti & Levien (2004a) identify keystone, dominator and niche player as particularly significant roles in business ecosystem. The roles are described in Table 2.

Table 2: Main roles in business ecosystem (Iansiti and Levien 2004a.)

Role	Description
Keystone	Fundamentally, a keystone acts to improve overall health of the ecosystem, and in doing so, benefits the sustained performance of the firm. It does this by creating and sharing value with its network by leveraging its central hub position in that network, while generally occupying only a small part of that network.
Classic dominator	Classic dominator acts to integrate vertically or horizontally to directly control and own a large proportion of a network. In so doing, dominators become directly and solely responsible for the majority of both value capture and creation in their ecosystem, leaving little opportunity for the emergence of a meaningful ecosystem.
Value dominator	A value dominator avoids control of the network and instead pursues control of value extraction alone. In so doing it provides little new value to its network, while at the same time capture most value for itself, leaving a starved and unstable ecosystem around it.
Niche player	Niche player acts to develop or enhance specialized capabilities that differentiate it from other firms in the network, leveraging resources from the network while occupying only narrow part of the network itself. Niche players constitute collectively the bulk of the healthy ecosystem in terms of total mass, value creation as well as variety.

According Corallo et al. (2007) parties in a co-evolutionary relationship activate selective pressure on the other, and consequently affect each other's evolution. Economical and social aspects are emphasized in business ecosystem; its evolution is due to competitive and cooperative interactions of its members. Members belong to an ecosystem for their own benefit and share the total value that the ecosystem creates. Each organization adds one or more distinct aspect of offering value to the value generated by the ecosystem. (Corallo et al. 2007)

Business model elements to describe ecosystem

In a simplified manner, *business model describes how a firm is creating and capturing value* (c.f. Shafer et al. 2005, Osterwalder and Pigneur 2009). Commonalities of business model can be identified although business model frameworks vary depending on source. As a summary and integration of literature, business model elements and components of are listed in Table 3 for describing a business ecosystem.

Table 3: Business model elements and components for describing business ecosystem.

Elements	Components
Actors	A firm, customer, co-operator
Value creation structure	Chain or network
Capabilities	Capabilities, activities, processes
Resources	Resources, competences
Offering	Offering
Revenue	Revenue logic, share of value
Cost	Cost of: resources, capabilities, upstream (suppliers, co-operators)

All studied frameworks identify customer and firm's offering that proposes value to customer. Offering is understood as source of revenue in this study and it includes

everything a firm can offer to its customers from raw material and components to products, services, tools and technologies. Value creation is build into all business models but emphasis is given on different aspects of it, such as resources, activities, value network and its participants. Costs are very basic element of all business models and costs result from other business model elements. For example, using and maintaining capabilities and resources, making acquisitions from value network and delivering an offering cause costs to a firm. Main actors in business model frameworks are a firm and customer. In addition, different kind of co-operators, namely suppliers, partners and players in value network are mentioned in literature. This elementary approach on business models is depicted in Figure 1.

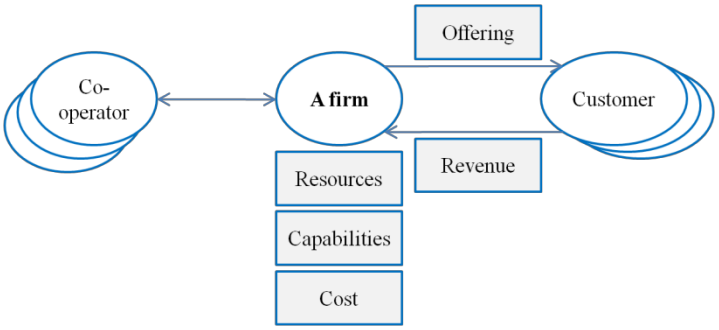

Figure 1: A business model framework and main elements.

The business model framework provides means to describe a firm and relationship between the firm and its customer. Describing business models of all actors in an ecosystem would provide a view on ecosystem in which actors are more or less interconnected to each other through customerships. Figure 2 introduces a theoretical view on business ecosystem based on actors' business models.

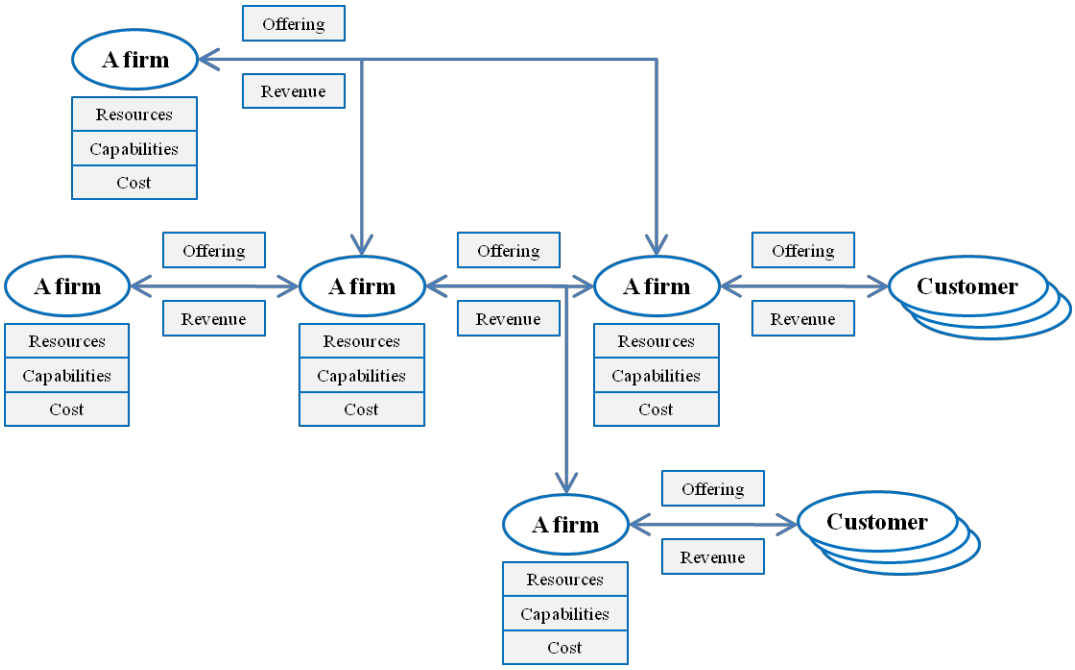

Figure 2: A theoretical view on business ecosystem based on business models of actors.

In a simplified manner, *business ecosystem is a loose network of interdependent business actors* (c.f. Iansiti & Levien 2004a). From theoretical perspectives, actors' business models

describes business ecosystem in several ways. Actors are connected to each other and ecosystem customers through relationships which are characterized by offering and revenue. Actor's offering describes value that the actor with its co-operators creates and proposes, and revenue is value that the actor captures from customers. An ecosystem offering is described as composition of the actors' offerings. Connections between actors describe value creation structure of an ecosystem. The structure of ecosystem can be a chain, a network or more likely mix of them. Position and necessity of each actor in an ecosystem can be changed over time and is determined by its resources, capabilities, offering and financial performance. Revenue gained by an actor has to cover costs of actor's resources, capabilities and upstream actors' revenue in order to survive in long run. Every business model elements has own role to describe business ecosystem.

By mapping each actor's business model one by one, the business ecosystem can be described as it is drawn in Fig. 2. If hundreds or even thousands of interconnected actors are fitted in the same view, the description of an ecosystem becomes very complicated. In addition, it could be impossible to draw exact boundaries of an ecosystem and figure out all the actors who belong to it. Thus, it might be reasonable to distinguish key actors from others, and consider "bulk" actors as groups when describing ecosystem. Business model elements, especially offering, capabilities, resources and/or revenue provide potential criteria for actors' classification and grouping.

CASE: SEMICONDUCTOR INDUSTRY ECOSYSTEM

Semiconductor industry overview

Semiconductor industry has evolved since invention of a transistor and an integrated circuit in some 60 years into a 300 BUSD yearly business. The industry itself serves other major industries like consumer electronics, information and telecommunications, transportation, medical, automation and energy industries. The industry provides fundamental enabling technologies for its customers and it has significant position in modern industry. The value chain of semiconductor industry is constantly evolving and roles of the actors in the ecosystem are changing (e.g. Li et al. 2011). Originally, so called integrated device manufacturers (IDM) dominated the industry due their strength in technology development for manufacturing processes, devices and applications. Over the years specialization took place as size of the required investments, capacity needs and diversity in applications and technological complexity increased (Ernst 2005).

Semiconductor industry ecosystem description

Semiconductor ecosystem can be fundamentally characterized as design and manufacturing ecosystem. It can serve or be part of other business ecosystems, such as ecosystems in consumer electronics or telecommunications. The ecosystem consists of various actors as described in Figure 3 (e.g. Ruippo 2005, Ernst 2005).

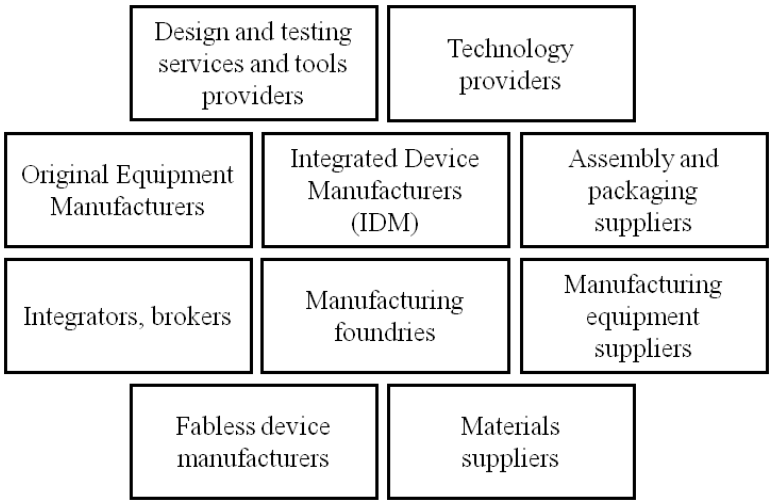

Figure 3: Main actor groups of semiconductor industry ecosystem.

In the ecosystem the original equipment manufacturers (OEM) are closest to the end users and applications served by retailers, services providers and public sector. Technical solutions, systems and devices are provided to OEMs by integrated or fabless device manufacturers, but may also be served by services providers, technology integrators or technology providers, which on the other hand provide their services to other actors as well. Manufacturing foundries provide manufacturing capacity, but also process technology and services to device manufacturers. Both independent and integrated foundries utilize materials and manufacturing equipment suppliers as well packaging services suppliers. Characteristic to the whole industry is that all actors may interact with each others, thus plentiful formations of value chains are possible.

In table 4 semiconductor industry ecosystem is described through the business model elements of its actors. In this study materials suppliers, manufacturing equipment suppliers and assembly and packaging supplier are omitted due to their limited role in serving only the ecosystem members who run manufacturing foundries. In the table, revenue and cost elements are not covered because these elements are by definition part of the business model description, but they do not specifically describe the ecosystem structure or function itself. Revenue and cost elements describe more the healthiness and dominance of actors in ecosystem value creation and value capture.

Table 4: Semiconductor industry ecosystem description by actor's business models.

Actor	Business model element		
	Offering	**Capabilities**	**Resources**
Original equipment manufacturer (OEM)	Ecosystem offering to customers and end-users.	Understanding end-user needs and solution development	R&D for product development, manufacturing operations, marketing
Integrated device manufacturer (IDM)	Devices to OEMs	Device technology and manufacturing process technology development, device development	R&D for devices and manufacturing processes
Fabless device manufacturer (FDM)	Devices to OEMs	Device technology development, device development	R&D for device development
Manufacturing foundry (FAB)	Manufacturing process technology and manufacturing capacity to IDM and FDM	Manufacturing process technology development	R&D for manufacturing processes, manufacturing capacity
Technology/IP provider	Technology to FAB, devices and OEM products	Technology development for devices and OEM products	R&D for product and device technology development
Design and testing services and tools providers	Services and tools for OEM, IDM, FDM, FAB, IP providers	Engineering tools and design methods for products, devices and manufacturing process development	R&D for engineering tools and methods; engineering services capacity
Integrators, brokers	IP brokering and integration services to ODM, IDM, FDM, FAB, IP providers	Engineering and IP acquisition for devices and OEM products	Engineering services capacity

In semiconductor industry ecosystem OEMs can be seen as the top of the ecosystem or the food chain, an actor group which the ecosystem is serving and finally dependent. In practice the semiconductor industry serves several types of OEMs which are acting in different end-user market segments or industries that utilize the semiconductor ecosystem. Therefore the industry is not dependent on only one group type of OEMs.

Integrated device manufactures (IDMs) can be seen as classic dominators which may occupy most of the value network. As only a few integrated device manufacturers can take care of and control almost the whole semiconductor value chain. If this kind of IDM acts as a classic dominator, there may not emerge meaningful ecosystem around it since majority of value capture and creation is based on the actor's own business model. In practice, the variety of applications and device market segments, and complexity of technologies have forced IDMs to act as a keystone, thus enabling emergence of niche players. Actors like technology and IP providers, integrators and services providers can be regarded to locate at the bottom of the ecosystem serving as niche players the rest of the ecosystem members, even directly the OEMs at the top of the system.

Also manufacturing foundries are acting like keystones for the entire ecosystem, enabling also emergence of fabless device manufacturers (FDMs), which consequently foster existence of niche players while competing against IDMs in serving the OEMs. Some specialized materials or IP suppliers might be able to gain a value dominator position, which could endanger healthiness of the entire ecosystem.

A semiconductor ecosystem with strong keystone players like IDMs and FABs is beneficial for all actors by thriving in competition and gaining more profit and revenue. Such ecosystem can create and capture more value than actors alone and produce wider variety of offerings and serving more OEMs, and thus serving end user applications in variety of market segments and industries. From table 4 it can be seen that business models of actors define a business ecosystem of keystone, classic dominators and niche players.

DISCUSSION

Business ecosystem that is defined systematically through actors' business models provides means for actors to analyze and develop business. At first, describing an offering actor by actor provides a rich perspective on composition of the ecosystem offering and the value that each actor adds to the offering. Then, defining ecosystem value sharing by actors' revenue and cost elements enables comparison of actors' financial performance. This information can be used for refining revenue logic and optimizing the cost structure of an actor.

Capabilities and resources are main distinctive factors between actors in an ecosystem and essential characteristics for explaining each actor's position and necessity in the ecosystem. For example, a niche player aims to develop specialized capabilities to add necessary piece of value to ecosystem offering. Strong actors hold and develop critical resources for ecosystem and they can behave as dominators or keystones in ecosystem based on behavioral roles (table 2). Strong dominating actor can hinder ecosystem development. With strong keystone players an ecosystem can create and capture more value than actors alone and produce wider variety of offerings in long run.

Having actors with diverse roles, strategies and business models is a precondition for meaningful business ecosystem. Significant role changes can be hardly done without rethinking a firm's strategy and furthermore, business models. After deciding the role to play in an ecosystem an actor may seek development paths that shape its performance and increase consistency of elements in business model. Actors' strategies and realization of strategies through business models determines how an ecosystem can evolve. Success of a business model can be proved only by testing it in practice. Dynamics and structure of business ecosystem should be considered when making business development decisions concerning strategy and business model.

CONCLUSIONS

Business ecosystem is a loose network of interdependent business actors. By defining each actor's business model one by one a description of business ecosystem is built. Actors' business models explain relations between and roles of actors. This study defines business

models systematically through elements, such as resources, capabilities and offering that are common for all actors. Each business model element has own role in the ecosystem description.

In business ecosystem described through business models, actors are connected through relationships which are characterized by offering and revenue in business models. An ecosystem offering is composition of the actors' offerings. Based on connections between actors, value creation structure of an ecosystem can be formed as a chain or a network. Position and necessity of each actor in an ecosystem will be changed over time and is determined by its resources, capabilities, offering and financial performance.

Dynamics and structure of business ecosystem should be considered when planning and making business development in a firm. Business ecosystem as described in this study is useful for ecosystem actors for that purpose. However, this description cannot predict evolution of business ecosystem that is dependent both on environment the ecosystem is working as well as actors' capabilities to innovate.

This study draws a generic view on defining and describing a business ecosystem. Validation of results is largely dependent on further research and practical applications. Further research could be done through in-depth case studies on business ecosystem.

A MULTI ERP IMPLEMENTATION CASE FOR A FIRM STRIVING SURVIVAL IN AIRCRAFT MAINTENANCE INDUSTRY

Dr. Farshad Salimi, www.reprocess.co
farshad@reprocess.co

ABSTRACT

This peculiar case study reviews a three stage ERPs implementation of major ERP packages at a survival firm in a shrinking market. The firm rationalized the process of ERP implementation as the key competitive advantage against its global competitors. The firm strived for efficiency by ERP implementation of three packages; SAP R2, BaaN IV, and Pentagon in a continuous improvement process. We identified the management involvement, project management, management control and ownership, recognition of striving for the organizational fit, strategic IT integration, and personnel dedication as key critical success factors (KCSFs) with in particular personnel dedication and their valuable contributions to changes.

Keywords: ERP Implementation, Key Critical Success Factors, Manufacturing, Service Industry

INTRODUCTION

The Enterprise, FKS.

FKS is part of the SK Aerospace Services division of SK Aerospace group. FKS has four business units for aircraft support services (AS), material support (MS), component support services (CS) and technical support services (TS). AS business unit core business is selling maintenance hours for aircraft maintenance in the base and out-of-stations; i.e. aircraft conversions and modifications; damage assessments and repairs; and painting aircraft. This core business concentrates on the Fokker aircraft market as the focus point in this case study. FKS was seeking new business in maintenance of Boeing, Embraer, Gulfstream aircraft, and in the combat aircraft market (F16). This case study investigated the application of ERP in the earlier and future FKS positioning, with a focus on one of its four strategic business units (SBU), i.e. business unit aircraft services (AS).

FKS Strategic Objective

FKS is an integrated knowledge based service organization that works in partnership with both the owners and operators of the aircrafts. FKS is an organization that enables the customers to have maximum availability of their regional aircrafts at the lowest possible costs while maintaining a profitable business. The intended Maintenance, Revision & Overhaul (MRO) partner must be able to deal with four key issues of technology, logistics, process and people from the airline carriers' MRO perspective. The carriers look for reductions of fixed MRO costs. They rationalize on direct MRO costs (i.e. staff, spare-parts, process management, resources, IT costs and so on), and on increased efficiency and flexibility in MRO activities.

FKS followed a unique rationalization approach by restructuring its internal processes for cost savings across the supply chain with external orientation towards the suppliers and clients i.e. inbound logistics and outbound logistics. The FKS core business offered complete services in aviation MRO with a "one-stop-shop" philosophy. FKS's target market was the FKS aircraft market with nearly 1100 aircrafts worldwide. In three phases of the restructuring process, FKS changed its ERP system from SAP R/2 to BaaN IV and then to Pentagon in order to achieve three objectives of (a) continuous improvement, (b) new business strategy, and (c) organizational fit.

In the course of ERP Pentagon implementation, FKS carried out a business case analysis in order to improve the chances of success in the post Pentagon implementation period.

PROBLEM DEFINITION AT FKS

FKS restructured its business processes on a continuous basis to comply with the upcoming internal and external clients' demands. After FK Aircraft bankruptcy, FKS, as an independent service provider, faced a total close down because of the decreasing number of FK aircraft in operation, and later due to September 11th impact on the MRO market. For a sustainable business, FKS searched for new ways of conducting business in new markets. Due to changing market, FKS searched for new objectives, new strategies and operational key critical success factors.

Because of the shrinking market, the AS MRO maintenance revenue had fallen from one million hours in 1992 to approximately four hundred and fifty thousand hours in 2002.
In the same period, FKS sales breakeven point rose from 500000 maintenance hours to 600000 maintenance hours.

Reasons for Changes

Because of its weak financial results, FKS anticipated shortcomings in its organizational structure and its market approach in aviation market. Therefore, the market approach had to be reengineered and objectives had to be reset to improve its market positioning. An internal and external analysis provided FKS with project goals in continuous reengineering of processes in: increasing the market share to a minimum of 25% to achieve the breakeven point; lowering internal costs by at least 20% in order to obtain a competitive man-hour cost price rate; speeding up the request for quotation (RFQ) processing; creating more transparency in processes; presenting mission and vision of FKS as a unique MRO supplier in the market, and developing and promoting a partnership attitude across the supply chain with suppliers and clients. For this reason, the markets perception of FKS had to be changed from an e-shopping mall, i.e. irregular, incidental and partial sales (Figure 1), to a potential partner for airliners in the MRO market, i.e. organized total package sales (Figure 2).

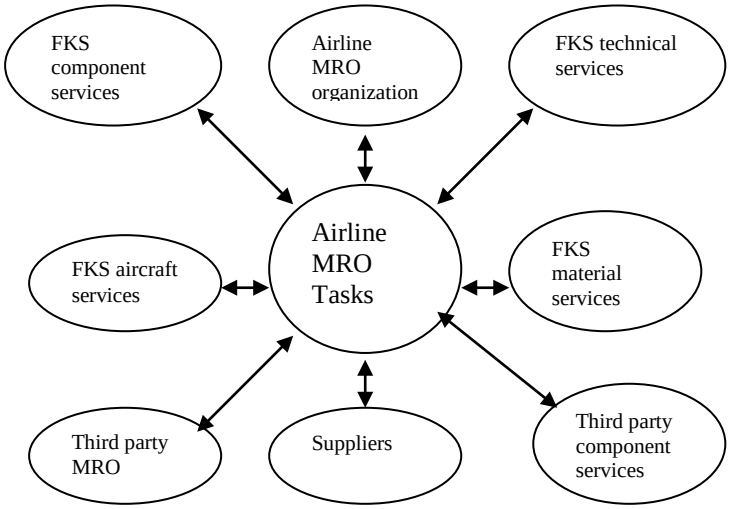

Figure 1: Airline market behavior and airline MRO outsourcing structure.

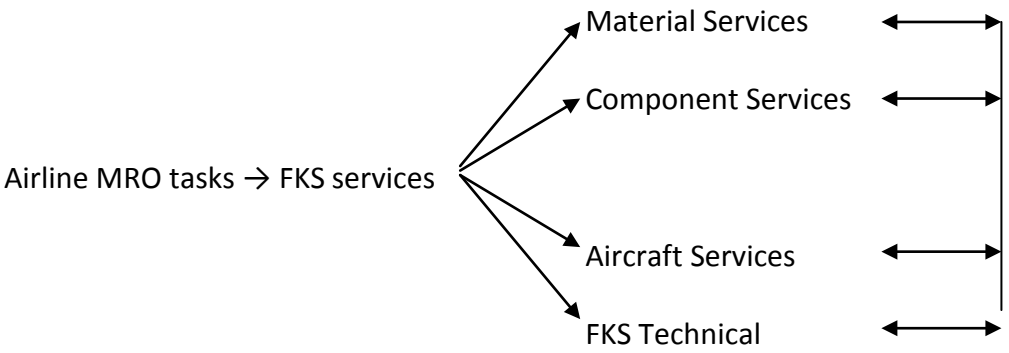

Figure 2: New business structure-partnership and collaboration.

FKS achieved four key issues in its restructuring processes; (a) internal and external integration of the four SBU's, (b) knowledge sharing with the client, (c) partnership with owners and operators, and (d) development of an active competitive advantage for each operator.

Market Threats

The crisis in external market provided new opportunities for FKS to benefit from. The airliners' MRO expenses were costs without yield; therefore, the costs needed to be as low as possible with the quality of maintenance and safety complying with the best standard practices. Traditional maintenance requires heavy investments. Airliners make tremendous MRO costs to anticipate the unpredictability of high quality and safe aircraft maintenance. The main MRO cost barriers are: manpower, logistics, tooling, IT costs and hangar availability. Although, all these key items are essential parts of the maintenance process, they have not always been utilized actively for the MRO activities. The improvement and utilization of these resources in an efficient way could result in a drastic reduction in the fixed MRO costs. Both MRO service providers and their clients, i.e. airliners, anticipated to

improve their positions in the market by sharing; (a) manpower, (b) logistics, (c) tooling, (d) IT costs, (e) hangar availability, and (f) other fixed costs. FKS competitive position was vulnerable. Reorganizing its business processes, structure, and market approach was the only business solution to strive for in the declining market.

BUSINESS SOLUTION AT FKS

In the past, FKS had focused on restructuring its internal processes at back-office and its related applications. These changes were essential for the switch over from SAP R/2 to BaaN IV due to Y2K problems with the SAP R/2 system. An explicit change of focus was apparent, from internal processes to external processes with the clients and suppliers. The external relations with the clients and suppliers became more important, and the internal automation was no longer the most important critical issue at FKS.

Project Goals (Restructuring)

Among the external threats FKS identified; presence of intermediaries, presence of other on-line service providers with in particular second hand brokers, low man hour rates in eastern and southern Europe, decreasing number of Fokker Aircraft in operation, declining American market share on the MRO due to Sept 11th, and an increase in "stand-alone" maintenance providers looking for MRO works. At the same time FKS identified new opportunities for profit due to; growth of the aircraft market in the Far East and Eastern Europe; development of digital salesman (lowering fixed costs) by the Fokker site, split of maintenance work from the core business by airliners, application of ERP by airliners, and lower transaction costs for FKS by increasing e-applications.

FKS manifested the necessity to target three main objectives of; (1) decreasing internal overhead costs, possibly through cost and efficiency drivers; (2) restructuring and ERP orientation at in/outbound logistics, referring to the two key areas of the procurement process and sales process; (3) sharing MRO data with airliners to increase MRO market share, being more transparent in processes and costs, being more market competitive, and by offering real partnership to the clients. To achieve these objectives, there were four main areas of focus in its MRO market positioning:

1. Maintenance Management: It is the support by skilled and certified aircraft maintenance technicians and services.

2. Engineering and Planning: This is the know-how to define aircraft configurations, maintenance programs, work requirements and associated documentations to meet regulatory and MRO specifications and operator needs. It is the ability to plan and schedule effective utilization of all resources including aircraft, materials, tools, people, and facilities.

3. Information Technology: This is the technology to manage, track and communicate across logistics, procurement, supply chain and mechanics, with the goal to make maintenance more predictive for client and vendor. Ideally, a service provider will electronically integrate an airline's flight scheduling and other information systems, for its overall operation and customer service.

4. Supply Chain: It is effective procurement, inventory, warehouse and transportation management processes, including a resource strategy, which will allow operations to be more efficient. With an aggregated supply chain, purchasing power is increased and inventory can be optimised across multiple carriers.

FKS offered four items as four individual items and not as a package to the market. The ERP was a tool to change the heading towards a complete and synergic MRO approach to the market.

After review, AS decided on the following six main conclusions and related recommendations: (a) *Growth through unity,* the growth of AS was possible through the unity of the four strategic business units of FKS, (b) *Synergy improvement,* the "four different companies with their own core-businesses" perception must be changed into a "one company-one core-business" perception, (c) *Internal integration*, the unity and synergy between the four SBUs, the world-wide scattered clients and the magnitude of the MRO data stream was only qualitatively manageable by ERP implementation and a well thought-out implementation strategy; (d) *External integration,* streamlining all FKS internal organizational processes and elements of the value chain network towards a full integration, (e) *Culture change*, changing corporate culture and adapting business-processes towards partnership were major KCSFs in improving its competitive position, (f) *E-Business development*, Incorporating e-business strategy as part of the traditional business strategy would also improve the traditional business strategy. In a continuous improvement process, for each of these items a thorough and detailed plan was developed with respect to ERP risk management and return on investment.

THE BUSINESS (RE) ENGINEERING PROCESS AT FKS

FKS worked towards client demands and reengineered its current business structure to adapt its processes towards a smooth integration with the clients. The maintenance value chain presents the added value contribution that Fokker Services could provide with an ERP application to its clients.

The maintenance value chain at FKS consisted of the following elements:
Maintenance Request → Trouble Shooting → Repair Order → Logistics Needs → Skilled Engineer Planning → Hanger Slot Reservation → Actual Repair Process → Testing → Closing Maintenance Request → Data Processing and Managing.
There were four possible maintenance options for FKS (Table 1);

1. Daily scheduled maintenance,
2. Daily unscheduled maintenance,
3. Periodical scheduled maintenance,
4. Unscheduled maintenance.

Each individual maintenance inquiry represents a process segment to four sub-chains of: Technology, Logistics, Process and Labor.

In turn these sub-chains were segmented into predictable and unpredictable key issues. The added value in processes could be obtained through decreasing the unpredictability, and supporting and encouraging partnership with the airliner. The maintenance value chain was designed in such a way that the same processes were present for all four possible maintenance options. After analysis of the maintenance value chain, FKS found the logistics support and unscheduled maintenance as the items to focus on. Since unscheduled repairs contributed to a dominant part (90%) of scheduled maintenance, this part of the chain was also important due to its unpredictability. Furthermore, the main items in the value chain difficult to predict were: Logistics (i.e. flow of spare parts and components-inbound logistics) and Labor (i.e. planning hours and allocation of man-hours). These two high cost items in the airliner business covered a substantial part of the airliner expense budget (12-15%) on MRO costs. Furthermore, it was striking to find that both "processes" and "technologies" were highly predictable in daily and periodical scheduled maintenance (table 1). The reason was the regulations dictated by authorities and the worldwide standardization of aviation maintenance.

In its new structure, FKS required only one design in maintenance processes for all four options resulting in benefits in design-costs and users ease.

Table 1: Maintenance Options.

TECHNOLOGY - LOGISTICS - PROCESS - LABOUR			
DAILY SCHEDULED MAINTENANCE			
Highly predictable	Highly predictable	Highly predictable	Highly predictable
DAILY UNSCHEDULED MAINTENANCE			
Highly predictable	***Unpredictable***	Highly predictable	Predictable
PERIODICAL SCHEDULED MAINTENANCE			
Highly predictable	***Unpredictable***	Highly predictable	***Unpredictable***
UNSCHEDULED MAINTENANCE			
Predictable	***Unpredictable***	Highly predictable	***Unpredictable***

ERP PACKAGES

ERP SAP R/2

At the time of our research, FKS was equipped with the SAP R/2 maintenance module to support its primary processes at MRO aviation services. The internal processes were modified prior to the SAP implementation. In this context, FKS strived for survival in the competitive market through internal cost savings measures. This measure was the primary reason for the ERP adoption as a whole.

ERP BaaN IV

In 1998, the management complemented the changes with implementation of another ERP package due to Y2K. Although the millennium problem was the main reason for the new ERP adoption, the report structure of SAP R/2, organizational fit and its fit to FKS internal processes also motivated the changes for a shift from SAP R2 to BaaN IV.

The customization of the SAP R/2 report structure and of the maintenance module into the business processes was no longer the only issue.

Reasons for the Changeover from ERP SAP R/2 to ERP BaaN IV

At FKS, the reasons for a new ERP adoption were Y2K and the misfit of the SAP report structure (s*hortcomings; low level, low quality, with no total overview of available information, and incomplete management report*). To change the ERP package, FKS benchmarked its ERP SAP with the other operating models. The objective was to find the best fit to FKS primary processes. The scope of implementation was replacement of the outdated ERP system, SAP R/2, with the BaaN IV system. Among other factors justifying this decision, the FKS quoted that "*First of all SAP was not a millennium proof package and the new version of SAP was not ready for implementation at the time and mother company SK was ready to switch from SAP over to BaaN IV for the entire organization. In a way, our business unit was pushed to switch over to BaaN IV. "*

Main Internal Processes at ERP BaaN IV

In the process of implementation, the main processes were identified as sales, projects, work preparation, MRO works, aircraft test, technical certification to authorities and project management. The main internal processes were logistics, control of shop floor, planning and report structure.

The project management progress reports played a key role in the success of the ERP BaaN IV implementation. During the one-year implementation period, FKS invested eight million euros in ERP implementation. The immediate intangible benefits were stock control, reporting, scheduling and planning.

The overall improvement in the system was in project control, reporting structure and speed of processes. A full-scale implementation plan was outsourced to an outside consulting company. However, FKS suggested that; "*the degree of training provided by the consultant for the new system was inadequate".*

Reasons for Changeover from ERP BaaN IV to ERP Pentagon

The FKS stated that "*In our view, BaaN IV did not meet the user expectations and intangible benefits, if any, they are hard to point out. In fact, one of the reasons to look for another system was the continuous costs associated with updating and changing (customization) the BaaN IV software up to our actual requirements.*

Even after the changes and adjustments, a lot of reports were just nearly 'good reports'. There was no major improvement in working with BaanN IV in comparison with its predecessor, SAP R2. Another major barrier with BaaN IV software was its configuration which was primarily made for maintenance services within the aircraft manufacturing industry (e.g. Boeing etc). "

In view of the above shortcomings mentioned, FKS decided to switch from BaaN IV to the Pentagon ERP system. The selection of Pentagon was a bottom-top technology strategic approach. FKS stated: "*It was the users' request to change over to Pentagon. It was, of course, the management decision to proceed with the change over."* BaaN originally designed an ERP manufacturing package, BaaN IV package, in partnership with Boeing to support the Boeing manufacturing system. Thus, the ERP MRO module did not fit directly into FKS operations; however, it was the closest match in organizational fit that FKS could find in the market. Pentagon was the new generation of a customized MRO package in aviation services. FKS finally replaced the earlier ERP BaaN package with Pentagon.

ERP Pentagon

Pentagon is a U.S. based IT firm specialized in aviation maintenance software and FKS was its first European client. Over the years, FKS spent its resources in restructuring its internal processes for the back-office systems and its related applications. This was necessary for the continuation of the processes after the change over from SAP to BaaN IV due to millennium impact.

This change was an explicit shift in focus from internal processes to external processes. In other words, the external relations with customers and suppliers were at the centre of the changes. FKS worked on the total integration of its business processes with clients and suppliers. This was to fulfill the FKS business strategy from cooperation to collaboration and partnership with the suppliers and clients.

"*The aviation industry is a complex business with respect to traceability of parts, components and tasks responsibilities. The Pentagon program seems to be the first program, which fulfils our requirements in the complex maintenance process*." This conclusion was based on the fact that the use of the Internet Application turned FKS into an e-shopping mall for airliners. The restructuring business strategy was to present the four business units as one to clients while clients only made use of services of one unit at a time. This client behavior had turned FKS into a kind of MRO discount centre.

Project Goals (Pentagon)

The project goal was integration of internal processes to external processes, e-strategy synergy, partnerships, and sharing information and knowledge across the supply chain with global clients. The external focus was on the customer side of the MRO value chain.
A marketing SWOT analysis by FKS identified those key areas in customer relationship together with the new opportunities in the market.

Tangible and intangible benefits (ERPs)
FKS expected that the fulfillment of project goals would lead to lowering MRO fixed costs (i.e. the costs of manpower, logistics, tooling, IT costs and hangar costs).

Onward and upward phases -Post Pentagon implementation business analysis
Figure 1 shows how the clients used the four SBU's of FKS frequently as four separate services while the SBU´s had the objective of working as one unit to the clients.

The clients used the most attractive parts out of the four SBU's in any inquiry. Because of this market behavior FKS had changed into a kind of MRO discount centre. In this format of outsourcing market to airliners, FKS only provided one of its capabilities with one option out of a multiple capabilities of MRO options to its clients.

CONCLUSION

Finally, the FKS case was a very special case with a remarkable struggle following a holistic, from global collective knowledge, and embedded, own innovative initiative, approach through three restructuring and ERP implementation processes in SAP R2, BaaN IV, and Pentagon. The firm strived for efficiency by ERP implementation in a tough shrinking competitive global market. We learnt about a number of KCSFs, with in particular personnel dedication and contribution to changes. The firm built up a particular experience in ERP implementation processes, from which we could all learn. They continued benchmarking these experiences in a continuous process of changes.

KCSFs

The relative benefits of ERP implementation at FKS were related to the following KCSFs: the management involvement, project management, management control and ownership, recognition of striving for the organizational fit, strategic IT integration, and personnel dedication.

ABSTRACT

Purpose: The migration from traditional management model to business process management (BPM) results on one hand in improvements in the process performance, and on the other, it promotes an increase in management complexity. Thus, there are restrictions or barriers to be overcome for the successful implementation of the new management model. The aim of this study was to assess the maturity level of companies in relation to business process management and identify the main barriers found in changing the management model. Design / Methodology / approach: a case-study with two companies operating in the service sector was conducted. In-depth interviews with managers of the companies studied were made. The interview used was structured in three blocks that corresponded to three task groups developed by Paim, Caulliraux and Cardoso (2008). Findings: It was found that these companies are at different maturity levels in relation to the business process management and people and organizational culture are present in both organizations as challenges to change the business process management model. Research limitations / implications: The research is based on an extensive bibliographic database with limited capacity of empirical validation. Originality / value - The paper describes an unprecedented empiric study in terms of BPM maturity and barriers to be overcome to implement the new management model. The survey does not only investigate which BPM tasks are performed, what is the importance of each task and which are the main challenges.

Keywords: Business Process Management, Business Process, Maturity level, Barriers in process management.

INTRODUCTION

Constant changes and growing competition are part of the reality of all companies, regardless of productive sectors, size or location. There is a trend of companies opting for a business process management structure rather than the traditional functional structure, due to factors such as: increased frequency of ordered products, need for rapid transfer of information, rapid decision making, need to adapt to demand changes and an increasing number of international competitors (Seethamraju and Marjanovic, 2009).

Neubauer (2009) highlights other challenges that companies are recently facing, including the ever-changing business requirements, decreased product life cycles, international competition and pressure of rising costs.

Thus, BPM is not only important for transparency in the company's internal environment in a context of changing economic environment, but it is also a way of dealing with the challenge of improving the company's business processes in order to optimize its performance (Trkman, 2010). In this sense, the focus of the organizations must be processes that add value to their customers (Kohlbacher, 2010).

To Neubauer (2009) and McCormack et al. (2009), the business process management (BPM) allows companies a quick organizational adaptation. Liu, Li and Zhao (2009) report that BPM enables organizations to create dynamic and flexible collaborations to synergistically adapt to the conditions of changing globalized market.

BPM provides the development and continuous improvement of business strategies and makes companies to focus on generating value for customers and improving their performance (Mccomack et al., 2009).

Houy, Fettke and Loos (2010) conducted a survey in order to provide an overview of the evolution of empirical research in business process management and concluded that the increasing number of articles published in journals, conferences on the subject and the institutionalization of graduation programs focusing BPM at several universities show that BPM is not a fad but a trend to progress to the administration science.

Neubauer (2009) reports that although the business process management is among the most important management issues because it allows companies to adapt rapidly to changing business requirements, only a very small number of companies follow a holistic approach and reached the status of companies focused on process.

Then, it becomes necessary to check how mature the companies are in relation to processes, and to meet this need, there are maturity models that, according to Jeston and Nelis (2006), are tools designed to assess the maturity level of organizations and help them achieve greater business benefits through the successful management of their processes. According to McCormack et al. (2009), reaching greater maturity in the business processes management, the organization will have better control of results, better forecasting of goals, costs and performance, will gain more efficiency to achieve the defined goals and improve the ability to propose new solutions.

But if on one hand, the migration from traditional management models to business process management results in improvements in the performance of processes, on the other, it promotes an increase in management complexity. Thus, there are restrictions or barriers to be overcome for the successful implementation of the new management model.

These barriers can be linked to the business segment, to people or to the company. The main barriers found in literature are: issues related to technology, the organizational culture, lack of knowledge about the concept of processes, little integration between methodologies, techniques and tools employed in the several areas of the company, lack of basic knowledge on business process management by all of the organization, lack of direct involvement of leadership and executive staff, lack of incentives and rewards to encourage the adoption of

new processes, and lack of essential resources to BPM or their mismanagement (Antonucci et al, 2009; Bandara; Gable; Rosemann, 2005; Bandara et al, 2007; Trkman, 2010).

According to Jeston and Nelis (2006), Trkman (2010) and Neubauer (2009), the importance of BPM leads to the question of how organizations are advanced in their BPM development, since BPM is a complex practice, and many organizations find it difficult to implement it to evolve to higher maturity levels.

Since there are few publications of case-studies on how organizations are advanced in relation to the business process management and the barriers faced to manage the process (Neubauer, 2009; Trkman, 2010), the general objective of this study was to assess the maturity level of the companies studied in relation to business process management and identify the main barriers found for the migration from traditional management model to business process management.

To achieve the objective of this study, a literature review was initially performed to learn about the fundamental concepts related to business process management, maturity in business process management, tasks related to business process management and barriers faced by companies to achieve higher maturity levels.

In-depth interviews were conducted with managers of two companies from the service sector using the instrument validated by Paim, Caulliraux and Cardoso (2008) as a guide. The data obtained were used to perform qualitative analyses that allowed the achievement of objectives.

Given the importance of what has been discussed above and due to the scarcity of studies that address this topic as the study by Trkman (2010), this paper intends to bring contributions for both professionals and academics, in terms of the BPM maturity and barriers to be overcome to implement the new management model.

THEORETICAL FRAMEWORK

Business Process Management

BPM is not just about designing, developing and implementing business processes, but more than that, it is to consider the interaction between these processes, control them, analyze them and optimize them, and, according to Kohlbacher (2010), the biggest difference between BPM and BPR concepts is that the former refers to the company management based on business processes, and the latter deals about a radical project of redesigning business processes.

According to Jeston and Nelis (2006), BPM can be defined as a practical holistic approach of organizational management where factors such as the understanding and involvement of senior officials, clearly defined roles, appropriate techniques, well-trained people and a culture receptive to business processes are critical to obtaining the desired result.

Trkman (2010) adds that BPM can help in implementing a strategic program, allowing a better match between organizational strategies and the company's business process. In this context, Ravesteyn and Batenburg (2010) suggest that when organizations start the implementation of BPM systems, they must realize that this is not an IT project, and that they should be based on the business goals due to its strategic relevance.

According to Antonucci and Goeke (2011), there is still no universally accepted definition of BPM; however, experts generally agree that BPM has evolved from a guidance for systems (technology) to a management practice in which the company has its processes customer-focused, with goals, people and technology focused in both strategic and operational activities. Therefore, for these authors, BPM is a discipline that integrates technology information and knowledge of business processes with the aim of transforming isolated efforts into integrated and measurable activities that provide competitive, operational and strategic advantages in order to obtain a holistic view of the end-to-end planning and management of business processes.

However, changing the functional structure of the company into a process structure means not only defining the responsibilities for the progress of processes, minimizing transfers, and thereby reducing errors and delays, but also maximizing the grouping of activities and reducing efforts.

According to Paim, Caulliraux and Cardoso (2008), in the functional management, processes are managed separately; the organization has characteristics of silos with low capacity of coordination and this approach shows low market orientation. In the business process management, there are changes in organizational structure and in other organizational elements aiming the prioritization of processes as a management axis of higher importance than the functional axis, thus guiding decisions whose priorities are processes. Figure 2 shows the spectrum of organizational decision-making of functional management versus business process management. In can be observed that in business process management, the decisions and the structuring of elements shown in Figure 1 are process-oriented.

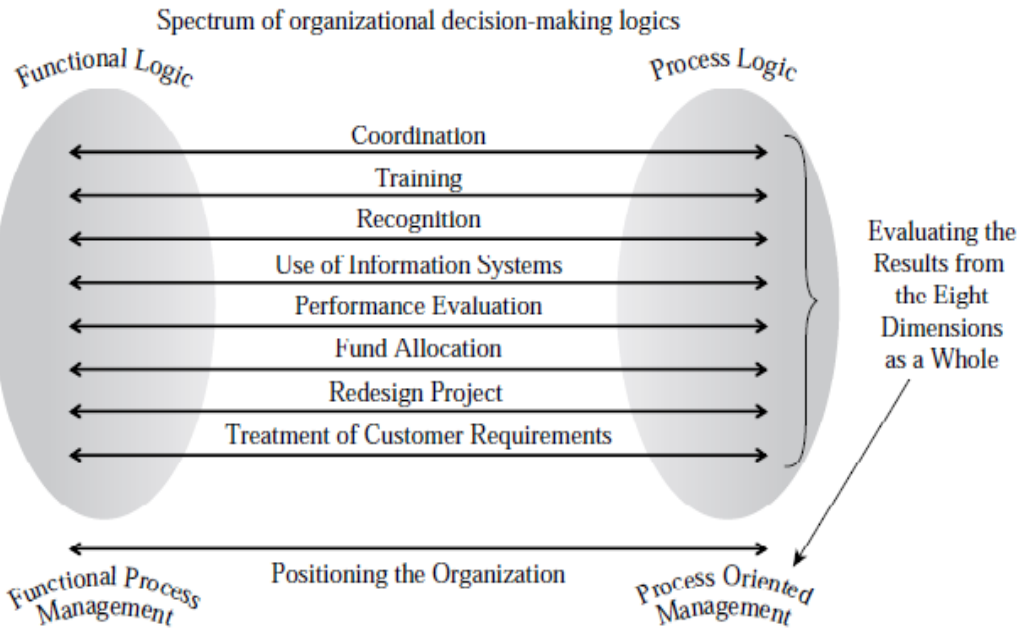

Figure 1: Spectrum of organizational decision-making: functional management versus business process management. Source: Paim, Caulliraux and Cardoso (2008), p. 709.

According to Jeston and Nelis (2006), the organizational change management represents the most important component of BPM implementation, because the involvement of people and the leadership of line managers are critical success factor to achieving the desired involvement. Palmberg (2010) shows that when the functional and hierarchical organization meets the new process-oriented organization, there is a clash between people who prefer to take orders and those who prefer greater responsibilities, and a way to soften the clash is to provide proper support to transition. The survey also reveals that the solution is not to choose between functional or processes, but to apply both in the organization, provided that there is space for negotiation and collaboration, in which managers can communicate and align the company's strategy with that of their area of operation and thus avoid the "approach of silos".

According to Neubauer (2009), a successful BPM project requires a well-organized team able to analyze, design, implement and continuously improve business processes according to the business strategy. Still according to the author, the following tasks must be performed by the main process manager - Chief Process Officer (CPO): creation and maintenance of business process models; consulting in business process management, integration of the major processes for the business strategy, definition of process targets, according to the process designer and process control.

Despite the importance of business process management, according to Neubauer (2009), Paim, Caulliraux and Cardoso (2008) and McCormack et al. (2009), the increased maturity level of BPM projects still occurs slowly. The maturity level will be the next topic that this article discusses.

Business Processes Management Maturity

Maturity models, according to Jeston and Nelis (2006), were designed to evaluate the competence, capacity and sophistication level of a selected area, thus becoming a tool that can help organizations to be more successful with BPM. Maturity models can be used for three purposes: (1) as a descriptive tool that allows an "as it is" evaluation of strengths and weaknesses of organizational processes; (2) as a regulatory tool that allows the development of an improvement guide; and (3) as a tool to allow a comparative measurement to evaluate the standards of other organizations.

The common basis for most maturity models has been the Capability Maturity Model (CMM), in which the maturity of the organization is evaluated through the five-point Likert scale, where "5" represents the highest maturity level.

Low maturity levels show companies with improvised or incorrectly performed processes, management focused on solving short-term problems, lack of measurement for assessing the quality of products or services, and little understanding of how process steps affect the quality of products or services. On the other hand, companies with high maturity levels are characterized by having organizational skills to define, implement and manage their processes, which are planned and documented. They are also characterized by having clearly defined roles and responsibilities, continuous updating of processes, support infrastructure to processes, quality control of products and services as well as of processes that produced them (OMG, 2008).

Neubauer (2009) analyzed the business process management in the market through research with 185 companies in order to assess the maturity level and how processes are managed. The results showed that only a small part of participating companies can be defined as process-oriented and that the vast majority of companies still have an orientation that includes end-to-end processes, measurement of results and business process management.

However, to efficiently implement BPM, specific tasks must be properly performed. For this, these tasks will be discussed below.

Process Management Tasks

Paim, Caulliraux and Cardoso (2008) identified a list of 24 tasks in the business management processes that have been classified by depth and importance, and thus grouped into three categories, generating a proposal that has been tested by a more thorough literature review and a questionnaire aimed to assess the importance of each task within the group and also identify the predominant type of management within the organization studied. These three task groups consider how the elements of organizational functions relate to the business management process, i.e., strategy, information and knowledge, innovation and improvement, information technology, people and skills, performance indicators, budget, standards and procedures, control and audit, work coordination and production systems.

In this paper, the development of the case-study in the surveyed companies, the three task

groups of the instrument developed, validated and tested by Paim, Caulliraux and Cardoso (2008) were used. The three task groups will be better shown and described in Table 1.

Table 1: Business process management tasks.

Task group	Description
Designing processes	Tasks including understanding the internal and external environments of the organization with respect to business strategy. This strategy includes objectives, goals and approaches to promote the change. Process teams must be formed and it is necessary to understand, select and prioritize processes. Thus, the following tasks are part of this group: understanding the external and internal environment, establishing the strategy and approach for change; ensuring the sponsorship for change, understanding, selecting, prioritizing processes and tools; forming teams of diagnosis and procedures; understanding and modeling processes in the current situation; defining and prioritizing solutions to current problems; defining management practices and implementation of processes; understanding and modeling processes in the future situation; defining and implementing changes in processes.
Managing day-to-day processes	Tasks including implementing processes and changes; promoting the performance of processes; monitoring and controlling the execution of processes; and accomplishing short-term changes.
Promoting development and learning	Tasks including recording the performance of processes; conducting the process benchmarking; recording and controlling impact deviations; evaluating the efficiency of processes, and recording the learning about the process. It is based on understanding the trajectory of process development through actions that increase the process predictability, understood as the best relation between promising or waiting for a performance and being able to deliver what was promised. This capacity basically depends on getting to know what the historical bases of performance are.

Jeston and Nelis (2006) claim that the leadership should recognize that there is no end in improving business processes; this is a program that must be continuously maintained. According to Antonucci et al. (2009), the measurement is important, but the measurement continuity, monitoring and controlling the process is even more important. To define what to measure, one must understand the desired results and observe the process as a whole in relation to customer satisfaction.

However, as previously mentioned, if on one hand, the migration from traditional management model to business process management results in dramatic improvements in process performance, on the other hand, it promotes an increase in management complexity, since firstly, the migration generates the need to coordinate and, secondly because the operations were able to expand their volume dramatically, becoming larger and more

complex. In this context, to migrate from the traditional model to business process management, companies will have to overcome barriers that certainly will be found in this changing process.

Barriers to the advancement of Business Process Management

The model of organizational structure based on functional management has limitations and appears to be restrictive to deal with this reality (PAIM, CAULLIRAUX AND CARDOSO, 2008). However, most organizations are managed at department level and still cannot perceive, in fact, the inter-relationships between organizational processes. In this sense, McCormack et al. (2009) reports that to develop the business process management, it is necessary to have an organizational structure that defines the process and roles of business processes management and breaks the old functional structure that inhibits the systemic vision of the organization.

Paim, Caulliraux and Cardoso (2008) highlight that the ready-to-use technology available in market is based on the current paradigm and not on the new one. In addition, the acquisition of new technologies represents a high cost. Another aspect highlighted is the unavailability of staff to operate these new technologies and according to the current model, managers tend to select IT solutions based on functions not on processes. According to Trkman (2010), the environment of an organization is an important variable in determining the IT investment level.

Trkman (2010) reports that companies must carefully align their business processes with the environment and ensure flexibility and continuous adaptation of their core processes. Therefore, they must determine that business processes are key processes to contribute to competitive advantage.

Sentanin, Santos and Jabbour (2008) conducted a BPM implementation study in a public research center that administered the challenges of progress along the stages and BPM levels and found that, considering the impossibility of a company to return to previous stages in its trajectory towards BPM, continuous improvement requires the participation of all members of the research center in a process where functional mentality must be broken and the view based on continuous processes has to be built. These are key conditions for overcoming the barriers to consolidating BPM.

One barrier to be highlighted is the organizational culture, since organizations long have privileged the functional coordination of work. In this case, according to Palmberg (2010), there is a big concern about people who rather take orders than assuming greater responsibilities.

Another difficulty to face is that the concept of processes is still little pervasive in organizations (TRKMAN, 2010).

Jeston and Nellis (2006) claim that often areas are working the same logical abstraction of the process, but with different names; the little integration between methodologies, techniques

and tools used in different areas; the different views of the set of activities, products, customers and other components of the process.

According to Antonucci et al (2009), the direct involvement of leadership and executive team, the process itself, incentives and rewards to encourage the adoption of new processes, the creation of cross-functional teams to participate and cooperate with the process, the development of continuous improvement, commitment to investment and alignment of the business strategy with the customer are key for the implementation of business process management. Bandara et al. (2007) point out that the lack of connection between strategy and BPM projects have been identified as one of the major flaws in business process management. Bandara, Gable and Rosemann (2005) in their study, identified stakeholder participation, information, expertise of the modeler, project management and support from top management for their success in modeling the business process. The need for involvement of top managers, the link between BPM and organizational strategies, the careful connection between IT and business strategy are critical success factors identified by Trkman (2010) in his study. In this context, communication, involvement of stakeholders, and support from senior management were critical successful factors for the implementation of BPM systems identified by Ravesteyn and Batenburg (2010). The authors suggest that large projects should not be developed without the support from a top-down approach.

Thus, the suggestion for the development of organizational learning is the participation in seminars, courses, presentation of case-studies and visits to companies that have implemented BPM, which involves not only the internal organization, but also customers, suppliers and partners.

SURVEY METHODOLOGY

This case-study was chosen because it is a qualitative construction of field research and represents the preferred strategy regarding issues like "how" and "why" (YIN, 2009). This case-study involves an intensive analysis of a relatively small number of situations. Yin (2009) adds that the case-study offers the richness of details obtained as advantage and as research effort, it contributes in a unique way for the understanding we have about the individual, organizational, social and political phenomena.

The criterion for selecting these companies was due to the fact that they are making major changes in their management model, for the decisions and actions that were relevant to the purpose of this work, and also due to the greater ease of access to respondents. Thus, the method used for the selection of cases in this study was the convenience sampling research.

In-depth interviews were made with the administrative director and manager of companies directly involved with the processes of organizations. For the development of the interviews, a questionnaire validated by Paim, Caulliraux and Cardoso (2008) was used, which identified and verified the importance of BPM tasks, and also identified the predominant management model in companies.

Thus, the interview guide used was structured in three blocks that corresponded to three task groups developed by Paim, Caulliraux and Cardoso (2008), which are: thinking, which refers to

the tasks of process design, acting, which relates to day-to-day process management, and learning, which corresponds to promoting the development and learning of processes, as shown in Table 5. Each task composing the groups above was evaluated in terms of importance for the studied company. The maturity level of companies in relation to the business process management and barriers found in implementing this management model were also identified.

Table 5: Task groups for the business process management and their variables.

Designing Processes (First group)
Understanding the external and internal environment
Establishing the strategy and approach for changes
Assuring the sponsorship for change
Understanding, selecting and prioritizing processes
Understanding, selecting and prioritizing tools
Forming teams for process diagnosis
Understanding and modeling processes in the current situation
Defining and prioritizing current issues
Defining and prioritizing solutions for current problems
Defining the management practices and implementation of processes
Understanding and modeling processes in the future situation
Defining the process changes
Implementing new processes
Managing day-to-day processes (Second group)
Implementing processes and changes
Promoting the performance of processes
Monitoring the implementation of processes
Controlling the performance of processes
Accomplishing short-term changes
Promoting development and learning (Third group)
Recording the process performance
Implementing process benchmarking
Recording and controlling impact deviations
Evaluating the process performance
Recording the learning about processes

Source: Authors are based on Paim, Caulliraux and Cardoso (2008).

PRESENTATION AND ANALYSIS OF CASES

The interviews were conducted in the first half of 2010. One of the companies surveyed is in operation for 40 years, and the other is a relatively young company that operates in the market for 7 years; however, both are reputable and well-known in the segment due to the quality level of their services. Another interesting aspect concerning the companies surveyed refers to changes in the way processes are managed; so it became possible to examine issues relating to the objectives of this study. The presentation and data analysis have been

summarized into four topics: description of companies, maturity level in business process management, importance of tasks in the business process management and key barriers.

Description of companies

The first company analyzed was called Company A, which is a provider of services in the advocacy segment that has branches located in important regions of Brazil. It was founded in 1969 and operates throughout Brazil, Mercosur, Mexico, United States and Europe in the following areas: Tax, Civil, Commercial and Corporate Law, Labor, Criminal, Administrative, Environmental and Biolaw, Cooperatives, Sports, and Paralegal Report and Control.
The second company surveyed was called Company B, which is a teaching and research institute in administration established in 2003 through the union of Administration teachers, researchers and professionals and currently has the support of about 200 teachers. It operates in three complementary areas: education, research and organization extension (consulting).

Maturity level in business process management

Based on literature review and in accordance with data obtained from the interviews, it could be inferred that Company A is at level two of maturity in relation to the set of tasks that are part of the process design, called acting by Paim Caulliraux and Cardoso (2008). According to Jeston and Nelis (2006), companies that are at level two of maturity have already had early experiences on BPM and with more people envisioning the organization from a process perspective, they begin to develop their BPM ability.

In the view of the interviewed manager, the concern for the customer is very intense in the mission and its values. He believes that: "*If I want to meet my client's needs and I have to stay alert all the time to what he is expecting: from the reception when he enters the company up to financial accountability. I have to involve internal staff to be aware of this and prepare our day-to-day activities to achieve this goa*l".

In relation to day-to-day activities involved with BPM, which compose the second task group, company A is at level one. At this early stage, according Jeston and Nelis (2006), companies make some unstructured and uncoordinated attempts of BPM. This becomes evident when the manager says that these activities are developed in isolation and alone, with no defined and transverse processes. For some activities, the interviewee believes that the best way to develop them is by business department.

The third group of activities related to promoting development and learning are still not developed by Company A that, therefore, is rated within category NA (not applicable). This is due to the fact that this company is at the beginning of the BPM implementation, i.e., it is still developing tasks from the first and second task groups.

On the other hand, in Company B, the seeking for certification as required by its customers made it develop faster in relation to company A in its business process management. The company hired a consulting firm that assisted in obtaining certification in all areas simultaneously, which also contributed to the implementation of the business process

management. Therefore, Company B is at level four of maturity in tasks from the first group - designing processes. According to Jeston and Nelis (2006), companies that have achieved this level begin to enjoy the benefits of having BPM strongly rooted to their strategy.

There was also a great evolution of Company B in relation to day-to-day process management, which, according to the interviewee, was achieved at the expense of much debate. Currently, activities are implemented in order to improve the production chain as a whole. An important fact to be highlighted is the need of the figure of a leader that monitors the process indicators and assists the implementation of processes so that no task is misaligned. At some point of the BPM implementation, this figure was not clear for the other team members and there was no monitoring of the BPM implementation and evaluation of processes, generating loss of efficiency in the implementation of the new management model. According to Antonucci et al. (2009), no use pointing out the mistakes, detecting failures and have no control. That was already highlighted by Company B.

In relation to the accomplishment of short-term changes, company B points out that not making these changes will affect the future of the organization, which happened in the functional management model.

Regarding the performance of processes, Company B is at the phase of readjustment of process indicators that need to be reviewed periodically, because those who do not help in any major decisions making are discarded. Company B makes use of benchmarking by means of the consulting firm that passes information on the best practices. Another factor highlighted is that only two companies in Brazil else than the researched company are certified.

Thus, with regard to the task group "promoting development and learning" Company B is at level three, because it has indicators that are being reassessed, obtains information on the improvement of processes by the consulting firm, but does record formal learning. It does not use reports or systems to generate information about rights and wrongs in relation to processes.

Importance of tasks for the BPM

Respondents were asked to rate each BPM activity contained in each of the three task groups according to their degrees of importance.

Company A rated most activities related to designing processes (first group) as extremely important. The manager said that the analysis of the environment is very important for designing the processes and establishing the change strategy and approach is part of the goals established by senior management.

Except for the activity of accomplishing short-term changes, which is considered by the manager of Company B as very important, all others from the group managing day-to-day processes (second group) were considered of utmost importance. Regarding the tasks of promoting development and learning (third group), since they are activities not yet

implemented in the company, for being at the beginning of the BPM implementation phase, they were classified as indifferent.

In relation to tasks from the group "designing processes", Company B considers most of the tasks very important. The emphasis was given to the analysis of internal and external environment, which was essential to define the migration of the management model. The organization came to be viewed as a whole and when deciding whether to certify only the teaching area or all areas of the company, the managers decided to make change in all areas, and since one area depends on the other, the lack of quality and process standardization in the research may undermine the teaching area.

Another task that deserves mention is the understanding, selection and prioritization of tools. According to Company B, this task is considered indifferent, since they consider tools important, but they are not priority. The company implemented the new management model only with the available tools.
Forming teams of diagnosis is extremely important for Company B, who needs to watch its steps and know how far it can get. The prioritization of solutions to current problems is of great importance, but they are taking too long to find the cause, perhaps due to the lack of knowledge on the interrelationship of all the processes involved by some people.

In relation to the second task group – day-to-day BPM, Company B considers the implementation of processes and changes irrelevant because it has already implemented all the processes, but stressed the great importance of monitoring the implementation of processes.

Regarding the group of promoting development and learning, Company B considers the tasks of great importance and was willing to develop them even though it is starting this phase, as previously it was focused on the tasks from previous groups.

Main barriers

Company A is fully aware of the benefits arising from the BPM and therefore has expended considerable effort to move forward in this management, in the attempt of overcoming the barriers found.

The main barriers found by Company A are: lack of methodology, involvement and perceptions of those involved in relation to BPM, large number of members with different perceptions, diverse profile of clients, cultural change, specific characteristics of the company's areas and lack of commitment from senior management, which have been identified in some studies as key success factors for BPM (BANDARA; GABLE; ROSEMANN, 2005).

The barriers faced by Company A are the result of a family-run model, which is fully departmentalized, operating for 40 years, with most staff working in the company for many years (on average 7 years, managers and partners - 20 years in the company). The difficulty in implementing any change in processes is very high due to an old pattern of corporate thinking.

The main barriers faced by Company B are: changing organizational culture, lack of consensus among people, lack of setting goals in common, lack of planning, proper job descriptions, understanding of problems and investment, and lack of knowledge on the need of recording learning as identified as success factors in some studies by Bandara, Gable and Rosemann (2005), Bandara et al. (2007), and Trkman (2010).

Company B has overcome some barriers by the help of a hired consulting firm, and thus developed training, made formal and informal meetings as an incentive to involve the staff and to overcome barriers as suggested by Antonucci et al. (2009).

Note that the main barrier found refers to the organizational culture, or to the departmental thinking of people, and the main barriers were faced during tasks from the first and second groups due to their impact on the organization.

CONCLUSION

Based on literature and field research, it could be concluded that companies recognize the importance of business process management, but their development levels are still relatively limited. With regard to the maturity level, it was observed that BPM is a complex practice for companies.

The BPM tasks emerged in response to increased competition between companies that have pursued their certifications, leading them to turn their attention to BPM. The tasks identified relate to project designing, day-to-day management and learning.

The migration from one management model to another, or from one paradigm to another, may be slow because the process of new practices may be restricted by various barriers. Since the overall objective was to assess the maturity level of companies in relation to BPM and the main barriers found for the migration of the management model, it could be concluded that companies are committed in implementing a management model focused on processes because they understand the importance of this management model to improve the quality of their services.

By analyzing activities related to BPM in general, it is possible to conclude that Company A is at level two of maturity as previously explained. The intention of obtaining the ISO certification has helped Company A to advance in business process management.

In general, Company B is at level four of maturity due to tasks already implemented. It could be inferred that this company is at higher maturity level due to the following factors that differentiate it from Company B: being a young company focused on research, the CEO's view about the importance of BPM and the hiring of a specialized consulting firm.

It should be observed that due to specific characteristics of the companies surveyed, they followed different lines of thought regarding the BPM implementation. While Company A considered it more appropriate to start implementing BPM in a gradual way, since the change in the management model in the company as a whole could generate a great impact on its

culture, Company B, in turn, decided to implement BPM in the company as a whole, since it clearly sees the transverse processes.

With regard to the importance of the tasks for companies, it could be concluded that in general, tasks are very important, despite the different maturity levels between the companies surveyed. Company B considers much more important the task group related to learning than Company A, in which this task group still does not apply due to the fact that this company is at the beginning of the management model change process and they will be important when it reaches a higher BPM maturity level.

There are barriers related to people and to business segment. The barriers faced by the companies surveyed are somewhat similar with regard to people, organizational culture and others features that are specific to each market segment, such as the diversity of the Company A's customers and the number of employees who have been working a long time in the company. On the other hand, Company B has already faced a financial barrier, not identified in company A.

One of the limitations of this study concerns the fact that this study is based on an extensive bibliographic database as opposed to a limited capacity of empirical validation.

DESIGN PROCESS AS A PART OF NEW PRODUCT DEVELOPMENT – CASE FURNITURE INDUSTRY

Päivi Haapalainen*, University of Vaasa, Finland
paivi.haapalainen@uwasa.fi, *corresponding author

Martti Lindman, University of Vaasa, Finland
martti.lindman@uwasa.fi

ABSTRACT

Time-based competition, first-mover advantages and a fast product development cycle time are some of the strategies used in order to gain competitive advantage in the current fast-changing competition environment. New product development (NPD) is one of the key components when implementing these strategies. Design process lies in the core of NPD, especially in the furniture industry. This paper aims at depicting the design process and the prerequisites to it being both fast as well as successful. The design process is seen as an interaction process between the designer, the entrepreneur and prototype makers. The process depiction and other results are also compared to some main NPD processes suggested in the reference literature. Three kinds of new products and related NPD processes are discussed: high tech products, low tech products with large innovations and low tech products with small innovations. This paper is based on empirical qualitative research conducted by observing and interviewing several designers and entrepreneurs in the Finnish furniture industry during the autumn of 2010. Some interesting observations have been made. It seems that the designer and the entrepreneur often see the design process in a different way: the designer feels that he should get a good picture of the company, its goals and strategies as well as current products before starting the design work whereas the entrepreneur expects the designer to create something new, more 'out of nowhere'. This may result in products that do not suite the company thus wasting precious time.

Keywords: New Product Development (NPD), design process, furniture industry

INTRODUCTION

Delivering a product to a customer rapidly can bring a company clear competitive advantage and the furniture industry makes no exception to this (Tammela, Canen and Helo 2008). Good quality and a low price are taken more and more for granted and this turns the focus to time (Wilding and Newton 1996). However, it is not only the actual delivery of a product to a customer being fast that can bring competitive advantage to a company but, also, bringing new products to the market quickly is important. A company developing products faster than its competitors may benefit by getting higher prices, more loyal customers, and a greater market share (Langerak and Hultink 2005). Time-based competition, first-mover advantages and fast product development cycle time are some strategies and tools for gaining these advantages.

The concept of time-based competition (also called time-based performance) was introduced by Stalk in the late 1980s. In this strategy, time is seen as a resource that should not be wasted any more than any other resource. The idea of time-based competition is to reduce the cumulative lead time of a product and thus gain competitive advantage. The cumulative lead time includes various processes throughout the organisations, e.g. new product development (NPD), production, procurement, sales, and transportation. (See e.g. Tammela et al. 2008; Vickery, Dröge, Yeomans and Markland 1995.) Research in first-mover advantage or pioneering advantage shows that the first company to enter a new market often gains larger market share than companies coming to the market later. It has been noted that this applies to different situations: consumer and industrial markets as well as growing and saturated markets. (Kardes, Kalyanaram, Chandrashekaran and Dornoff 1993; Michael, 2003.) 'Fast product development cycle time', 'rapid product development', and 'new product development speed' are all terms that refer to attempts to speed up the product development process in order to gain competitive advantage. These concepts mean generally how fast a company can turn an idea into a product in the market place. (Chen, Damanpour and Reilly 2010; Gupta and Souder 1998.)

Vickery et al. (1995) have been investigating time-based competition in the furniture industry. Historically this industry has often been connected to long delivery times. However, competition has also forced companies in this business to try to find ways of attracting more customers. Vickery et al. (1995) discovered that the product development cycle time was the sole predictor for market share in comparison to the new product introduction time, production lead time and delivery speed.

In industries like the furniture industry design lies in the core of the new product development process. There are various definitions for 'design' in the literature. Keeping the furniture industry in mind, this paper uses the definitions of Walsh, Roy and Bruce (1988): "[design is] *the configuration of elements, materials and components that give a product its particular attributes of function, appearance, durability, safety and so on*" and Ulrich and Pearson (1998): "*product design is the activity that transforms a set of product requirements into a specification of the geometry and material properties of an artifact*". Gupta et al. (1998) state that effective design is important to companies for various reasons. First, even though the cost of design may only be less than 10% of the whole costs of the NPD process, the decisions made in this phase determine as much as 80% of the total NPD costs. Secondly, making changes at this point is much cheaper than making changes during the actual production. Furthermore, customer satisfaction often depends on how well the product is designed.

This paper focuses on the design process part of new product development in the furniture industry. The objective is to depict the design process and the prerequisites to it being both fast as well as successful. Successful in this case means that the product should meet the end customers' needs, suite the manufacturing company's strategy and be effective to produce by the company. This paper is built as follows: theoretical background of new product development in general and some new product development models are introduced in the next chapter. This is followed by the introduction of the empirical research as well as its results. At the end of the paper the findings are discussed in comparison with the theory introduced earlier.

THEORETICAL BACKGROUND

New product development

Product development has to be done within all industries. However, the nature of the industry (high tech vs. low tech) and the amount of innovation (incremental improvement vs. radical improvement) affects the product development process a great deal (see Figure 1.). Electronics and computers are examples of high tech industries whereas the furniture industry represents low tech industries. Banbury and Mitchell (1995) define incremental innovation as "*refinements and extensions of established designs*". Compared to incremental innovations, radical innovations aim at bringing about something totally new either from a technological or some other point of view (Verganti 2006). While product development in high tech industries concentrates on technological innovations and following the rapid changes in technologies (Datar, Jordan, Kekre, Rajiv and Srinivasan 1996) the strategies in low tech industries have to be different. Typically in the furniture industry the main emphasis is on shapes, materials and ergonomics and sometimes, as Verganti (2008) presents, radical innovations are searched for in meanings.

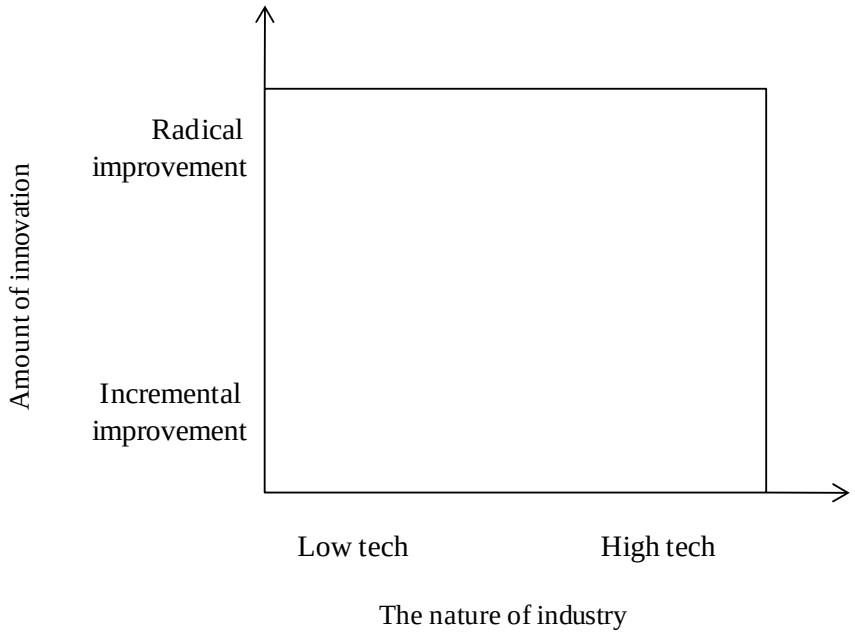

Figure 1: Different cases of product development.

Fast product development cycle or time to market is considered an important source of competitive advantage especially in industries in which product life cycles may be even less than two years (Datar et al. 1996) but also in various other industries (see e.g. Vickery et al. 1995). Chen et al. (2009) list a number of antecedents that have an effect on new product development speed. These antecedents are goal clarity, process concurrency, iteration, team leadership, team experience, team dedication and internal integration. Menon, Chowdhury and Lukas (2002: 324) on the other hand emphasise the learning perspective: "*change, flexibility, dynamism, cooperation, invention, innovation and information*

utilisation should be embraced" in order to gain rapid product development.

Product development models

Generic product development process

Ulrich and Eppinger (1995) have introduced a five-phase product development process model (see Figure 2) that has influenced both academic discussion and practices in companies. The model provides tasks for each phase and also the responsibilities of the different functions of the organisation in different phases. A product development process is defined as "*the sequence of steps or activities that an enterprise employs to conceive, design, and commercialise a product*" (Ulrich et al. 1995: 14).

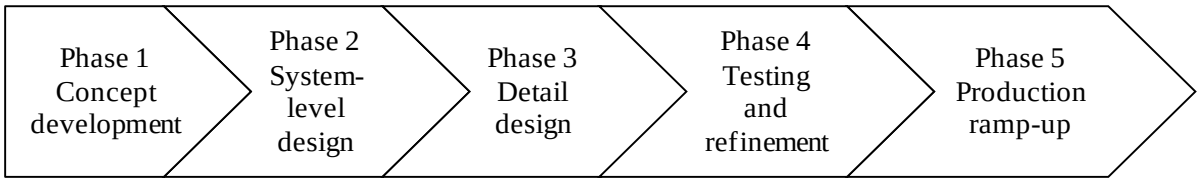

Figure 2: Product development process (Ulrich et al. 1995: 9).

In phase 1 "Concept development" new product ideas are created based on the needs of the target market. A number of concepts are then created based on these ideas. Finally, one concept is selected for further development. A concept does not only include description of the product but also deals with market potential, competition and economical issues. In the second phase "System-level design" the product is broken down into smaller subsystems and components. Strong emphasis is also on the actual production or assembly process. (Ulrich et al. 1995.)

The next phase "Detail design" takes the process even deeper. All the unique parts of the product are defined in detail: specifications of geometry, materials and tolerances are prepared. Standard parts to be purchased are identified and detailed plans for parts to be manufactured are made. In phase 4 "Testing and refinement" the product is tested from various points of view. Alpha prototypes are intended for making sure that the design works and satisfies the customer. The objective of beta prototypes is to assure that the performance and reliability of the final product is sufficient. (Ulrich et al. 1995.)

The final phase "Production ramp-up" aims at preparing for the actual production. The production process is refined and workers are trained. At some point the ramp-up phase turns into full production and the product is launched to customers. (Ulrich et al. 1995.)

Stage-gate model

The stage-gate model seems to be the most common product development model used by companies. According to Cooper and Edgett (Cooper and Edgett 2005: 133) about 54 % of businesses use it properly with well defined stages, gates and activities but the number of companies that have some sort of stage-gate model in use is even higher. The stage-gate

model is based on years of academic research with a large number of new product development projects. The first versions of the model were introduced in the beginning of the 1980s and since then it has been further developed to suit different companies and various situations. (Stage-Gate® is a registered trademark of the Product Development Institute Inc.) (Cooper et al 2005.)

The stage-gate model can be considered both a philosophy as well as an operation model for product development. The main idea is to turn product development into a well-structured process with clear and well-defined stages (to go through certain activities) and gates (to make a go/kill decisions). At each gate a project may be terminated. The model consists of six stages and five gates (see Figure 3). (Cooper et al. 2005.)

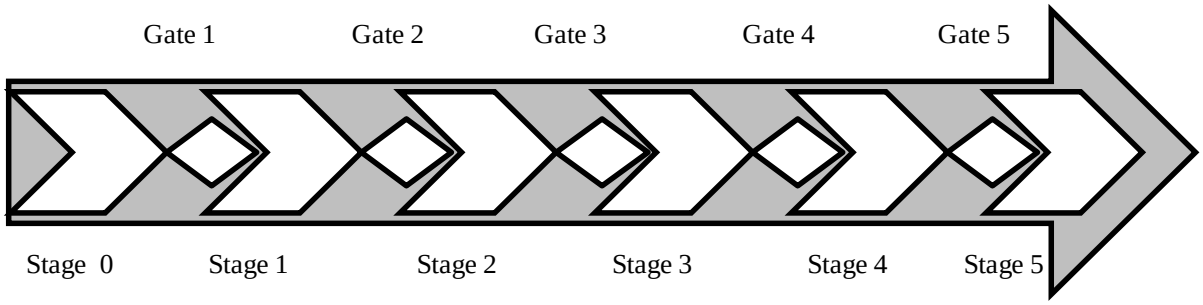

Figure 3: Stage-gate model (modified from Cooper et al. 2005: 140).

The stage 0 “Discovery” is for creating/finding opportunities and new product ideas. Based on the decision at gate 1 only some ideas will continue further. The stage 1 “Scoping” means preliminary research that will quickly provide information about the opportunity/product idea which will help make the decision at gate 2. In stage 2 “Build the Business Case” further investigation is done and this leads to product definition, project justification and a project plan. This investigation is carried out on both market as well as technical aspects. This stage is again followed by a gate that will determinate some of the projects. Stage 3 titled “Development” deals with the actual design and development of the product (or even service). Some testing should also be included in this stage. If the product still has potential enough it will pass gate 4 and continue to stage 4 titled “Testing and Validation”. And finally, after gate 5 only some products go on to stage 5, “Launch”. (Cooper et al. 2005.)

It is important to note that also the stage-gate model is a general model in the sense that it does not provide detailed answers to companies using it. The model gives hints for what to do and ask at each stage but the companies themselves have to modify the model to fit their own business. However, this forces the companies to actually define their new product development process which may lead to improvement.

A number of other new product development models can also be found in the literature. For example Peters, Rooney, Rogerson, McQuarter, Spring and Dale (1999) introduce a new product design and development model that includes three parts: pre-design/development, design and development process and post-design development. These parts are divided into six phases: idea, concept, design, pre-production validation, production/distribution and post-company. This model is different to the two models presented before in the sense that

it links post-design development stronger into product development but otherwise the product development process is fairly similar.

EMPIRICAL RESEARCH

The research presented in this paper is part of a project called Experimental Design Lab, "EDEL". The main purpose of EDEL is to create and test new ways of working for the Finnish furniture industry. One way of achieving this is to bring professional designers and manufacturing companies to work together stronger than before.

This paper is based on qualitative research conducted by observing and interviewing several designers and entrepreneurs in the Finnish furniture industry during autumn 2010. A total of 8 designers were given a task to design a piece of new furniture based on a brief. Three of the designers have industrial designer qualifications and the rest are interior architects. The briefs used are as follows: a social kitchen as the heart of the home, a bedroom for senior citizens and a home office.

The designers spent about four weeks in a small village in Western Finland (in periods of 1 to 2 weeks at the time) so the researcher had a possibility to observe their work and discuss with them several times. Observations were also made when the designers met with the representatives of local furniture companies and interacted with joiners. All the designers were also interviewed. A semi-structured interview was used so that the designers would have the possibility to freely describe the design process as well as their work. The themes used in the interviews included:

- ☐ the road through which the person became a designer
- ☐ the design process (e.g. starting the process, inspiration, co-operation and interaction with the furniture company)
- ☐ ideal way of working vs. reality

In addition to the designers the researcher also discussed with several representatives of furniture companies. The objective was to illustrate the new product development processes used in the companies.

RESULTS

A process chart of the actual design process was drawn based on the discussions with the designers (see Figure 4). The design process is, in this case, limited to the part of the product development process the designer is mainly responsible for. This is the part of product development in which the appearance, materials as well as function(s) of a piece of furniture are decided. Although each designer has a unique approach to design work, the design process itself seems to often be fairly similar.

The process begins with creating ideas. Normally a designer has a brief from the customer, e.g. to design a new dining table for the current line of products or to design a piece of furniture for senior citizens. It is not easy for a designer to point out the source of the idea in a particular case. Designers seem to "collect inspiration" wherever they go and whatever

they do and then use this “collection” when they design something. Ideas may come from the nature, professional or other magazines, buildings, people, interesting shapes or colours or just about anything.

There are a great number of issues to be considered when a designer is planning a new piece of furniture. One group of issues is related to the use of the furniture: the planned use or multiple ways of using the furniture, the user, non-planned use, and the space in which the furniture might be used. Another group of considerations is related to the furniture itself: shapes, colours, material, and ergonomics are all examples of these issues. Designers also have to consider the production of the furniture: how will it actually be manufactured. The structure and different parts of the furniture are important from this point of view.

Sometimes creating ideas involves gathering information. The designer may not possess enough knowledge about e.g. the users or the materials. They may discuss with the representatives of the user group or read some studies about the non-familiar issue. However, the designers say, without this work a good result cannot be reached.

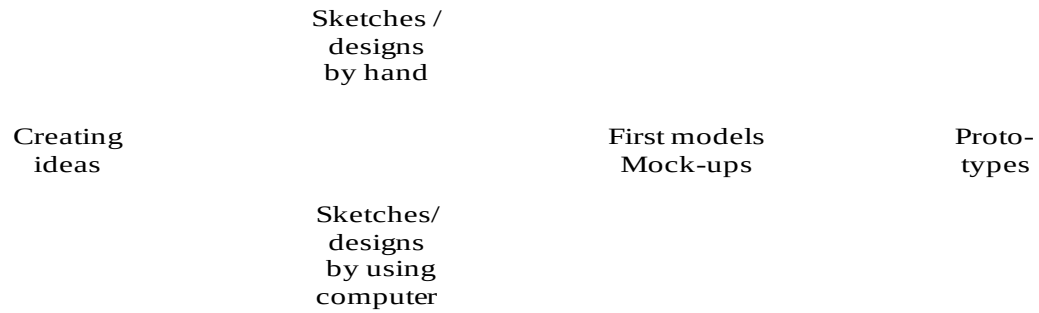

Figure 4: The design process.

The next phase of the design process is to prepare sketches and designs either by hand or by using some computer software. For some designers sketching and creating ideas are one activity and some designers think about the idea first for so long that it is almost ready when they actually begin to draw it. Sometimes a designer makes sketches first by hand and only after that uses the computer to prepare final designs. Moving back and forth between creating ideas and making sketches and designs seems to be typical for the design process.

Concrete, three dimensional models or mock-ups are built in the next phase of the process. The designers say that it is sometimes difficult, even for them, to perceive for example the proportions of the finished piece of furniture without actually seeing it and therefore mock-ups can be built. Sometimes a designer wants to see how the material can be used and models are built for that purpose. Shape, too, can be the reason to build a model and in this case it can be built also of other materials or in another size than the actual furniture. Based on the experience of the models the designer may go back to the previous phase and

redesign some parts or the whole piece of furniture.

In the final phase a prototype or more is built. The purpose of the prototype is to show what the piece of furniture will look like when produced in the actual size and of the actual material that has been designed. Building a prototype also gives viewpoints for planning the actual manufacturing process. In this phase the designer may need help from someone who builds the prototype – either the customer company or an external party.

There are two important things to be noticed about the design process of furniture: 1) it is not a linear process, and 2) the designer should not be left alone with the process. The process does not often move on from one phase to another linearly. It goes back and forth between the phases and sometimes different phases can be carried out simultaneously. This makes it difficult to see how the process is actually proceeding.

Even though the designer is responsible for the process, she should not be left alone with it. Strong input from the furniture manufacturing company is needed throughout the process. Designers say that it is important for them to understand the company, its history, strategy and needs. That way they can design something that suits the company. It is also important for the designers to know what the company can produce from a technological point of view. Sometimes there is crucial knowledge about the materials and manufacturing techniques in the company that should be included in the design process. Therefore the design process should be a continuous interaction process between the designer and the company which will make it possible for new product development to be both fast as well as successful.

During the discussions with the designers a special case of new furniture development came up: designing totally new, innovative products. All the interviewed designers agreed that this should not/cannot be carried out by the designer alone; instead there should be a cross-professional team. For example if the objective is to create innovations in the field of furniture for senior citizens, the team might consist of an expert in geriatrics, technological expert(s), representatives of the user group and manufacturing companies in addition to the designer.

DISCUSSION

The purpose of the design process presented in this paper is not to replace the product development processes introduced earlier. Instead this paper aims at opening up the product development process from the designers' point of view to the manufacturing company and its management. Good design can bring a competitive advantage to a furniture company and in order to gain this advantage, co-operation is needed. Involvement of both the company and the designer is needed in successful new product development process which is highlighted also by Peters et al. (1999). And the more radical innovations are pursued, the more important it is to have a multi-skilled team.

Another objective of this paper is to complement the earlier product development models from the furniture industry's point of view. The main challenge in combining the design

process as the designers have presented it with the earlier product development processes lies in the fact that these product development models are strongly linear: when one phase is finished, you should move to the next and no longer return to previous phases. However, the design process of a piece of furniture is more iterative. Good solutions are searched by a trial and error method. Creating ideas and concepts, designing models and building prototypes are mixed together until the solution is found.

Is this because most product development models have their origin in high tech industries and furniture industry is a low tech industry? Or can the reasons be found in the differences of incremental and radical innovations? Perhaps neither of these explains the situation. It is likely that the earlier product development processes have a strong managerial view. And from this viewpoint the important matter is decision-making. The manager might not be so interested in the actual design process (that is hidden somewhere in the phases or stages) but in the results that can be used when deciding whether to continue the process or not. This could also be the viewpoint of a large company where the management might not be so involved in the actual design work. However, it seems that for the manager of a small furniture company the only way to survive might be getting interested and involved in the design process, too.

DEVELOPING ORGANIZATIONS' INTERNAL COMMUNICATION BY COMMUNICATION AUDITS

Dr. Mirja Vaananen*, University of Oulu, Finland
mirja.vaananen@oulu.fi, *corresponding author

ABSTRACT

Organizational communication is critical for any organization to function well. By the means of communication, knowledge is transferred and shared in organizations. In addition, communication is an enabler for organizational learning. It is important to continuously invest in developing organizational communication. Communication audits provide means to gain information of the current state of and to enhance organizational communication. This paper discusses what kind of methods should be used for a communication audit to enhance organizational communication. Prior literature presents several processes and methods for communication audits. Both quantitative and qualitative methods have been used. The purpose of this paper is to understand what kind of process and methods are suitable for ICT circumstances.

The paper starts by literature review concerning communication audits. Advantages and disadvantages of different methods are argued. Then, the paper presents a communication audit method used by the author. This method was used in five product development project cases to understand the current state of organizational communication and to enhance communication in each case. Based on the findings of this paper, organizations can choose methods suitable for their purposes to conduct a communication audit and to enhance organizational communication.

Keywords: Communication, communication audit, internal communication, communication audit methods

INTRODUCTION

Organizational communication has been interest of researchers already decades. It has been noticed by both academics and practitioners that communication is critical for any organizational to function well. Communication provides means for knowledge creation, transfer and share, and thus enhancing organizational learning.

There has been enthusiastic interested towards assessing the current state of communication and based on assessment, generating development actions communication to better functioning. Organizational communication audits are means to provide management information concerning organizational communication and its effectiveness. Communication audits are used for exploring, examining, monitoring, and evaluating communication. Audits are used to reveal gaps in the communication process and to provide suggestions for improvements (Henderson, 2005).

Communication audit provides new information of the organization. Typically audits consider communication as a process related to other organizational processes (Downs & Adrian, 2004). For example, an audit may reveal weaknesses in human resource management related issues like feedback from management on one's contributions in one's job. As a consequence of an audit, enhancements may be gained, in addition to communication process, in many organizational processes. The results of organizational communication assessment – how the personnel view the organization, management and strategic goals – can also be used to benefit strategic planning of the organization (Hargie & Tourish, 2009).

In addition to that communication assessments benefit communication practices, an audit itself can be considered as a communication method (Downs & Adrian, 2004): to conduct a communication audit gives an impression that management is interested in perceptions of the personnel. For those participating in the auditing process, it also provides an opportunity of influencing one's own work. The participants involved in the planning and follow-up phases of the auditing process are provided with a comprehensive approach to the whole communication process.

Essentially, communication audits emphasize the viewpoint of personnel involved in the communication processes to be audited. An audit gives management verified information on how personnel perceive communication and related processes. Instead of relying on rumors or grapevine a communication audit substantiates and checks the accuracy of personnel perceptions. It gives feedback to the management on how the communication process is perceived to be working (Zwijze-Koning & de Jong, 2007).

Multiple methods have been used in communication audits. Previous literature has shown the advantages of both quantitative (Clampitt, 2000) and qualitative (Dickson, 2000; Millar & Gallagher, 2000; Dickson, 2009) methods. The most often used include interviews, surveys, focus groups, observations, network analyses, content analyses, communication diaries, and critical incident analyses. Typically, different methods are used to complement each other (Hargie & Tourish, 2009).

Zwije-Koning and de Jong (2005) argue that, among the organizational communication audit literature, there is a lack of discussion of what kind of information can be sought through different methods used in communication audits. They state that triangulation is important but not sufficient requirement when selecting methods used in an audit. In addition, although it may be that the research process and selected methods need to be case specific, the suitability of each method for collecting the needed data (regarding the purpose of the research) has to be considered.

Only rarely the studies argue what methods are suitable under which circumstances, and what should be considered when selecting the methods to be used. Methods affect the type of data gained, which further affects what kind of conclusions can be made and what kind of results can be expected from the audit process. In addition, there may be organization-specific constrains related to data gathering methods: for example, do the personnel have their own computers in use (then e.g. internet-based questionnaire is suitable option) or not (then e.g. surveys need to be made by paper form).

The aim of this paper is to discuss *what kind of research process is suitable to study (intra-project) communication effectiveness in high technology product development organizations?* In the following chapter examples of the typical methods used are placed and their advantages and disadvantages are discussed. Then, the paper presents a communication audit process and discusses the strengths and limitations related to the proposed process.

METHODS TO STUDY ORGANIZATIONAL COMMUNICATION EFFECTIVENESS

Communication audit process may involve different kind of methods. It is typical that the audit process includes a survey. By surveys auditors are able to collect quantitative data of the communication in the organization.

Surveys are very popular methods used in communication audits. The most popular surveys are Communiaction Satisfaction Questionnaire (CSQ by Downs & Hazen, 1977), ICA Audit Survey (Goldhaber & Krivonos 1977, Goldhaber 2002), and LTT audit questionnaire (Wiio & Helsila 1974, Wiio 1977). These may also be accommodated into case-specific circumstances. These surveys have slightly interest towards communication process and the themes covered are slightly different (Table 1).

Table 1: Themes covered in communication audit surveys.

Survey	CSQ	ICA Audit Survey	LTT
Themes covered	Communication climate	Amount of information received versus amount of desired (various topics)	Overall communication satisfaction
	Relationships with supervisors	Amount of information sent versus amount of desired (various topics)	Amount of information received from different sources (current state vs. ideal)
	Organizational integration	Amount of information received versus amount of desired (various sources)	Amount of information received about certain job items (current state vs. ideal)
	Media quality	Amount of information received versus amount of desired (various channels)	Areas of communication that need improvements
	Horizontal (informal) communication	Amount of follow-up versus amount of desired	Job satisfaction
	Organizational perspective	Timeliness of information	Availability of computer information systems
	Relationships with subordinates	Organizational relationships	Availability of computer information systems
	Personal feedback	Satisfaction with organizational outcomes	Respondent's general communication behavior
			Organization-specific communication
			Information-seeking patterns

Surveys presented in Table 1 have been validated meaning that the tool measures the things it is supposed to measure. However, from the table it shows that the contents of the surveys differ as well as the viewpoint they take to what is considered to be important. Based on the themes covered by the surveys as presented in the table, it can be concluded that these most popular surveys all have slightly different viewpoint to communication process and to what is considered important. CSQ includes communication climate and related aspects like organizational integration, informal horizontal communication. In addition, there is a strong emphasis on superior-subordinate communication. On the other hand, ICA audit survey highlights receiving and sending information. LTT survey has special attention into information seeking and computer information systems. The themes covered by the survey are, of course, related to each others. However, it can be concluded that in a communication audit, if a survey is used, its contents can be planned case-specifically depending on the current interests.

Communication Satisfaction Questionnaire (CSQ) is a quantitative tool providing statistical data about employees' communication satisfaction (Zwije-Koning and de Jong, 2007). CSQ is a method to analyze respondents' satisfaction with ten dimensions of communication system (Zwije-Koning and de Jong, 2007). CSQ has been used e.g. in a research by Zwije-Koning and de Jong (2009) where each item was measured on a scale from 1 to 7, and mean scores for each item and confidence intervals for each dimension were calculated.

There are also other surveys used to audit organizational communication. For the basis of the research process developed in this paper and presented in following chapters, two other surveys were analyzed. These include a survey by Müller (2003) and COMPASS survey by Construction Industry Institute (1996) (compare the context from Appendix 1). The survey by Müller concentrates on information management viewpoints. The COMPASS has a wider outlook. The strengths of the COMPASS include that it is in electronic form: the respondents can fill in an electronic form to answer the questionnaire.

Hargie & Dickson (2007) studied organizational information flows in four organizations using Episodic Communication Channels in Organization (ECCO) questionnaire. ECCO questionnaire was developed to measure personnel's knowledge of in-house policies regarding to informal and formal grievance policies. The questionnaire was sent altogether to 832 disproportionatedly selected persons.

The advantages of using the ECCO questionnaire include providing exact information of employee knowledge level. ECCO questionnaire can also be implemented in variety of contexts and purposes. Shortcomings of using ECCO include that it is time consuming. In addition, there is a risk that the questionnaire is seen as a test of employees rather than a feedback channel. Additionally, the tool provides only quantitative data and lacks of respondents' explanations or interpretations of the causes. (Hargie & Dickson, 2007). The critics towards ECCO questionnaire include also that it does not made any difference of the role of the respondents: people working in different roles or organizational units may perceive information flows differently.

Besides survey, also other methods to collect and analyze data can be used in communication audits. Critical Incident Technique (CIT) and Network analysis are among the

most popular ones. CIT is a qualitative tool studying any communicative incident towards that the employees have positive or negative feelings (Zwije-Koning and de Jong, 2007). Critical incident technique investigates personnel communication experience (Hunt et al. 2000).

Critical incident technique (CIT) has been used e.g. by Hunt et al. (2000) in a study of communication experiences by education managers. In this study interviewees were asked to (regarding communication) document three critical incidents that occurred during their working. The interviewees were also asked to document the main strengths and weaknesses of communication within the organization. Based on the gathered data, a content analysis was made to identify respondents perceptions of communication processes, main patterns of communication incidents and current communication climate in the workplace.

Network analysis can be used to reveal communication structure within the organization. The data can be used to detect information blockages and to generate new communication structures. (Zwije-Koning and de Jong, 2009)

More than one method in the audit process

It is typical that the audit process includes more than one method to collect and analyze data. For example, CSQ has been used in different kind of audit processes to supplement data gathered by e.g. interviews, critical incident technique, and network analysis.

Zwije-Koning and de Jong (2007) present a study where they analyze the reliability and validity of Communication Satisfaction Questionnaire (CSQ) by comparing it to Critical Incident Technique (CIT). Special attention was paid to that does the CSQ covered the themes found to be important based on the CIT analysis. In addition, they analyzed whether both of these tools can be used by the researchers to explain employees overall communication satisfaction and do these two different types of tools point to same directions of communication satisfaction or dissatisfaction.

Zwije-Koning and de Jong (2007) found out that the CSQ is a suitable tool for generating an overall view of how the employees perceive organizational communication. However, they argue that CSQ is not so suitable for identifying specific challenges related to communication or, for generating proposals of how to develop communication.

In another study, Zwije-Koning and de Jong (2009) in their communication audit among three large high schools from Netherlands utilized network analysis, the critical incident technique, and the CSQ. All data was gathered in interviews from 45 minutes to two hours. For the network analysis they asked personnel to identify with whom they interacted the most, about which topics (the topics were categorized into coordination, strategic issues, and personal ones), and how often. After that, a social network analysis program UCINET (Borgatti et al 2002), was used to calculate network analyses.

In their research, Zwije-Koning and de Jong (2009) utilized different types of methods for organizational communication audit. Each method provided different type information and

thus supported making analysis and conclusions of the shortcomings of communication within the studied organizations. For example, in interviewees stated that decisions were made without their involvement which was supported by that 21% critical incidents pointed at decision making and that network analyses showed strongly centralized decision making networks.

In her research, Vos (2009) introduces a different type of an instrument to study communication quality and added value in municipalities. The instrument is based on balanced scorecard by Kaplan and Norton and quality control procedures that the European Foundation of Quality Management (EFQM) utilizes. The used instrument covers interviews of communication professionals and general managers. The interviewees were asked to name indicators of communication quality and examples of good or bad communication regarding corporate communication, policy communication and, organization-related communication. In addition, the auditors searched for facts and figures to support the findings made from interviews. The process ended with a seminar with relevant stakeholders to discuss the outcomes of the research process.

Vos (2009) reports that the validity of the instrument could be improved by using external auditors and by providing more facts and figures to support the findings from the interviews. She also reports that the seminars promoted creating a common understanding and improvement plans. Vos (2009) argues that this kind of research enhances dialogue between communication professionals and top managers, and that after the research the top managers better understood the effects of communication.

SPECIFIC NEEDS FOR THE METHOD IN ICT CIRCUMSTANCES

In this chapter a discussion is presented concerning what to consider when generating a communication audit for ICT product development.

In ICT companies, the speed of product development is crucial. Thus these companies invest in efficiency and effectiveness of product development operations. For example, there are continuous investments in increased speed of new product introductions (Mallick & Schroeder, 2005) after the product development is essentially the life-blood of an ICT company (Campbell & Holmes, 2004).

Organizing product development in ICT companies has some special features that shape communication systems of these organizations. For example, ICT product development projects typically involve a network of companies and subcontractors (van Echtelt et al. 2008). In such projects, engineering personnel need to interact both with the employees by his/her own company and with the employees of the other companies involved in the cooperation. Thus, personnel need to be aware of agreed practices related to communication over organizational boundaries. It is not only the managers but also the engineering personnel who have the responsibility to put efforts of effective inter-organizational communication.

ICT product development is complex from the viewpoint of communication. The personnel in product development projects are typically geographically distributed i.e. multi-site

(Paasivaara 2005). Even though the project may not be multi-site, there are often many national cultures involved (multi-cultural, Harvey & Griffith, 2007). Additionally, there are several on-going projects in the product development, and the personnel maybe involved in several projects at the same time (Killen et al., 2007). In ICT projects the product itself is complex (complex product structure, Birk & Heller 2007) and may involve professionals with different backgrounds: e.g. software designers, electronics designers, mechanics designers, system designers (multi-technical projects) (Edmonson & Nembhard, 2009). These aspects should be considered when planning a communication audit.

Communication in ICT product development projects is enhanced typically with the newest communication technologies. Computer-aided communication is present in everyday interaction in these projects. In the case that a communication audit studies the current situation of the communication system in the organization, the audit should also recognize the position of all these technologies used in the organization. The auditor may also use this as an advantage: if the personnel are familiar to use different communication media, why not to use those as data collection tools in the audit.

An important constrain for conducting a communication audit in ICT product development is that time is critical in ICT business: the auditor is expected to use as little time of the persons involved as possible for conducting the audit. When possible, the auditor should acknowledge this when planning the auditing process.

DESCRIPTION OF THE DEVELOPED PROCESS

The process developed to study (intra-project) communication effectiveness in high technology product development organizations is presented in this chapter. The process was developed based on the literature review of communication audits.

As recommended by the earlier literature, multiple data collection methods were decided to be used. The methods (Figure 1) were selected in order to them to provide both quantitative and qualitative data of the phenomenon under study. In addition, it was considered important that the methods would cover not only the viewpoint of management but also employees working in the project. The aim was to provide rich data of the phenomenon. At the same time the aim was to use as little time as possible of the people participating to the research. An important intention was to, during the research, check from the empiric whether the methods needed some revisions (i.e. did the planned research process and methods correspond enough to the reality matters). Following steps were selected to the research process:

- initiation (getting started with the research in the company)
- thematic semi-structured interviews;
- documentation by the organizations;
- a web-based survey;
- focus group work;
- analysis and interpretation.

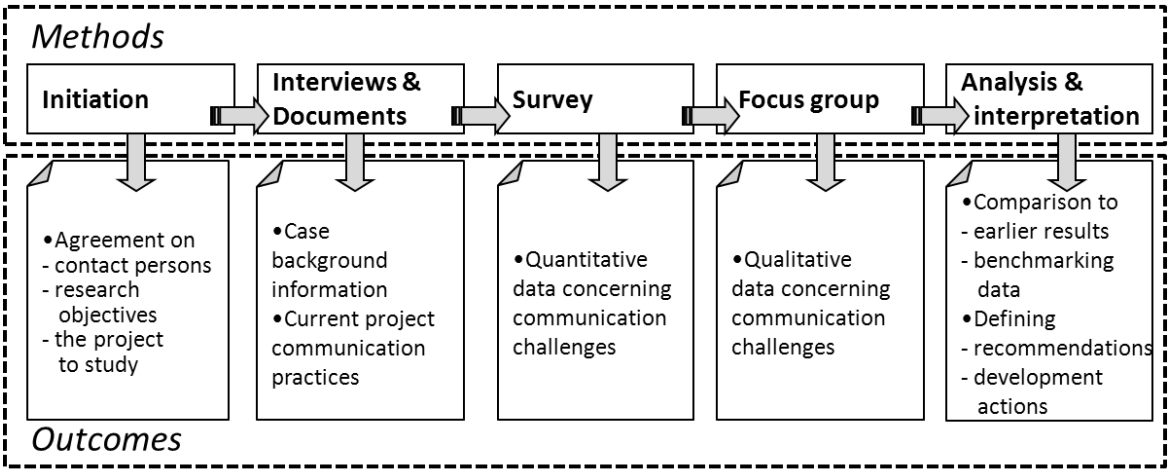

Figure 1. Methods and related outcomes.

The purpose of the *Initiation* phase was to get started with the research in the company as smoothly as possible. The second step, *thematic semi-structured interviews* were used to provide qualitative data from the personnel interviewed. Next step, *documentation by the organizations* would provide mainly qualitative data (it is possible that this phase includes also quantitative data) that is objective and represents the organizations' official guidelines. This phase is expected to either provide different information than the interviews, or to support findings from the interviews. The third step, a web-based survey, was used to provide quantitative data for the auditing process. *Focus group working* was included in the auditing process to enhance dialog within the organization to be audited as well as between the auditor and the organization. The last step in the auditing process is *Analysis and interpretation*. This phase was decided to include as it would provide an opportunity for a wider viewpoint to the phenomenon: the results of current auditing could be compared to e.g. earlier results. In the following, the rationale and realization of each step is explained in more detail.

Initiation

Using an external auditor brings it important to have some kind of initiation phase before starting the research. Suring this phase a common understanding between the auditor and the audited party should be gained about what is going to be done and what to expect from the process. This should include discussion about the purposes and goals for the process: what outcomes each party may expect to come about and how the outcomes will be documented and shared. There should also be a common understanding of the exact methods used e.g. the contents and the structure, what each method is expected to reveal, and how much time will their utilization require. In addition, the roles and responsibilities of the parties involved should be made clear, as well as the contact information and frequencies. For example, it is good to document who has the responsibility to define and provide contact information of the participants to the following research phases. Also other possibly case-specific roles are to be discussed and agreed.

Interviews & documents

The main data gathering methods in the research process documented here are the survey and the focus groups. To support these, interviews and studying certain organizational documents are conducted beforehand. The objectives of the interviews are the following:

- to familiarize the auditor with essential current project communication practices in the case. Based on this information the auditor can check whether all relevant aspects of communication system within this specific organization are covered in the survey.
- to familiarize the auditor with the current communication follow-up practices and earlier development actions related to project communication in the organizations. This information can be used as a reference data of earlier surveys within the company.
- to document background information of the studied projects. This kind of information is important to documents especially if the data gained during this audit is used as a benchmarking data.

The first two objectives are supplemented by studying organization specific internal documentation. The documentation may include such as guides for conducting a project plan, or earlier survey reports. Organizational documents provide information about the official communication system within the organization and may reveal e.g. essential communication processes, the main media used, and utilized data bases.

Survey

Communication audits typically include a survey. To develop the survey for this research process, the strengths and weaknesses of other similar-like typically used surveys were analyzed. This analysis was used as a starting point to a survey questionnaire to be developed. From this analysis it shows that in addition to consider the contents of the survey, one has to make certain decisions on technical realization of it. At first, the selection of paper or electronic forms brings further choices to consider: how much do we set limits for the time and place for the respondents to give their answers. These considerations affect the internal and external validity of the audit. External validity i.e. the generalizability of the results is weakened by low response rate. Thus, we may want to make giving responses as easy as possible by e.g. sending an email with an internet address where the respondent can give his/her reply. On the other hand, being able to give answers whenever and wherever suitable to the respondents lessens the auditors control over the process, and possibly lessens the internal validity (i.e. real existence of the professed causal relationships). For example, how can we be sure that the responses given are truly given by the person we expected?

Considering these aspects the survey was decided to be conducted using a web-based questionnaire. Utilizing internet applications enables more flexibility to the audit process: the respondents may give their answers whenever it is suitable for them. In addition, it lessens the paper work related to the audit, and provides the data in an electronic and easily handled form.

A web-based questionnaire requires a technical solution i.e. a platform where the questionnaire runs. To avoid the development efforts of a technical platform, a web-based questionnaire provider was chosen (ZEF Solutions Ltd.). There are several advantages for using the tool. Firstly, the questionnaire was easy to develop due to user-friendly user-interface of the tool provider. This allowed time savings in the audit process as a total. In addition, the tool was perceived as user-friendly for the respondents, which was important in order to the response rate to be as high as possible. Also, during the initiation phase the company representatives emphasized the importance of the ease of the audit process for the respondents. With the selected tool the respondents were easy to reach (email). Additionally, the tool provided data in a form that was easy to analyze.

Contents of the communication audit questionnaires differ. In this audit process, the purpose of the survey is to reveal how satisfied project personnel are with different communication aspects present in product development. The questionnaire was developed utilizing earlier research of communication audits, especially CSQ (Downs & Hazen 1977), ICA Audit Survey (Goldhaber & Krivonos 1977, Goldhaber 2002), and LTT audit questionnaire (Wiio & Helsila 1974, Wiio 1977). In addition, research done by Müller (2003) and the Construction Industry Institute (1996) was used. The questionnaire was then modified based on the information found during the interviews and documents review. In this modification phase certain questions were added in order to the contents of the questionnaire better cover the realities of high technology product development projects. The contents of the survey are presented in Appendix 1.

The purpose of the survey was to reveal how satisfied the personnel are to project communication and how much support individuals get from their superiors or from the organization. Thus, the questionnaire covered perceived satisfaction of horizontal (team, other project members, members of other projects, subcontractors, customer) and vertical (superior, briefings) communication, and typical communication media in the organization. In addition, the questionnaire explored perceived satisfaction of communication about roles and responsibilities, personal feedback, lessons learned and change management. The items gathered for the questionnaire were divided into eight modules (see Appendix 1).

The draft of the questionnaire was refined based on the discussions and findings from the interviews. The final questionnaire form included altogether 66 questions. However, because the case projects had somewhat different communication media in use, the number of questions for each case organization varied: of the 66 questions 60 concerned case A, 50 case B, 51 case C, 50 case D, and 52 concerned case E (see details in Appendix 1).

The final questionnaire had three kinds of questions:

- questions with multiple choices the respondent could choose from;
- questions with Visual Analogue Scale (VAS) (Metsämuuronen 2001);
- three open-ended questions at the end of the questionnaire.

When answering the multiple choice questions each respondent could only pick up one option. The VAS questions allowed answers to be given on a continuous scale. VAS questions have been used especially in measuring the status of health and quality of life (De Boer et al. 2004). Most of the VAS questions used in the survey had two dimensions:

importance and satisfaction (or importance and frequency). For example, if the question was about "communication planning", the respondent would give his/her answer at the same time to questions "How important is communication planning?", and "How satisfied are you with communication planning in your project?" (see Fig. 2). Thus, the respondents gave their answers to both dimensions at the same time.

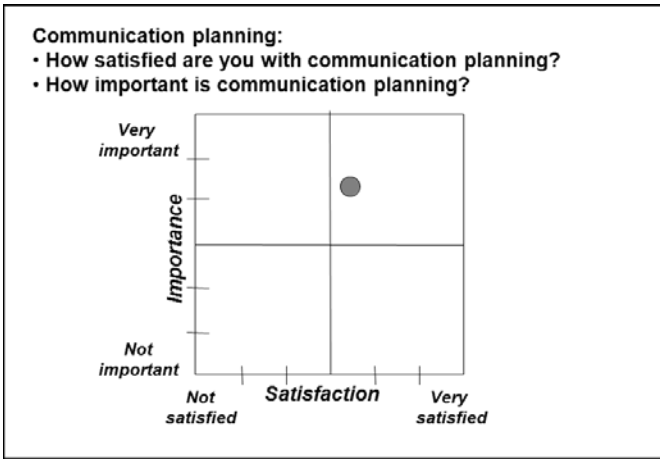

Figure 2. An example of a VAS-scaled question with two dimensions.

The extreme positions for the VAS questions were:

- Importance: Very important – Not important;
- Satisfaction: Very satisfied – Not satisfied;
- Frequency: Frequently enough – Not frequently enough.

Focus group

The rationale for the focus groups was to complement the audit by providing qualitative data about the strengths and weaknesses of the communication within the organization.

Focus group method is a group interview where a group of people are gathered to discuss a specified topic (Wilkinson, 2004). The essential information is the contents of the discussions during the working. Thus, focus groups are a way to collect qualitative data. Advantages of focus groups include that, compared to e.g. individual interviews, focus group method allows communication concerning the topics (Krueger & Casey, 2000): during a focus group session the participants can discuss their viewpoints, ideas and perceptions about the theme given. Focus group method is expected to enrich the understanding of strengths and weaknesses found based on the survey. Audits are done to check the current situation and to propose some development actions. Focus groups may point out possible constrains related to planned development actions originating from organizations realities. Additionally, focus groups provide a possibility for arguments for and against of the coming changes. This will enhance building commitment to the new direction of operations.

An important phase in using focus group method is the design of the group composition. Or the discussion to be fruitful, there should be suitable number people with relevant background. A survey could well cover large number of people, but for a focus group from 6 to 8 persons is typical (Morgan 1998). In this audit process it was considered important that

a wide understanding of the personnel perceptions was gained. Thus, the focus group participants would represent different roles from the project: designers and other engineering personnel, supporting functions (e.g. quality support for the projects), and project management.

Focus groups should have a predefined agenda including topics or themes to be discussed. In this case, the agenda of the focus groups were defined to include two main steps:

1. identification of project communication related topics that focus group participants considered requiring improvement actions the most;
2. generation of ideas on how to develop each topic named in the first part of the focus group working.

The interest in the working of the focus groups was manifold. From the phase one it would be interesting to note whether focus group participants would choose the same topics that were highlighted in the survey results, and if not, why. It is possible that certain weaknesses are because of practical constrains of the organization, and thus cannot be really sorted of. From the phase two, new ideas on how to develop project communication would emerge. This information can be utilized in organizational development projects.

The described process was applied in a research of project communication among five high technology companies (Väänänen 2010). The process included data collection from five cases. Thus, a cross-case analysis was conducted and provided for the cases participated as a benchmarking data.

Analysis and interpretation

In this phase the data collected during the earlier phases was analyzed and compared to each other. This was found to be important after the data from different phases, to some extent, pointed to different communication challenges. After the audit process was completed, it was clear that it was useful to include all these different data gathering methods as they truly provided more information for the auditor.

In addition, in this phase the data collected could be compared to the results of possible earlier audits, or, if available, other analyses done within the same industry. This kind of benchmarking analysis was included into this phase.

CONCLUSIONS

Organizational communication has been an interest for academics and practitioners for decade. Efficient communication is essential for effective management of any organization. It is essential to continuously invest in communication development. Communication audits are means to gain information of the current state of and to enhance organizational communication.

Earlier literature presents different methods used in communication audits. The selection of methods may include both quantitative and qualitative methods. An auditor needs to

consider which methods are suitable in each audit process. This paper aims to present a process to be used in ICT product development projects' communication audits.

The paper suggests that, in order to gain comprehensive understanding of the current situation, a communication audit in the studied context should include multiple data gathering and data analysis methods. Still, the process should require time from the personnel involved as little as possible.

This paper presents a process used for communication audit in ICT product development projects to include six phases: initiation (getting started with the research in the company), thematic semi-structured interviews, documentation by the organizations, a web-based survey, focus group work, analysis and interpretation.

Data collection methods were divided into four steps. The first one includes thematic semi-structured interviews that were used to provide qualitative data from the personnel interviewed. Next step, documentation by the organizations was included to provide mainly qualitative data that is objective and represents the organizations' official guidelines. The document supported findings from the interviews. The third step, a web-based survey, was used to provide quantitative data for the auditing process. The fourth step was focus group working and its purpose was to enhance dialog within the organization to be audited as well as between the auditor and the organization.

Data analysis was conducted after each data collection step to provide information for the next data collection step. In addition, after the four data collection steps, an analysis and interpretation phase was included to compare all data to each other and to provide comparison to possible earlier audits within in the company or in other companies (benchmarking analysis).

Communication audits should be conducted regularly. The aim is to provide information on where possible problems are developing before serious problems arise. If conducted regularly, communication assessments also provide information on how the organization is progressing in relation to communication (Downs & Adrian 2004).

The limitation of this paper include that the communication audit process presented in this paper was applied in five cases in ICT sector companies. Interesting themes for future research include applying the presented process in different companies operating in ICT or other industries.

EXPANSION OF RESEARCH AND DEVELOPMENT BRINGING FRESH INNOVATION AND RELEASING INTERNAL RESOURCES

Toni Niemi, University of Vaasa, Finland,
p86901@student.uwasa.fi

ABSTRACT

Product development is one of the most valuable tools to help a company survive in the market field. Competition is getting more and more brutal every year and only those who can change their business habits and products quickly enough can survive to make profit in the long-term. Rapidly changing markets force companies to research and use the newest possible technologies. Due to the rapid evolution of products, customers are demanding more and more all the time. Besides the demands of the technical improvements, customers are starting to take into account the impact their purchases have on the environment which is starting to become more of a driving force in their decisions. Holt (2002) said that the key for success in the business is developing new products and improving old products.

The product development process is very long and includes countless decisions. One wrong choice can lead the whole project failing. Ulrich (2000) has found that more than 50% of all R&D projects will fail totally and only a select few actually create something new and revolutionary. Companies which use their R&D skills to compete in their market field have to decide what their best strategy is. Trott (2008) has defined the four different product development strategies; First to market, follower, imitator & lower of the costs and satisfier of special segments.

In the "First to market" strategy, companies have to make sure that they are the first to offer a new technology or application to customers. This strategy includes lots of risks and demands a high knowledge of the newest technologies. The "Follower" strategy also demands a high level of acknowledge so that the company can produce cheaper and superior versions of the rival product which are already in the market. "Imitator and lower of the costs" strategies are normally the most difficult strategy to maintain for a long period of time. The main idea is to manufacture and sell products very cheaply to attain profits through a larger volume. In Trott's final strategy, "satisfier" of special segment" the company concentrates on filling the gaps in the markets which the rivals have left open. The case company of this research is partly focused on this strategy.

In this research we have used Ulrich's theory called the "Expansion of Research and Development" in our case company to help their own overloaded R&D team. To help the adaptation of the new R&D process, we undertook interviews and filled out questionnaires in the case companies own R&D team to find out their thoughts and attitudes about the outsourcing of R&D. The results of the interviews from the case company's own experts shaped the final form of this study.

Keywords: R&D, Outsourcing, networking

BACKGROUND

Researchers have long known the importance of product development on a company's future. Outsourcing is now one of the hottest subjects in the business world and still divides opinion. Even though most of the newest studies support outsourcing, it is surrounded by lots of doubts and fears which slow down the growth of the outsourcing trend. Burkholder (2006) has listed the most common myths and doubts around outsourcing; there is a high risk involved in outsourcing critical parts of the business, the costs of outsourcing are higher than the costs of reducing the number of your own employees or the motivation of the employees of the supplier or not as high as it would have been in an internal team.

None of these claims are true. In a lot of cases the company has already outsourced critical parts of its business, for example the car industry started to outsource the manufacture of motors a long time ago and a reliable motor is a very important part of the company's image. The costs of outsourcing are actually much lower than the employees trying to reduce costs and an outsourcing company will gain access to new tools and technology from the supplier without any extra investment. The motivation of the supplier's employees is often higher because the company and the supplier both have same goal; satisfied the customer. In a relationship between two companies, conflicts are much more uncommon than in an internal organization.

The outsourcing of product development is a pretty new idea but many global companies have already done it for a long time now in low cost countries. In Finland the trend of R&D outsourcing was raised very quickly before the latest depression. In the best case scenarios some engineering and design companies' turnover and number of employees grew by 30% in just one year.

Outsourcing used to be more important for big companies whose market area and products were focused on low level technology. Now outsourcing is also used in high level technology companies. They are aware of the fact that in the current economic climate no company can rely solely on their own R&D teams. Outsourcing also refreshes the company's organization and rules. Internal R&D teams have to concentrate more on standards and provide documents so that the supplier can understand the wishes and demands of the client. Superior documents will also serve the company much better in the future.

Outsourcing can also save money, despite experts saying that if the only reason to outsource is to cut losses the attempt will fail. Tidd and Trewhella (1997) say that sometimes outsourcing is a faster and more efficient way to get results than building the necessary and missing skills within the internal organization. Companies will gain most from outsourcing when their goals are to gain access to new technologies, tools or expertise. Outsourcing will release the internal team to focus on their core competence and the whole company will benefit as a result.

TRADITIONAL R&D

Basically all research and development processes obey the same fundamental structure. Cagan (2001) summed up the three main steps; product planning, plan approval and product launch. The time in-between steps one and two is divided into identifying, understanding, and carrying out the new ideas. After approval the time will come to refine the product, manufacture the prototype and begin preparations for product launch. According to Cagan(2001), if a company obeys these steps it will be able to reduce the number of potential development problems.

The case company in this research is a high technology company which has a very efficient and strong internal R&D team. The company runs a huge amount of R&D projects every year and they have formed very strict protocols and rules on how to handle all the new ideas. The case company's own gate model is well prepared and it is easy for them to coordinate and control a lot of projects at the same time. The main idea of the gate model is that before the project continues to the next step, it has to pass the previous gates demands. This model takes a lot of time and human resources because every gate means meetings and tasks for the people who are participating. The progress of the projects is slower and more expensive. All the ideas and points of view are coming from within the same company.

Interviews during this research revealed that the employees thought that no-one knows everything. It is common sense that the person who knows most should be in charge.

EXPANSION OF R&D

According to Cagan (2001) and Vogel (2001) a company needs to be successful at using the appropriate R&D tools, a good plan and a team which works well together using the correct methods. To find and use these correct methods requires a lot of resources. Research and development is not only for one internal department but for the whole company. Every company should underline the importance of R&D to its whole staff, because in many cases the best initial idea comes from production where employees are in contact with the real products on a daily basis.

Ulrich's (2001) idea is to expand R&D not only to other internal departments of the company but also to suppliers. Below we have diagram of Ulrich's theory. This figure has been the frame theory and point of view for this research.

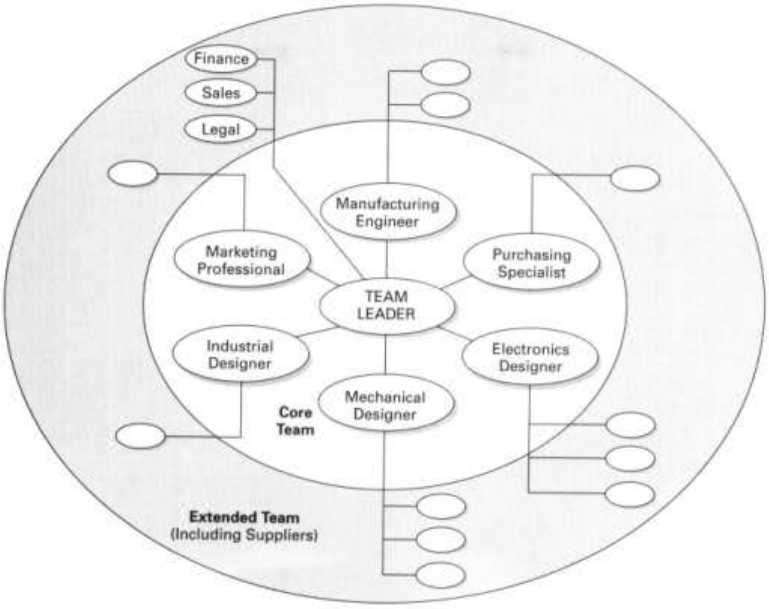

Figure 1: Ulrich theory of expanding R&D process.

CASE STUDY

The main target for this research was to find a new R&D methodology for our case company. The case company's internal R&D team was heavily overloaded and stressed and the company was oblivious to the fact that this kind of situation could cause serious damage to the capability of whole internal team. Champion (2002) stated that if the R&D team can focus without stress on one project at a time, the results will be remarkably higher and employees would be less likely to suffer from burn out.

The case company was highly committed to their own gate model so we arranged interviews in different departments within the company and a wide scale questionnaire for the whole internal R&D team. The aim was to find out their doubts, opinions and attitudes for and against the outsourcing of the R&D project. We collected a lot of information from inside the company and used that to represent our idea of outsourcing one certain product's development project.

The beginning of the project was good and the results started to show after only a few weeks work. The supplier who was selected to complete this project did an excellent job and the case company's old product got a new structure and small face lift. After the prototype was manufactured we arranged a questionnaire for the supplier about the behavior of the case company. Even though the case company was a client and could potentially provide an excellent opportunity for the future, the supplier was not afraid to give words of advice. Most of the feedback was very positive and showed that supplier was very content with the case company and for the opportunity it got due to this research.

CASE STUDY RESULTS

This research was successful, because in the beginning both sides decided that if the prototype was ready on time, the project would pass. The other goal was to cut manufacturing costs by 25-30%. The supplier believed that and it probably would have managed to reach these savings but the case company wanted to play more safely. In the middle of the project they denied some of the suppliers' ideas. If the prototype one day became a volume product, manufacturing costs would drop by about 10-15 %, so we could say that this goal was achieved. The main target of this project was of course to see how the outsourcing of R&D fitted into the case company's organization. The questionnaires show that outsourcing is possible when the transition toward it is slow enough. The supplier gave the outside party its opinion of the behavior and actions of the case company. All the information we collected during this study is very valuable for the case company's management in the future. It will help them to make decisions concerning outsourcing in general and especially in the research and product development fields.

VALIDITY, OBJECTIVITY AND RELIABILITY

We selected the supplier by evaluating the skills of their R&D department by having interviews and by implementing a small design task. Besides interviews and tasks we checked the products that they were manufacturing at that moment. After these checks we found that choosing the supplier was very easy.

The case method for this research was theory of expanding research and development by Karl Ulrich. Ulrich's theory is widely accepted and used also in a few other case studies. There are also other theories such as Trott's product development strategies, which have been used for this research that have been recently published by well-known groups of theorists. Interviews from this research have been made in several different departments and only one person at a time. These features will increase the objectivity of the answers because everyone will be able to state their individual point of view on the case.

Each person interviewed in the case company had more than 10 years of experience from same business field. 75% of employees from the internal R&D team who answered the questionnaire had more than 5 years of experience within the case company. The past experience of these interviewees increased the reliability of the data which was collected for this research. We also arranged questionnaires for the supplier and all five people who answered had at least 8 or years experience within the company. The supplier company also has almost 10 years of experience offering wide-ranging outsourcing services to global companies. This should make the feedback from the supplier in this case study more reliable.

DISCUSSION

The case company was looking for solution to its overloaded internal R&D team in an economical period when it was almost forbidden to hire new employees. The internal R&D

team was very stressed and the management of the company knew that if they didn't do something results and especially innovation would start to collapse. We used this research and Ulrich's theory of expanding R&D to help alleviate some of these problems for the case company. Of course this case study didn't solve the whole problem, but it worked as a first step. This research helped the internal team to see new possibilities for their situation. Employees got extra energy when they noticed that someone is interested in their job and that energy removed some of the stress from whole team.

Overall the case study was a success and will make it easier for the company to outsource in the future if they see fit. The internal team will probably always be the main driving force for development within the case company and maintain the responsibility of all R&D projects, but after this case study it will be easier for them to remove non-core competence tasks to someone else.

It was vital for the success of this research to find a reliable and skillful supplier. Choosing a supplier from the case company's own network sped up the project because the relationship between the case company and supplier had already been established.

FURTHER STUDIES

This research provides excellent opportunities for further studies. Results of this research allow further studies to focus on both the practical and also the theoretical point of view. From a practical point of view it would be good to observe the full life cycle of the prototype and answer several questions. Does it survive the rest of the tests that the supplier did not run? Will it ever be a volume product? What new ideas did this prototype give to its product families and How did the internal R&D team cash in on new innovations of the prototype?

Theoretical study could be used in this research as a starting point to business intelligence research. Business intelligence is quite a new term and will be studied more and more in the future. According to Laitala (2003) business intelligence means all kinds of critical information, which has been collected from every possible source. The managers of the case company will be able to use this valuable information in the future when making important decisions. This research includes a lot of business intelligence and it would be very easy to collect more information about the other segments of the business from both the supplier and the case company.

REQUIREMENTS ON METHODS FOR MODERN PRODUCT DESIGN- MASTERING THE BALANCING ACT BETWEEN STANDARDIZATION AND CUSTOMIZATION

Christoph Schrödl, Lappeenranta University of Technology, Finland
christoph.schrodl@lut.fi

ABSTRACT

The industrial revolution having taken place in Central Europe and the US during the 19th century significantly altered production methods as a result of newly developed technologies such as power engines. The consequence of available power machines was an increasingly standardized production process allowing for unprecedented cost-efficiency decisively contributing to thrive and prosper. Once wealth was established however, people's taste continuously rendered sophisticated and customer orientation gained in importance. The major objective of this article hereby is to investigate the correlation of the conflicting factors of economic success, namely customer satisfaction and cost-efficiency, and identify the crucial parameters behind them. This is accomplished by a three-step approach starting out from the manifold requirements business-level strategies imply. In a second step corresponding product design regimes are incorporated and analyzed for differences and commonalities in the third step. The result is that the various product designs may in fact all be explained by the same control factors, each appearing in alternating intensities of course. The obtained findings contribute to a 'catalogue of requirements' prescribing the essential criteria for an integrated product design methodology in the future.

Keywords: Modularity, Product Platform, System-level Design, Product Architecture

INTRODUCTION

No doubt – the common pursuit for economies of scale driven by the paradigm of capitalism appearing at the terminating 19th, beginning 20th century essentially contributed to the evolution of the western industry countries as well as the involved wealth and advancement. Thereby the simple parabolic logic 'the more you produce of something, the less costly manufacture is going to end up' respectively put in today's wording 'the more standardized components are, the cheaper you will be able to offer your products', dramatically influenced production processes and significantly changed the body of thought at that time. Not later than Henry Ford presented the idea of the moving production line coupled with his famous announcement of "one can have any color car as long as it is black", a new era was heralded - an era of previously unaffordable luxury and conveniences such as traveling, mobility and efficiency to be mentioning only a few.

As a downside of the above mentioned industrial and mechanized production operations however, a progressive displacement of the traditional craft-based businesses (which is one

skilled laborer occupying substantial control) became evident. Since benefits from specialized assembly and "task-partitioning" were not confined to car industries only, as a matter of course, followers of economies-of-scale principles continuously expanded to other areas of life as well. Hence previously tailor-made consumer and even commodity goods were subjected to standardization and price competition, with the single positive side-effect of ever decreasing sales prices for consumers (price-based strategy).

Yet initially described, economic status remarkably advanced during the course of the 20th century just as people's taste rendered sophisticated - once wealth is established. This became apparent in man suddenly desiring another color car than Ford's plain black beside a broad range of other more or less unique features to satisfy his personal preferences. As a consequence state-of-the-art offerings and involved standardized design paradigms lead to an increasingly unsatisfied buyership – preferably in the consumer good business areas. Hence producers needed to enter a business strategy rethinking in order to keep up with previously experienced successes and first of all not to be squeezed out of the marketplace. A trend displaying a more careful customer orientation in the products was becoming apparent. Thus, the strategic development in industrial production partly headed backwards to its roots which were originally lying in handcraft manufacturing and thereby fully customized goods. So, the solely goal no longer is to pricewise outperform the closest competitors, instead of rather carefully differentiate one's products towards customer desires in the respective market segment [10].

However, one major question remaining is how to best realize sufficient customer satisfaction and therewith organizational revenues without running the risk of producing a multitude of similar products and its often involved economic downsides such as high production costs due to low volumes. Another goal of this article is to uncover the parameters that control the required trade-off between customer satisfaction on the one side and cost control on the other. The findings of this analysis will then strictly merge into a "catalog of requirements" for product design methods and may act as a reference during the evaluation of existent product design approaches for their goodness in mastering the balancing act between the two extremes of standardization and customization. Also Lampel and Mintzberg [6] share this view in their observations for which reason they maintain that:

"…customization and standardization do not define alternative models of strategic action, but, rather, poles of a continuum of real-world strategies."

The article is structured according to the three-step method applied. First, the various strategic options in compliance with present strategic management doctrines are highlighted and introduced in order to visualize the "poles" and the intermediate "continuum of real world strategies". In a second step, the different business-level strategies are equipped with corresponding system-level design regimes as they are established and proven in industrial practice. The third and very essential part is analyzing the previously identified design strategies for differences and commonalities which are resulting in the common product design parameters. The obtained findings are thereafter

transferred into general criteria and establish the “catalogue of requirements” for an integrated product design methodology to be developed.

BUSINESS STRATEGIES: THE BACKBONE OF ANY PRODUCT DEVELOPMENT EFFORT

As it became yet evident in the introductory part, the transition of the two extreme poles of maximizing cost efficiency through standardisation on the one hand and increasing revenues as a result of improved customer satisfaction on the other hand is blurred. Hence, it is for a good reason that Lampel and Mintzberg [6] name this interspace a “continuum of real-world strategies” rather than defining distinct borderlines, since the latter simply wouldn’t come up to reality. Consequently, the challenge for strategic management as well as involved design engineers is obvious: there is a likely risk of opting for a merely suboptimal business strategy considering the on-hand business environment without ever getting to know or, even worse, becoming apparent way down the curve of the product development process. Thus, there is an obvious need for a comprehensive, business-strategy spanning support tool that is allowing to do both analyzing the economic performance of the product as it is designed according to the predetermined strategy and simultaneously overlook plausible strategic alternatives to after all assure an optimum profitability of the particular customer solution.

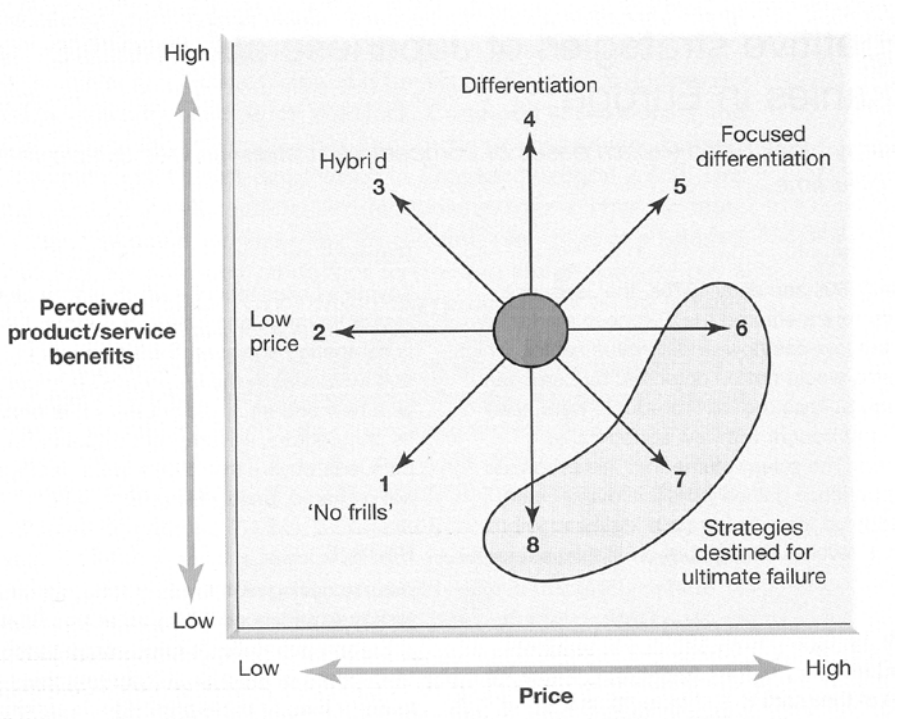

Figure 1 “The Strategy Clock”: Highlighting the various strategic options on the Business-Level [5]

On this account, the various business strategies as proposed by current strategic management doctrines shall be recalled in the first place. The so-called “strategy clock” introduced by Johnson et al. [5] has proven to be a valuable, since illustrative, tool for this purpose (Figure 1). Thanks to its highly self-explanatory character a further illustration may

be waived in this context and instead be referred to accordant literature. Moreover, the major concern of this article is to create the systematic link-up between corporate strategy and product design, that is, successfully delivering the corporate message to product engineers and via the product to final customers. On this account, first of all abstract strategic management terminology had to be altered in order to satisfy precise engineering specifications. Therefore, "perceived product or service benefit", previously applied as a measure for product value, is from now on going to be replaced by "AVERAGE CUSTOMER SATISFACTION", that is an expression for a product's adaptability to its potential buyership. In turn, the rather unclear term "price" is substituted by "PRODUCTION COST" as an accurate measurement for a design's cost base respectively economic efficiency.

TRANSLATING STRATEGIC SPECIFICATIONS INTO TECHNICAL TERMS FOR DESIGN ENGINEERS

Having identified the various strategic alignments on the business unit level, the second step of the method is now concerned with linking them to corresponding product design approaches as they are proven and established in industrial practice. Figure 2 grants an insight into the nature of the various product design strategies and their specific capabilities in adapting to discovered customer needs. The illustration thereby shows the relationship between average customer satisfaction and the respective degree of product sharing, that is the amount of a product design's overall buyership (# of customer types) divided by offered product variations. This rationale is thereby following the basic logic of "the more different customers need to get along with one offering, the more unsatisfied they need to be" due to insufficient reflection of customer desires in the single product. Doubtlessly, there is being found a certain share of buyers that might be thoroughly satisfied with one specific offering for which reason the criterion of "average customer satisfaction" was created. The circumstance becomes obvious by considering the two extreme poles, custom and standardized product: whereas in the former, products are individually developed towards even single customer orders (in the extreme case), in the latter, the design is considered the more successful the more customers it may embrace (economies). Accordingly, customized design features the (theoretically) highest satisfaction rate amongst the below shown design strategies.

As it became yet apparent, the introduced design paradigms show varying emphases. In order to adhere to the previous examples, standardization is strictly following the principle of economies of scale that is reducing production costs till the edge (price-based). In contrast, customized products are not primarily concerned with production economies and involved sales prices as in fact on utmost product performance (customer-based). Modular product platforms instead take an intermediate position in this hierarchy, since they are well capable of balancing the extremes of both, customer orientation and economic efficiency.

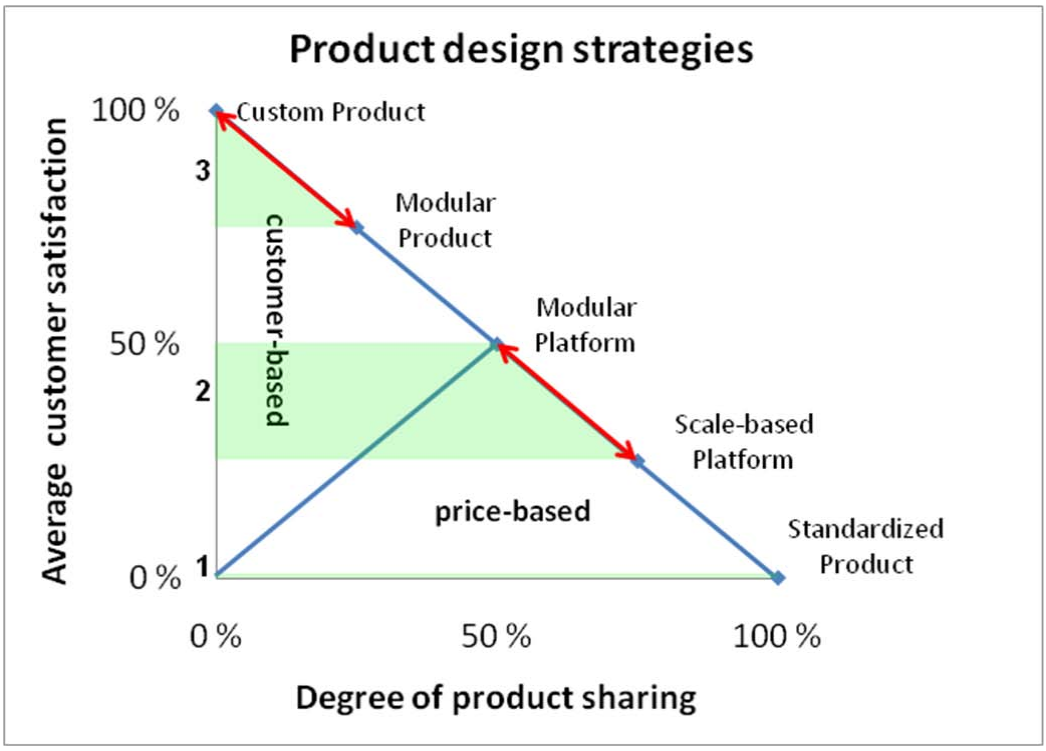

Figure 2: The various product design strategies defined by average customer satisfaction and product sharing (schematic). Thereby three major design strategies become apparent: 1) low customization, 2) price-sensitive customization and 3) performance-sensitive customization.

Following Figure 2, there are moreover plausible design alternatives away from customized products and Modular Platforms towards improved cost-efficiency dependent on individual company and customer preferences. Thus, modular product and scale-based strategies open up an array of design opportunities with varying emphases on customer orientation and cost-efficiency on both levels, price-based and customer-based. After all, three major design strategies emerge:

1) Low customization – optimizing economies of scale for a competitive cost-base
2) Price-sensitive customization – increasing revenues at a superior cost-base
3) Performance-sensitive customization – special purpose, low-volume products

Having accomplished a rough classification of the various product design strategies in accordance to the individual degree of customization, they shall be further elaborated now. Therefore the design approaches have been transferred to the initial situation of the "strategy clock" for explanatory purposes (Figure 3). In the meantime, the parameters have been changed to "average customer satisfaction" and "production cost" instead of the previous criteria "product benefit" and "price" in order to satisfy precise engineering standards. The explanations will proceed from the low-customized end onwards.

1) Low customization

Standardization

First time implemented on a large scale by Henry Ford, standardized products are ideal for the automation of (whole) production processes – an idea emerging during the 1980s – which was regarded as the remedy for long lead times, quality problems due to difficult assembly operations, monotonous work (see also "Taylorism"), bad ergonomics and heavy administration as a result of high part counts [1]. However, it does not solve all problems since multiple part numbers complicate material handling, automatic feeders may rarely handle more than a few different types of components and the layout around automatic assembly lines turns out to be often space demanding. Further, automated systems proved to be less flexible than corresponding manual assembly and, thanks to heavy investments in machinery, standardized product designs are naturally rigid for change and development. Consequently, standardized design should not be applied in rapidly changing business environments where flexibility is a key criterion. Otherwise there is a likely risk of exceeding product variants swallowing the positive effects of speeded-up assembly and superior quality.

→ successful strategy in e.g. process-intensive industries (bulk products) and commodity goods (grocery chains)

2) Price-sensitive customization

Scale-based platforms

Initiated at the edge of the 21st century, scale-based platforms put a focus on shortening development lead times and increasing commonality between products. The conception is, of course, cost reduction in development and production through sharing common components and technologies between the different product variants. Thereby, a platform design is considered to be the more successful the higher the degree of commonality and the better the products overall performance. As a consequence, products turn out to become fairly integrated which in turn results in physically similar products that are merely distinguishable by their overall performance such as speed, size, power etc. In this context Erixon [1] observes *"a risk with product platforms...that the products may lose their identity – their profile."* and further *"may compromise the brand image and result in decreasing sales volumes"*.

→ Scale-based platforms are successfully implemented where high degrees of customization may easily be disregarded and, in fact, the degree of optimization and price level are crucial in purchase decision-making. Examples include Pratt & Whitney jet engines [8], and Black & Decker universal motors [7].

Modular product platforms

Modular product platform designs are approaching profit creation from both sides, cost-cutting through shared components and technologies – just like scale-based platforms – and increasing revenues by flexible product adaptation towards (ever) varying customer demands. Unlike the predecessor on the "strategy clock", modular product platform designs are consequently the more profitable the higher the amount of products sharing the same components (economies of scale) and the better products may satisfy individual customer demands. In order to optimize the cost-base of the design however, it should be spread across as many marketplaces as it is technically feasible with all the challenges diverging customer requirements implicate. This seemingly paradox situation may only be solved out by physically separating parts that control individual customer desires from those that are kept common throughout the product family. Once mastered though, many variants of final products serving different market segments can be covered without increasing a company's internal complexity also referred to as "mass customization". Due to the building-block-structure, this product design turns out to be extremely flexible and therefore is very suitable in fast changing business environments. However, the price for high flexibility and reduced complexity may be a somewhat diminished overall product performance for which reason this design is an option for markets where such integrated measures like size, efficiency, output and weight for instance are of subordinate importance.

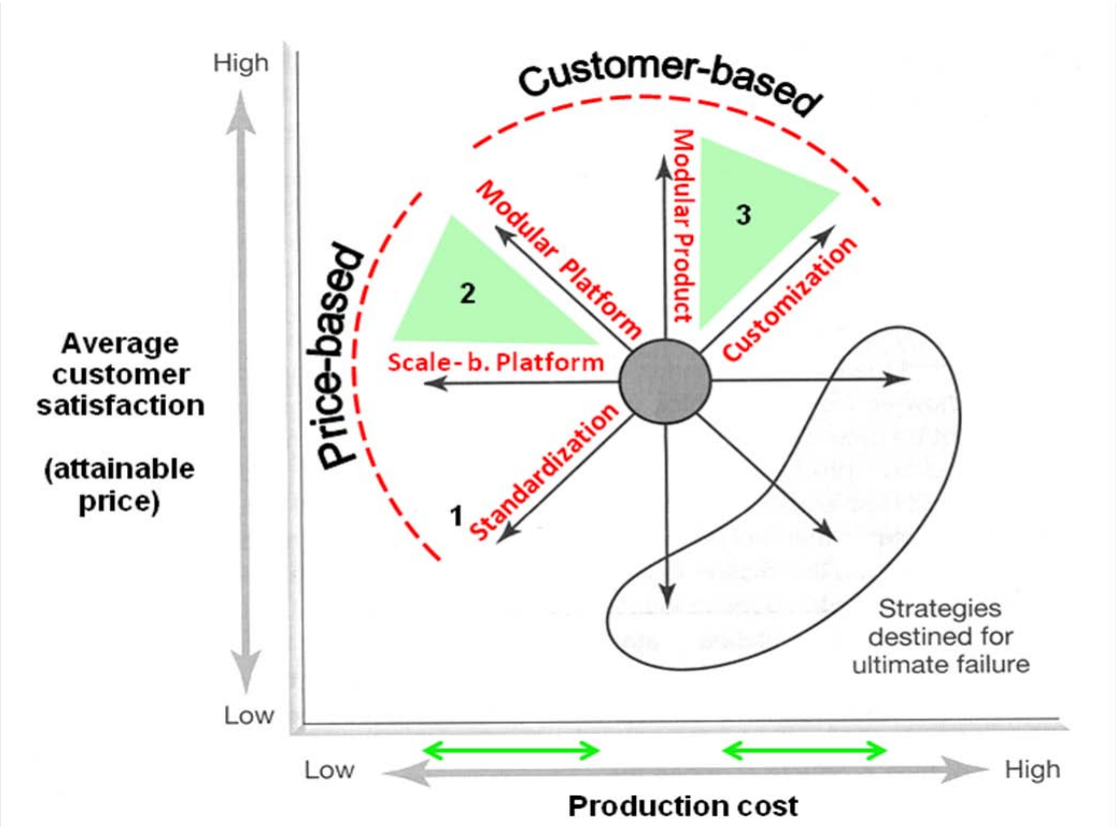

Figure 3: The original outlay of the "strategy clock" now enriched by relevant product design strategies. As opposed to the first major design strategy, Nr. 2 and 3 embrace a multitude of plausible design configurations for which reason they emerge as a blurred interspace here.

→ Industrial examples where modular product platforms have been excelling in range from the Sony Walkman™, via Scania truck cabs [1] to the Black & Decker power tool family [7].

3) Performance-sensitive customization

Customized product

Customized products, as the denotation yet suggests, are usually targeted at individual market niches or even single customers in an often made-to-order context. Hence, flexibility does not depict a key design driver as products are made-to-measure and not produced unless a potential client has pronounced its personal features or a firm is originally constraining its operating range to a single market niche, respectively. As a consequence, products do not need to be designed around building blocks as in the previous example and instead may be straightforwardly optimized to their later field of application. This naturally leads to a rather integrated product architecture for which reason customized designs are a great option in high-performance implementations or unique circumstances. As a result of the high degree of specialization however, customized products often turn out to be extraordinary pricy unless sales volume and market share allow for large-scale production (economies). Another flaw is a generally weak flexibility which, in fact, may be avoided by careful business model selection.

→ Cases of successful customization strategy implementation are manifold and numerous those of which should be mentioned the delivering project businesses in here e.g. ship construction and power plant production [2].

Modular product

Modular product design is representing the counterpart of customized designs in the field of performance-sensitive customization – just as scale-based and modular platforms in the area of price-sensitive customization. Unlike customized products however, modular designs are not exclusively constrained to single market niches, rather they are capable of embracing, for instance, all market niches within a specific segment (“market segmentation grid”, [7]) thanks to the above described building-block-system. Accordingly, it is possible for the customer to compose the product by choosing amongst a given variety of options for selected product functions due to standardized interfaces and carefully separated building blocks. This significantly enhances flexibility and efficiency as opposed to designing from scratch, each time a new customer desire is emerging. As it was yet observed however, global product performance features may rarely be met by modular architectures [11] which in turn necessitates green-field development.

Unlike the platform relative, modular product designs merely feature a fixed set of functions which renders them incapable adapting to more than one market segment. Consequently, there is no possibility for leverage by spreading common functions across multiple market segments involving poorer economic overall performance as opposed to the modular

platform counterpart for instance. In fact, reality shows that 'design for platform' is not always technically feasible (e.g. unrelated or very specialized segments) and moreover strategically plausible as platform development induces a significant cost-extra (time, resources) holding an explicit risk in case of failure [11]. On this account, for many companies 'design for platform' is not an option respectively at a later point in time when the risk, usually involved in new product development efforts, is manageable.

→ prevalent approach in the consumer goods business, e.g. Swiss Watches [7]. Increasingly customers are asked to enter their preferences into configuration software which thereafter composes the "customized" product ready for purchase.

The above illustrated product design strategies for both price-sensitive and performance-sensitive customization merely highlight the extreme positions towards either the modular or the integrated direction in the respective field. Consequently, they span a space of intermediate design options where it is essential discovering the optimum solution on the basis of the organization's business environment and individual strategy directives. An appropriate method, able to visualize and analyze the varying design performances may be helpful in the decision-making process, especially under complex product circumstances. The next section according to the methodological prescription comprehends the identification of common influencing factors by which all the product design approaches discussed in the context of this article are determined. This is in order to define the specifications for an adequate design support tool to be applied in engineered products industries.

RESULTS

1) Common parameters controlling product design

Reflecting on the above considerations, several factors appear that enable a link-up of the various product design strategies towards a coherent scheme (Figure 4). Hence, a closer look uncovers peculiarities within as well as between the two major levels on the way up of the customization ladder.

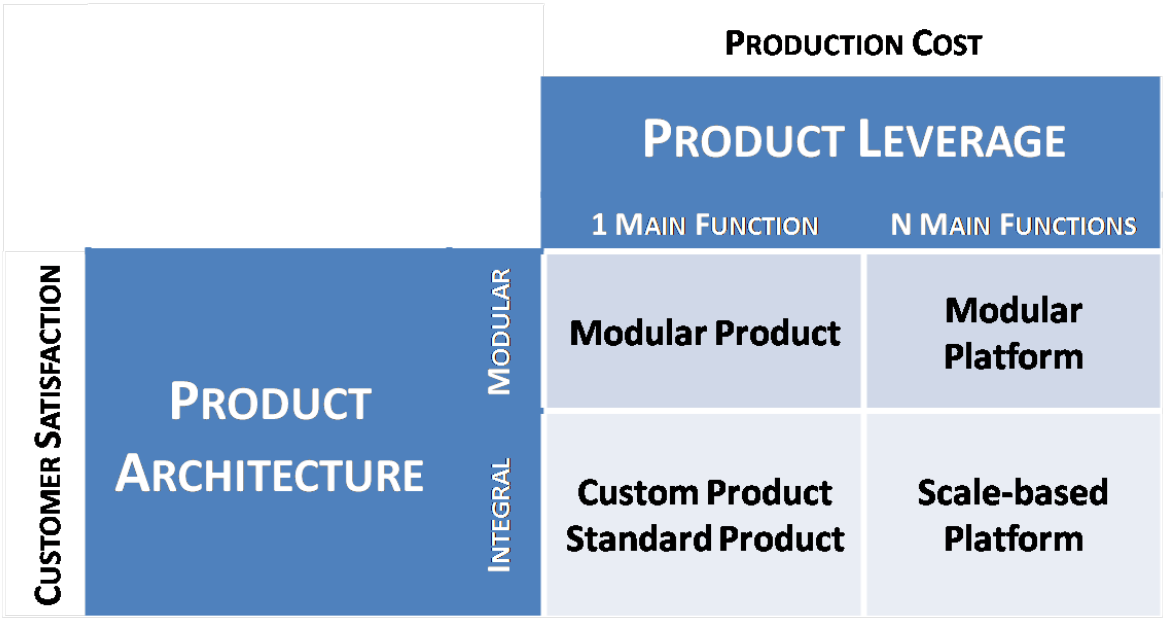

Figure 4: The various product design strategies (matrix) now defined by their common design drivers as they could be derived from previous business strategy analysis

Facing both of the major levels simultaneously, it becomes apparent that the range within of which a product's individual architecture may vary remains common, although the whole objectives are still significantly differing. It is now about to shed light onto the receivable extreme values, namely modular respectively integral architectures, in order to identify the first common parameter behind product design.

The concept of modularity is far from new and traces back to the ancient Romans where the word modulus was used as a unit of measure in classical architecture, although the term module had a purely structural meaning at that time. Thus, the term is originating from and influenced by architectural streams. Hence, during the era of Functionalism at the beginning 20th century (Bauhaus school), the idea of combining standardization with functional thinking received more attention and for the first time functional user requirements ought to be linked up with industrial production efficiency. However, functionality aspects weren't yet coupled with the modules rather they were defined by their interface geometry ('building blocks'). More recently and particularly in the mechanical engineering and engineering design, the linkage between modules and technical functions is emphasized [9, 11]. Consequently, modular product architecture needs to feature the following two properties according to present definitions [11]:

1) *Chunks implement one or a few functional elements in their entirety*
2) *The interactions between chunks are well defined and are generally fundamental to the primary functions of the product*.

Accordingly, the most modular architecture is one implementing each functional element of the product by exactly one physical block and where are few well-defined interfaces between the chunks. As a matter of course, such architecture inherently allows a design change to be made to one module without requiring changes to another enabling independent module design. More modern research however suggests that by means of specific metrics, flexibility between modules may be maintained though incorporating more than only one functional element ('redesign flexibility metric') [3].

Consequently, it is the independency between the various modules that may well be considered as the central element in modularity, because simply without it, a single module wouldn't be more than a conventional subassembly or subsystem. In fact, it is the independency criterion that triggers a multitude of advantages such as high flexibility/variability, reduced product development lead time, simultaneous development of product and production, improved quality, service and upgrading and leaner administration.
On the other hand, the deliberate separation of product functions into independent physical elements may cause under certain conditions technical performance trade-offs in comparison to their rather integrated counterparts in the field. Following Hölttä-Otto [3] and Whitney [13] there is a tendency away from modular product structures as soon as entering the field of products with generally high technical and therefore optimized performance requirements, e.g. high power mechanical products. They maintain that on those occasions a modular product is most likely larger, heavier and less energy-efficient. Or the other way round, using Ulrich & Eppingers' remarks on product performance [12], modular product architectures less likely succeed in business environments where *'global performance characteristics'*, such as the afore mentioned, are sales-relevant. Due to volitional independency of the various product elements, optimization efforts may only take effect unless reaching relevant module boundaries. That is what Ulrich comprises with the term *'local performance characteristics'*.
This moreover explains the necessity and existence of the integrated equivalent in either sector the price-sensitive as well as the performance-sensitive. Again citing Ulrich [11], an integrated architecture exhibits one or more of the following characteristics:

1) *"Functional elements of the product are implemented using more than one chunk.*
2) *A single chunk implements many functional elements.*
3) *The interactions between chunks are ill defined and may be incidental to the primary functions of the product."*

According to the previous definition integrated products are characterised by product functions spread across multiple parts of the product (components), thus satisfying *highest possible performance criteria* (optimization) and often disguised or even non-existent boundaries between the various product sections. In a similar vein as functions may be distributed across the entire product, they may be combined into a few physical components in order to *optimize dimensions* of performance (size, weight) also known as function sharing. In the first case, modifications to any one particular component or feature may cause extensive redesign of the product since sections to be switched or modified are

not separately accessible or alterable without significant interference of residual components. The same applies to the second case unless functions to be integrated within physical elements were not wisely selected under consideration of interface complexity (see 'redesign flexibility metric') and product strategic aspects. Thus, consequently accounting for these criteria, also products designed along a modular regime may well be competitive in dimension-sensitive business areas.

Practice shows [3] that the truth lies somewhere in-between on the one hand fully modular architectures where one function is explicitly accommodated by one physical component of the product and on the other hand completely integral structures where all functions are placed within a single physical unit respectively one single function is spread across multiple/all product sectors. Thus, facing the involved risks and tradeoffs in either extreme case, it is not surprising that real-world products feature a more or less modular architecture with relative amplitude to either the modular or the integral direction, dependent on the particular business environment and its customer preferences. Since the ultimate goal of business though is profitability, the cost-side which is including e.g. total production, redesign and development costs and which may significantly vary for each design option, is often the crucial criterion when opting for one certain product architecture.

Having discovered the first common product design driver (product architecture) that moreover turned out to be of likewise significance to both the performance-sensitive and the price-sensitive customization level, it is essential to shed light onto the major differentiator in order to determine the second parameter. Hence, as it appears from Figure 3, the platform representatives decisively outperform their high-end customization counterparts in terms of cost-efficiency. This section will now be concerned briefly introducing strategic rationale for either way as found in corresponding literature and thereafter classifying the examined product designs on grounds of performance characteristics to demonstrate the impact of the structural differences on cost-efficiency.
Yet mentioned in the previous chapter, each and every one of the product design strategies takes advantage in certain business environments as it turns harmful in others. According to this, performance-sensitive strategies are specifically favoured in so-called *Market-Pull* contexts where an opportunity for a promising product solution is spotted and appropriate technologies are developed or selected in order to outperform present competitor offerings. In accordance with Ulrich and Eppinger [12], classic applications are found in the consumer sector like sporting gear, furniture or tools to be mentioning a few. Further, circumstances often privileging performance-sensitive strategies are *Technology-Push* (contrary to market-pull; new technology is discovered and requires field of application, e.g. Gore Tex), *Customization* (response on special customer desires; characterized by highly detailed development process and individual design values) and *High-Risk* (high given uncertainty regarding technology, market place, budget and schedule) business areas. Even though technically feasible in some of the aforementioned cases, an initial constriction/specialization is advisable from a strategic viewpoint here – hazarding the consequences of a momentarily diminished economic efficiency.

Though overcome initial flaws in newly developed technology and having proven its utility in meeting customer demands as well as controlling development inherent risks, an expansion of firstly limited product deployments may well be contemplated. This discloses a multitude of cost advantages (price-sensitive strategies). Hence, subsequent products built upon platform designs (derivatives) are significantly simpler to develop as opposed to green-field designs due to shared components within the product family (commonalities). Moreover, Ulrich and Eppinger [12] mention a potential cost sharing effect as a result of development costs spreading across multiple variants ("leverage effect"), though higher front-end expenses for platform development may initially be met with criticism. As a result, platform designs are even qualified to advance into marketplaces that otherwise did not justify the development of a unique technology. Due to the obligatory design flexibility (standardized interfaces) platform designs are a specifically suitable strategy in the context of complex system industries (e.g. electronic, mechanical engineering).

Though recommendable from a strategic standpoint, the wish to create a product platform is often subdued by technical restrictions which shall be emphasized in the following. In accordance with established engineering design paradigms a product is defined as "a system that realizes a given internal function" [4]. Pahl and Beitz [9] take this approach one step further and decompose a system into subsystems so that the system architecture can be looked at different levels of abstraction. Consequently, a system is designed to satisfy one main function as it was directly derived from customer and market analysis [1]. Recalling the above said on the situational preferences of modular and integral product architectures, a main function has to exhibit rather local or global performance characteristics accordingly. On this account a main function shall be defined as follows:

"(1) A main function of a product or system is realized by the mutual interaction of global and local performance levels and is ultimately dependent on the customer requirements.

(2) The main function of a product or system can be modified by adaptation of either the global or the local performance level.

(3) In case both performance levels require changes simultaneously in order to embrace customer demand, a new and from the previous independent product or system needs to be designed."

Hence, Hubka & Eders' product definition [4] may be altered towards the product *as a system that realizes a given main function*. In other words, a product is determined by the main function it implements which in turn implies two products not to be considered different unless their main functions are – be it on global or local performance level or both (1st notion).

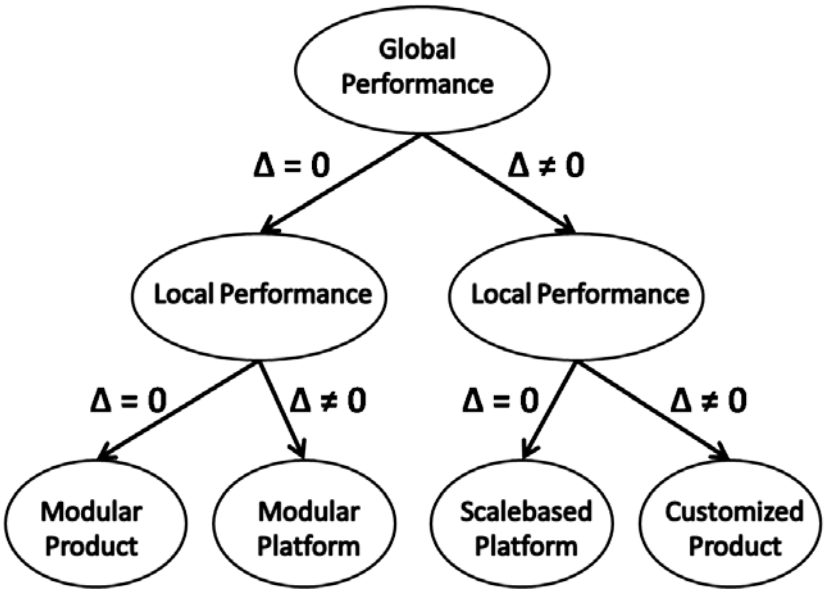

Figure 5: Definition of the four major design strategies based on global and local performance difference (main function notions). For platform suitability only one performance stage is allowed to change in order to not compromise the cost-efficiency surplus.

The above classification is specifically important in the light of product platforms discussed here, since a platform – modular or scale-based (integral) likewise – may only be deemed such if it spans not less than two different products or main functions respectively (2nd notion). Thereby this notion is not to be mistaken for 'product variation' which is no more than a different option model of one and the same product concept (main function).

Figure 5 illustrates the above introduced main function notions and their impact on the four major design strategies given that corporate guidelines don't prescribe any different. Consequently, a *modular product* is not intended to accommodate performance changes on global or local level for which reason it may embrace merely one main function. In a similar vein, *customized products* are aiming for one main function implementation. As the name yet suggests, they are strictly designed towards the client's individual performance perception.

For cost-efficiency excellence however, one product design must aspire launch on as many marketplaces as possible to achieve the essential economies due to shared production and development costs. As initially mentioned this is subdued by technical constraints since such design requires managing a multitude of different customer demands on global and local performance levels. Though, simultaneous change of global and local levels would entail an exhaustive extra in development cost (3rd notion) and therefore undo the potential of cost

savings, a required main function change may be executed on either the global (‘*scale-based platform’*) or the local performance level only (‘*modular platform’*).

2) Catalogue of Requirements for Integrated Product Design Method

Thanks to a holistic procedure combined with structured analysis of both the business strategies and the accordant product design equivalents, it was able to identify a coherent scheme of influencing factors generally driving system-level design (Figure 4). Based on this a catalogue of requirements for an integrated product design method is derived the latter of which shall replace dated, subjective, single-edged or otherwise insufficient existent design methods and enable organizations to fully exploit their resources and competencies. Thereby the general criterion is:

Support of *performance-sensitive* (one main function/single product) as well as *price-sensitive* product designs (multiple main functions/multiple products).

This requires in detail:

1) Support of *modular and integral* product architectures (local and global performance characteristics)

2) Identification and *separation of common* from customized product sections

3) *High reliability* for application in a complex system context (quantitative aid)

4) Consideration of company-internal or project dependent *design drivers* (including selection and individual importance weighting)

5) Optimization of product architecture towards *maximum profitability*, that is, best possible performance (global & local) at lowest possible overall cost (production/assembly, development + contingent redesign cost)

Conclusion

One major task at the outset of this article was to shed light onto the mutually exclusive correlation of customer satisfaction and therewith organizational revenues on the one side and the risk of poor economic performance as a result of a multitude of similar products on the other side. Another goal of this theoretic study was to uncover the common parameters that control the aforementioned trade-off between customer satisfaction and cost-efficiency clearing the way for a general “catalogue of requirements” including the essential criteria to an integrated product design method. For this purpose a three-step approach was chosen. First, the array of business-level strategies as the later field of application was examined in order to incorporate the appropriate system-level design regimes in a second step. The third and crucial section of this work was concerned identifying peculiarities within

as well as between the various customization levels resulting in the common influencing factors product architecture (modular versus integral) and product leverage (single versus multiple main functions). Moreover, established design paradigms could be altered by the 'main function notions', now allowing for explanation and identification of platform suitability in e.g. existent product families. The ultimately derived 'catalogue of requirements' including its postulation for optimized product architectures consistent with the accordant business environment, thereby sets the benchmark for existent and future system-level design approaches.

DEVELOPING A HYBRID MODEL FOR REMANUFACTURING FACILITY LOCATION PROBLEM IN A CLOSED LOOP SUPPLY CHAIN

N.Zulkifli, University Putra Malaysia, Malaysia
norzima@eng.upm.edu.my

A.Alimoradi, University Putra Malaysia, Malaysia

R.M. Yusuff, University Putra Malaysia, Malaysia

ABSTRACT

In today's competitive environment, the movement of raw materials to processing units, components assembly plants, and finished goods plants throughout the supply chain are crucial. On the other hand, design of supply chain is usually based on an open loop configuration or forward flow of materials, which means that the recent attentions from governments, manufacturers, and customers for recovery of materials are not considered in supply chain in spite of their importance. In our research, we are going to design a closed loop supply chain constituted of suppliers, manufacturing plants, warehouses and distribution centers, customers or retailers (which are characteristics that form the generic configuration of facility location problem), and also we add new concepts of recovery centers, and remanufacturing plants and try to find the optimized location for these facilities in a discrete space. In uncapacitated facility location problems (UFLP), there are usually uncertainties about future factors such as customer demand, price of land, pool of expert labor, government's regulations, and other factors which put restrictions on decision making about facility locations. To cope with the vagueness's of factors; we will implement the concepts of artificial intelligence, and will use the fuzzy sets to simulate restrictions of our suggested new facility location decision which consist two new tiers and use them to solve the problem. Since our main object is to locate new facilities, fuzzy TOPSIS methodology will be implemented to find the best place.

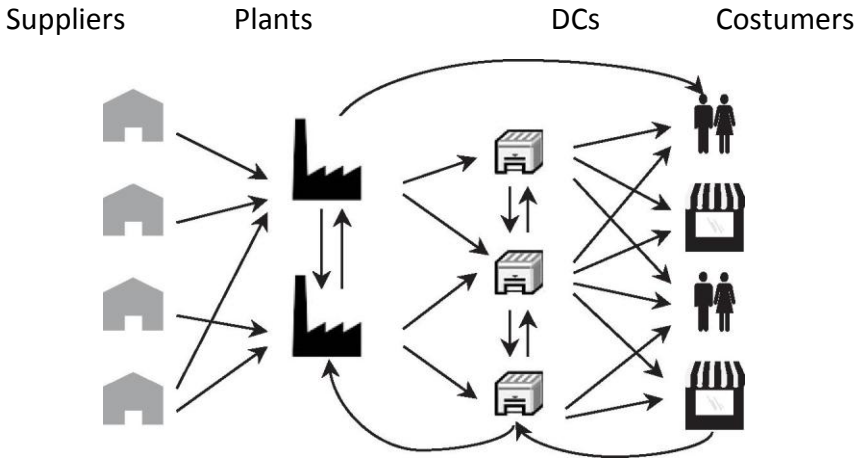
Keywords: recovery facility; remanufacturing; fuzzy TOPSIS; Facility location.

INTRODUCTION

A traditional supply chain is an integrated system which synchronizes a sequence of manufacturing processes in order to acquire raw materials and parts from suppliers, convert these raw materials and parts into finished goods, which increase value of raw material and change raw material to final products, distribute and promote the final products to either distributer centers or final customers. The main objectives of a traditional supply chain are to provide better movement of information, increasing competitiveness and profitability of firms, effectiveness and efficiency throughout the supply chain. This aim can be achieved by increasing efficiency and effectiveness of all tiers in supply chain, then whole supply chain will experience a better productivity which in turn will enhance the profitability of the firms which constitute the supply chain. Usually a generic supply chain is constituted of four tiers which are suppliers, manufacturing plants, distributions centers, and customers respectively [1] as fig1.

Amongst the strategic decisions is deciding where to locate a facility to best adapt with other tiers of supply chain and also best serve the costumers. This problem has devoted a fruitful and rich literature to itself and is known as facility location decision and has a long term effect and cannot be modified easily. By the definition, supply chain is divided into two major categories, centralized and decentralized [2]. In a centralized supply chain, decisions about strategies or long term plans are made at the strategic level, usually these decisions have a long term effects and cannot be changed in short term except by a huge cost and long period of time.

Fig1: A generic supply chain with four tiers.



In a generic supply chain there are many problems to deal with such as procurement, production, inventory management, distribution of goods, logistics or routing, and may be the most crucial of them facility location decision. In fact, in addition to all canonical management consideration supply chain designer should answer questions about manufacturing decisions,

inventory policies, information sharing between tiers, and location of plants and distribution centers all to design a perfect supply chain for profit maximization [1, 2].

Usually decisions about manufacturing, inventory, and procurement of materials may be modified due to the changes in conditions (such as availability of raw materials, labor costs, component prices, transportation costs, inventory holding costs, exchange rates and tax codes [3]) and in short term, but decision about facility location, once it is made, cannot be changed easily even in long term. Selection of inefficient locations for production and assembly plants, distribution centers, and warehouses will result in excess costs throughout the supply chain; no matter how precisely the production plans, transportation options, inventory management, and information sharing decisions are designed in response to changing conditions. So designer of supply change must consider and include all the affecting factors in decision making about location of facilities before locating any facility in supply chain [1,2, 3].

Some of the affecting factors that designers should consider are costumer consciousness, government legislations for used products, and most important of them manufacturing cost of products. During the last decades, manufacturers were seeking ways to reduce production costs; meanwhile their products were distributed and used by consumers until they were wasted. These wasted products were left in environment causing environmental costs and landfills. Environmentally consciousness of people all around the world had made governments to legislate rules for remanufacturing products that make manufacturers responsible for collection of their used products and reuse of them in new products and also avoid production of waste materials. These factors have led supply chain designers to closed loop supply chain. This new concept requires inclusion both forward and reverse logistics in supply chain. Traditional supply chain implement forward flows of materials, moving them from suppliers through supply chain to costumers. Sometimes, reverse logistics take place simultaneously to forward logistic, moving used products from costumers to remanufacturing plants. But in order to form a closed loop, there must be logistic of materials from remanufacturers to suppliers, manufacturers, and also directly to customers [1-4].

Combination of these two concepts will constitute closed loop supply chain which is environmentally consciousness, and since in this configuration new materials are not needed except for substituting those materials which could not be recovered from end users returned materials, so the cost of production will considerably decrease [19, 20,21].

The reminder of this paper is as flows: section 2 comprises literature review about reverse logistics and the necessity for embedding recovery centers in supply chain to constitute closed loop supply chain. Our methodology for locating remanufacturing facility will be explained in section 3. Also the main problem of locating the new facility based on fuzzy TOPSIS is explained in section 4, prior to conclusion of the method and suggestion for future researches in section 5.

LITERATURE REVIEW

By the advent of sophisticated manufacturing practices, and with recent attentions made to customers; which ultimate efforts are made to satisfy customers throughout the supply chain, and also with the new regulation legislated all around the world to reduce, reuse, remanufacture, and recycle, supply chains have changed their generic configuration to new enhanced mode which can deal with all the expectations from suppliers to the end customer in forward logistics and from costumers to manufacturers in reverse logistics [19, 20].

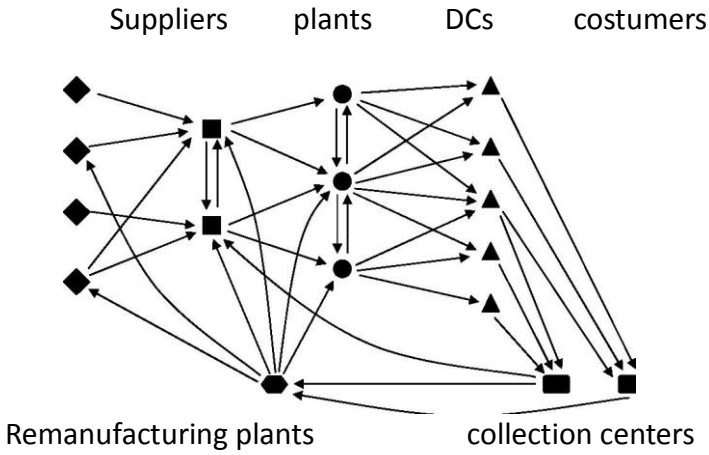
The definition of reverse logistic based on the American Reverse Logistics Executive Council is" "*The process of planning, implementing, and controlling the efficient, cost effective flow of raw materials, in-process inventory, finished goods and related information from the point of consumption to the point of origin for the purpose of recapturing value or proper disposal*"[20, 21].

Recent focus is on remanufacturing and recycling which are the main pillars of reverse logistics and constitution of closed loop supply chain. Remanufacturing is an emerging concept in manufacturing and refers to refurbishing used products returned by costumers by substituting degenerated or defective components, and reselling the product. This can be accomplished by original manufacturer (OM's) or another company. There are a number of important reasons for doing this. First is that a remanufactured product can be sold for about 50% of the cost of a new product. Second is that the process requires mostly unskilled and semiskilled workers, which is very interesting for developing countries. And finally in the global market, for instance European legislators are increasingly requiring manufactures to take back used products and also design and fabricate products that are recyclable (Design for recycling) and a specified percent of parts are able to be disassembled (Design for disassemble)and remanufactured as new products or recyclable parts to be recycled, this means fewer products end up in landfills and there is less depletion and waste of natural resources such as raw materials and fuel [19-22].

All the factors mentioned above have led designers to a new configuration for supply chain which is closed loop supply chain. In fact closed loop supply chain has been formed by two different concepts and flow of materials; reverse logistic which connects customers or "end of pipe" users to remanufacturing plants and transfer cores form costumers to remanufacturing plants, and "forward flow" which transfer remanufactured product directly to customers or to manufacturing plants[19, 20, 22, 23].

In this configuration shown in fig.2, uncapacitated facilities, called remanufacturing plants and recovery centers, are located in supply chain to serve all the tiers not only to collect returned product at any level of production (from material in process, semi finished goods, or final product), but also products that are damaged, have any faults or malfunctions, discarded by consumers after end of life cycle.

Fig2: New configuration to form closed loop supply chain.



In general, a closed loop supply chain design starts with the identification of potentially interesting sites for new facilities and the required capacities. Typically, large amounts of capital must be allocated to a new facility, either recovery centers or remanufacturing plants, thus making this type of investment a strategic decision [1]. Therefore, facilities that will locate are expected to operate for an extended time period. Future changes of some factors during a facility life time can change a good decision to a poor one which can cause lose of profit, or customer dissatisfaction. Accordingly, sophisticated facility locations decisions should consider all the crucial factors which may change a good location decision to a poor one [19, 20, 23,24].

V. Jayaraman et al [19] state that the flow of materials can take place in both directions of forward and reverse logistics. They develop a mixed integer linear programming model that deal with location of new facilities and also transshipment, production, and stocking of the optimal quantities of remanufactured products and cores. Although they mentioned that collection of goods in reverse logistics is supply-driven flow, and usually there is uncertainty about return rate and demands of customers, hence they build up their location model, neglecting this aspect of closed loop supply chain design.

Although Z.Lu and N.Bostel [20] consider remanufacturing, based on benefits and possibility, as main option of a recovery system, they include other characteristics of closed loop supply chain such as reuse, repair, refurbishing, cannibalization, and recycling. In their model, since recovered products are introduced as new products, interactions of forward and reverse flow were considered simultaneously. For purpose of modeling, they assume that the product demand and available quantities of returned products at the costumers are known and deterministic and based on this assumption they formulated an uncapacitated facility location model for remanufacturing network system. The objective function of their model is to minimize total cost including fixed and variable costs.

Since the efficiency of reverse logistics mainly depends on facility location decisions, Y. Zhang, and J. Xu [21] formulated the facility location problem as to minimize sum of transportation and

operation costs. They proposed a mixed integer programming model for facility location problem. Here they consider the demand and capacities as uncertain parameters, so their model was hybrid. Their model is very basic for the facility location and can be used in traditional supply chains, without implementing concepts of reverse logistics to form closed loop supply chain.

Focusing on 3R's operations concepts in green supply chain, H.F. Wang, and H.W.Hsu [22] also try to optimize logistics and location selection. They divide closed loop logistics model to two parts: forward logistic which deliver final product to demand points or costumers, and reverse logistics which is flow of used products for recovery. This system ensure of least waste of materials. They also consider distribution centers as collection centers and suggest that this distribution/collection centers have flexible capacities for distribution or collection of products. From their point of view, if the interactions of capacity in distribution/collection centers are not considered, the model is a "prolonged model of supply chain" without any loop. Finally they suggest an integer linear program model with given demand of customers and recycling rates which its aim is to minimize total cost of transportation and operations by determination of facility locations.

N.Ö.Demirel, H.Gökçen [23] emphasize on reverse logistics as an strategy for firms for making profit under competitive circumstances which deals with how to retrieve products from customers. They also consider the concept of recovery network for collection of used products to take them back into reusable condition and distribution to customers. In their research, recovery is accomplished through repairing, refurbishing, remanufacturing, cannibalization, and recycling. Finally, they provide a mixed integer linear programming model for remanufacturing in reverse logistics environment.

Although N.Ö.Demirel, H.Gökçen[23] in their research used numerical data to test their model, F. Schultmann et al[24] used an example of automotive industry to model the reverse logistics tasks in a closed loop supply chain considering the end-of-life vehicle (ELV) treatment in Germany. They suggest that there are two main distinct motivating factors to integrate product life phase into existing supply chain; legal and profit for tiers in supply chain. In spite of previous researches which consider products return as either waste stream system or a market driven system, they consider legal and profit as motivators for recycle or reuse of spent products. Accordingly, establishment of recovery network which ensures efficient coverage of demand and supply area is a crucial task of supply chain network designers for providing a free of charge return of products from demand points. Realizing recycling steps, they define the objective function to minimize cost for establishing a product recovery network and fulfill recycling goals [24].

In this paper we are going to design a material recovery system, which include product life expansion through repair, remanufacturing, and recycling based on decision makers opinion which is in fuzzy linguistic form. By incorporating traditional supply chain in which flow of materials take place in forward logistics and reverse logistics channels, a closed loop supply chain for material recovery will constitute. In this system suppliers are divided to two

categories; new material and used material suppliers. When components cannot be supplied by recovered materials, new materials are supplied by suppliers. Here costumers are suppliers of used products and demand point for new products simultaneously. Extensions of product life cycle accomplish by remanufacturing and repair systems which are the main part of recovery system in closed loop supply chain. Usual focus in remanufacturing is on management of material's (or cores) flow from costumers through reverse logistics to recovery and remanufacturing plants, and also from these plants to manufacturing facilities to produce new products for costumers in forward flow [19-23].

METHODOLOGY

Since there are many factors in a facility location decision, and the designer tries to choose best place to locate the facility to suite all the criteria's, this problem can be defined as a multiple-criteria decision-making (MCDM) problem, and TOPSIS which was first initiated by Hwang and Yoon [5]can be implemented for decision making. This technique is based on the concept that the ideal alternative has the best level for all attributes considered, whereas the negative-ideal is the one with all the worst attribute values. TOPSIS defines solutions as the points that are simultaneously farthest from the negative-ideal point and closest to the ideal point, and is successfully applied to selecting the location of a manufacturing plant [6, 7].

In the process of TOPSIS, the performance ratings and the weights of the criteria are given as crisp values. Thus, the measurement of weights and qualitative attributes did not consider the uncertainty associated with the mapping of human perception on a number. However, crisp data are inadequate to model real-life situations since the evaluation data of the facility location under different subjective attributes and the weights of the attributes are often expressed linguistically [6, 7]. Thus, a more realistic approach may be needed to use linguistic assessments instead of numerical values. Recently, some researchers have focused on the fuzzy TOPSIS method to solve the plant location selection problem [8, 9 10].

However, existing fuzzy TOPSIS methods are not efficient enough due to the fact that to obtain the "fuzzy positive-ideal solution" and the "fuzzy negative-ideal solution", fuzzy ranking approaches are used, even though it is well known that no one can rank fuzzy numbers satisfactorily in all cases and situations [6].In addition, it is tedious to calculate the distance from the ideal solution and the negative-ideal solution. To solve these problems in fuzzy decision-making, a new fuzzy TOPSIS approach is proposed. In this method, the ratings of each alternative and the weights of each criterion can be represented as triangular fuzzy numbers. The results of multiplication of rating and weight can be calculated as crisp numbers by the canonical representation of multiplication operation on triangular fuzzy numbers. Then, the "fuzzy positive-ideal solution" and "fuzzy negative-ideal solution" can be determined easily without ranking fuzzy numbers [6, 7].

In addition, the distance from the ideal solution and the negative ideal solution can be calculated easily, which makes the proposed method more efficient than existing methods [6, 7].

WHERE TO LOCATE A NEW FACILITY?

Since facility location is a strategic decision[1], in order to locate a new facility to form a closed loop supply chain, which can support all tiers and be supported by them reciprocally, the tiers must provide their opinions about location of new facility. Strategic decision means that senior managers will decide about location decision as decision makers for locating a new facility in order to remanufacture returned products from demand areas. These decision makers are representatives for suppliers, manufacturing plants, distribution centers, and costumers which are showed by D_1, D_2, D_3, and D_4 respectively.

Initial screening shows that four possible sites A_1, A_2, A_3, and A_4 are feasible candidates to choose base on the crucial criteria listed as closeness to manufacturers, availability of machines and tools, closeness to customers or demand points, and availability of proper logistics which are C_1, C_2, C_3, and C_4 respectively. In order to deal with poor definition of criteria's, linguistic variables are used which are in form of words and sentences to evaluate all the situations. These linguistic variables are then changed to fuzzy numbers.

The decision makers have weighted criteria's based on their positions in supply chain hierarchy as table 1.

Table2 shows the rating of four linguistic criteria under each candidate location, based on decision maker's opinion.

Table1: criterias weights

	D_1	D_2	D_3	D_4
C_1	L	L	H	M
C_2	VH	H	M	M
C_3	M	H	M	H
C_4	VH	VH	H	M

Table2: decision maker's ratings

Criteria	Candidate	D_1	D_2	D_3	D_4
C_1	A_1	VG	G	G	VG
	A_2	G	G	P	G
	A_3	G	VG	G	P
	A_4	P	P	VG	VG
C_2	A_1	G	VG	G	P
	A_2	VG	G	P	VG
	A_3	G	P	G	P
	A_4	G	VG	VG	G
C_3	A_1	F	P	G	VG
	A_2	G	G	F	F
	A_3	P	F	G	G
	A_4	VP	G	F	G
C_4	A_1	VP	G	F	VG
	A_2	P	VG	G	G
	A_3	F	G	P	F
	A_4	G	P	F	P

Tables 1 and 2 illustrate that all factors are in linguistic format, and it is necessary to change them to crisp numbers for ordinary operations. As mentioned before, there is an ambiguity associated with each factor and criteria, so in order to deal with this vagueness we use fuzzy sets and provide some definition of fuzzy sets and numbers [12, 13].

Definition1. ("Fuzzy set") *Let X be a universe of discourse. Where $\tilde{A}$ is a fuzzy subset of X; and for all $x \in X$, there is a number $\mu_{\tilde{A}}(x) \in [0, 1]$ which is assigned to represent the membership of x in $\tilde{A}$, and is called the membership of $\tilde{A}$ [12, 13].*

Definition2.*A triangular fuzzy number $\tilde{A}$ can be defined by a triplet (a, b, c) which means $\tilde{A}$= (a, b, c) [12, 13].*

Based on definition 1 and 2 and also normal scale in TOPSIS in which linguistic factor “low” is “0” and “very high” is “10” ,table 3 and 4 are defined as combination of these definitions to change each linguistic variable of weights to fuzzy numbers as table 3 and decision makers linguistic ratings as table 4.

Table3: Fuzzy linguistic for weights.

Very low(VL)	(0.0,0. 1, 0.3)
Low(L)	(0.1,0. 3,0. 5)
Medium(M)	(0.3,0. 5,0. 7)
High(H)	(0.5,0. 7,0. 9)
Very high(VH)	(0.7,0. 9, 1.0)

Table4: Fuzzy linguistic for decision makers rating.

Very poor(VP)	(0, 1,3)
Poor(P)	(1, 3, 5)
Fair(F)	(3, 5, 7)
Good(G)	(5, 7, 9)
Very good(VG)	(7, 9, 10)

As shown in table 3 and 4, all the numbers are positive triangular fuzzy numbers, and in order to retrieve the graded mean integration representation of triangular fuzzy number definition 3 is used:

Definition3. *Given a triangular fuzzy number $\tilde{A}$ = (a, b, c), the graded mean integration representation of triangular fuzzy number $\tilde{A}$ is defined as [12, 13]: P ($\tilde{A}$) =1/6(a+4b+c).*

Definition4. *Let $\tilde{A} = (a_1, a_2, a_3)$ and $\tilde{B} = (b_1, b_2, b_3)$ be two triangular fuzzy numbers. The representation of the addition operation $\oplus$ on triangular fuzzy numbers $\tilde{A}$ and $\tilde{B}$ can be defined as [12, 13]: $P(\tilde{A} \oplus \tilde{B}) = P(\tilde{A}) + P(\tilde{B}) = 1/6\{(a_1+b_1)+4(a_2+b_2)+(a_3+b_3)\}$.*

Definition5. *The canonical representation of the multiplication operation on triangular fuzzy numbers $\tilde{A}$ and $\tilde{B}$ is defined as [12, 13]: $P(\tilde{A} \otimes \tilde{B}) = P(\tilde{A}) \times P(\tilde{B})$.*

In order to reduce the complexity of fuzzy calculations the above definitions are crucial, yielding a crisp number instead of a fuzzy one which eases the comparison of alternatives [6, 14].
By applying Definition 3, the graded mean integration representation of the importance of weights and decision makers rating will be crisp values as table 5 and 6

respectively (based on method used in [15] and *definition 3* mentioned in [13], in which triangular fuzzy numbers range fall into [0, 1].

Table5: Graded mean of weights.

Very low(VL)	0.1167
Low(L)	0.3
Medium(M)	0.5
High(H)	0.7
Very high(VH)	0.8834

Table6: Graded means of decision makers rates.

Very poor(VP)	1.167
Poor(P)	3.000
Fair(F)	5.000
Good(G)	7.000
Very good(VG)	8.834

In this section, the decision matrix of alternatives ratings based on new hybrid TOPSIS with fuzzy triangular linguistic variables will be constitute. The method used here is same as [6, 14, 17, 18] except for determination of positive and negative ideal solutions for fixed cost which is based on method of [5, 15].

Steps are as below:

Step1. *Aggregation of importance of weights.* This step is summarized as table7 and is called the aggregated importance weight $W_{j.}$

Table7: Aggregated weights W_i.

C_1	0.45
C_2	0.6459
C_3	0.6
C_4	0.7417

The final weighted matrix based on criteria (m) and decision maker (n) will be W_j as:

$$\begin{pmatrix} 0.45 & 0 & 0 & 0 \\ 0 & 0.6459 & 0 & 0 \\ 0 & 0 & 0.6 & 0 \\ 0 & 0 & 0 & 0.7417 \end{pmatrix}$$

Step2. *Aggregation of rates assigned by decision makers*. Based on table 2 and 6, result of aggregation of rates based on graded mean integration will be a (4*4) matrix called decision matrix R_{ij} and the final result of operation is:

$$R_{ij} = \begin{pmatrix} 7.917 & 6.459 & 5.954 & 5.001 \\ 6 & 6.917 & 6.0 & 6.459 \\ 6.459 & 5.0 & 5.5 & 5.0 \\ 5.917 & 7.917 & 4.542 & 4.5 \end{pmatrix}$$

Step3. Construction the weighted decision matrix and its normalization.

The decision matrix S_{ij} is a 4*4 matrix as $S_{ji}=W_j \otimes R_{ij}$ in which operation $\otimes$ is as *definition 5*. By application of this operation the complicated fuzzy interval operations on membership functions has converted to crisp arithmetic [6, 15]. The resultant matrix S_{ij} will be:

$$S_{ij} = \begin{pmatrix} 3.5626 & 2.9000 & 2.6815 & 2.250 \\ 3.8754 & 4.4676 & 3.8754 & 4.1718 \\ 3.8754 & 3.000 & 3.3000 & 3.0000 \\ 4.3886 & 5.872 & 3.3688 & 3.3376 \end{pmatrix}$$

Step4. *Embedding fixed cost factor in decision matrix*.

Since our model deal with uncapacitated facility location, usually there is a fix cost in model which is representative of cost of land, construction of buildings or any other fixed cost related to locating a facility [3, 5, 6, 14].

This fix cost assessed by decision makers is not crisp, and is fuzzy number with equal cores for all candidate location here. These fuzzy numbers are:
A_1= (62, 72, 80)
A_2= (65, 72, 81)
A_3= (63, 72, 79)
A_4= (64, 72, 80)

In order to add these numbers to decision matrix, they must be rated [6, 14]. Based on definition and operations in [6, 13, 14], since they are categorized as fixed cost, so their rating will be:

RA_1=0.8699
RA_2=0.861
RA_3=0.8689
RA_4=0.8647

Now the decision matrix R_{ij} will have 5 columns, representing C_1, C_2, C_3, C_4, and C_5.

Step5. *Normalizing of the decision matrix.* In TOPSIS, normalization of decision matrix is accomplished as matrix $V = [v_{ij}]_{m \times n}$ [5], Where:

$$vij=\frac{rij}{\sqrt{\sum_{i=1}^{m}(rij)2}} \qquad (1)$$

By applying (1), decision matrix will convert to normalized matrix V_{ij}, which all the elements are in range [0, 1] as below:

$$\begin{pmatrix} 0.4524 & 0.3421 & 0.4022 & 0.3447 & 0.8699 \\ 0.4922 & 0.5270 & 0.5812 & 0.6391 & 0.8610 \\ 0.4922 & 0.3539 & 0.4948 & 0.4596 & 0.8689 \\ 0.5574 & 0.6927 & 0.5052 & 0.5113 & 0.8647 \end{pmatrix}$$

Step6. *Positive (A^+) and negative (A^-) ideal solution determination*. In positive ideal solution maximum and for negative ideal solution minimum variables of normalized decision matrix for each candidate location will be chosen [5, 6, 14]. The result will be:

(A^+)= (0.5574, 0.6927, 0.5812, 0.6391, 0.861).

(A^-)= (0.4524, 0.3421, 0.4022, 0.3447, 0.8699).

Note: since C_5 is cost and usually firms try to eliminate any costs, even fixed costs [3, 5, 15], here we assume it as negative criteria and based on [5], in positive and negative ideal solution, minimum and maximum value is considered respectively. In [6], it is not considered so, causing deviation of the best alternative opt.

Step7. *Finding distance of each decision variable to ideal solution [5, 6, 14].* By definition, this distance is known in literatures as *Euclidean distance* [3]. The Euclidean distance of a variable to positive ideal solution and negative ideal solution is as table8:

Table8: euclidean distance of each alternative

	d^+	d^-
A_1	0.5027	0.0
A_2	0.1780	0.3931
A3	0.3984	0.1533
A_4	0.1487	0.4153

Step8. *Calculate closeness coefficient of each alternatives.* In order to specify which alternative best suit to decision maker's criteria's, the closeness coefficient is defined as:

$$CC = \frac{(\mathbf{d}-)}{(\mathbf{d}+) + (\mathbf{d}-)} \qquad (2)$$

The closeness coefficient measures how far an alternative is from its best and ideal solution. The best alternative is the one with biggest closeness coefficient. The closeness coefficient for alternatives will be:

CC_{A1}= 0.0
CC_{A2}= 0.6883
CC_{A3}= 0.2778
CC_{A4}= 0.7362

The best alternative to locate remanufacturing plant with specified criteria based on decision maker's fuzzy linguistic ratings is the one with maximum closeness coefficient, which is A_4.

CONCLUSION

Deciding where to locate a new facility in a supply chain is an old problem, but design of a closed loop supply chain is a new concept in supply chain design. Since there are many reasons for remanufacturing, reuse, and recycle of products (3Rs), it seems that locating new facilities to implement these Rs is inevitable. In this paper we use the fuzzy TOPSIS method to determine location of remanufacturing facility and design a closed loop supply chain. Since uncapacitated facility location decisions have a fixed cost in objective function, this concept was considered as fuzzy numbers along with other criteria chosen by decision makers. The fuzzy linguistic method implemented, reduces the complexity of fuzzy operation and enable decision makers to deal with ambiguity factors fast and easily, and determine where to locate new plant based on fuzzy linguistic decision makers rates. Previous researches were on mixed integer linear models to find best place to locate new facility, but these models eliminate uncertainty in parameters such as demand or cost. The future research should include the uncertainty of factors in decision making and to build a mixed integer linear model with hybrid variables. The concept of rough and fuzzy variables can be implemented simultaneously to cope with uncertainty of parameters.

ABSTRACT

To modern enterprises of all sizes, designing and improving green supply chains to create value and competitive advantage posits new challenges. Policy makers today, in the pursuit of both economic performance and environmental sustainability, need to adopt Green Supply Chain Management (GSCM) practices to create supply chains' overall value and ensure that environmentally conscious products and processes are well designed and performed. This paper presents a hierarchic framework to aid policy makers in decision making to achieve such a goal. The first focus of this study is on finding agents, required functions, and critical enablers of GSCM to build the hierarchic framework. Five strategic enablers are identified and considered in this work: green purchasing, green manufacturing, green distribution, green marketing, and reverse logistics. The second focus of this work is on prioritizing these five enablers of GSCM. The Fuzzy Analytic Network Process (FANP) is employed to find priority weights. We also empirically illustrate our hierarchic framework's applicability to GSCM problems involving major chemical companies in Taiwan. Our framework enables policy makers to explore the problem context and decide on the strategic direction in value creation and environmental sustainability.

Keywords: Green Supply Chain Management (GSCM), Green Supply Chain Strategy, Fuzzy Analytic Network Process (FANP)

INTRODUCTION

Since the publication of *Competitive Advantage: Creating and Sustaining Superior Performance* Porter (1980), a lot of progress has been made in understanding the managerial, technical, and sociopolitical responses of the firm in an internal/external supply chain setting. Enhancing the efficiency and effectiveness of a value chain, the focal point of Porter's value chain model, has therefore been the hallmark of operations and supply chain management. Today's focus, however, is different. Industry leaders such as HP, Apple, Dell, and Wal-Mart are now seeking broader goals such as protecting the environment and developing communities. Green Supply Chain Management (GSCM) today, as a result of this new focus, seems to play a significant role in this new world of sustainable development (Srivastava, 2007; Chung and Wee, 2010; Park, et al., 2010).

Srivastava (2008, p.536) defines GSCM as "integrating environmental thinking into supply chain management including product design, material sourcing and selection, manufacturing processes, delivery of the final product to the consumers as well as end-of-life management of the product after its useful life." Thus, several key challenges centered around reducing wastes, conserving resources, and increasing throughputs and supply chains' overall value exist. Despite this understanding and development in the field of GSCM, many published studies, however, focused either on the performance of green operations (e.g. Zhu and Sarkis, 2004; Zhou, 2009) or on GSCM from the perspective of green design (e.g. Srivastava, 2007; Chung and Wee, 2010; Park, et al., 2010). Srivastava (2007), for example, pointed out that green design consists of two fields: life cycle analysis (LCA) and environmentally conscious design (ECD). The former is normally used to help policy makers quantify the environmental impact of supplied goods and services. The latter allows supply chains to minimize the environmental impact of products and to turn waste into profitable products (Zhang, et al., 1997). To respond positively to such pressures, achieve both supply chain value and environmental sustainability simultaneously, and be able to compete in today's environmentally conscious market, modern enterprises need to develop their own strategies to enable general applications of GSCM and Porter's value chain model. Adopting the GSCM way and a holistic view based on Porter's model at the same time, however, is not an easy task. To overcome this, we ponder the following research questions in this study:

- What specific agents, functions, and strategic enablers (i.e. content variables) should policy makers consider in the context of green supply chains?
- How can policy makers measure the potential contributions of green and valuable supply chain strategies in the Asia-Pacific region?

The answers to the first question are derived from literature review. For the purpose of our scientific inquiry in the first phase of this study, we propose a hierarchic framework called green and valuable supply chain. This model serves as a basis for the follow-up inquiry. The answers to the second question are based on the operational procedure of Fuzzy Analytic Network Process (FANP). The use of FANP helps to capture the imprecision in human judgment and set priorities for designing and improving green supply networks. To illustrate our scientific inquiry process and also to identify the key strategic enablers for designing and improving green supply chains, major chemical companies in Taiwan were contacted to

participate in this project. Focus on our hierarchic framework and operational procedures can help firms improve their green supply chain overall performance.

THEORETICAL DEVELOPMENT

In order to develop our hierarchic framework to aid policy makers in decision making, we look to the existing literature. Three fields that arise from the literature are: Supply Chain Management (SCM), Porter's value chain model, and Green Supply Chain management (GSCM). We shall briefly discuss them here.

Supply chain management

The five basic entities of typical supply networks are suppliers, manufacturers, distributors, retailers, and customers (Fiala, 2005). These five entities can enhance the overall performance of the entire supply chain via cooperation, collaboration or alliance (Fiala, 2005). They are considered to be agents in our proposed hierarchic framework. Supply Chain Management (SCM) is normally employed to develop such capabilities and capacities. Madu and Kuei (2004) define SCM with two simple equations where each equation represents the letters that make up SCM. The definition is as follows:

Supply Chain = A production-distribution network; and
Management = Enabling conditions for integrity, integration, process optimization, operational efficiency, continuous improvement, and sustainable competitive capabilities.

Value can be added at every stage of the product and service realization. The use of SCM ensures that the best value is obtained for each product or service (Errasti, et al., 2009; Wei and Wang, 2010; Yang, et al., 2011).

Value chain model

Value chains exist for the purpose of creating value and competitive advantage (Porter, 1985). A typical value chain involves five primary activities: inbound logistics, operations, outbound logistics, marketing, and services. It starts with inbound logistics and ends with the service function. They are considered to be functions in our proposed hierarchic framework. Supporting activities such as procurement, technology, human resource management, and firm infrastructure also play important roles in customer satisfaction. According to Porter (1985), these networked organizational units need to work together to reduce costs, minimize transit time, improve quality and operational efficiency, and improve customer service. The value chain model has been widely used as a means for improving the overall value of the entire chain in question (Bhattacharya, et al., 2010; Ehret and Cooke, 2010; Jin and Zailani, 2010).

Green supply chain management

While both Porter's value chain model and SCM have brought significant benefits, moving on, modern enterprises have also ranked the environment one of the major challenges facing

businesses in the future (Errasti, et al., 2009; Bhattacharya, et al., 2010; Jin and Zailani, 2010). Zhu, et al. (2008, p.578) defines Green Supply Chain Management (GSCM) as "a recent and important inter- and intra-organizational set of environmental practices useful for logistics management." The organizational context in such a supply chain setting includes: green purchasing, green manufacturing, green distribution, green marketing, and reverse logistics (Li and Cai, 2008; Srivastava, 2008; Zhou, 2009; Wooi and Zailani, 2010). They are regarded as enablers (i.e. content variables) in our proposed hierarchic framework. In the world of sustainable development, green supply chain strategies and practices are considered by modern enterprises to be a new source of corporate competitiveness (Rao and Holt, 2005; Menzel, et al., 2010; Thun and Müller, 2010).

To create a capable green supply chain and leverage the benefits of Porter's value chain concept, Supply Chain management (SCM), and Green Supply Chain Management (GSCM), modern enterprises today need to set priorities among supply-chain-wide green and valuable supply chain management programs and projects. A strategic framework thus needs to be developed and promoted to enable the consideration of both economic performance and environmental protection. Such a framework will be described in the next section.

THE BIRTH OF GREEN AND VALUABLE SUPPLY CHAINS

In order to accomplish the first goal of this study, a hierarchic framework is introduced. As shown in Figure 1, our hierarchic framework is a complex system which effectively connects major components identified from (1) Supply Chain Management, (2) Porter's value chain model, and (3) Green Supply Chain Management. This conceptual model is referred to as a green and valuable supply chain in this study.

As suggested by our hierarchic framework, the best chance of meeting the value creation and environmental protection goals simultaneously is to formulate green and valuable supply chain strategies to (1) know the role of specific agents, (2) understand required functions, and (3) realize the full potential of GSCM. To meet such a challenge, as can be seen in Figure 1, the first path centers around primary channel partners along a typical supply chain. As discussed in the previous section, policy makers need to address specific concerns of suppliers, manufacturers, distributors, retailers, and customers. Channel partners are the premise of every enterprise's existence. This model can then be extended to address the five primary functions suggested by Porter (1985): inbound logistics, operations, outbound logistics, marketing, and services. This extended model shows the roles policy makers should play to set the stage for the implementation of green and valuable supply chain systems. With the stage set, how do modern enterprises then achieve value and environmental sustainability simultaneously? To answer this, it is most important for policy makers to consider another path for both policy deployment and strategy formulation. It is evident from Figure 1 that the GSCM way can embrace the new focus on green and valuable supply chain. Our research has identified five strategic enablers (i.e. content variables) influencing the effectiveness of GSCM. They are: green purchasing, green manufacturing, green distribution, green marketing, and reverse logistics. As can be seen at the bottom of Figure 1, each of the content variables that are of interest to the modern enterprises is respectively evaluated. For example, green purchasing consists of three

elements: non-toxic, reusable, and recyclable. The ultimate aim here is to ensure that the development of any of the content variables will achieve value and environmental sustainability simultaneously.

This framework can assist policy makers in managing value creation and environmental issues simultaneously, designing a complex green and valuable supply chain, spotting strategic problems early, and developing plans to better serve the channel partners. However, a strategic analysis is also needed to enable policy makers to identify the most critical GSCM content variables that will ultimately influence the successful development of green and valuable supply chain systems. The Fuzzy Analytic Network Process (FANP) is thus employed to accomplish the second goal of this study. This operational procedure will be illustrated in the next two sections.

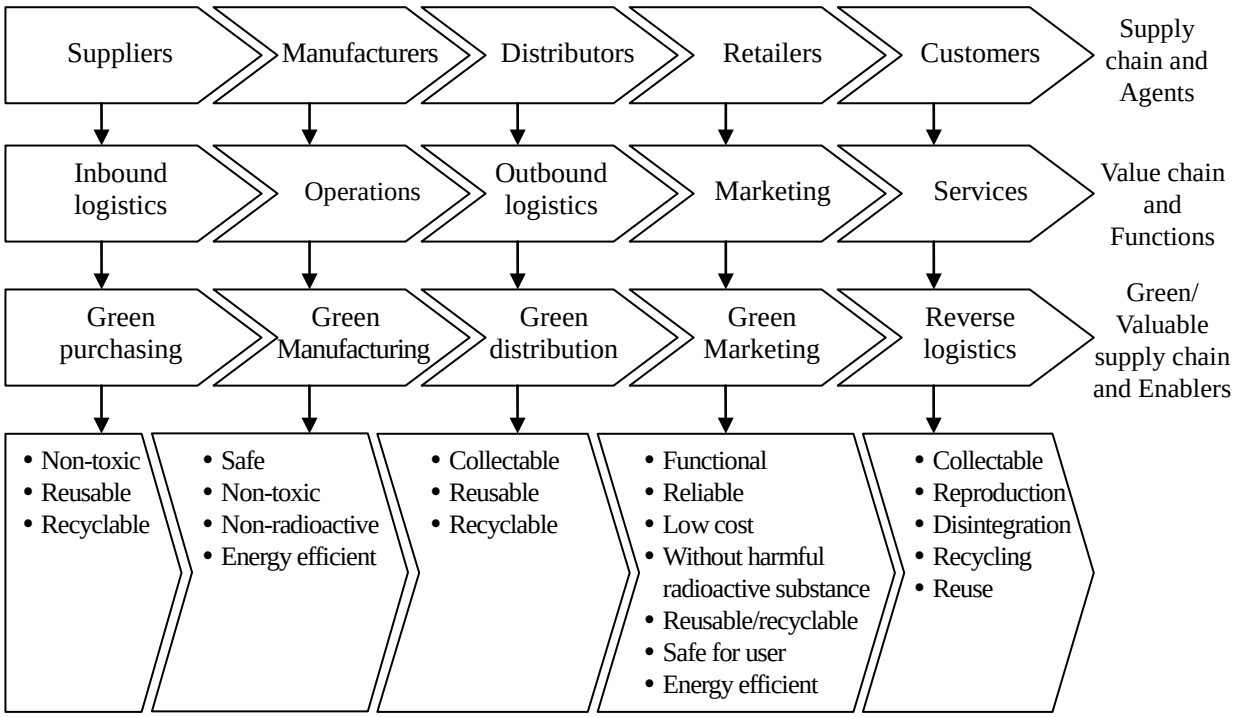

Figure 1 : Dimensions of Green and Valuable Supply Chains.

MODELING

The second part of this study applies a Fuzzy Analytic Network Process (FANP) in the context of green and valuable supply chains. To facilitate this process, we need to first develop the ANP-based decision hierarchy. In this section, the Analytic Network Process (ANP) modeling approach and the operational procedure of FANP are briefly discussed.

The ANP-based decision hierarchy

As noted by Saaty (2004, p.129), the Analytic Network Process (ANP) "provides a general framework to deal with decisions without making assumptions about the independence of

higher-level elements from lower level elements and about the independence of the elements within a level as in a hierarchy." Sarkis (2003, p.408) also pointed out that the ANP modeling approach allows policy makers the flexibility to "identify and incorporate major interdependencies among many factors and clusters in a "dynamic" fashion." In other words, the modeling of dependencies among elements of the problem is possible. Also, a complex problem can be broken down into a decision hierarchy for further analysis. By referring to Figure 1, dimensions of green and valuable supply chains, a decision hierarchy is developed here. As shown in Figure 2, the top-most component in the ANP-based decision hierarchy is green and valuable supply chain. This is further decomposed into enablers (i.e. content variables) and sub-components (i.e. sub-criteria). Five key enablers are presented in Figure 2. They are: green purchasing, green manufacturing, green distribution, green marketing, and reverse logistics. In the case of green purchasing, for example, three sub-components are considered, namely, non-toxic, reusable, and recyclable. As shown in Figure 2, we also propose that no interrelationships exist at the upper component levels. Interdependencies are considered only at the sub-component level. Interviews with corporate executives need to be conducted to test our proposed model.

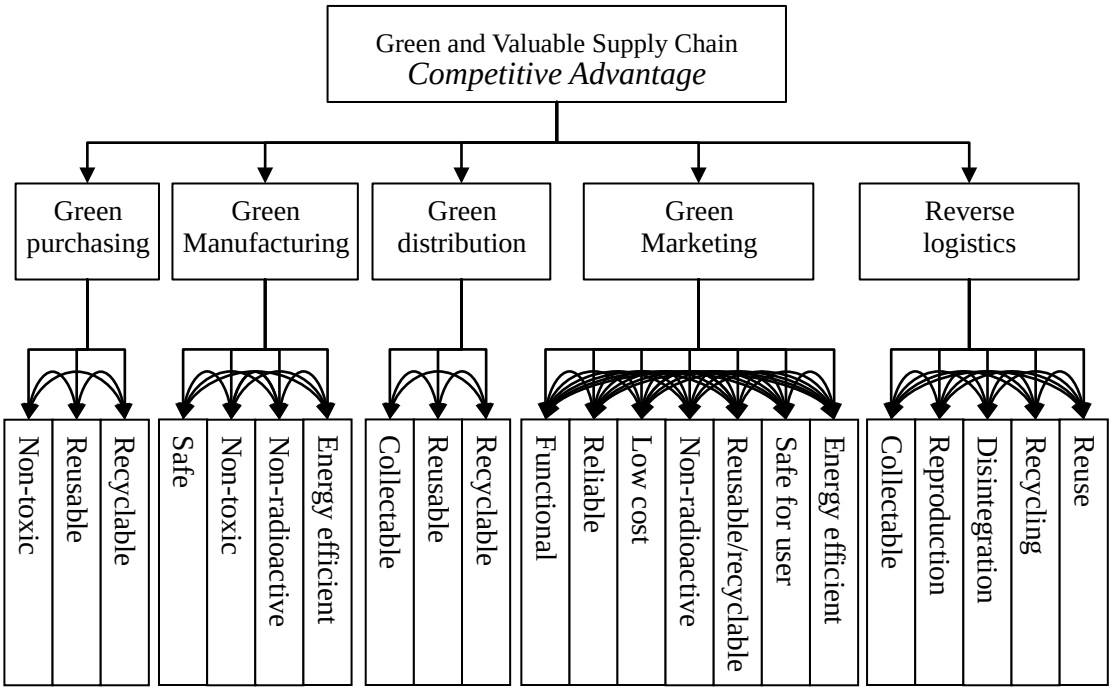

Figure 2: Decision Hierarchy.

The fuzzy-based ANP procedure

To prioritize enablers (i.e. content variables) and sub-components (i.e. sub-criteria) presented in the decision hierarchy (see Figure 2), the general approach of the Fuzzy-based ANP data collection and Super-matrix analysis procedure described by Ayag and Ozdemir (2009) needs to be followed. The approach consisting of three steps is shown below:

Step 1: Prepare pairwise comparison matrices based on the proposed decision hierarchy

(see Figure 2) and collect field data. A nine-point fundamental scale is used in these pairwise comparisons. Appendix A shows the comparison matrix designed for the pairwise comparison at the enabler level.

Step 2: Record data by using fuzzy scales, defuzzify the fuzzy values, and convert group defuzzified values to a single value (if group inputs are available).
The process is described as follows. First, we need to transform the linguistic terms into triangular fuzzy numbers (see Appendix B). The triangular fuzzy numbers are defined as $\tilde{M} = (l, m, u)$, where $l \le m \le u$.

Following are the triangular fuzzy functions:

$$u_M(x) = \begin{cases} 0 & x < l \\ x - l/m - l & l \le x \le m \\ u - x/u - m & m \le x \le u \\ 0 & x > u \end{cases}$$

According to the characteristics of triangular fuzzy numbers, we can calculate the fuzzy values. For instance, two triangular fuzzy numbers $\tilde{M} = (l_1, m_1, u_1)$ and $\tilde{N} = (l_2, m_2, u_2)$ can be calculated by using the following equations:

$$\tilde{M} \oplus \tilde{N} = (l_1 + l_2, m_1 + m_2, u_1 + u_2)$$
$$\tilde{M} \Theta \tilde{N} = (l_1 - l_2, m_1 - m_2, u_1 - u_2)$$
$$\tilde{M} \otimes \tilde{N} = (l_1 \times l_2, m_1 \times m_2, u_1 \times u_2)$$
$$\tilde{M} / \tilde{N} = (l_1 / l_2, m_1 / m_2, u_1 / u_2)$$

In such a study, if we need to deal with judgments from a group of experts, as noted by Condon, et al. (2003), we can use one of the following approaches to handle group inputs: the center of gravity method, the center of maxime (CM) method, and the α-cut method. Klir and Yuan (2005, pp.336-338) also reported that the resulting number must "summarize the elastic constraint imposed on possible values of the output variable by the fuzzy set." In this study, we therefore select the CM method. The defuzzified value, as a result, is defined as the average of the smallest value and the largest value in a fuzzy interval.

Step 3: Obtain the initial weights for each pairwise comparison matrix by using M.S. Excel, construct the initial Super-matrix, and use SuperDecisions software (http://www.superdecisions.com/) to obtain the final weights for each survey item.

The ultimate goal of this operational procedure is to identify survey items' local and global priorities. Appendix C provides a schematic representation of the decision hierarchy we proposed to conduct the ANP-based analysis in the SuperDecisions modeling environment. This operational procedure will be illustrated with our follow-up empirical work.

EMPIRICAL ASSESSMENT

Two tasks will be conducted to achieve the second goal outlined in this study: (1) pretesting the conceptual model, and (2) conducting case studies.

Pretesting the conceptual model

We will interview industry experts and corporate executives from companies in the Chemical Industry in Taiwan to confirm that the sub-criteria of our proposed ANP-based conceptual model are suitable. Based on the results of our interview, if needed, we will revise our decision hierarchy. Figure 3 depicts our pretest procedure. This goal can be reached in a reasonably short time frame.

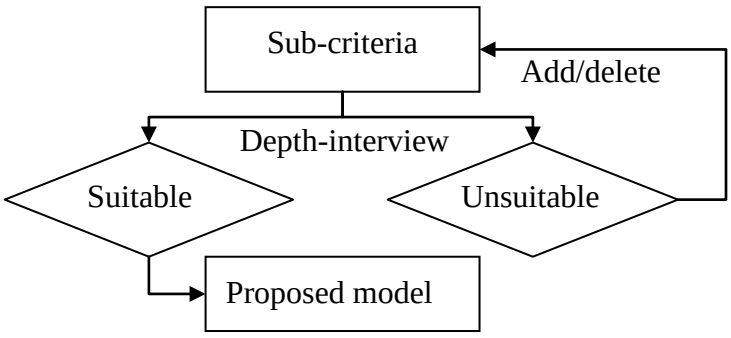

Figure 3: Pretest Procedure.

Case study

When our proposed model is confirmed with industry experts and corporate executives from major chemical companies in Taiwan, we will test our model by using the case study approach. This procedure is outlined as follows: We will interview top-level managers in company A (a major chemical company in Taiwan) and then contact one of its suppliers (company B) and one of its customers (company C). At the conclusion of this interview, we will send questionnaires to ten practicing managers from company A randomly. We will also contact companies B and C for the purpose of data collection. This procedure is shown in Figure 4. Survey items' local and global priorities will be obtained by following the FANP approach. This goal can be reached in two to three months.

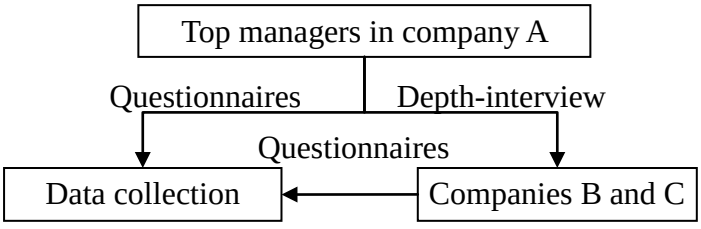

Figure 4: Scientific Inquiry Procedure.

SUMMARY AND EXPECTED RESULTS

The main contribution of the first part of this work is to build a hierarchic framework to help policy makers make better decisions in the context of green and valuable supply chains. The ultimate goal is to achieve value and environmental sustainability simultaneously. The general hierarchic framework and strategic analysis procedures shown in this paper can offer good guidance in effectively designing and improving green supply networks. In practice, however, it is also necessary to consider the entire operational conditions of green and valuable supply chains from different agents' perspectives when developing green supply chain strategies. To this effect, empirical works are needed. The current work, however, is a report of preliminary findings and our decision hierarchy. Our research team will continue our ongoing investigation of green and valuable supply chains. Through empirical studies, we expect to (1) obtain a concept map to assist policy makers in the decision making process, (2) find survey items' local and global priorities (see Figure 5), and (3) further identify implications for both practice and theory. It is our belief that the second goal of this work can be reached in a reasonably time frame.

ABSTRACT

Socially responsible investing (SRI) is the financial investment process that takes into account social, environmental, and corporate governance impacts and/or investment in the community – as well as shareholder activism. SRI investors encourage corporations to improve practices on environmental, social, and governance issues.

The debate surrounding the financial needs of investors and the impact on society of investment is considered to be a very important research topic due to the growth of socially responsible financial markets. The main objective of this research is to study the perception of the Spanish public about SRI criteria and real-life investment needs – and identify the most relevant sustainable financial products.

To examine the Spanish perception of *SRI, we conducted a field survey among 525 Spanish citizens between April 2010 and November 2010.*

The results show that SRI is in an early stage and Spanish investors need more exact information regarding social, environmental, and governance criteria in order to invest in socially responsible companies and products.

Keywords: socially responsible investing (SRI), SRI criteria, sustainability, sustainable financial products.

INTRODUCTION

SRI is the financial investment process that takes into account social, environmental and corporate governance impacts and/or investment in the community – as well as shareholder activism (SIF, 2009). Socially responsible investment decisions have been studied in the economic and financial literature in recent years from various perspectives (Anand and Cowton, 1993; Williams, 2007) that have sought to establish the determinants of these investment choices.

* **Acknowledgments**: This work is supported by grant FPU-AP2008-01043, the University Jaume I via the P1•1B2010-13 and P1.1B2010-04 investigation projects, MTIN through the project F10289 and the Master in Sustainability and Corporate Social Responsibility offered by University Jaume I of Castellon, Spain.

The objective of this article is to study the Spanish perception of SRI criteria and real-life investment needs. A questionnaire was developed to obtain the necessary information.

Through the media it is possible to see a reinterpretation of financial investment criteria and a more in-depth analysis and assessment of the environmental, social, and ethical behaviour of companies (Nieto and Fernández, 2004).

In recent years, SRI has become a key factor for institutional investors and is especially relevant for individuals. The European SRI market has increased from €2.7 trillion in 2007 to €5 trillion at the end of 2009; a growth of about 87% over two years (Eurosif, 2010). This growth can be partly attributed to changes in regulation regarding the disclosure of social, environmental, and ethical information by pension funds and listed companies (Renneboog, et al., 2008).

SRI is considered a very important topic in research due to the growth of financial markets. The inclusion of environmental criteria in the investment decisions of investors is making corporate behaviour more sustainable (Brammer and Pavelin, 2005). Firms and investors recognise that investing in accordance with the principles of sustainability can create long-term value (Bebbington, 2001). Moreover, investor behaviour has become one of the most important drivers encouraging Western governments to introduce regulatory initiatives to stimulate SRI.

This paper is structured as follows: the introduction is followed by a brief explanation of the Spanish SRI market. Subsequently, we show the methodology used and the results obtained. The final section provides the main conclusions.

SOCIALLY RESPONSIBLE INVESTMENT MARKET IN SPAIN

SRI is interpreted differently in different geographical areas, with distinct characteristics linked to the particularities of each financial market and the legal and cultural framework of each country (Cañal et al., 2008).

SRI was first discussed in Spain in the late 1990s when the first socially responsible investment funds (SR fund) were launched. Specifically, the first Spanish-based SR fund was launched in 1997 – the *Iber Fondo 2020 Internacional* – which included companies whose investments were aligned with the views of the Catholic Church. In the same year, the *Arco Iris de Ahorro Corporación* launched an investment fund for environmentally friendly technology companies. Two years later in 1999 several more SR funds appeared on the Spanish market.

The main feature of the SRI market in Spain is the difference between the institutional market, the core market for SRI in Spain, and the retail market. According to a report published by the *Observatorio de Inversión Socialmente Responsable* (2010) assets invested in SRI in Spain at December 31 2009 totalled €14,053,875,000 (10% more than 2008); and the total number of investors with SR criteria was 814,766 (up 0.229% on the previous year). Some €13,919,368,000 of the total assets invested in SRI (representing 99% of total SRI market) was invested in the institutional market and primarily consisting of occupational

pension funds. Assets invested on the retail market totalled €134,507,000, or 1% of the total. This fact emphasises the importance of institutional SR investors in Spain, especially with respect to occupational pension funds, despite the absence of legislative measures to encourage SRI.

In November 1999, the Spanish Association of Investment and Pension Funds (INVERCO) issued guidance on the use by mutual funds of the terms 'ethical', 'ecological' and any other term regarding social responsibility. This guidance was approved by the Spanish Securities and Investments Board (CNMV) and its objective was to define the criteria that investment funds must meet to include these terms in their names. To standardise this situation and give greater transparency to ethical fund policies, the Spanish Standardisation and Certification Association (AENOR) published in 2002 a standard entitled: 'Requirements for Ethical and Socially Responsible Financial Instruments' (PNE 165001 EX) that specifies the requirements for ethical and socially responsible financial instruments created and sold by any organisation legally permitted to do so (Muñoz, et al., 2004). Regulation 31 of the Sustainable Economy Act -BOE, 5/03/2011- (*regulations for the dissemination of information on pension fund investment policies)* states that further regulations will be issued regarding the dissemination of information on social, environmental, and good governance criteria in the investment policy of pension funds.

In addition to SRI, other mechanisms are available for investors wishing to implement sustainability in their decision making processes: sustainability rating agencies and sustainability indices. Sustainability indices facilitate the selection of investments – but restrict the investor's choice of socially responsible criteria.

The first Spanish sustainability stock index – the 'FTSE4GoodIBEX' – was launched in 2008 and includes medium and large companies from the Spanish stock exchange. The index is part of the FTSE4Good family of indices and follows an established inclusion and exclusion criteria.

METHODOLOGY AND SAMPLE

The survey

To examine the public perception about SRI criteria and the real-life needs of investors we conducted a user study. The multidisciplinary method employed uses several research techniques to analyse the various aspects and features of the relationship between the information and the user (Martin, 2007). Specifically, we have designed a self-administered survey because: (1) this approach enables the study of a large number of both objective and subjective aspects that are not directly observable; (2) information is obtained from a wide range of people in different geographical areas and within a relatively short period of time; (3) the approach facilitates comparison between responses; (4) the results can be generalised, etc. The disadvantages include the relatively low response rate and absence of personal contact with the respondents (Martin, 2007).

525 individuals were surveyed from around Spain between April 2010 and November 2010. However, the final sample was reduced to 66% of the valid responses. This reduction was

made for two reasons: firstly, a lack of awareness of the product by many respondents – this phenomenon could be the result of the poor development of SRI in Spain. Secondly, as the survey was self-administered, this sometimes led to multiple answers being given to question where just one answer was required – and thereby preventing subsequent data analysis.

Research using small sample sizes is not uncommon in this field of study, for example: Bigné et al., (2005) studied the perception of CSR (corporate social responsibility) in four nations with sample sizes smaller than of 155 subjects per nation (418 total responses); Anand and Cowton (1993) explored socially responsible investor behaviour with a sample of 125 observations from the EIRIS database; Lewis and Webley (1994) observed that the majority of investors showed an attitude revealing a positive predisposition to make social and environmental investments using a questionnaire given to 100 investors; McLahan and Gardner (2004) provided a comparative examination of 55 conventional and 54 socially responsible investors, with the aim of identifying the factors that lead investors to choose socially responsible investment products.

The questionnaire for the study was made up of 28 items and included five sections: 1) general questions; 2) questions related to Spanish investors; 3) questions related to SRI; 4) questions related to socially responsible funds; and 5) questions related to sustainability indices and sustainability rating agencies. Various references were used in designing the questionnaire – such as those issued by Balaguer et al. (2008) to managers; the previously cited Bigné, et al., (2005); or *Economistas sin Fronteras* and UNED (2007).

The sample

The results for the profile of socially responsible investors are not unanimous. However, many studies show that socially responsible investors tend to be university-educated women (Tippet and Leung, 2001; Schueth, 2003; Williams 2007); university-educated men (Haigh, 2008); in late middle-age (Lewis and McKenzie, 2000 a, b, ESF and UNED, 2007); and with an above-average income (Lewis and McKenzie, 2000 a, b, Haigh, 2008). This lack of consensus may be due to the size of the samples, the use of differing methodologies, differing survey designs, and the varying nature of the nations studied, etc.

Coinciding with the literature, in our study socially responsible investors are mostly women, middle-aged, university-educated, and with average incomes – and students (Table 1). This last feature, which differs from results in the literature, can be explained by the fact that 19% of our sample is made of post-graduate students of corporate social responsibility and advanced finance.

Table 1: Profile of sample rates.

Variables		Total sample (N=345)	Socially responsible consumer[1]
Sex	Male	53.3%	4.9% of all men
	Woman	46.7%	6.8% of all women
Age	18-24 years	9.9%	5.8% of total
	25-34 years	39.7%	6.6% of total
	35-45 years	27.2%	5.3% of total
	45-54 years	8.7%	3.4% of total
	55-64 years	9.9%	8.8% of total
	65 or older	4.6%	0
Education	No education	0.3%	0
	Primary school	3.8%	7.6% with no education
	Secondary school	18.8%	4.6% secondary school
	Degree	16.8%	8.6% with degree
	Post-graduate	60.3%	53.4% with graduate studies
Occupation	Student	16.5%	8.8% of total students
	Working	69%	4.6% of total workforce
	Homemaker	2.7%	0
	Retired	9.6%	12.1% of total pensioners
	Unemployed	2.3%	0
Family household income	€ 0-1000	7.8%	7.4% of total
	€ 1,001 € 1,500	10.7%	16.2% of total
	€ 1,501 € 2,000	15.4%	9.4% of total
	€ 2,001 € 2,500	18.3%	1.6% of total
	€ Over 2,500	47.8%	3.6% of total
Percentage of income saved	0-10%	34.5	6.7% of total
	10% -30%	37.7%	6.9% of total
	30% -50%	18.5%	3.1% of total
	50% -70%	7%	4.2% of total
	Over 70%	2.3%	0%

RESULTS

The main results of the study are presented below. Firstly, the data is statistically analysed by applying percentages, and secondly, the possible relationships between the variables are explored.

Statistical analysis

Socially responsible investing

The decision-making process of a socially responsible consumer is more complex than the process for consumers of traditional financial products. This is because social and environmental criteria are sometimes more important than financial criteria (Cañal et al., 2008).

[1] Any individual buying a socially responsible financial product is considered to be a socially responsible consumer.

Table 2: Results of questions on SRI.

1. Have you heard of SRI?			
	YES	NO	No answer
N=345	54.2%	44.3%	1.5%
N=20	100%	0%	0%

2. Have you bought a socially responsible financial product?			
	YES	NO	No answer
N=345	5.8%	87.2%	7%
N=20	100%	0%	0%

3. Which socially responsible financial product have you bought?						
	SRI	Bonds and other SR loans	Guarantee funds	Funds for micro-credits	SR cheque and savings accounts	Other
N=345	1.4%	0.9%	0.6%	0.3%	2.3%	1.6%
N=20	25%	15%	10%	5%	40%	20%

4. Why have you chosen, or would choose, a financial product that includes social and environmental variables?						
	High returns	Security of investing in sustainable products	Advice from bank	Ethical or religious reasons	Social pressure for more responsible behaviour	Other
N=345	28.1%	39.7%	7%	23.3%	5.5%	14.8%
N=20	10%	40%	25%	20%	5%	15%

5. Why have you not chosen, or would not choose, a financial product that incorporates social and environmental variables?						
	Low returns	Doubts about relationship between ethics and returns	Failure to publicise the existence of SR products	Lack of support or endorsement by the state	Charity and donation	Other
N=345	10.7%	18.3%	50.4%	6.6%	5.5%	17.1%
N=20	10%	20%	45%	20%	0%	5%

6. Do you know what ethical banking means?			
	YES	NO	No answer
N=345	31.3%	65.2%	3.5%
N=20	70%	30%	0%

7. Have you heard of any of these ethical banks?						
	Triodos Bank	Citizens Bank of Canada	Cooperativa de crédito Oiko Credit	Southshore Bank	Banca Ética Italiana	Other
N=345	19.4%	6.7%	1.7%	2.3%	3.2%	6.7%
N=20	40%	20%	15%	10%	15%	15%

SRI is at an early stage in Spain and for this reason just 54.2% of the sample recognise the term SRI – while 45.8% do not recognise the term.

Only 5.8% of the total sample has ever purchased a socially responsible financial product. The most frequently purchased products are SR current account and savings deposits (2.3% of the sample and 40% of SR investors). The lack of information about the existence of these products seems to be the most common cause for non-purchase (54.4% of the sample and 45% of SR investors). While the security implied in investing in sustainable products is the main reason for purchasing a SR financial product (39.7% of the sample and 40% of SR investors).

Some 31.3% of the respondents had heard of ethical banking and Triodos Bank was the best known ethical bank (19.4% of the sample and 40% of SR investors). Triodos Bank is the European benchmark for ethical banking with clients in the Netherlands, United Kingdom, Belgium, Germany, and Spain since 2004. It has offices in Madrid, Barcelona, Seville, Valladolid, Valencia, Zaragoza, and the Basque country.

SRI funds

The rapid growth of socially responsible mutual funds is certainly linked to the increased level of interest in socially responsible investing observed in recent years and SRI mutual funds are probably the most prominent financial instrument in the field of ethical finance (Bassso and Funari, 2010).

Table 3: Results of questions about SRI Funds.

8. Have you received information about SR investing?			
	YES	NO	No answer
N=345	12.8%	85.2%	2%
N=20	70%	30%	0%

9. If you were to invest in an SR product what would you value most?				
	Returns	Ethical aspects	Social aspects	Environmental aspects
N=345	55.1%	15.9%	22.6%	6.4%
N=20	35%	20%	25%	20%

10. What is the most valued or positive criterion for you when deciding to invest in SRI?					
	N=345	N=20		N=345	N=20
Equal opportunities	7%	10%	Pollution control	4.3%	5%
Recycling	0.6%	0%	Workplace safety	4.3%	15%
Conserve energy and natural resources	16.5%	20%	Training help	3.5%	10%
Information transparency	21.7%	5%	Corporate investment	0.9%	5%
Social solidarity	31.6%	25%	Others	9.6%	5%

11. What is the most excluding or negative criterion when deciding to invest in SRI?					
	N=345	N=20		N=345	N=20
Gambling-related activities	0.6%	0%	Nuclear production	2.3%	5%
Activities relating to tobacco and alcohol	1.2%	5%	Activities that abuse the environment	5.5%	5%
Practices related to embryo research	0.6%	0%	Activities related to pornography	2.9%	5%
Abortion practices	7.8%	0%	Animal testing	1.4%	5%
Activities that abuse and human and labour rights	36.5%	35%	Support for repressive or dictatorial regimes	13.9%	20%
Lack of transparency in business practices	12.2%	0%	Genetic manipulation	1.2%	0%
Activities related to armaments	7.5%	10%	Others	6.4%	10%

12. In your opinion, when compared with traditional investment funds, SRI is:					
	Riskier	A little riskier	Similarly risky	A little less risky	Safer
N=345	6.4%	11.6%	62%	11.3%	8.7%
N=20	10%	10%	50%	15%	15%

13. In your opinion, when comparing SR in the long run with traditional investment funds, SR offers:					
	Much better returns	Better returns	Similar returns	Lower returns	Much lower returns
N=345	1.2%	7.8%	50.4%	35.4%	5.2%
N=20	0%	10%	50%	35%	5%

14. Do you recognise any of the ethical, environmental, and other SR investment funds offered in Spain?					
	N=345	N=20		N=345	N=20
Santander Central Hispano Responsabilidad FIM	8.4%	25%	BBVA Solidaridad FIM	9.3%	30%
Santander Central Hispano Solidaridad FIM	7%	25%	DWS Ecoinvest FIM del Deutsche Bank	1.4%	15%
BNP Fondo de Solidaridad FIM de la BNP	2%	5%	Other	10.1%	25%

One of the market problems is that Spanish fund managers have not developed appropriate strategies for publicising SR funds – and specifically in the financial sector (IPES, 2002). Less than 12.8% of the sample had received information about investing in SR funds.

Reviewers positively evaluated SR products for profitability (55.1%), followed by social aspects (22.6% of the sample), ethical aspects (15.9%), and environmental aspects (6.4% of the sample) (Table 3).

SRI mutual funds apply a combination of various types of screens: negative screens and positive screens. The negative screens consist of negative (exclusion) criteria that exclude certain investments; while positive screens identify those companies with best behaviours. The use of positive screens is often combined with a 'best in class' approach.
There is no consensus in the literature regarding the social aspects that most concern investors (Tippet and Leung, 2001). These aspects vary depending on the legal framework (Cañal et al., 2008) as well as the cultural and social issues in each country (Katz et al., 2001; Sirmon and Lane, 2004).

The exclusion criterion most valued by respondents are activities that abuse human and labour rights (36.5% of the sample and 35% of SR investors); while the least valued exclusion criteria are gambling-related activities and practices related to embryo research (0.6%) (Table 3).

The most highly valued positive criterion for most respondents was a commitment to social solidarity (31.6% of the sample and 25% of SR investors); and the least valued was recycling (0.6% of the sample).

Another major problem in the Spanish SRI market is that many investors are unaware that the returns on SR are the same as with any other fund in the same category, given that the management approach is the same. Some 40.6% of the respondents believe that financial returns on SR are less than traditional investment funds. In terms of risk, 18% of respondents believe that these funds are riskier than traditional funds.
Most empirical results discussed in the literature suggest that SRI mutual funds produce better or similar returns to other funds (Statman, 2000; Geczy, et al., 2006, Bauer et al. 2006, 2007). However, some empirical results support the opposite conclusion (Chang and Witte, 2010).

The best known SR funds are managed and marketed by the two largest Spanish banks (Santander and BBVA) (Table 3).

Sustainability rating agencies and sustainability indices

Sustainability indices, in the same way as traditional stock market indices, are indicators of the price trends of the most representative shares in a stock market. However, in this case, the market is limited to socially responsible companies. These indices are also used as benchmarks in the management of socially responsible portfolios (Fernández and Muñoz, 2009). While these indices help investors choose investments, they also restrict the application of an investor's own criteria regarding social responsibility.

Sustainability rating agencies are the link between stakeholders and companies (Schäfer, 2005). It is clear that these agencies are growing due to two key factors: the expansion of the securities markets (resulting from the rapid transformation from bank-based to market-

based financial systems); and the growth of regulation (Ferri and Liu, 2005) regarding the disclosure of social, environmental, and corporate governance information.

Sustainability rating agencies study businesses and use their own research methodologies to make evaluations on social, environmental, and corporate governance aspects. Normally, evaluations are made by using complex questionnaires and an analysis of public information sources. The criteria used by sustainability rating agencies are later reflected by the most prestigious sustainability indices.

Table 4: Results of questions on sustainability rating agencies and sustainability indices.

15. Have you heard of stock indices for socially responsible investment?

	YES	NO	No answer
N=345	26.1%	73%	0.9%
N=20	55%	45%	0%

16. Do you recognise any of the SRI stock indices in the financial market?

	N=345	N=20		N=345	N=20
Ethibel Sustainability Index	1.4%	10%	ASPI (ARESE Sustainable Performance Indices)	0.6%	0%
Dow Jones Sustainability Index	16.2%	40%	FTSE KLD 400 Social Index	1.7%	5%
FTSE4Good	7.5%	20%	Calvert Social Index	0%	0%
FTSE4Good Ibex	7.8%	20%	Other	1.4%	0%

17. Have you heard of sustainability analysis agencies?

	YES	NO	No answer
N=345	17.7%	79.1%	3.2%
N=20	30%	65%	5%

18. What is the most important or positive test for you when deciding to responsibly invest?

	N=345	N=20		N=345	N=20
EIRIS	2.9%	5%	SAM	1.4%	5%
Oekom research AG	0.9%	5%	ASSET4	1.4%	5%
Vigeo	1.2%	5%	KLD Research & Analytics Inc	0.9%	0%
Accountability	3.5%	10%	Other	3.2%	5%

19. What do you think will be the tendency in Spain regarding socially responsible investment?

	Decrease	No change	Increase	No answer
N=345	2.6%	18%	58%	21.4%
N=20	0%	15%	75%	10%

Sustainability indices and ESG (environmental, social, and governance) agencies are important sources of information for the socially responsible investor. However, these agencies remain little known by Spanish investors.

Only 26.1% of the sample has heard of sustainability indices. The best known index is the Dow Jones Sustainability Index (recognised by 16.2% of the sample and 40% of SR investors), followed by FTSE4Good Ibex (7.8%), FTSE4Good (7.5%), FTSE4 KLD 400 Social Index (1.7%), Ethibel Sustainability Index (1.4%), others (1.4%), and ASPI (0.6%). None had heard of the Calvert Social Index (Table 4).

The percentage of respondents who understand something about the role of sustainability rating agencies is 17.7%. The best known sustainability rating agencies are: Accountability (3.5% of the sample); other agencies (3.2%); EIRIS (2.9%); SAM (1.4%); ASSET4 (1.4%); Vigeo (1.2%); Research Oekom AG (0.9%); and KLD Research & Analytics (0.9%). The lack of familiarity with these agencies may be because agencies reveal little when explaining the

evaluation criteria used, particularly those related to risk management. As a result, a direct analysis of information by investors is difficult (Escrig et al., 2010).

Some 58% of respondents believe SRI will grow in popularity in Spain.

Factor analysis

Factor analysis is a multivariate statistical technique whose main aim is to synthesise the observed relationships among a set of variables in a concise and reliable manner as an aid to building new concepts and theories. Several studies in the literature have used this technique to analyse relationships of dependence and independence between variables of CSR (corporate social responsibility) or SRI (Anand and Cowton, 1993; Bigne et al., 2005). In our study we have examined these relationships with the following questions:

(4) Why have you chosen, or would choose, a financial product that incorporates social and environmental variables?
(5) Why have you not chosen, or would not choose, a financial products that incorporates social and environmental variables?
(10) What is the most important or positive criteria when deciding to invest in SRI?
(11) What is the most exclusionary or negative criteria when deciding to invest in SRI?

The results from the correlation matrix show that the only variable that can be eliminated in all cases (having a low factor loading) is the variable 'others' – it being the only variable with redundant information.

The logistic regression model

To analyse the influence of gender, educational level, and occupation in the various cases we used a linear probability model, namely, the logistic regression model (Alderete, 2006). This is a generalisation of the classic linear regression model for categorical dependent variables (Ato and Lopez, 1996). The main features include: (1) assumptions of normality and equality by variance-covariance matrices do not have to be met; (2) the model is more robust than other techniques when these assumptions are not met; (3) the use of continuous and categorical independent variables is enabled; (4) direct statistical tests are included; (5) nonlinear effects can be incorporated and the model is useful for diagnosis (Hair et al., 1999); and (6) the model is widely used in observational, survey, and experimental studies. Various studies have opted to use this model to analyse socially responsible relations and attitudes (Balaguer et al., 2008; Tranter and White, 2001; Chan and Wickramasinghe, 2006).

In our study, we have used three types of logistic regressions based on the type of dependent variable analysed. These regressions are: multivariate binary logistic regression when the dependent variable has two categories; multinomial logistic regression when the dependent variable has more than two categories; and ordinal logistic regression when the order of dependent variable categories is fixed.

Hypotheses

Below we identify the attitude and factors that motivate Spanish investors, and study the influence of gender (male-female), education level (university-no university), and occupation (employed-unemployed and non-actives).
Table 5 shows the hypotheses. The outcomes of the first analysis of the logistic regression test can be seen in the results column.

Table 5: Hypotheses for investors.

Dependent variable	Independent variable	Hypothesis	Test	Nature of the relation
Awareness_SRI	General level, education, occupation	H_1: Awareness_ SRI depends on the general variables, education, and occupation.	Multivariate binary logistic regression	H_1 depends on gender, education and occupation
Purchase_ SRI	General level, education, occupation	H_2: Purchase_ SRI depends on the general variables, education, and occupation.	Multivariate binary logistic regression	None
Awareness_ethical banking	General level, education, occupation	H_3: Awareness_ethical banking depends on the general variables, education and occupation.	Multivariate binary logistic regression	H_3 depends on education and occupation
Information_ SRIfunds	General level, education, occupation	H_4: Information_SRIfunds depends on the general variables, education, and occupation.	Multivariate binary logistic regression	H_4 depends on education
Evaluation_ SRIfunds	General level, education, occupation	H_5: Evaluation_ SRIfunds depends on the general variables, education, and occupation.	Multinomial logistic regression	H_5 depends on gender and occupation
Criteria _ positives	General level, education, occupation	H_6: Criteria_positives depends on the general variables, education, and occupation.	Multinomial logistic regression	H_6 depends basically on occupation
Criteria _ negatives	General level, education, occupation	H_7: Criteria_negatives variable depends on the general variables, education and occupation.	Multinomial logistic regression	H_6 depends basically on education and occupation
SRIfunds _risk	General level, education, occupation	H_8: SRIfunds_risk variable depends on the general variables, education and occupation.	Ordinal logistic regression	None
SRIfunds _returns	General level, education, occupation	H_9: SRIfunds_return variable depends on the general variables, education, and occupation.	Ordinal logistic regression	None
Awareness_indices	General level, education, occupation	H_{10}: Awareness_índices variable depends on the general variables, education, and occupation.	Multivariate binary logistic regression	H_{10} depends on education

Awareness_agencies	General level, education, occupation	H_{11}: Awareness_agencies variable depends on the general variables, education, and occupation.	Multivariate binary logistic regression	H_{11} depends on education
Tendency_ SRI	General level, education, occupation	H_{12}: Tendency_ SRI variable depends on the general variables, education and occupation.	Ordinal logistic regression	H_{12} depends on education and gender

Results of the model

After confirming the hypotheses H_1, H_2, H_3, H_4, H_{10}, and H_{11} which are related to the level of awareness and information, it appears that the gender variable does not influence in SR investment decisions except in H_1. The level of education variable is statistically significant, with some degree of relaxation ($p<0.10$) in H_1, H_3, H_4, H_{10} and H_{11}; while with some degree of relaxation ($p<0.10$) the occupation variable is significant in H_1 and H_3 (Table 6). We can therefore say that the degree of SRI awareness depends mainly on the education variable – as higher education generates a more informed society.

Statistical significance ($p<0.05$) would be an overly restrictive term, but a certain degree of relationship does exist (for example, $p<0.10$). The looseness of these recommendations is because a standard that is as restrictive as $p<0.05$ may lead to a failure to include in the model covariates with a weak association with the dependent variable in isolation. However, these covariates may prove strong predictors for the dependent variable when read in conjunction with other covariates. Research using statistical significance ($p<0.10$) is not uncommon in the literature such as Kale et al., 2002 and Co and Chew, 1997.

If we use for $p<0.05$ for the analysis then only the education variable is be significant in H_1. This may be due to the inclusion of interactions that involve excessive stratification for the available sample.

Table 6: Hypothesis tested through binary logistic regression.

			B	S.E.	Wald	gl	Sig.	Exp(B)

Hypotheses H_5, H_6, and H_7 are related to the evaluation of SRI funds and the positive and negative criteria for making an investment in this type of fund. For these hypotheses, we obtained the following results:

H_5: Gender is key variable when deciding to invest in SRI funds for the social aspects, and gender and occupation are crucial when considering environmental aspects (Table 7).

Table 7: Test for H_5: Evaluation_SRI.

H_5: Evaluation_SRI		B	Standard error	Wald	gl	Sig.	Exp(B)
Social aspects	Intersection	-,813	,201	16,366	1	,000

	[Occupation =1]	0[b]	.	.	0	.	.

H_7: The gender variable is statistically significant – with some degree of relaxation ($p<010$), for criteria regarding activities that abuse the environment. The level of education variable is statistically significant with some degree of relaxation ($p<0.10$) for criteria regarding activities that abuse human and labour rights, lack of transparency and support for repressive and dictatorial regimes. Finally, the occupation variable is statistically significant, with some degree of relaxation ($p<0.10$), for activities such as nuclear production and animal testing, (Table 9).

Hypotheses H_8, H_9, H_{12} relate to risk, performance, and SRI trends in Spain. It can be seen that the gender, educational level, and occupation variables are not statistically significant for H_8 and H_9. Meanwhile, the gender and educational level variables for H_{12} are statistically significant – with a certain degree of relaxation ($p<0.10$) (Table 10).

Table 10: Test for H_{11}: Tendency_ SRI.

CONCLUSION

In this paper, we set out to study the perceptions held by the Spanish public regarding SRI criteria and real-life investment needs. We have conducted a field survey among 525 Spaniards.

The percentage of socially responsible individual investors in Spain is marginal (5.8% of the total sample). Most of these investors are women, in late middle age, highly educated, with middle and higher incomes – and students. The occupational and educational variables are the most important determinants when making investment decisions.

A certain lack of awareness was observed regarding SR financial products. The sustainability rating agencies and sustainability indices are the SRI market instruments least known by the Spanish respondents. On the other hand, ethical banks are the most known SRI market instruments.

As a result of our research we propose some aspects that could be improved in order to correct the main weakness to the growth of SR financial products in Spain are: (1) failure to publicise the existence of these products; (2) a perception of low returns; (3) a lack of adaptation of these products to the needs of investors; and (4) the limited development of SRI in Spain.

To tackle these problems, SRI Managers must create products and generate an economic return that reflect the social and environmental values of investors. In addition, retail investors must be informed in detail about the characteristics of these products. There is also the need for a greater promotion of SRI by the government.

Nevertheless, despite these drawbacks, there is an existing basis for growth (58% of the sample believes that SR investments will grow in the future).
Future work will seek to extend the study of the perception of SRI from Spain to a European level in order to evaluate the degree of integration enjoyed by these products and instruments in various European societies.

ABSTRACT

China has become the second largest nation of consuming oil since 2002 and a net oil imported country from 1996. At the same time, global crude oil price and Russia Trading System Index (RTSI) also substantially went up to 2290.51 on June 2008 from 87.35 of 1996. Theses economic phenomena raise two issues discussed in this paper: Does the China oil demand carry the rising of the oil price? The second issue is how much the impact of China oil demand on RTSI? Estimates of Structure Vector Auto Regression models, employed for testing the impact of China oil imported on oil price and RTSI, bring up two conclusions: first, the continuing oil imported of China have a positive impact on oil price; second, the China oil imported also has a positive impact on RTSI. Therefore, the China oil demanded not only affects RTSI and Russia economic during Putin's Presidency but also the world crude oil price. These results indicate that China oil demand has a strong explanatory power to global oil price and RTSI fluctuation.

Keywords: Structure Vector Auto Regression; Russia Trading System Index; Johansen Co-Integration Test.

INTRODUCTION

Driven by economic continuing growth, China has become the second largest nation of consuming oil since 2002. Oil consumption raised from 173.8 million tones of 1996 to 368 million tones of 2007. But oil production only increased 28.2 million tones at the same time (BP Statistical Review of World Energy, 2008). Therefore, China becomes a net oil imported country from 1996. Crude oil imported, a remarkable growth from 36.61million tones of 1999, was up to 163.12 million tones in 2007. Meanwhile, the crude oil price rose to 2.74 times from 1999 to 2007. And Russia Trading System Index (RTSI) also went up from 59.7 of 1999 to 2290.51 of 2007. Figure 1 illustrates that global oil consumption grew at an average annual rate of 1.73% from 1996 to 2007. The increasing of oil demand results in the rising of

oil price. However, an average annual rate of China oil Consumption contribution to global growth of oil consumption is 29.06%.[1] The contribution rate reaches to 59.80% in 2006. On the other hand, the market value of energy industry is the most important component of RTSI. The top 3 of RTSI trading volume in 2007 were Gasprom ordinary shares with a turnover of 102.1 billion dollars, followed by LUKoil with a turnover of 46.4 billion dollars and RAO UES of Russia with a turnover of 41 billion dollars. The percentage of these securities in the turnover was 26.19%, 11.9% and 10.51% respectively (RTSa, 2008). Therefore, it is assumed that the increasing of oil demand results in the rising of oil price and the rising oil price will have an impact on RTSI.

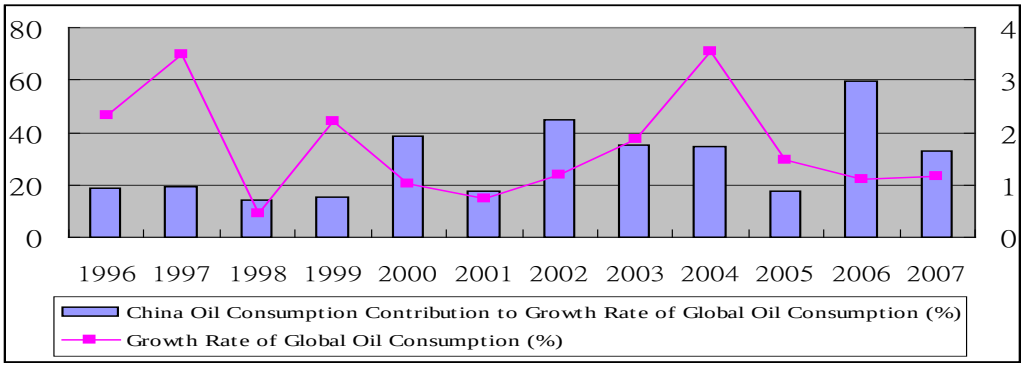

Figure 1: China oil consumption contribution to global growth of oil consumption and growth rate of global oil consumption, 1996– 2007.

Source: The data is from BP's Statistical Review of World Energy 2008.

Note: The number in the right side is the china oil consumption contribution to growth rate of global oil consumption and in the left side is the growth rate of global oil consumption.

Theses economic phenomena, with ascending trend from 1999, raise two issues discussed in this paper. Does the China oil demand carry the rising of the oil price? The second issue is how much the impact of China oil demand on RTSI?

The basic data used for investigating these two hypotheses are presented in figure 2-4. Estimates of Structure Vector Auto Regression (SVAR) models, employed for testing the impact of China oil imported on oil price and RTSI, suggest two conclusions: the quantity of China oil imported has a positive impact on oil price between the first and the third period and the result is statistically significant; second, the quantity of China oil imported also has a

[1] An average annual rate of China Oil Consumption Contribution (China_coms) to Global Growth of Oil Consumption (Global_coms) is calculated by following formula: [China_coms(t)-China_coms(t-1)] / [Global_coms(t)-Global_coms(t-1)]. And an average annual rate of China and India oil consumption contribution to global growth of oil consumption is 38.33%. In other words, the increment amount of India oil consumption contribution to the increment amount of global growth of oil consumption only 9.27%. Therefore, we think that the increment amount of China oil consumption is a main reason of the rising of global oil consumption.

positive impact on RTSI between the first and third period, and is statistically significant. The demand of China oil imported has a positive impact on crude oil price. The rising of crude oil price leads to increase the quantity of Russia oil output. At the same time, the oil industry is the most important industry relative to Russia Macroeconomic environment.[2] Therefore, the demand of China oil not only affects the world crude oil price but also RTSI and Russia economic during Putin's Presidency. It implied that the oil demand of China affords benefit to Russia[3].

THE QUANTITY OF CHINA OIL IMPORTED, OIL PRICE AND RTSI ON 1996-2008

Figures 2-4 present the quantity of China oil imported; Price of West Texas Intermediate Crude and RTSI; Price of West Texas Intermediate Crude estimated in constant dollars. Monthly quantity of China oil imported, Price of West Texas Intermediate Crude and RTSI from 1996-Jan to 2008-June are unadjusted. The quantity of China oil imported and the Price of West Texas Intermediate Crude have a statistically significant correlation coefficient that is 0.8730. The three series indicate statistically significant upward trends.

The Models

Blanchard and Quah (1989) proposed the approach of long-run SVAR to examine the sources of the macroeconomic fluctuations. The advantage of the long-run SVAR model is that the model doest not impose contemporaneous restrictions, but it allows the data to determine short-run dynamics based conditionally on particular long-run restrictions. This approach is popular to employ in examining the sources of macroeconomic fluctuations. For example, Lastrapes (1992) extended this approach in examining resources of real exchange rate fluctuations. Chen and Wu (1997) also applied the long-run SVAR model to analyze the influence of real shocks on the fluctuations of real exchange rates for four Pacific Basin countries. The long-run SVAR model used to analyze the impact of the quantity of China oil imported on oil price and RTSI is stated here. The variables are defined as the quantity of China oil imported (O_q), oil price (O_p) and RTSI (rts). All variables are in logarithms.

The conventional VAR model is:

$$Y_t = B_0 + B_1 y_{t-1} + \ldots + B_p Y_{t-p} + U_t \quad \text{--- (1)}$$

Where $Y = [\Delta O_q \;\; \Delta O_p \;\; \Delta rts]'$, $B_i's$ are matrices of unknown structural coefficients.

Y_t can consist of the unobservable disturbances and be represented by:

$$Y_t = A(L)U_t, \quad \mathrm{Var}(\mathrm{U}_t) = I \qquad (2)$$

Y_t has a unique Wold-moving average representation:

$$Y_t = C(L)V_t, \quad \mathrm{Var}(\mathrm{V}_t) = \Omega, \quad \mathrm{C}_0 = I \quad (3)$$

To obtain $C_i's$, we can invert the estimated coefficients, after estimation the vector autoregressive representation of Y_t. Comparing equation (2) and (3), one can obtain:

$V_t = A_0 U_t,\ \text{and A}_\text{i} = C_i A_0,\ \text{i} = 1,2,...,\text{p}$

A_i can be solved when A_0 is known, since C_i is obtained by inverting VAR's estimated coefficients. In this paper, A_0 is 3*3 matrix; therefore, the unique determination of the nine elements of A_0 require three independent restrictions.[4] Therefore, we need three restrictions to solve the A_0. In this paper, we assume that oil price shocks and RTSI shocks have no long-run effect on the China import Oil demand and RTSI shocks have no effect on oil price in the long run.[5] Using there restrictions, along with those restrictions provided by the variance covariance matrix, can be determined the A_0 matrix and therefore get all A_i matrices. Finally, on can figure out the process of Y_t form equation (2) under having the matrices of U_t and $A_i's$. Our purpose is to use the impulse response functions and variance decompositions to capture the important dynamic characters of the empirical model and the sources of fluctuations.

Analysis of Empirical Results

Unit Root Test and Johansen Co-Integration Test

Before proceeding with our estimation, we need to determine the stationary of data. We employ the conventional Augmented Dickey-Fuller (ADF) unit root test to examine the integration properties of the quantity of China oil imported, oil price and RTSI. The lag of unit root test was determined by minimal Akaike Information Criterion (AIC). Both statistics of $\tau_\mu$and τ_τ show that all variables are non-stationary (i.e. I (1) process) except that O_q variable in τ_τ statistics is stationary in 5% (see table 1). However, it fails to reject the null in 1%. To avoid the possibility of spurious estimation from the structure VAR model, we will question the co-integration among the quantity of China oil imported (O_q), oil price (O_p) and RTSI (rts) given the fact that we fail to reject the I(1) null for data. We therefore apply the multivariate co-integration techniques provided by Johansen (1991) to examine the existence of a long-run relationship between the previous three variables. The lag order of the level VAR is selected by minimal AIC and it suggested that the optimal lag order is 3.

Table 2 illustrates the results of the co-integration test which were derived using the

[4] The variance covariance matrix $A_0' A_0' = \Omega$ provides six restrictions.

[5] According the report of National Center for Policy Analysis, the world's oil supply will not be exhausted until the year 2056 (David, 2003). In addition, China's oil demand has not reduced because of the oil price greatly rises from past history, and the oil demand of China is mainly influenced from Chinese economic growth, not from RTS. Therefore, we assume oil price and RTS have no effect on China's oil demand in the long-run. At the same time, the factors of affecting oil price may be due to the oil demand of China or depreciating dollars, not RTS.

Johansen method. Both the maximum eigenvalue $(\max\lambda)$ and the trace statistics demonstrate the existence of non co-integration among variables. The finding of no co-integration implies that there is no linear long-run equilibrium relationship among variables. Therefore, the VAR model can be applied to examine the sources of RTSI fluctuations.

Table 1: ADF Unit Root Test.

Level	τ_μ	τ_τ
O_q	-1.200 (3)	-3.596* (3)
O_p	0.801 (0)	-1.401 (0)
rts	-1.109 (1)	-2.418 (4)
Diff		
O_q	-10.520*(2)	-10.487* (2)
O_p	-10.821*(0)	-10.960* (0)
rts	-10.382*(0)	-10.344*(0)

Note: The lag order of ADF model is in brackets which obtains by min AIC.

Table 2: Johansen Co-integration Test.

$H_0:\gamma\le 2$	6.639	12.518	6.639	12.518

Notes:

1. Maxλ denotes the maximum-eigenvalue statistics

2. The critical values of the trace and the maximum-eigenvalue statistics are obtained from Johansen and Juselius (1990).

Variance Decompositions

The variance decompositions analyze the relative contribution of forecast error variance of each shock as a function of forecast horizon. It is a convenient measure of the relative importance of shocks to the system. Table 3 are reported by the variance decompositions of the quantity of China oil imported of SVAR for second, eighth, and fourteenth forecast

periods. For example, the fraction of the forecast error variance in the quantity of China oil imported attributable to a RTSI shock is 11.24 percent in the second forecast period. RTSI structural errors can explain 13.67 percent of the forecast error variance of the quantity of China oil imported in the eighth forecast period at their maximum. At the same time, the fraction of the forecast error variance in the quantity of China oil imported attributable to the oil price shock is 12.27 percent in the second forecast period, and these estimates are statistically significant.

Table 3: Variance Decomposition of the quantity of China oil imported.

	2	8	14
ΔO_q	76.49	74.42	74.42
ΔO_p	12.27	11.91	11.91
Δ rts	11.24	13.67	13.67

Notes: Each row gives the percentage of the forecast error variance of the quantity of China oil imported in a given month with respect to the structural error of the row variable.

Source: The estimates are derived from SVAR model.

Table 4:Variance Decomposition of the crude oil price.

	2	8	14
ΔO_q	13.76	13.68	13.68
ΔO_p	85.59	84.88	84.88
Δ rts	0.65	1.44	1.44

Notes: Each row gives the percentage of the forecast error variance of the crude oil price in a given month with respect to the structural error of the row variable.

Source: The estimates are derived from SVAR model.

Table 5:Variance Decomposition of the RTSI.

	2	8	14
ΔO_q	20.34	20.18	20.18
ΔO_p	1.46	2.30	2.30
Δ rts	78.20	77.52	77.52

Notes: Each row gives the percentage of the forecast error variance of the RTSI in a given month with respect to the structural error of the row variable.

Source: The estimates are derived from SVAR model.

The variance decompositions of crude oil price derived from SVAR model in table 4 are also robustly estimated. At their maximum, the fraction of the forecast error variance in the crude oil price attributable to the quantity of China oil imported shock is 13.76 percent in

the second forecast period. The structural errors of the quantity of China oil imported can explain the fractions of the forecast error variance of crude oil price. On the other hand, the fraction of the forecast error variance in the crude oil price attributable to a RTSI shock ranges from 0.65 percent in the second month to 1.44 percent in the fourth and eighth month of the forecast horizon, and these estimates are statistically insignificant.

Table 5 are listed the variance decompositions of RTSI. The quantity of China oil imported structural error contributes 20.34 percent of the forecast error variance of RTSI in the second forecast period. These estimates almost stay at 20.18 percent from the eighth to fourteenth forecast period. These estimates are statistically significant. By contrast, the fraction of the forecast error variance in RTSI attributable to crude oil price shock ranges from 1.46 percent in the second month to 2.3 percent in the eighth and fourteenth month of the forecast horizon, and these estimates are statistically insignificant. It may be that the quantity of China oil imported has a very strong relationship to crude oil price.[6] Therefore, the impact of crude oil price on RTSI had been explained on regression.

Impulse Response Functions

The impulse response functions reveal the dynamic effects of a positive one-standard-deviation shock to a variable on other variables. Figure 5 illustrates the responses of China oil imported, oil price and RTSI with respect to structural shocks came form China oil imported, oil price and RTSI, respectively. The magnitude of the shocks and the resulting impulse responses for 10 months of the forecast horizon are measured in terms of one standard deviation. It is interesting that the response of the quantity of China oil imported with respect to a one-standard-deviation structural shock to the oil price, the responses of the level of oil price to the quantity of China oil imported disturbance, and the responses of the level of RTSI to the quantity of China oil imported disturbance in Figure 5.

The quantity of China oil imported is affected negatively in the first forecast month by a positively shock in the crude oil price. The relationship between the quantity of China oil imported and the crude oil price in the first forecast month is negative because of the rule of demand. However, the second response of the quantity of China oil imported to the crude oil price is positive which corresponds to a strong oil demand of China, and the result is statistically significant. This effect seems to be smaller from the third forecast period.

The response of crude oil price to a one-standard-deviation structural shock in the quantity

[6] The quantity of China oil imported and the Price of West Texas Intermediate Crude have a statistically significant correlation coefficient that is 0.8730.

of China oil imported from SVAR model. The initial response of crude oil price to a positive structural error in the quantity of China oil imported is positive because of a strong oil demand of China, and it is statistically significant. The response becomes zero after the third forecast period. On the other hand, the response of RTSI to the quantity of China oil imported is also positive and statistically significant in the first forecast month. This effect also becomes smaller from the third forecast month.

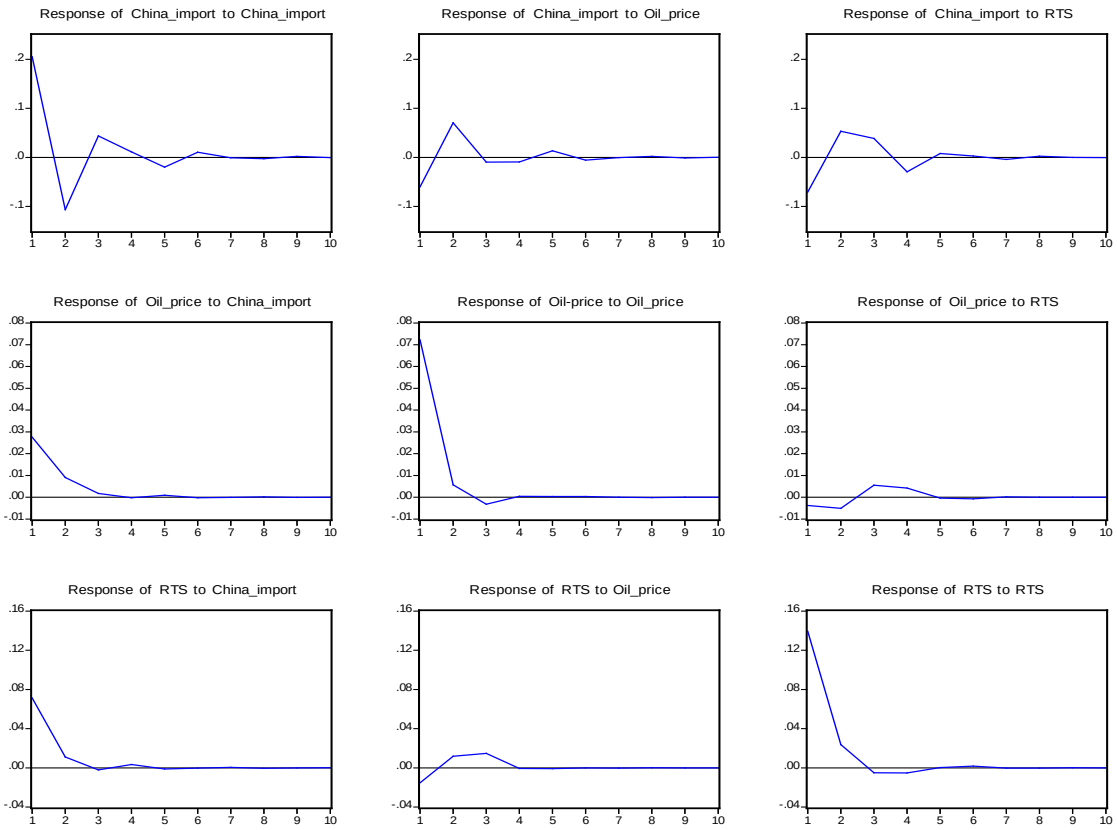

Figure 5: Impulse Response Function (Response to Structural One S.D. Innovations).

Source: The estimates are derived from SVAR model.

CONCLUSION

Two conclusions and economic phenomena implications emerge from these estimates and analysis. First, the evidence provided by the variance decomposition and the impulse response functions is conclusive with respect to the impact of the quantity of China oil imported on the global crude oil price. Second, the quantity of China oil imported also has an impact on RTSI and is statistically significant. However, the rising of the oil price is the main reason of Russia economic growth and political stability. Wu (2008) use the Granger Causality test and Impulse Respond Function to examine causality between crude oil price and per capital GDP and the impact of changing crude oil price on per capital GDP from 1992

to 2007. He found that the increase in crude oil price is shown to be a significant influence and positive impact on the growth rate of Russian per capital GDP. In other words, the global crude oil price was driven by the demand of China crude oil. And the rising of global crude oil price has a positive impact on Russian economic growth. Therefore, Russia economic growth seems to be driven by the demand of China crude oil. The results indicate that China oil demand has a strong explanatory power to global oil price and RTSI fluctuation from 1996-Jan to 2008-June.

ABSTRACT

This paper discusses a timely issue of trust in work relationships as a basis for collaboration in intra- and inter-organizational interactions and a driver for innovativeness, accordingly. In organizations, renewing of human capital enhances innovativeness and creativity. In general, managers and leaders are those who are liable for knowledge sharing, motivation and learning culture needed for renewal of human capital. Trust is a main element of social capital and a basic dimension of leadership for innovative organization culture. Especially in the knowledge era, trust building is seen as a leader's essential task, especially in knowledge intensive organizations. Vitality and innovativeness in organizations are fostered through 'leadership by trust'. In the empirical study, the data includes stories collected by a method of empathy-based stories and analyzed by content analysis and analysis of narratives. The paper discusses actors' experiences and perceptions of trust in intra-organizational relationships and how trust is related to organizational culture to foster innovativeness. More specifically, the purpose of this paper is to discuss how muteness and the 'habit' of unopen communication in Finnish workplaces might be a block hindering trust building and restoring of it.

Keywords: Interpersonal trust, trust building, trust breaking, organizational innovativeness, method of empathy-based stories

INTRODUCTION

Trust as a multidisciplinary issue has been widely studied over the last few years in different fields of science (Ebert 2009). However, trust is a complex, multifaceted phenomenon, and different conceptualizations of the nature of trust exist in interpersonal relations, for example, trust between peers, supervisor-subordinate trust, managerial trust and organizational trust (Möllering et al. 2004). Trust is a main element of human capital and a basic dimension of innovative organization culture. In Finland, the significance of trust in leadership is visibly recognized and highlighted by the Development Program of Finnish Innovation Fund SITRA and *leadership by trust* is seen as a source of national vitality and a key element of innovativeness (Nurmio and Turkki 2010; Savolainen 2011). Within organizations, the role of trust is crucial when generating social capital and fostering job satisfaction, organizational behaviors and

commitment, turnover and job performance (e.g. Lewicki et al. 2006; Bijlsma, K. and Koopman, P. 2003).

In leadership, trust is seen as the essential element of intra- and inter-organizational social system, as a 'building block' and connecting 'device' of relationships. Trust enables more open interpersonal communication in groups and organizations thus contributing to information and knowledge sharing in network relationships (Savolainen 2010). Trust is often taken for granted at organizational level and in interactions until it is broken. Effects and consequences of trust are many such as promoting of adaptation to new organizational forms, for example, to network relations, and even crisis situation, flexible organizing of groups, reducing negative conflicts, and decreasing transaction costs. On the contrary, if a leader refuses guidance and support and criticizes the followers, trust collapses.

The purpose of this study-in-progress (aimed to be a doctoral dissertation) is to increase and deepen understanding of the development, maintenance and repair of dyadic trust within the Finnish organizational contexts. First, the research aims at describing how leaders and subordinates describe their experiences and perceptions of intra-organizational trust and distrust. Second, the study poses to questions how leaders and managers enact on building and sustaining trust in organizations and how leaders develop trust-building and -repairing skills to enable innovativeness in the organization. Hence, the issue is closely related to trustworthiness (Savolainen and Häkkinen 2011). Furthermore, the paper aims to discover whether the method of empathy-based stories (MEBS) can be applied to trust research.

THEORETICAL FRAMEWORK

Concept and nature of trust

Early trust researchers such as Deutsch (1962) depicts that trust comprises of a person's beliefs and expectations on how the trustee will behave. Rotter (1967), also one of the early trust theorists, has defined interpersonal trust as expectancy by an individual or a group that the word, promise, verbal or written statement of another individual or group can be relied upon. Recently, scholars have distinguished between relation-based trust which has an affective basis, and character-based trust which has a cognitive basis (Zucker 1986; Dirks and Ferrin 2002; Gillespie and Mann 2004). Relation-based affective trust refers to the role of emotions and the process of trust development; character-based trust refers to beliefs about another's trustworthiness (Gillespie and Mann 2004). In psychology trust is investigated in the levels of cognition, affection and behavior. According Jones and George (1998) the states of trust are conditional, unconditional and distrust and the experience of trust and the interplay of individual's values, attitudes, and moods and emotions is emphasized in the process. The key component of trust is willingness to be vulnerable. Mayer et al. (1995) have developed a model of organizational trust in which several characteristics of the both parties lead to trust, which is defined as:

> The willingness of a party to be vulnerable to the actions of another party based on the expectations that the other will perform a particular action important to the trustor,

> irrespective of the ability to monitor or control that other party. (Mayer et al. 1995, 712).

Trust is dynamic, volatile and contextual in nature (Lewicki et al. 2006, 992). The attributes of uncertainty, complexity and risk describes the concept. Trust involves a risk to become betrayed or wounded despite of the positive endeavours of trust in developing openness, and effective co-operation (Savolainen 2010). Uncertainty originates from the risk and expectations (Savolainen 2008, 3). Trust is about taking risk (McAllister 1995, 184) and involves willingness to take risk (Mayer et al. 1995). Thereby trust is exposed to blindness and deceptive action (Nooteboom 2003, 1; Ferrin et al.). Activities are based on knowledge, knowing and especially exploitation. Trust is 'fragile' and can be broken easily (Savolainen and Ikonen 2010, 2).

Trust is built in the course of time and of compatible words and actions (Mishra 1996, 268; Lewicki and Bunker 1996, 119). In addition trust is based on mutual, legal and psychological agreements. Trust development is a process and a psychological state (cf. Kramer 1999, 571) and functional state with different phases and levels. The process seems complex, non-linear, and non-straight forward with more of a wave like development (Laaksonen 2010; Savolainen, 2011; Ikonen and Savolainen 2010). McAllister (1995) have provided evidence for the fact that trust has cognitive and affective aspects (Lewis and Weigert, 1985). Trust can be founded on emotions and cognition of an actor. Cognition-based trust expresses rationalism and knowledge (McAllister 1996, 25-26).

Trust is a foundation for cooperation between organizational actors. Currently, virtuality and e-business extend fast emerging increasing challenges in building sustaining trusting relationships within and between organizations. They call for new approaches to organizational leadership such as e-leadership (Avolio et al. 2009). Successful relationships are seen to enable organizations to cope with levels of uncertainty in times of changes (Atkinson 2004). As to the development of trust, prior research has presented various perspectives on that except of the strategy process view which is not yet explored. Researchers have suggested models comprising stages (Lewicki and Bunker 1995; 1996) and interactive processes of trust development (McAllister, Lewicki and Chaturvedi, 2006, 1). According to Lewicki and Bunker (1996, 120) trust develops in three stages. They call the stages as follows: *calculus-based trust, knowledge-based trust and identification-based trust*.

The model is a linear type of progressive model and is criticized and questioned among others by Savolainen (2009; 2010; Ikonen and Savolainen 2010; see also Laaksonen 2010). She has elaborated a theoretical idea of integrating the LMX-theory of leadership 'making' by Graen and Uhl-Biem (1995) with Lewicki and Bunker trust model. Trust develops dynamically in relationships in three stages that also describe the changes in *the foundations of trust.* The development of trust proceeds from calculative-based to competence-based trust, and finally, to identification-based trust. The better the other party is known the deeper the relationship between the parties develops in the course of time. These two models can be linked with each other in the sense that they look at a developmental nature of relationships and are also

related to trust in relationships. Development is assumed to be progressive, i.e., relationships are seen to progress towards a deeper or more advanced level.

Both models are based on the same progressive assumption, which can be critiqued, as the process may not be linear in reality. It is the purpose of the study to explore the process. In the theoretical model, progressing towards a higher level of trust requires *reciprocal, continuous interaction.* This fits the trust definition adopted in the paper (Mayer et al. 1995). Integration of the leadership development model and trust-building model *synthesizes the two perspectives* for identifying three developmental stages of trust in leader-follower relationships: the alien-calculative, acquaintance-competence, and company-identification stages of. Therefore, the integration of the models forms in fact a way to study trust development *processually*, i.e., to understand and analyze the main dimensions, stages, features and factors related to the process and dynamics of how interpersonal trust develops between actors.

Leader-Member Theory

The theoretical framework of the study draws upon the Leader-Member Exchange (LMX) theory and the stage models of trust development (Graen and Uhl-Bien; Lewicki et al. 2006). The theoretical perspectives are integrated to form a way to study critically and understand the nature, main dimensions and factors of trust development. According LMX-theory which is used as a salient frame of this study, there is a unique relationship that the leader builds with each follower. Trust has a central role in this process. LMX-theory emphasizes the importance of interaction and communication but also reciprocal trust, respect and commitment. Trust building is essential in leadership and one of the leaders' tasks among others. That is why it is also feasible to talk about 'making leadership' and 'being a leader' in relation to Leader-Member exchange theory. The theory is applied in the study because the assumptions and interests are closely aligned with theories of interpersonal trust. The conceptions are relevant to use as a part of theoretical frame of current study, because leadership is seen as a process over time in LMX-theory (see also Scandura and Pellegrini 2008). Graen and Uhl-Bien (1995, 240) have stated building leadership into three phases of life cycle of leadership making: strangers, acquaintance and maturity. Mature partnership exchanges are not only behavioral but also emotional mutual - support, respect and trust empowers and motivates both (Graen and Uhl-Bien 1995).

LMX theory seems to be salient for this current study because of its useful concepts describing the development of leader-member relationship. In prior research, trust is examined within LMX framework (e.g. Brower et al. 2000). Generally, LMX theory is strongly developed by quantitative methods. In other words, the ontological and epistemological assumptions of most of studies concerning LMX theory so far are different from the methodology of our paper. However, the qualitative roots of studying leader-member exchange relationships do exist (Fairhurst 2007, 120); and theory can be build forward through different approaches by integrating results. A more constructionist approach in understanding LMX relationships provides an opportunity to gain in-depth understanding of the leader-follower relationship and

trust within it (see, e.g. Fairhurst 2007). The role of the framework is to form a pre-understanding on the topic in seeking answers to research questions.

METHODOLOGY

Qualitative approach

Trust research has a long quantitative tradition. In this study, a qualitative approach has been adopted, as the interpretive approach and qualitative methods have become more common in leadership research (Koskinen et al. 2005). This approach pursues descriptions of the phenomena studied and aims to gain understanding of the *perceptions* of actors, individuals and groups, in their own contexts. The starting point of interpretive research is the idea of an organization as a socially constructed reality. Therefore, this reality can be investigated from multiple and different points of view not excluding one another. The paper discusses the actors' perceptions of trust in intra-organizational relationships. In the empirical study, the data includes stories written by students, which are collected by a method of empathy-based stories and analyzed by content analysis and narrative methods (Eskola 1997b; Kovalainen and Eriksson 2008). We argue that the earlier results only provide an incomplete picture about the trust development in intra-organizational relationships.

Method of empathy-based stories

The method of empathy-based stories (MEBS) was developed in Finland in 1980s. The method is based upon the assumption that people can express their understanding of social situations and episodes in a form of a story rather than answering to researcher's questions (Eskola 1997a, 173). The advantages of MEBS are its ease of use, low price and quickness (Eskola 1977b, 32). Furthermore, it solves most of the ethical problems of trust research and the saturation of the data is reached rather easily. On the other hand, data never saturates, because in a sense a researcher can analyze the data from different perspectives over and over again. Nevertheless, MEBS provides both challenges and unusual possibilities of analysis. For example, the method facilitates the capture of cultural meanings of a particular situation, such as trust building or trust violating in the present study.

The empirical data of the study is collected by the method of empathy-based stories (MEBS) among students of the university. The empirical data includes stories written by students and these stories are analyzed by content analysis and narrative methods. MEBS provides both challenges and unusual possibilities of analysis.

Data collection

The stories were collected from 42 students of the course of Qualitative Methods in Business Research at the University of Eastern Finland, Joensuu Campus, in November 2010. In the beginning of the lecture, the students were guided by a few words of the theme of the study ("trust in leader-follower relationships") and they were allowed to use their imagination in empathizing in the situation of the frame story:

> Imagine, that you are working as a summer trainee accounting assistant at a local company. Marketing director Mr. Petri/ Ms. Petra Lumivuori behaved in a trust building/ breaking manner towards you. Describe what happened. [Translation M.I.]

Each student got one of the four variations of the frame story on a sheet of paper and was asked to continue the story for 10-15 minutes. The only background information required was the gender of the writer.
The study includes four (4) variations of the frame story:

A. Trust building by a male leader (11 stories)
B. Trust breaking by a male leader (12 stories)
C. Trust building by a female leader (10 stories)
D. Trust breaking by a female leader. (8 stories)

Narrative and content analyses

Narratives, or stories, are typical ways to clarify reality, and narration is close to normal speech (Kovalainen and Eriksson 2008). In fact, the human world is based on story-telling and listening and the stories and tales have become interests of research. Narrative research is interested in how people themselves interpret events and then, researcher interprets these interpretations. All in all, narrative research covers a multitude of possibilities to carry out research.

As a preliminary analysis, we have developed *metastories* from these individual stories focusing on trust building and trust breaking by selecting items that might be significant and relevant to the logic of the story (Eskola 1997a, 174). Then, these metastories have been analysed by content analysis. Content analysis (regarded as a qualitative analytical methodology) is often the first qualitative technique for analyzing qualitative data when other methods are also utilized. In the analysis of the stories we have concentrated on what changes in the stories in the variations. The method enables to capture cultural meanings of a particular situation such as trust building or trust violating in this case.

The data is analyzed holistically in qualitative research. During the analysis, the attention is drawn to essential issues and details on the basis of the theoretical framework and the research questions. In our interpretation, we have aimed at finding something that not said out straightly. As usual in qualitative research, the interpretation is more or less speculative.

FINDINGS

Preliminary findings of the study support the prior results of the research group (Ikonen 2010a; Ikonen 2010b; Ikonen and Savolainen 2010a; Ikonen and Savolainen 2010b; Häkkinen et al. 2010; Häkkinen et al. 2011) indicating that integrity, listening to subordinate, appreciating his or her opinion, and keeping promises are the main elements of efficient functioning relationship in organizations. These findings by themselves are quite unsurprising indicating

that informal discussion with subordinates, appreciation of their work and opinions and honesty are the most important elements of trust building. Furthermore, standing with subordinates and giving both responsibility and help are crucial in trust development in leader-follower relationships. These findings have been reported in other studies (Brower et al. 2000; Bijlsma and van de Bunt 2003; Gillespie and Mann 2004). The consequences of trust building appear reciprocity, mutual appreciation, motivation and positive emotions such as safety and boldness which can create the atmosphere more encouraging and foster innovativeness.

Our most interesting results, however, are found when we investigate trust breaking behaviors within our data. Surprisingly, gender differences were not emphasized in the stories but a kind of muteness and the 'habit' of indirect and unopen communication in workplaces. A typical reaction of a subordinate in a case of trust eroding seems to be *avoiding* discussion with the leader but telling to workmates:

Story B2: I am disappointed with the behavior of the marketing manager. In future, I will discount her words. I shared my disappointment with my nearest colleagues. [Translation M.I.] (Male account assistant and male marketing director)

Therefore, we need to ask how this kind of muteness and indirect communication in Finnish workplaces are related to trust building in leadership as a source of national vitality for competitiveness, and how it influences innovativeness. Is it a block or hindrance? Does this kind of atmosphere resist and hinder even sincere attempts to building and restoring trust? Evidently, interpersonal trust formation is a reciprocal process between actors, anyway. According to our data, competency is highly appreciated as an antecedent of trust in Finnish workplaces. Competency, or ability, is one of the dimensions of trustworthiness (Bijlsma, K. and van de Bunt, G. 2003) which is emphasized within our results. For example, if a leader refuses guidance and support and criticizes the followers, trust collapses:

Story B1: Mr. Lumivuori insisted that I have miscounted the marketing budget. Still, it is obvious that he is the one who do not understand the numbers. He has estimated the costs substantially low and now I am just wondering how a person who do not understand numbers at all could be in the position he is in a company. The situation was handled by CEO who clarified the reasons of calculations to Mr. Lumivuori. Yet he argued that I had given unclear reasons to him. [Translation M.I.] (Male account assistant and male marketing director)

However, it seems that few male subordinates are more determined to straighten out their differences strictly with their leaders whereas a few of female subordinates are tempted to discuss about these problems with their workmates. In general, building trust among leaders and followers in organizations takes time; yet, trust is tested in relationships and can be broken in a moment. Misunderstanding and miscommunication are common in work relationships (e.g. McAllister 1997). However, repaired trust can become more confident than trust that has never been tried:

Story D3: I discussed privatively with her explaining my point of view and gave reasons why her behavior towards me was inappropriate. In the discussion, the highly charged situation was settled down constructively which brightened up our mutual trust. [Translation M.I.](Male account assistant and female marketing director)

The preliminary findings indicate that the intra-organizational actors' perceptions of trust differ by position, tenure and gender. Interestingly, the perceptions of distrust were described with strong emotions and discrimination between organizational actors. The national organizational culture is strongly reflected in students' stories. The leaders are mainly responsible for the change of the organizational culture. On the other hand, gender differences are not emphasized in the current study. As managerial implications, the study shows, for example, that repaired trust can become more confident than trust that has never been tried. Leaders should be encouraged not only to build trust in their relationships with subordinates but also learn to sustain it as Scandura & Pellegrini (2008, 107) suggest. In conclusion, the results of the study shows that the method of empathy-based stories can claim to provide a richer and deeper view on interpersonal trust in renewing human capital. Especially, the method of empathy-based stories (MEBS) demonstrated a promising alternative for data collection concerning a mundane and complex phenomenon.

CONCLUSIONS

The findings imply that the role and practices of trust needs to be considered more carefully and dynamics of intra- and inter-organizational relationships understood more deeply, as the relationships may be multiplex. Arising the level of awareness of the significance of trust and developing trust building skills in organizations may remove obstacles in pursuing trusting network relationships (Savolainen 2010). For further research the paper suggests that trust development needs to be studied empirically in real life contexts. Despite increasing amount of research work on social and inter-organizational networks, it is the dynamics and processes of interpersonal trust development in relationships that are still largely unknown.

Practical implication is that trust is crucial to develop and encourage in organizations; in development of leadership skills building trust and showing trustworthiness cannot be overestimated in the current business environments making strong requests of cooperative abilities in daily leadership practices (Ikonen and Savolainen 2011). Practices of trust show also how intra-organizational trust in work relationships affects *inter*-organizationally, customer interaction, in this case (Savolainen, 2010). Dynamics seem to work through organizational climate, functioning of interpersonal relationships which involve also trustful behaviour towards peers.

The results of the study indicate that trust is crucial in knowledge sharing and acceptance of diversity. Currently, diversity is one of the main culture-related issues in business life. It is also to do with innovativeness. The fruitful environment for innovations emerges from cooperation

of different professionals and specialist working, for example, with same issues and problems. The success of innovative networks is based on expertise and knowledge sharing and ability to combine several perspectives and approaches. Innovations are often created in the interfaces of knowledge and for that trust building is crucial (e.g. Kansallinen innovaatiostrategia 2008).

THE CONCEPT OF TRUST IN ORGANIZATIONAL LIFE IN EXAMPLE OF POLISH ENTERPRISES[1]

Joanna Paliszkiewicz, Warsaw University of Life Sciences
Joanna_paliszkiewicz@sggw.pl

ABSTRACT

The concept of trust has become popular in public debate and academic analysis. In high income countries this interest is associated with concern for the decline of trust in governments and professionals, and in developing countries has been prompted by debates around the motion of social capital. Trust has been identified as a major factor influencing such thing as capital investment, relationship marketing, cross-cultural communication, learning and various types of cooperation. Trust management become also very important inside organization. The study will examine empirical research on organizational trust inside organization in opinion of polish managers. The research was done in 163 polish enterprises among 335 managers.

Key words: trust management, organizational trust, building trust

INTRODUCTION

Trust is a topic that has been studied a lot lately. The world in which we live has become extremely interdependent. Extremely high uncertainty has become the institutional context of postmodern societies, and therefore there is great need for trust and social capital. Trust enables people to live in risky and uncertain situations (Deutsch, 1962; Mayer et al., 1995). It provides the means to decrease complexity in a complex world by reducing the number of options one has to consider in a given situation (Luhmann, 1979; Barber, 1983; Lewis and Weigert, 1985). Trust can also be viewed as a kind of social capital that makes coordination and cooperation between people possible (Putnam, 1995; Misztal, 1996). Trust leads to successful relationships and improves communication and satisfaction (Anderson and Narus 1990; Doney and Canon 1997; Mohr and Nevin 1990; Morgan and Hunt 1994). It binds friendships (Gibbons, 2004), facilitates negotiations (Olekalns, Smith 2005), and even resolves international political conflicts (Kelman, 2005). It is a fundamental ingredient in any positive and productive social process. In the world of business, trust is key to successful transactions and long-term relationships (Bharadwaj, Matsuno 2006; Koehn, 1996). It has even been proposed as an alternative form of control in place of price and authority (Creed and Miles, 1996).

Within organizational settings, trust has been demonstrated to be an important predictor of outcomes such as cooperative behavior (Zalabak, Ellis, Winograd, 2000), organizational citizenship behavior (Van Dyne, Vandewalle, Kostova, Latham, Cummings, 2000), organizational commitment (Aryee, Budhwar, Chen, 2002), effectiveness in organization (Zand, 1972; Zand, 1997; Lewis and Weigert, 1985; McAllister, 1995; Lane, 1998; Rousseau

[1] Article connected with the realization of research project entitled "*Orientation on trust and organizational performance*" (No. N N115 549238) financed by Ministry of Science and Higher Education in Poland.

et al., 1998; Nooteboom, 2002), and employee loyalty (Costigan, Ilter, Berman, 1998). To build employees' trust in an organization should be a desirable goal for all employers (Zhang, Tsui, Song, Ch, Jia 2008).

The aim of the article is to define elements of the trust in organization, which influence on trust building among managers and subordinates and to present conclusions from the research connected with this topic, made in polish enterprises.

CONCEPTUAL BACKGROUND OF TRUST

Trust as an individual future

Viewed from the individual level, trust is best understood by looking at the psychology of the person. Such a perspective can explain why a person trusts and why trust declines or increases (Tyler & Kramer, 1996). Personality psychologists such as Wrightsman (1966) and Rotter (1967) have viewed trust as a personality trait that reflects the general expectancies of the trustworthiness of others. These expectancies are relatively stable dispositional characteristics that depend on personal experiences and previous socialization. This observation also confirms Luhmann (1979). According to him risk and some information about the potentially trusted person or situation are seen as necessary conditions for trust to exist. J.R. Gibb (1978) a psychologist has created theory that trust is instinctive, and, as a feeling, is so close to love. Trust is also regarded as an attitude, which is neither subjective nor objective, and does not simply involve mechanical influences from the environment since it has to be learned (Luhmann, 1979). Viewing trust as a psychological state implies that people vary in terms of when and how much they are willing to trust (Das & Teng, 2004). Such willingness to trust, according to Tyler and Kramer (1996), is based on people's estimation of the probability that those trusted will reciprocate the trust.

Trust as a part of relationship

Lewis and Weigert (1985) stress that individuals would have no occasion or need to trust apart from their relationships with others. This assertion emphasizes the sociological function of trust instead of its supposed psychological function. Trust is an essential ingredient in the initiation and maintenance of stable social relations, just as exchange obligations promote trust (Blau, 1964). Barber (1983) identifies three kinds of expectations in relation to trust: (1) an expectation of the persistence and fulfillment of the natural and social order, (2) an expectation of the technically competent role performance from those involved with an individual in social relationships, and (3) an expectation that partners in interactions will carry out their fiduciary obligations and responsibilities. The three presented perspectives on trust as an expectation highlight trustors' beliefs that the trustees are good and honest in dealing with the goods, material or non-material, entrusted to them despite their ability to cheat or betray the trustors. Trust is partially a product of people's capacity to assess the trust- worthiness of their potential partners (Sheppard & Sherman, 1998).

Commonly, trust has been viewed as an expression of confidence between the partners in an exchange or a relationship of some kind (Bateson, 1988; Garbarino and Johnson 1999), a

belief that no partner to the exchange will exploit the other's vulnerability (Dwyer and Oh, 1987), or the willingness to rely on the other party (Moorman, Deshpandt, and Zaltman 1993). Similarly, trust has been defined as positive expectations about another party's motives in situations entailing risk (Das and Teng 1998).

Lindskold suggests that there are four different kinds of trust, which exist in any relationship. These relate to the following:

- objective credibility (It can be viewed in terms of whether that person's or group memebrs' words can be believed, and whether their actions correspond with their words);
- the attribution of benevolence (examines the motives of an individual's actions);
- non-manipulation (based on the perceived level of self interest of the party);
- costs for lying (balances the costs of deceit against the possible gains).

In organization trust facilitates more open communication, information sharing and conflict management. Trust is believed to be critical as it is seen to increase predictability, adaptability, and strategic flexibility. In general trust is seen to reduce transaction costs such as management costs, internationalization costs, social complexity. It also paves the way for informal network collaboration and collaborative innovation. It is also acknowledged that trust may be a critical factor in enhancing business performance and a source of sustainable competitive advantage (Seppanen, Blomqvist, Sundqvist, 2007).

Trust is not static; it is a dynamic process that evolves according to the development of the relationship (Porras, 2004). Lewicki and Bunker (1996) established a model of trust in three levels linked in a sequence where, once trust has been established in one level, it moves to the next level. Those levels of trust are calculus-based, knowledge-based, and identification-based. At the calculus-based level, parties fear punishment, but also anticipate the rewards from preserving trust; in other words, trust is based on a calculus of costs and benefits. Knowledge-based trust develops over time in the permanent contact between participants; it is "grounded in the other's predictability - knowing the other sufficiently well so that the other's behaviour is anticipatable. Knowledge-based trust relies on information rather than deterrence" (Lewicki, Bunker, 1996). Identification-based trust is "based on identification with the other's desires and intentions" (Lewicki, Bunker, 1996). At this stage, parties know each other and may anticipate the reactions of the other participant; thus, they can act for the other. Ultimately, high trust implies an expectation that a relationship will continue in the future.

Trust is highly relevant when the trustor depends on the trustee's future action(s) to achieve her own goals and objectives (Lane, 1998). For trust to develop, it is required that the trustee does not indulge in opportunistic behaviour, so that the trustor can put herself in a vulnerable position with regard to the action(s) of the trustee. This requires a stable normative frame. In other words, for trust to be possible, the trustor needs to believe that the trustee wishes to continue the relationship into the future (Lindenberg, 2000; Hardin, 2002).

For interpersonal trust to be built in long-term work relations, both individuals need to have their actions guided by a stable normative frame. According to Six (Six, 2007) there are four operative conditions that play an essential role in stabilizing normative frames:
(1) the suspension of opportunistic behaviour, or the removal of distrust;
(2) exchange of positive relational signals;
(3) avoiding negative relational signals, i.e., dealing with trouble;
(4) the stimulation of frame resonance, or the introduction of trust-enhancing organizational policies.

An organization needs to ensure all four conditions, but depending on the particular environment it operates in, the emphasis may differ. The more an organization meets all four conditions, the more likely it is that interpersonal trust can be built successfully in the work relations within it (Six, 2007).

Trust as a part of social and economic exchange

Trust is essential in economic and social exchange. According to Blau (1964) social exchange is the voluntary action of individuals who are motivated by the returns they are expected to bring and typically do in fact bring from others. He wrote that the benefits involved in social exchange are not definitively priced in terms of a single quantitative medium of exchange. This is the reason why obligations in social exchanges are not specific, while economic exchanges are moored on a formal contract that specifies the exact amount to be exchanged. Though both exchanges conceptually differ, both depend on trust for their continuation (Buskens, 1998; Doney et al., 1998; James, 2002), and both exchanges involved varying amounts of uncertainty and risks (Molm, Takahashi, Peterson, 2000).

Viewed from an economic standpoint, trust is an expectation that people will not be exploited by others, which exists when there are no strong incentives for people to behave opportunistically (James, 2002). Hosmer (1995) refers to trust as the reliance by one person, group, or firm upon a voluntarily accepted duty on the part of another person, group, or firm to recognize and protect the rights and interests of all parties engaged in a cooperative endeavor or economic exchange. According to Anderson and Naurus (1990) trust is the firm' belief that another company will perform actions that will result in positive outcomes for the firms as well as not take unexpected actions that result in negative outcomes.
Tullberg (2008) argues that in most economic exchanges, not everything can be verified before the occurrence of a transaction, thereby making the elimination of risks impossible and thereby necessitating trust. For example, within marketing, customers need to determine the extent to which they trust the company and its personnel to make purchases and long-term relational commitments (Doney & Cannon, 1997). According to M. Sako (1992) trust can be treated as a state of mind, an expectation held by one trading partner about another, that the other behaves or responds in a predictable and mutually acceptable manner.

The concept of trust can be explain in different ways for example as an individual future, as apart of relationship and as a part of economic and social exchange, also we can look at definition of trust in different disciplines. For example, the economists define it as trusting the institutions and their accounts while the psychologists explain it with the reliable and

unreliable behaviour of the individual and the sociologists use it as the reliable, fair and ethical behaviour in interpersonal relations. Author (Paliszkiewicz, 2010) see trust as the belief that another party: a) will not act in a way that is harmful to the trusting firm, b) will act in such a way that it is beneficial to the trusting firm, and c) will act reliably d) will behave or respond in a predictable and mutually acceptable manner. Trust can be seen as a bridge between past experiences and anticipated future.

THE STRUCTURE OF TRUST

Trust has emerged as a critical construct in a variety of disciplines, and, as a result, there exist several different conceptualizations of the structure of trust.

Despite its importance in organizational research, the study of trust has not been without problems. There have been some inconsistencies in the conceptualization and measurement of trust in previous research (Bigley, Pearce, 1998; Dirks, Ferrin, 2002). The most serious criticism is the lack of agreement about the structure of trust, and in particular the inability of researchers to distinguish between the antecedents and the construct of trust itself (Bhattacharya, Devinney, Pillutla, 1998; Mayer, Davis, Schoorman, 1995). For example, Costa, Roe, and Taillieu (2001) conceptualized trust as a multi-component variable with three distinct but interrelated dimensions. These dimensions consist of propensity to trust, perceived trustworthiness, and cooperative and monitoring behaviors. This definition includes a dispositional variable, propensity to trust, as well as cognitive and behavioral dimensions. In order for the field to move forward, it is imperative that researchers maintain a clear conceptual distinction between propensity to trust, defined as an individual's general willingness to trust others, and actual trust or trusting behaviors (Mayer et al., 1995).

Variations in propensity to trust among people can be attributed to their developmental experiences, personality types, and cultural backgrounds (Mayer et al., 1995). Trusting propensity or trusting impulse could be specific or general – it could refer to a specific category of people or it could encompass all people (Sztompka, 1999).

As a stable factor, trust determines the likelihood that people will trust, just as it influences how much they trust others prior to the availability of any data about them (Mayer et al., 1995). Rotter (1971) argues that people's propensity to trust influences their levels of trust in their interactional partners, especially in cases when the former has limited knowledge about the latter.

In the model of initial trust formation by McKnight, Cummings, and Chervany (1998), propensity or disposition to trust is proposed to be one of the determinants of trusting intention. They identify two types of disposition to trust: faith in humanity and trusting stance. Faith in humanity refers to the belief that others are well- meaning and reliable; whereas trusting stance means that people believe that they will obtain better interpersonal outcomes by dealing with others as though they are well-meaning and reliable, regardless of whether those others are reliable or not.

McKnight, Choudhoury, and Kacmar (2002) define trusting intention as people's willingness

or intention to depend on their interactional partners. Willingness to depend (volitional prepared- ness to make oneself vulnerable to the trustee) and subjective probability of depending (perceived likelihood that one will depend on the other) form two distinct subconstructs of trusting intention.

Mayer et al. (1995) proposed the Integrative Model of Organizational Trust, a theoretical framework examining trust in an organizational setting involving two individuals: a trustor (the individual trusting) and a trustee (the individual being trusted). In their model, trust is defined as "the willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party" (Mayer et al., p. 712). Mayer et al.'s definition of trust has become widely accepted in the organizational literature (e.g., Rousseau, Sitkin, Burt, Camerer, 1998). Unlike past conceptualizations of trust, this definition separates trust from its antecedents. In Mayer et al.'s (1995) model, both the disposition of the trustor and the perceived characteristics of the trustee influence trust. According to this model, trust does not involve risk per se, but rather a willingness to engage in risk-taking with the trustee (e.g., sharing sensitive information). Thus, trust represents an intention to take a risk in a relationship.

In assessing the trustworthiness of interaction partners, people can use a set of criteria to come with a reliable assessment. These criteria or factors of trustworthiness (Mayer et al., 1995) include ability or competence (Barber, 1983; Luhmann, 1979; Mayer et al., 1995; McKnight et al., 1998), benevolence (Luhmann, 1979; Mayer et al., 1995; McKnight et al., 1998), integrity or honesty (Mayer et al., 1995; McKnight et al., 1998).

Based on the characterization of Mayer et al. (1995), parties in transactions are assessed to be trustworthy when they (1) have the required skills, competencies, and characteristics that enable them to exert influence within a specific domain – a description for the ability or competence criterion, (2) are believed to do good to trustors, setting aside an egocentric motive – thereby meeting the benevolence criterion, and (3) are perceived to adhere to a set of principles that trustors consider acceptable – a definition of integrity.

Sztompka (1999) also claims that people employ three criteria in estimating the trustworthiness of their transactional partners: reputation, performance, and appearance. Reputation refers to a record of past deeds; whereas, performance includes actual deeds, present conduct, and currently obtained results. Appearance also matters as one's look and self-presentation can exude trustworthiness or stimulate suspicion on the part of the looker. In the literature we can find also different models of trust a lot of them are static or take the perspective of the trustor only (for example, Mayer, Davis, Schoormann 1995). Zand (Zand 1972) is one of the few who propose a truly interactive model: "Let P denote one person and O the other. If (1) P lacks trust, (2) he will disclose little relevant or accurate information, be unwilling to share influence, and will attempt to control O. (3) Assume O also lacks trust, (4) perceives P's initial behaviour as actually untrusting, and (5) concludes he was right to expect P to be untrustworthy; then (6) he will feel justified in his mistrust of P. Since (7) P sees O's behaviour as untrusting, he (8) will reinforced in his initial expectation that O would not be trustworthy and (2) P will behave with less trust than when he entered."

Some features of trust were presented by A. Argandoňa (1999):

- It is interpersonal: between concrete individuals;
- Situational rather than global: trust is placed in one particular person;
- Voluntary: properly, trust must spring from choice and cannot be compulsory;
- Fee, since no party can (sufficiently) control the other party's behavior;
- Committed, since each party depends on the other (without being able to control her);
- Conscious: each party is aware of the other party's trust;
- Vulnerable, because betrayal or breach of trust are possible;
- Relevant, in the sense that the consequences of breach of trust by one of the parties cannot be considered insignificant by the other;
- Dynamic or temporal, because it evolves over time: trust is established, grows, diminishes and dies;
- Action oriented, implicit in the goal of the alliance;
- Uncertain, since before the alliance is established it is possible to question the reliability of the other party and, once it is under way, the question is whether the other party will have change of heart and betray the terms of the relationship;
- Based on communication, and
- Experimental.

Bidault and Jarillo (1997) argue that trust can be based on different sources. Contract establish a foundation for developing trust; ethics provides rules and values for actors to behave in different circumstances; the role of time and experience is important because trust increases with the number of transactions made by participants while familiarity relates to participants knowing each other before a transaction. Bidault and Jarillo (1997) consider trust as a coordinating mechanism that can make transactions cheaper, in the sense that, once trust has been established, contracts will not be needed between participants.

Nicholson, Compeau, Sethi (2001) define trust as confidence in the other party's reliability and integrity. Recently, some researchers in marketing have suggested that in addition to integrity and reliability (which they equate with credibility), trust also consists of a benevolence dimension (Ganesan, 1994; Kumar, Scheer, Steenkamp, 1995). A closer examination of the benevolence dimension reveals that it encompasses both friendship between partners and making sacrifices for the other partner (Ganesan, 1994). McKnight, Cummings, and Chervany (1998) also suggest that trust consists of two main dimensions: trusting intentions (i.e., willingness to depend on other) and trusting beliefs (i.e., believing that the other is benevolent and honest).

TRUST IN ORGANIZATIONS IN OPINION OF POLISH MANAGERS

The research was done in enterprises from Mazovia Province. The questionnaire was done among 335 managers from 163 companies from November 2010 to February 2011. The enterprises are the best enterprises according to Journal Forbes in Mazovia Province.
According to the author trust in organization consists of reliability, intention and abilities (Figure 1).

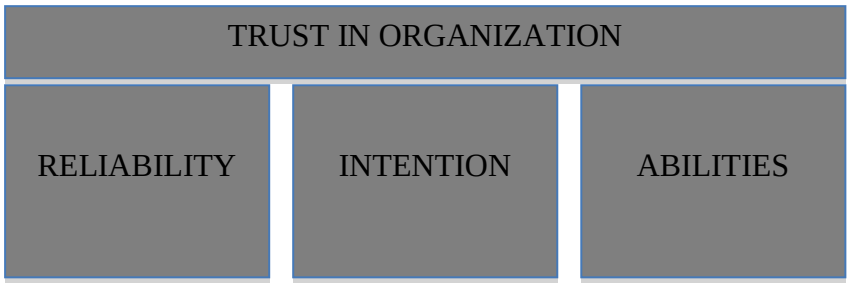

Figure 1: The model of trust in organization.
Source: Author's research

Reliable means capable of being relied on. In the table 1 there are presented questions which were used to check opinion of managers about reliability in organization. The possible answers for the questions were: 1 - I strongly disagree, 2 - I disagree, 3 - I do not know, 4 - I agree, 5 - I strongly agree.

Table 1: Questions connected with reliability.

No	Reliability
1.	I trust my subordinates
2.	All employees are treated fairly
3.	Company cares about employees' interests
4.	Most people in company keeps promises
5.	People in company avoid the gossip and participation in an unfair criticism of others
6.	In company there are good relations between employees

Source: Author's research

After suming a points, the answers were divided into three groups. The best from 23 to 30 points, the medium from 15-22, and the weak from 6–14 points. The results are presented in table 2.

Table 2: Level of reliability.

Groups	Group I 23-30 points	Group II 15-22 points	Group III 6-14 points
Number of managers (in%)	52%	47%	1%

Source: Author's research

According to opinion of managers, 52% of them have a very good opinion about reliability in their organizations, 47% medium and only 1% weak.

The next element of trust in organization is intention. Intention is a course of action that one intends to follow. In table 3 there are presented question, which were used to check opinion of managers about intention in opinion of managers. The possible answers for the questions were: 1 - I strongly disagree, 2 - I disagree, 3 - I do not know, 4 - I agree, 5 - I strongly agree.

In this case the best answer for organization have 5 points, so the answer for the questions from 1 to 5, were accounting as follows: if the answer was 1 it has 5 points, for the answer 2 – 4 points, for the answer 3 it was 3, for answer 4 it was 2 points, and for an answer 5 – one point.

Table 3: Questions connected with intentions.

No	Intentions
1.	In dealing with others, people never should be too careful
2.	You should not trust other people until you do not know them well
3.	Most people will lie if it enable then to get something
4.	Employees in your company when the opportunity arises to gain something will be dishonest
5.	In these days in your company you can only count on yourself and only trust yourself
6.	In your company employees can openly talk about what they do not like, or how something should be changed

Source: Author's research

After suming a points, the answer were divided into three group as in the first case. The best group from 23 to 30 points, the medium group from 15-22, and the weak group from 6 – 14 points. The results are presented in table 4.

Table 4: Level of intentions.

Groups	Group I 23-30 points	Group II 15-22 points	Group III 6-14 points
Number of managers (in%)	20%	70%	9%

Source: Author's research

According to opinion of managers, 20% of them have very good opinion about intentions in their organizations, 70% medium and only 9% weak.

The next elements of trust in organization are abilities. Ability is the group of skills, competencies and characteristics that enable a party to have influence within some specific domain. In table 5 there are presented question, which were used to check opinion about abilities. The possible answers for the questions were: 1 - I strongly disagree, 2 - I disagree, 3 - I do not know, 4 - I agree, 5 - I strongly agree.

Table 5: Questions connected with abilities.

No	Trust: Building abilities
1.	In the company managers are primarily advisors and intellectual partners to subordinates
2.	In your company results are most important, the main concern is how to do the best tasks, the employees are very ambitious and driven to achieve
3.	Your company is implementing new ideas and improving work conditions
4.	In your company your employees feel accountable for their tasks and do not have to be monitored
5.	In your company staff for most of the time trying to be helpful to others and do not care only about self-interest
6.	Your company prefers a stand-alone risk-taking, innovation, originality

Source: Author's research

After suming a points, the answer were divided also in three groups as in the other cases. The results are presented in table 6.

Table 6: Opinion about abilities.

Groups	Group I 23-30 points	Group II 15-22 points	Group III 6-14 points
Number of managers (in%)	40%	58%	2%

Source: Author's research

According to opinion of managers, 40% of them have a very good opinion about abilities connected with trust in their organizations, 58% medium and only 2% weak.

At the end of analysis all elements were bring together and the level of trust was account. The results are presented in table 7.

Table 7: Level of trust according to opinion of managers.

Groups	66-90	42-65	18-41
Number of managers (in %)	**37%**	**63%**	**0%**

Source: Author's research

Among researched managers, most of them present medium level of trust – 63%. Very high level was identified in the group of 37% of managers. No one of them was in the worst group.
The research was done in the best enterprises, so maybe that is way the managers present so high scores and the good level of trust.

CONCLUSIONS, LIMITATIONS AND MANAGERIAL IMPLICATION

There are several reasons why the research of trust has long remained problematic. First of all, there has been lack of clarity of the key concepts such as trust and risk. The antecedents and outcomes of trust have also been blurred and the roles of trustor and trustee haven't been clear enough. Perhaps the interdisciplinary interest in trust is one of the reasons why

the concept of trust lacks clarity. Since trust research has spread to several disciplines, a single researcher needs to collect the bits and pieces of trust related studies in various disciplines and try to make his or her synthesis to add something new to the scientific discussion of trust. However, for a new researcher, trust as a research topic gives many possibilities. For example, trust is also one of the key concepts in the knowledge-based competition of the network era and has been kindly studied recently in computer science related areas. New technologies have raised the interest in trust all around the world. Examples of currently researched topics are studies questioning what make consumers trust a certain webside and how trust can be built in online buyer-seller relationships.

Several limitations to the proposed theory should be recognized. First, the theory presented here is limited to trust declared by managers to subordinates and further research is needed to extend it to other forms of trust such as trust in organizations or trust among all members of organizations. A second limitation is that the article focused on work relations within organizations, and the research was done only in the best enterprises.

The research contributes to the understanding of trust by proposing the method of measurement. The findings of the current study have implications for organizations. Some recent changes in the workplace, such as an increase in the use of project-based and virtual teams, require employees to form new cooperative relationships quickly, often based on limited information about the coworkers. Given this new reality, it is important for researchers and practitioners alike to explore how trust forms initially, and how it can be maintained over time. The interplay between perceptual and dispositional factors, the focus of the current research, represents one way for research that could be fruitful in gaining a better understanding of trust.

EXPLORING TRUST DEVELOPMENT IN MANAGEMENT STRATEGY WORK: AN INNOVATIVE WAY OF STUDYING AND FINDINGS FROM QUALITATIVE STUDIES

Asko Kinnunen, University of Eastern Finland, Finland
asko.kinnunen@uef.fi

Professor Taina Savolainen, University of Eastern Finland, Finland
taina.savolainen@uef.fi

ABSTRACT

This paper aims to bring the view of management innovations in organizations into discussion by presenting an innovative way and framework of exploring management strategy process from the perspective of trust development in strategy work. Trust in managerial leadership is seen as intangible, intellectual capital. It is defined as a skill, way of leading, and power for influencing. A more specific question is how trust develops in the strategy work of the top management.

This paper reports of a study - in early progress towards doctoral dissertation – that explores trust development in the strategy process at the top management level. As the perspective of trust and development of trust in strategy process (formation) are very scarcely studied so far both theoretically and empirically, the paper discusses and outlines a theoretical frame for studying trust in the strategy process. Preliminary findings based on qualitative data from top managers are presented.

Keywords: strategy process, strategy work, trust, ideology, strategy discourse

THEORETICAL FRAME OF THE STUDY

Introduction

Strategy work and trust development

In the paper, strategy work is conceptualized according to the well known model by De Wit & Meyer (2005, 8). Moreover, trust and the process of trust development in strategy work are explored from the relational perspective (Mayer et al., 1995). In other words, trust is seen to develop (be formed, sustained, and restored) in discursive interaction between organizational actors. Knowledge management, and sharing in particular, is linked to trust formation (Savolainen, 2008). Knowledge is ideological in nature and sharing at least partly relational in the sense of trust development. The aim of strategy and strategy work is commonly organizational change or transformation (De Wit & Meyer, 2005).

Knowledge transfer and sharing, trust, and strategy work are all constructed socially in discursive interaction at the boundary surfaces where innovations are developed as well. That is why discursive practices may provide answers to the question about the role of trust

and how trust develops in strategy work between top level managerial actors. Discourse is not only a language for strategic thinking or knowledge sharing per se but an action which, in turn, changes discourse, and goals, models and schemas, accordingly (Sveiby, 2010: De Wit et al., 2005; Ståhle et al., 2002; Kerttula, 2010).

Trust in managerial leadership is seen as intangible, intellectual capital. It is defined as a skill, way of leading, and power for influencing (Savolainen, 2010). Knowledge sharing is also discussed as related to trust and leadership in strategy making.

Cooperation between organizational actors faces increasing future challenges in building sustaining trusting relationships within and between organizations. Successful relationships are seen to enable organizations to cope with levels of uncertainty in times of changes (Atkinson, 2004)

Trust is dynamic, volatile and contextual in nature (Lewicki, Tomlison & Gillespie, 2006, 992). The attributes of uncertainty, complexity and risk describes the concept. Trust involves a risk to become betrayed or wounded despite of the positive endeavours of trust in developing openness, and effective co-operation (Savolainen, 2010; Mayer, Davis, & Schoorman, 2005). Uncertainty originates from the risk and expectations (Savolainen 2008, 3). Trust is about taking risk (McAllister, 1995, 184) and involves willingness to take risk (Mayer et al., 1995). Thereby trust is exposed to blindness and deceptive action (Nooteboom, 2003, 1). Activities are based on knowledge, knowing and especially exploitation. Trust is 'fragile' and can be broken easily (Savolainen & Ikonen, 2010, 2).

Trust is built in the course of time and of compatible words and actions (Mishra 1996, 268, Lewicki & Bunker, 1996, 119). In addition trust is based on mutual, legal and psychological agreements. Trust development is a process and a psychological state (cf. Kramer, 1999, 571) and functional state with different phases and levels. The process seems complex, non-linear, and non-straight forward with more of a wave like development with (Laaksonen, 2010; Savolainen, 2010b; Ikonen & Savolainen, 2010). McAllister (1995) have provided evidence for the fact that trust has cognitive and affective aspects (Lewis & Weigert, 1985). Trust can be founded on emotions and cognition of an actor. Cognition-based trust expresses rationalism and knowledge (McAllister, 1996, 25-26).

Researchers have suggested models comprising stages (Lewicki & Bunker, 1995, 1996) and interactive processes of trust development (McAllister, Lewicki & Chaturvedi, 2006, 1). According to Lewicki and Bunker (1996, 120) trust develops in three stages. They call the stages as follows: calculus- based trust, knowledge-based trust and identification-based trust. The model is a linear type of progressive model and is criticized and questioned among others by Savolainen (2008, 2010), Ikonen and Savolainen (2010). In addition McAllister (1995) argues that trust develops contextually based on cognition and emotions. Savolainen (2009) has integrated model of trust development by Lewicki & Bunker (1996) and LMX-theory of leadership development by Graen & Uhl-Biem (1995). According to Savolainen (2009, 4) integrated model of trust development includes following phases such as convenience, acquaintance and matured partnership phases.

Top managers play a key role in strengthening strategic competitiveness of the organization. They are not only influenced by other actors but also their own "black boxes" which may limit or stimulate their thoughts and ideologies. It is to be asked, what happens in reality in the manager's strategic thinking and action processes, and how it is related to and appears in trust development within TMT and between team members.
The top management is influenced by multiple actors and parties not only in side of the organization but outside during the strategy process as well. However, a top manager is exposed to different kinds of beliefs, ideologies, paradigms, schemas and mental maps, dominant logics and personal abilities in strategic management and leadership processes. In strategic thinking, this has an influence on the management. Additionally, it should be noticed that the thinking, reasoning and decision making of top management is restricted by their mental abilities (De Wit & Meyer, 2005).

In addition, top management is acting as an agent as explained in the agency theory. There is a remarkable risk of the conflict of interests which may have impact not only on strategic thinking and strategy forming but on strategic change as well. This aspect cannot be disregarded in interpreting the top management discourse considering how trust is developed in a strategy process.

TMT strategy work and innovations

Top management members emphasize innovation as one of the most important issue in the strategy work. Business Week´s annual survey of TMT in 2010 reported that 83 percent of TMT members said that "innovation will be a key part of our strategy". In addition they argued for innovation as a "top three strategy priorities" (Andrew, 2010).

Innovation is defined from different perspectives and thereof more explicit definition is required in this paper. As trust and trust development has not studied in the context of strategy work, particularly, using the concept of ideology as a research setting is ultimately innovative in its nature.

An innovative organization renews itself inside out as if itself (Ståhle et al., 2002). According to classical perspective innovation seeks technical or process improvement in order to boost efficiency and productivity (Roger, 2003). However, innovation is not only rational but also creative process in social and interactive context. Innovation consists of new idea, perspective, solution, way of working, or product. (Ståhle, 2002, 108).

Extension of definition indicates also importance of intellectual and social and human capital. Innovation develops at boundary surfaces where knowledge, interests, perspectives, ideas, procedures, and competences meet in an interaction. Thereof bases for innovation are laid on intellectual or human or social capital of people because social discourse and interaction gives birth to innovation. (Roger, 2003; Ståhle, 2002).

Knowledge based theory challenges classical innovation theory as knowledge is according to Sveiby (2010) alternative to product and competitive strategies as drivers of growth. Theory leads to be dependant of relationships and learning (knowledge). People are the actors. Value creating takes place when they transfer or convert knowledge either internally or

externally in interaction (Sveiby, 2010). Sveiby argues that value grows every single time when people transfer or convert knowledge. There has to be knowledge as much as possible,that is value free, for the ground of innovation (Sthåle, 2002). Interaction adds knowledge, and it is where people use their capacity and competence.

As knowledge is according to Polanyi (1958; Sveiby, 2010) private or personal or even beliefs with meanings the worlds are constructed in subjective system, and which does not represent common reality. That reality can be seen in actions of the actor. That leads to individual competence, capacity-to-act, in changing situations.

Interaction, and particularly discourse, between actors is vital not only for formation of strategy, transferring knowledge and developing trust but for developing innovations and ideologies as well. Innovative way of exploring trust development in the strategy work is to study that phenomenon from a perspective of developing ideologies and as ideology.

The concept of ideology is applied to top management strategic thinking presuming that a managerial ideology and reality are formed of intellectual, mental and ideological concepts. By them are meant cognitive, psychological and influencing processes through which reality with meanings are constructed in dynamically changing situations (cf. Gubrium & Holsten, 2000, 487; Savolainen, 1997). That is why in the research setting of the paper, trust development is suggested to be ideological in nature developing through analytical process of knowing and intending, a cognitive process of strategic thinking and reasoning for sense-making, and a psychological influencing process for building and sustaining trust. Within these processes constructed reality is an emerging process of communication and discourse.

Concept of ideology

The concept of ideology in organizational management (Savolainen, 1997) has been developed further and used appropriately in interpretation. Ideas are determined by a society. According to Boas (1973) ideas may born randomly or few have thought, written or discussed about them. Ideas may be pounded together by a logic or thematic coherence. In the discursive environment, ideas may emerge, grow and flourish, wither and mold or ultimately die. (Savolainen, 1997, 128).

Ideologies spread by authors propagating them. Secondly adopters embrace or become interested in the idea, ideology or doctrine. Ideology may model people´s mind, thinking and behavior. Finally ideologies may obtain canon. Ideologies may saturate to usable knowledge. The manager's black box is affected by three views being at the same time nested as following (Figure. 1.): intellectual, mental, and ideological views. The reality is constructed in interaction with these three views.

First of all, people can commonly think within adopted doctrines, paradigms or models. This intellectual view is called an analytical process of knowing and intending. Intellectual view shapes the ideology, that is to say, trust development in this case. The intellectual view includes dogmas, paradigms and models. Secondly, people are not only intellectual beings but they have mental views as well. That is a cognitive process of strategic thinking and

reasoning for sense-making including cognitions, abilities and mind-maps for driving the trust development. This view includes, for example, mind maps, schemas, dominant logics, beliefs, assumptions etc., which are learned by education, and also tools used. Thirdly the ideological view is a psychological influencing process for building and sustaining trust. That has activities, effects, influences (power-games) and consequences.

Figure 1: Trust development in TMT strategy process.

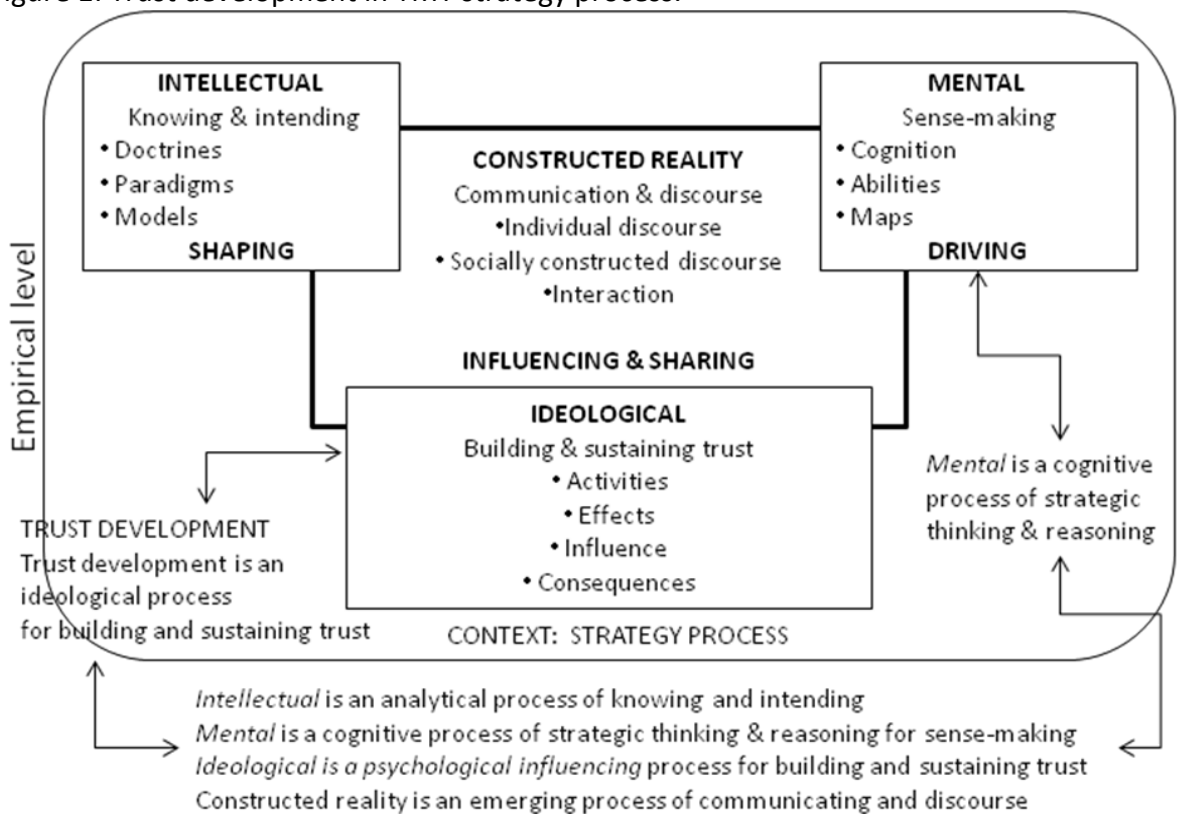

Figure 1. Framework of the study: Trust development in TMT strategy process (adapted from Savolainen (1997); elaborated by Kinnunen)

Empirical study and its findings support specific innovative trust development model, trust as psychological influencing process. As following specific issues from chosen cases are presented for support of concept.

RESEARCH METHODOLOGY AND DATA

The paper describes chosen case-reports based on empirical studies made in companies operating in health care, and media, and development aid industries. The health care company, case A, was in an internationalization process from domestic to Nordic. The media company, case B, was in a financial crises coping with turmoil, and the development aid organizations was in a change of leadership and management systems.

Secondary information and data were collected using participatory discussions, interviewing and observing the top management team members, MDs and CEOs. Data includes notes from interviews, researcher´s diary notes, made by the researcher acting as management member, and written distributed strategy material. The data is used to sett research frame

of the study - in early progress towards doctoral dissertation – in order to clarify pre-understanding of the phenomenon. Primary data will be analysed in order to explore trust and trust development as ideological process.

Figure 2: Sources of data by cases

	Sources of Data	Case A	Case B	Case C
1.	Senior management and CEO discussions/interviews	2	1	1
2.	Managing director/Business director discussions/interviews	10	4	5
3.	Management & leadership observation	20	10	5
4.	Strategy document analyses	5	2	5

Figure 2. describes the sources of data according to the cases and sources.

In summary, there are three conceptual views combined in Figure 1. Each view is actualized in interaction in constructed reality inducing to a new ideological understanding of trust development. Constructed reality is an emerging process of communication and discourse including sharing and influencing. Reality is constructed based on intellectual and mental, cognitive processes (visible or invisible realities) forming into ideologies. This leads the development of trust to emerge in the context of strategy process.

The management strategy work should be done, using participatory methods involving all key managers (cf. Mantere & Vaara). In each case the purpose of strategy meetings was strategy work including strategic thinking and strategy formation in order to manage strategic changes in each organization.

The themes of analyses were made, focused on trust and trust development from different perspectives. The research questions are formulated as following.

How does trust appear in the strategy process?

Two other questions have been asked for empirical analysis.

What processes and factors are related to trust development?

How does trust emerge and develop in the course of the strategy process?

Findings are presented according to issues found to be critical in trust and trust development in the context of strategy work.

PRELIMINARY FINDINGS

Intellectual factors shape knowing and intending

People can commonly think within adopted doctrines, paradigms or models (De Wit et al., 2005). Intellectual view shapes the ideology, that is to say, trust development in this case. The intellectual view includes dogmas, paradigms and models.

Intellectual aspect appears when some model, doctrine or paradigm is used in the strategy thinking and formation processes such for example as strategy tools. In addition

perspectives in strategy work may influence dramatically in trust development. In the individual thinking and reasoning process it shapes strategy thinking. At the same time it limits knowing and intending according to the ideology of the model or doctrine used. Strategy work includes all kinds of important actions which aim to ensure the mission of the organization and thereof its existence. Moreover, discursive approaches of strategy work are success factors in terms of motivating ones participation. That is to say that intellectual, models, paradigms and doctrines, are realized in interactive and discursive strategy work including self-actualization, dialogization and concretization (Mantere & Vaara, 2008).

Organization is for certain purpose. Purpose-oriented organization is goal-driven with leadership pursuing to meet needs of people (cf. De Wit et al., 2005). However, perspectives of proceeding with strategy work may vary occasionally as cases indicate.

Intellectual view shapes the ideology, trust development in this case. The intellectual view includes dogmas, paradigms and models. Strategy work is called as analytical process of knowing and intending.

> Company A was in an internationalization phase from saturated domestic to fragmented Nordic markets. According to the model of corporate scope, in other words, company and corporate growth dimensions, it was decided to grow within business through horizontal integration and withdraw from not core businesses. That is called the concept of market development. (cf. De Wit et al., 2005). In the change, like that, it was asked various questions such as how should the expansion happen in terms of perspectives? What organizational systems are required to manage the company?
>
> Management knowing and intending was shaped by models, corporate doctrines and paradigms of corporate growth which consulting partners used. Strategy tools were used to shape intellectual capacity to focus on key issues. Used concepts gave common language, process and agendas for the strategy meetings (Stenfors, 2007; Kinnunen, 2008). For the post merger process of integration it was called various mixed groups and teams to work for strategic steps to manage change.
> Chosen tools gave process and language for strategizing it was found in the study, however, that these were critical hidden agendas individually and between management members. That shows importance of individual communication skills and especially courage to take leadership despite of different opinions. Due to unfriendly atmosphere some pulled out into capsule or grouped with sole mates in terms of strategic perspectives. After some time management members grouped according to perspectives of strategic thinking (logical vs. creative), and strategy formation (deliberated vs. emerged), and strategic change (radical vs. continuous) arguing for chosen perspective. That indicates power unbalance between members and also possibilities of power games in terms of organizational systems and own positioning. In addition this is a sign of ideological view based on intellectual knowing and intending process.
>
> Despite of sound intellectual aspects, high participation and drive for future vision trust development was not supported collectively in the social reality and

constructed discursive interaction. In other words, trust found different forms and ways to be grounded. Trust development was based trough common intellectual base like models, doctrines and paradigms used. The base provided language and agenda for a discourse and thereof opportunities for relational and professional interaction.

Findings indicate surprisingly that mixed management groups (lower, middle and top) did not realized expected integration in knowing and intending from the perspective of trust development between management groups. That may be due to the fact that management skills concerning particularly internationalization were poor and self-actualization, dialogization and concretization did not reached point of saturation. In other words, integration included too much mystification, disciplining and technologization (Mantere & Vaara, 2008) just because of poor strategic skills. That did not develop participation in reality which, in turn, hindered management dynamics.

This case challenges participation where members reach required level of competence and skills. However, in the case corporate strategy was implemented despite of distrust between some management members. Trust towards organization was firm due to promising future prospects and realized acquisitions. Strategy tools (theirs ideologies) provided common ground for discourse and relational interaction which, in turn, resulted into trustworthy shared vision. Vision as issues and ideology, however, joined parties together. Trust on vision was shaped by using intellectual process of knowing and intending.

Power balance between individual management members and the board of directors ended up to changes in management like rotation and out-soursing. In terms of years all management was changed for reason or another. Summing up reasons it seems that hesitation in strategic action and poor dynamics of strategic leadership may be main reason to created distrust on the management. In addition poor competence in communication, strategic management and, particularly, in internationalization seems to be reason to hesitation and poor dynamics of some management members.
Trust development was built on intellectual process of knowing and intending based on analytical approach. In other words, models, doctrines and management paradigms like strategy tools, processes, language, and management ideologies.

There are still other issues to be considered developing trust as power for influencing such as mental drivers and all together constructed reality.

Mental drivers and hindrances influence on strategic thinking and reasoning

People are not only intellectual beings but they have mental views as well (see figure 1.). That is a cognitive process of strategic thinking and reasoning for sense-making including cognitions, abilities and mind-maps for driving the trust development. This view includes, for example, mind maps, schemas, dominant logics, beliefs, assumptions etc., which are learned by education, and also supported by used strategy tools (cf. De Wit et al., 2005).

The Case B have evoked critical question concerning the perspective of trust development and knowledge transfer. From strategic point of view both issues are ranked drivers of sustainable growth and development (cf. Savolainen 2010, 2011). Both of them necessitate openness as key value.

Results show importance of hidden agendas and interest. Different mind maps, schemas, dominant logics, beliefs, assumption, which are base on earlier experiences and learned thinking and reasoning model, may have impact on strategic thinking and reasoning. Secondly it may drive strategy work and formation in such a manner that all aspects and perspectives are not taken under consideration due to conflict of individual interests or agendas. That is due to unbalance of power between members and one´ s capabilities in communication and argumentation. In addition individual ability to think may be limited not only due to knowledge or reasoning but because of self-interests in valuing strategic issues.
Satisfaction surveys are to be criticized because their results seem to communicate of power unbalance and capabilities in open discursive interaction. People work relatively open manner but, in turn, they seem not to trust without hesitation, and rather communicate anonymously.

> Results indicate that from mental perspective trust building is driven by strategic thinking and reasoning for sense-making in the context. Some times cognition, abilities and mind maps hinder trust development. On the other hand, they promote feelings and different views during the process of strategic thinking and reasoning, for sense-making, supporting trust development
>
> In addition in case companies were carried regularly employee satisfaction surveys. People answered to questions anonymously which encouraged answering in inconsiderately manner as well. However, a conflict was found between stated values of the organization concerning openness and methodology of the surveys encouraging secretive ways of communication.
>
> There was also conflict concerning knowledge transfer as value creation point of view. Such personnel satisfaction surveys introverted organization culture encouraging individualism and power games. The survey enforces informant to communicate in unripe manner which, in turn, does not create value and trust in a value network.
>
> Instead of using leverage to create value through knowledge transfer, communication and interaction management accepts a risk to be wounded by unspoken words and judgement. That does not develop trust either between team members or individuals. From strategy work and strategy formation point of view knowledge is vital and even crucial in building trustworthy stakeholders relations and strategies.
>
> Sveiby (2010) argues that the value grows every single time when knowledge is transferred and conversion takes place. Knowledge transfer develops competence and strengthens values acting of all parties. This perspective makes the issue of

methodology of current employee satisfaction surveys even more critical. Should the feedback be curried out at the round table or face-to-face? It is also to be asked, should the organization accept talking behind as a character of trustworthy culture. Instead there should be trust enabling innovative and creative culture.

Findings support the fact that feedback is not discussion without real communication at the presence of parties where all communication elements can be observed and used. In used satisfaction surveys there are hidden messages and make too much noise or provide misleading information as communication theory explains.

Mental is a cognitive process of strategic thinking & reasoning for sense-making. That is argued to evoke open and bipolar discursive interaction. Methods should support the goal of trustworthy culture.

Strategy work as constructed reality is sharing

In all cases change or transition took place as a result of new strategy. Karvonen (2003, 3-4) has argued that understanding and knowing depend on ones position. That is to say that world appears and gives meaning from the position of an observer. All information may change the social reality.

Knowledge arises in a dialog with data and researchers orbicular hermeneutics reasoning process. That means collecting data, discourse and observation, analysing written material and diary notes and interpreting case as holistic phenomenon.

Social life is a reproduction of an experienced world. Discourse is a reflection of a social life (Meyer, 2009, 38). The data from a social research object is already grouped and interpreted by the society. Thereof reality is socially constructed. That can be studied by analyzing meanings and implications of language as an awareness of a reality and shared meanings (Meyer, 2009, 38). In reality education and experiences are combined in actual situations. People make sense and give meanings to events they experience, which are often combined into previous experiences (Heikkilä & Holma, 1990, 24-25; Kerttula, 2009, 17).

Hence, people aim to analyze themselves as a part of the society. Various changes enable creative rethinking and sense-making (Kaplan & Maxwell, 1994). These discursive and interpretive approaches are in connection with the situation and methods used.

In the case C strategy work was carried in co-operation and highly participatory way. Communication and discourse were observed and analysed. Specifically agendas and mind maps (mental), models and doctrines (intellectual), and in different forms were observed. Strategic work happened in interaction and discursive communication using new strategy tools.

Findings suggest that strategy tools not only create the foundation for strategic thinking and discourse but also thereby support trust development and communication in TMTs through paradigms and ideologies (see also Kinnunen,

2008). Specifically, trust development is enhanced by the updated strategy tools and management procedures used. They have positive impact on the individual, dyadic, inter- and intra-organizational trust. On the other hand forcefulness given to strategy thinking and discursive leadership in the strategy process, strategy tools act in constructed reality, as an intermediary means between invisible thinking, and visible actions.

In addition to this, not only individual abilities and communicate but also power balances and reflections of the agent´s interests were considered. Those factors construct a reality of an individual manager. The reality is represented by the language and behavior, which are reflections of thoughts and environmental or situational determinants. As a reflection of trust, experienced by the manager, consequences can be seen in dynamics and behavior. In other words this is seen in hesitation and willingness to take action and to interact.

However, 'the other side of the coin' in the development in managers' professionalism has created distrust among sponsors and civil activist in some organizations studied. The findings show that changes in the development of 'professionalism' in top management over time has created distrust among sponsors, members and civil activist of the volunteer organization. The change has jeopardised the bases of values and funding activities. The change of drifting apart has affected the sponsorship and key partners.
In addition, the transformations from non-governmental organization to professional consulting organization, has increased distrust among highly active supporters. However, intellectual processes for knowing and intending were shaped not only by ideologies of the strategy tools and processes but also by doctrines.

In addition communication was driving, and at the same time hindering, mental processes of strategic thinking and reasoning. Each of cases showed that management has also its own agendas and interests which has an impact on dynamics and behaviour of a manager. That has a critical effect on trust development. It is question about human capital. Constructed reality is an emerging process of communicating and discourse

DISCUSSION AND CONCLUSIONS

First of all, the case A reflects ideological aspects such as vision driving for internationalization and better corporate growth opportunities. The case B indicates ideological aspect like survival from economical crises and creating the new media concept. The case C reflects influence and sharing of language, processes and ideology provided by the strategy tool used. Hence, strategy was shaped in all cases by intellectual means. Trust development is supported by an ideological process. Hence, ideological process is a psychological influencing process for building and sustaining trust.

Despite of the fact of intellectual shapers of strategy, all cases indicate strong mental limitations concerning abilities, mind maps, hidden agendas in individual, interpersonal or

dyadic thinking and strategy formation issues. Hence, constructed discursive realities, in each case, included issues not supporting trust development. Mental is a cognitive process of strategic thinking and reasoning for sense-making.

The case A perspectives and hidden agendas were hindering discursive strategy work, even though, participation was high. Abilities and mental limitations did not drive for mutual strategy. The case B shows high participation and drive for new strategy and tremendous change in performance. However, mental abilities and mind maps hindered renewal after good start and power game of the middle management with own interest and agendas was realized. As a result transformation was slowed down. Trust development was based on participation and communication but distrust was supported by poor human capital concerning abilities to communicate on strategic level that management level expects. More explicitly trust is as a skill, way of leading, and power for influencing (Savolainen, 2010). Trust in managerial leadership is seen as intangible, intellectual capital.

Participation does not guarantee trust development if intellectual competence and mental abilities and transparence do not reach required strategic management level. The intellectual base provides language and processes for knowing and intending. The mental base provides opportunity to address results of own strategic thinking and reasoning, agendas and views for strategy work. However, interest, power games and power unbalances may hinder open communication and discourse.

It seems that intellectual aspect is easier to accept than mental. In the intellectual process trust development seems to be more process, doctrine and model driven. In the mental processes trust development seems to be more ability and cognition and psychologically driven where feeling and emotions and interest play key role.
Summing up findings from trust and trust development perspective using, concept of ideology, it can be argued that trust and trust development is an ideological influential process based on issues instead of singular thing or factor. Trust development process can be called thereof issue-based design. Trust develops about certain issue or ideology that is having active influential power. In other words singular things or process phase may not be that strategic in terms of trust development than strategic issues as factors.

Thereof trust can be high or strong enough to support trust leadership in strategic change or transformation in question. The case A indicates internationalization as an ideological issue, the case B indicates survival as an ideological issue and the case C indicates an ideological vision of modernization of management system.

Trust development has been argued to be a process with different stages, or contextual (Lewicki et al., 2996; McAllister et al., 2006), or integrated (Savolainen, 2009). Trust as an issue or ideology can be argued to be like a fire of a vision or good news like a gospel.
Ideology is a driver of motivation towards a desired direction or goal and excellence. Ideology is seen as a mean of influencing (Savolainen, 2008). Hence, if trust is an ideology, then it can be argued that trust is a way of influencing (influential power) boosting to better performance and developing competitive advantages as well.

Strategy work is a psychological influencing process for building and sustaining trust. In constructed reality strategy work is ment to be an emerging process of communication and discourse including sharing and influencing. That is to say that in interactive (discourse, communication, participatory) strategy work trust is shared and is a relational influencing power. Reality is constructed based on intellectual and mental, cognitive processes (visible or invisible realities) forming into ideologies. Intellectual and mental processes have to be realized in order to emerge trust in the context of strategy process.

Thereof the ideological view can be called a psychological influencing process for building and sustaining trust. That has activities, effects, influences (power-games) and consequences. Trust can be argued to be psychological influencing process as ideology.

Finally boundary surfaces (interfaces) of constructed realities are important not only to the birth of innovations but also to trust development in the context of strategy work. Interactive interfaces are even more inevitable for TMTs as theirs influence is critical in terms of development of ideologies.

This paper encourages continue the study with analyses of primary - in early progress towards doctoral dissertation – due to exceptionally interesting phenomenon and its strategic significance.

USE OF FINANCIAL INFORMATION IN SMALL BUSINESS MANAGEMENT IN POLAND - ENTREPRENEUR'S INFORMATION NEEDS AND THEIR ENDOGENOUS FACTORS*

Dr. Jacek Jaworski, Gdańsk School of Banking, Poland
jjaworski@wsb.gda.pl

ABSTRACT

The main problem of small firms is their low "survival". Limited access of small enterprises to reliable and well-prepared information about their condition is mentioned as the cause of that situation. Such information determines the rationality of decisions and the effectiveness in achieving objectives which each company sets ahead. One of the key types of information used in management is financial information. It concerns the resources and financial flows in the enterprise. It is the basis for investment and financing decisions that are the essence of each enterprise.

The main goal of the paper is to present the results of the questionnaire survey and their analysis conducted in mid. 2010 among managers of small enterprises in Poland. The survey was used to recognize the usefulness of financial information in decision-making, to diagnose information needs of entrepreneurs and to identify factors affecting these needs.

Keywords: information needs, small business management, information in decision making

INTRODUCTION

The importance of small companies in the modern economy cannot be underestimated. In 2008 they produced 37.1% of Polish GDP, employed 51,8% of all employees and accounted for 98,95% of active companies in Poland (Wilmańska, 2010). In other European countries the situation is similar.

Nowadays, the main problem of small firms is their low "survival". The limited access of small enterprises to reliable and well-prepared information about their condition is one of the main reasons for this situation. Such information determines the rationality of decisions and achieving objectives which each company sets ahead. In turn, one of the key types of information used in management is financial information. It concerns the resources and financial flows in the enterprise. It is the basis for investment and financing decisions that are the essence of each enterprise. Therefore, from the perspective of further development of small businesses, it is utmost important to recognize the degree of utilization of financial information by entrepreneurs in decision-making, and thus to diagnose their information needs. It was achieved by the questionnaire survey. It should be noted that such survey was conducted in Poland for the first time. The main goal of the paper is to present the results of this research.

* This paper is based on the research financed by Polish Ministry of Science and Higher Education within habilitation project No. N N113 292538 - *Use of Financial Information in Small Business Management in Poland - Current Status and Development Prospects.*

In addition to recognition and evaluation of manager's information needs, I have decided to identify their factors by testing the hypothesis that these needs mainly depend on education of the entrepreneur, the size and nature of a business activity and the life-cycle phase in which the company is. The discussion of the empirical research results was complemented by a brief description of the financial information and their role in management. The description was prepared on the basis of the review of the contemporary professional literature.

FINANCIAL INFORMATION AND ITS ROLE IN CORPORATE MANAGEMENT - LITERATURE REVIEW

Information Determinants of Enterprise Management

In theory of information (Przybyłowicz, 2008, p. 1), it is assumed that information is a primary concept. It means that defining information using simple terms is not possible. Therefore, the explanation of the meaning of information is made with reference to human intuition. Generally, information is defined as (Szymczak, 1993, p. 788): "notification of something, communicating something, message, indication, instruction...". This definition focuses on the utilitarian sense of information. Such an approach to information in economic sciences examines the management theory. It defines information in many ways:

- "information – it is communication, the communication, which eliminates the uncertainty" (Shannon, 1943, p. 17),
- "information is a knowledge transfer to the recipient of information, because its value allows him to reduce uncertainty" (Ackoff, 1969, p. 21),
- and concludes: "information is a kind of resource that can increase our knowledge about ourselves and the world around us" (Kisielnicki, Sroka, 2005, p. 15).

These definitions underlie a valuable and pragmatic theory of information.

In view of the first theory, information is assessed by determining its values for the decision. This theory allows us to maximize the benefits from the information during decision making [Rokicka-Broniatowska, 2002, p. 78]. Treating the information as one of the corporate resources, the most important commodity, whose value is assessed through the prism of usefulness in business processes, is a feature of the pragmatic theory. Such information is called economic information. Management information is a particular type of economic information. It allows us to carry out basic functions of management (planning, organizing, leading and monitoring). In this way, it reduces the uncertainty of particular actions and ensures the correctness of *a priori* decisions [Wrycza, 2010, p. 62].

The information is classified according to various criteria. Table 1 shows the most frequently mentioned classifications and characteristics.

Managers of modern companies try to obtain relevant and well-prepared information. The characteristics of such information are [Wrycza, 2010, p. 64]:

- relevance - the information must be relevant to the problem and help to solve it,

- detail - the information should be detailed enough to resolve a problem (accurate and precise); too many details create excessive costs, but too much vagueness increases the risk of making a mistake,
- completion - the provided information must include, as far as possible all aspects of the analyzed problem,
- reliability - the source of information must be credible and the information itself must be reliable and true,
- timeliness – the information should be provided within a proper time, it should primarily focus on future periods, but without losing connection with the present,
- adequate addressing – the information should be delivered to a proper and competent person who is responsible for solving a problem,
- proper transmission – the information should be provided by the appropriate communication channel (face to face, in public, via e-mail, traditional post, etc.).

Table 1: Classification of Information (Wrycza, 2010, p. 63; Kisielnicki, Sroka, 2005, p. 15).

Criteria	**Classification**	**Characteristic**
Source of the information	• internal, • external,	• the source is an internal system of organization, • the source is the organization environment,
Measurements	• quantitative, • qualitative,	• measurable; numerical description of the problem is possible, • immeasurable; numerical description of the problem is impossible,
Time	• historic, • current, • future,	• about the past (retrospective, *ex post*), • about the present, • about the future (prospective, *ex ante*),
Level of management	• operational, • tactical, • strategic,	• important for short-term decisions, • significant in medium-term decision making, • important for long-term decisions,
Area of management	• marketing, • financial, • R & D, • about workers	• concerning the market on which the organization operates, • related with financial categories, • concerning the undertaken studies and implemented innovation, • concerned with the use of human resources

The information with the above characteristics is an essential element of the decision making process. Its algorithm presented by J. Kumal (1976) includes the information flows intertwined with objects and decision-making entities:

1) decision situation (information about the decision-making situation),
2) decision problem (information necessary for solving a decision-making problem),
3) variants of the decision (information about possible developments in decision-making situation),
4) criteria for decision-making,
5) the decision (the solution to the decision-making problem),
6) the responsibility for a decision and the implementation of a decision,
7) information about the effects of decisions and their control.

Consequently, there are three types of decision-making conditions depending on the degree of knowledge about the problem (Mytlewski, 2010, p. 56):

- decisions undertaken in the conditions of certainty - the manager can correctly predict the results of all activities covered by the decision on the basis of the information,

- decisions undertaken in the conditions of risk – the information allows managers to estimate the probability of all consequences of possible decisions,
- decisions undertaken in the conditions of uncertainty – there are not known potential consequences of taken decisions, or there are no estimates of the probability of their occurring in the future.

In the context of the discussed conditions, the identification of information content, information needs and the implementation the proper information system are very important tasks for the manager. The realization these tasks, leads to more decision-making in certainty, and less decision-making in the conditions of uncertainty.

Types and Domains of Financial Information in the Enterprise

The corporate finance includes all economic phenomena related with the collection and spending funds on business activities of the company (Bień, 2002, p. 14). They also include the analyses and decision-making regarding the choice between the financial sources and their uses available for the company (Brealey, Myers, 1999, p. 31). It means that financial decisions are significant components in corporate management and they require support by relevant information.

The information, whose content concerns financial flows in the enterprise, may be called financial information. Such information carries messages and decisions concerning the formation of all economic phenomena related with the corporate finance. In the classification of financial information, multiple criteria can be used. Taking into account the usefulness of this information in management, the key criteria will be:

- the period for which the decisions are taken,
- the scope of those decisions.

As regards the first criterion, the future of the company is usually divided into two periods where decisions are taken (Brealey, Myers, 1999, p. 45; Bień, 2002, p. 25):

1) short term (up to 1 - 3 years) – operational management,
2) long term (over 3 years) – strategic management.

Taking into account the subject of management, financial decisions (information) can be classified into three areas (Ross, Westerfield, Jordan, 1999, p. 20; Bień, 2002, p. 21-22; Jaworski, 2010, p. 36):

1) capital budgeting – it is based on identifying ways of investing in the company assets;
2) building the financial structure – it is the result of the selection of the available financing sources (own and foreign);
3) working capital management – it means decision-taking determining the levels of current assets (inventories, receivables and cash) and their turnover rate in relation with the current liabilities payment deadlines.

The first two areas primarily relate with long-term decisions; as for the third area, the domain is short term.

In the short term, the company usually seeks to achieve a satisfactory profit which, in effect, it wants to transform into additional, unladed (free) cash flow (Bień, 2002, p. 16; Jaworski,

2010, p. 25). In this respect, in particular, the decisions taken by the company should be aided by information about:

- ability to generate profits (profitability),
- shaping the current and future revenue,
- and incurred and planned costs.

In addition to profit maximization, decisions in the area of working capital management should also include a second important task - the maintenance of liquidity (ability to regulate current liabilities). It is a very important task, because the loss of liquidity is the main cause of bankruptcy of today's companies (Ross, Westerfield, Jordan, 1999, p. 21; Jaworski, 2010, p. 36). Direct information about the current and expected liquidity should also be accompanied by:

- information about the demand for cash in the short term,
- information about the efficiency and effectiveness of management of current assets and liabilities.

In accordance to the widely accepted opinion (Ross, Westerfield, Jordan, 1999, p. 26; Jaworski, 2010, p. 25] the main long-term financial goal is to maximize the company's value. In this context, information about current and projected value of the company appears to be significant information for long-term management. This value derives primarily from the long-term financial performance and the relationship between assets and capitals of the enterprise. Therefore, relevant information in long-term management also concerns:

- profitability of investments,
- shape of the company's financial structure (the company's debt),
- cost of the capital used in assets financing,
- company's financial condition in relation to its competitors and business sector,
- and of course – expected financial results of the planned long-term activities.

EMPIRICAL RESEARCH AND ITS RESULTS

Research Methods

As a practice shows, small enterprises do not often have a system of providing a sufficient quantity and quality of information. Therefore, to optimize the cost of its acquisition, the information needs of managers should be identified carefully. For this purpose I conducted the questionnaire survey among 1008 small enterprises in Poland in mid. 2010.

The surveyed companies were selected according to the proportion resulting from the indicators in the general population in relation to the size of the enterprise, nature of the business activity and geographical distribution. It means that the selected sample can be regarded as representative.

The survey was conducted using CATI method (Computer Assisted Telephone Interview). I asked the entrepreneurs: what financial information they usually expect to receive before taking short-and long-term decisions. In both areas, the respondents had a choice between 7 types of information selected in the previous section of the paper (table 2).

The entrepreneurs chose, in their view the appropriate type of information and had to assess its importance in decision-making using a 1-5 scale. The evaluation could concern a

few types of information with the possibility of the multiple use of the same assessments. The main goal of the used scale was to characterize the subjective view of the entrepreneurs on the importance of information types in decision-making (1 – the least important, 5 – the most important). This numerical weighting allows for using the statistical measures for the assessment of the response's distribution.

Table 2: List of Financial Information Types Used in the Survey.

Short-Term management	**Long-Term management**
Information about: ➢ ability to regulate current liabilities (liquidity), ➢ ability to generate profits (profitability), ➢ efficiency of the activity, ➢ short-term demand for cash, ➢ current and future income, ➢ current and future costs, ➢ other information.	***Information about:*** ➢ level of debt, ➢ cost of capital, ➢ profitability of investments, ➢ current and future value of the company, ➢ company's financial condition in relation to its competitors and business sector, ➢ expected financial results of planned long-term activities, ➢ other information.

In addition to the main subject, there were some questions in the questionnaire which allowed me to extract the endogenous factors forming these needs: the entrepreneur's education, the size and nature of business activity and the life-cycle phase of the company. The structure of the surveyed sample according to the mentioned factors is presented in Table 3.

Table 3: Structure of Surveyed Entrepreneurs.

Partition	**Quantity**	**Percent**	**Partition**	**Quantity**	**Percent**
Size of enterprise			**Nature of business**		
Kept themselves	201	19.94	Services companies	439	43.55
1-9 employees	448	44.44	Commercial companies	302	29.96
10-19 employees	204	20.24	Production companies	147	14.58
20-49 employees	155	15.38	Combined business	120	11.90
Company's age			**Life-cycle phase***		
Up to 1 year	314	31.15	Entry phase	58	5.75
1 – 3 years	255	25.30	Dynamic growth phase	145	14.38
3 – 6 years	189	18.75	Stability phase	253	25.10
Over 6 years	250	24.80	End-stage phase	422	41.87
Entrepreneur's education					
Basic or vocational	30	2.98	Higher humanistic	91	9.03
Secondary vocational	85	8.43	Higher technical	333	33.04
Secondary general	229	22.72	Higher economic	240	23.81

*- life-cycle phase was based on the answers to questions about changes in income, profits and investment needs in the enterprise.

To examine the relationship between the diagnosed information needs and the above factors, I have used the chi-square compatibility test (Balicki, Makać, 2000, pp. 227-231). The mathematical aspect of the Chi-square test is reduced to calculate the statistics:

$$\chi^2 = \sum_{i=1}^{k}\sum_{j=1}^{l}\frac{\left(n_{ij} - \hat{n}_{ij}\right)^2}{\hat{n}_{ij}} = \sum_{i=1}^{k}\sum_{j=1}^{l}\frac{n_{ij}^2}{\hat{n}_{ij}} - n \quad ,$$

where:

l, k – kinds of first and second variables (entrepreneur's score for each kind of information and assumed factor),

n_{ij} - empirical numbers of the simultaneous co-occurrence of pairs of variables *i* and *j*,

$\hat{n}_{ij} = \frac{n_i \times n_j}{n}$ - expected numbers of the simultaneous co-occurrence pairs of variables *i* and *j*,

n - the number of all respondents' answers.

The calculated statistics is compared with the theoretical value of chi-square distribution (read out from the statistical tables for specific values *k* and *l* and the significance level). If χ^2 is less or equal to read value, then there is no reason to reject the hypothesis about the independence of variables. Otherwise, there are reasons for accepting the alternative hypothesis saying that the variables are dependent.

To determine the strength of the correlation between the examined factors and entrepreneurs' evaluation of information needs, I have used T-Czuprow and C-Pearson contingency coefficients (more: Makać, Urbanek-Krzysztofiak, 2001, pp. 152-162). Mathematical definitions of these coefficients are presented in Table 4.

Table 4: T-Czuprow and C-Pearson Contingency Coefficients (Makać, Urbanek-Krzysztofiak, 2001, p. 155)

T-Czuprow	**C-Pearson**
$T = \sqrt{\frac{\chi^2}{n \times \sqrt{(k-1)\times(l-1)}}}$	$C = \sqrt{\frac{\chi^2}{\chi^2 + n}}$

The values of both coefficients are in the range (0-1). The correlation between the examined variables is stronger when the coefficients' values are higher. For the purpose of this research it is assumed that (Barańska, 1999):

- the correlation is weak when both indicators are less than 0.30,
- the correlation is moderately strong when the indicators are in the range (0.30 – 0.60),
- the correlation is strong when the values of coefficients are higher than 0.60.

The significance level for chi-square distribution is set on 0.1.

For the overall evaluation of the survey results (the entrepreneur's responses), I used the structural analysis based on the central tendency measures (the arithmetic average, median and mode). These methods have also been applied in the description of the respondent's answer distribution according to the statistically significant diagnosed factors. The analysis results are presented graphically, which supplements the written description.

Research Results

Diagram 1 presents the global results of entrepreneurs' answers about information needs in short-term decision making.

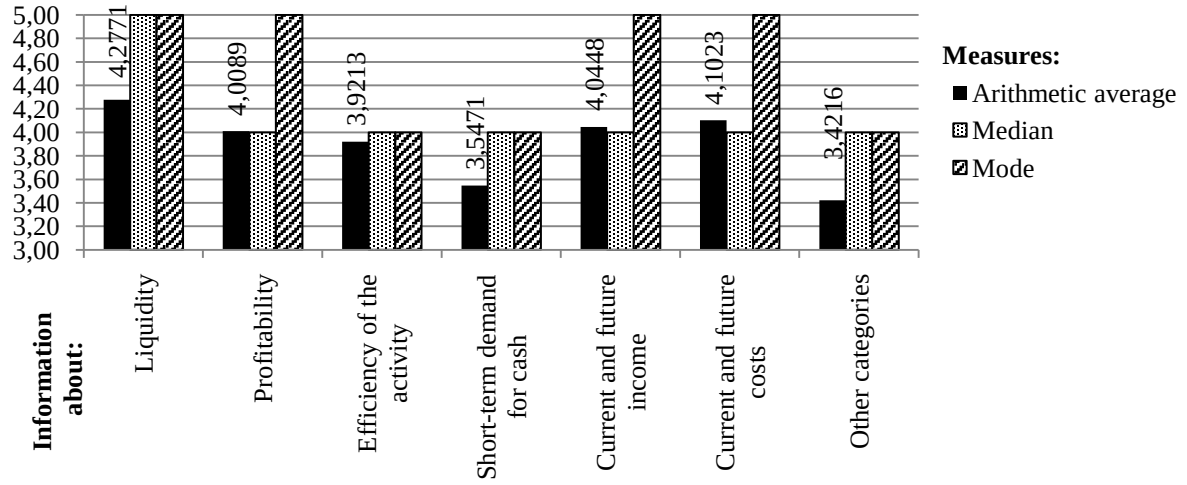

Diagram 1: Assessment of Information Types Expected in Short-Term Decision Making.

In all managers' opinion, the most important information in short-term management is about the ability of the company to regulate current liabilities (liquidity). The importance of that information was most frequently evaluated by entrepreneurs to 5.0 (mode). The same level is noted for median. The arithmetic average is 4.2771. The information about current and future costs obtained not much lower average score (4.1023). However, in this case, half of the ratings were less than or equal to 4.0 (median). Entrepreneurs, being equally important, found information about current and future income (4.0448). The ratio of incomes and costs or profitability of the enterprise is also significant (4.0089). Information about efficiency is less important in short-term decision making (3.9213). This last type of information was the most often assessed at 4.0 (mode). The information about future demand for cash is the least important for entrepreneurs in short-term management (3.5471). The same situation concerns other information (3.4216).

Summing up the results for short-term management, very high average scores for most of the assumed types of information should be noted (above 4.0). It means that small business managers attach great importance to short-term decisions, and in turn it causes high demand for all information about the achievement of short-term corporate goals.

Ratings for the long-term management are a bit lower (see Diagram 2). The information about the level of the company's debt and about profitability of investments has usually obtained the highest scores (mode: 5.0). The average assessment is 3.9740 and 3.9095 respectively.

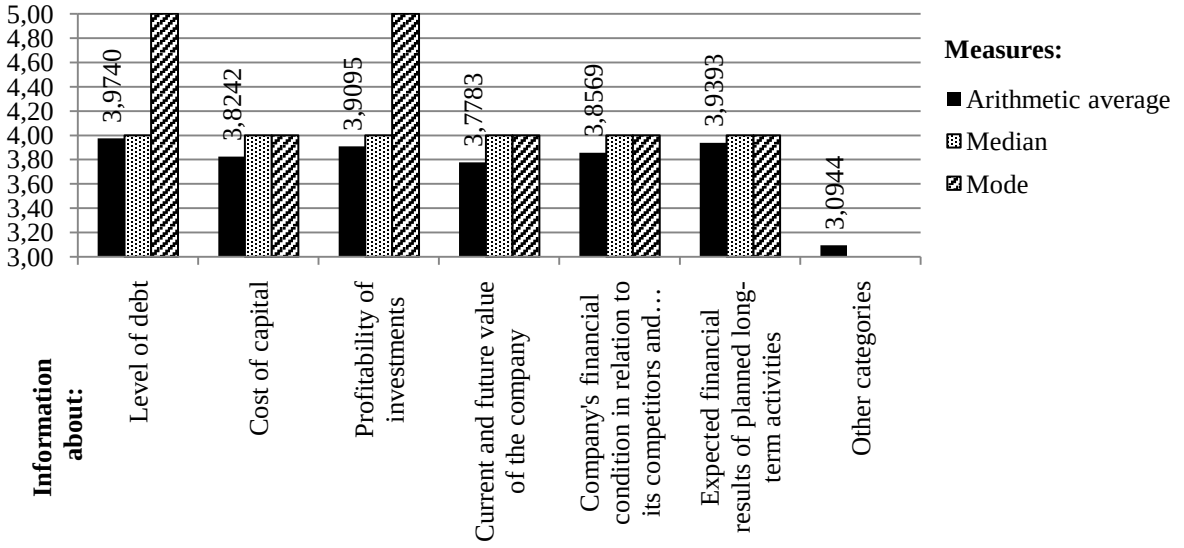

Diagram 2: Assessment of Information Types Expected in Long-term Decision Making.

The information about financial effects of the planned long-term activities received very high average scores (3.9393). Median and mode 4.0 mean that entrepreneurs assessed this area of information as very stable and balanced. The information about the company's financial condition (3.8569) and the cost of capital (3.8242) were rated similarly, but slightly lower. Some entrepreneurs pointed also other categories of financial information, but their importance rated quite low (3.0944; mode and median 3.0).

Table 5 presents calculations of Chi-square statistics and contingency coefficients for selected factors in short-term management.

The presented calculations show that the entrepreneurs' information needs depend mainly on the size of the enterprise. To some extent they are affected by managers' education. The weakest dependence can be observed for a life-cycle phase in which company is. For the rest selected factors (age of the company and nature of the business), the dependence does not exist.

Table 5: Influence of Endogenous Factors on Entrepreneur's Information Needs in Short-Term Management.

Dependence	Not exist	Not exist	Not exist	Not exist	Not exist	Not exist	Not exist
Factor	**Company's age**					**Theoretical** χ^2 = 18.55	
Empir. χ^2	7.78	9.74	6.93	8.21	10.01	10.53	7.64
Dependence	Not exist	Not exist	Not exist	Not exist	Not exist	Not exist	Not exist

In the case of the company size, it influences the entrepreneurs' responses in the five areas of financial information (liquidity, profitability, efficiency, costs and other financial categories). Entrepreneurs' education shapes their information needs in three areas - information about profitability, efficiency and demand for cash. However, the life-cycle phase only in two categories – information about the demand for cash and cost levels. In all cases of dependence, the correlation is weak: T-Czuprow and C-Pearson coefficients are less than 0.3. Diagrams 3 – 5 present distribution of entrepreneurs' answers for diagnosed dependencies.

The research clearly shows that the larger enterprise the more attention is paid to all types of information concerning short-term management. Differences in the assessment range are from 4% in the case of information about the demand for cash to 10% in the case of information about liquidity. Larger companies assess (3.6471 to 3.2571) the importance other information as higher. This indicates that the size of the company determines increased demand for information. The distribution of received scores for each type of information is the same as for the whole population (see Diagram 1).

The distribution of assessments, depending on entrepreneurs' education is considerably more diverse (Diagram 4). The highest rating for all dependent information is made by entrepreneurs with higher economic education, while the lowest by managers with higher technical education. Relatively high ratings are issued by entrepreneurs with basic and vocational education. From the three presented types of information, the most important is information about profitability (3.6296 – 4.2042) and the least important is about the demand for cash (3.2319 – 3.8033).

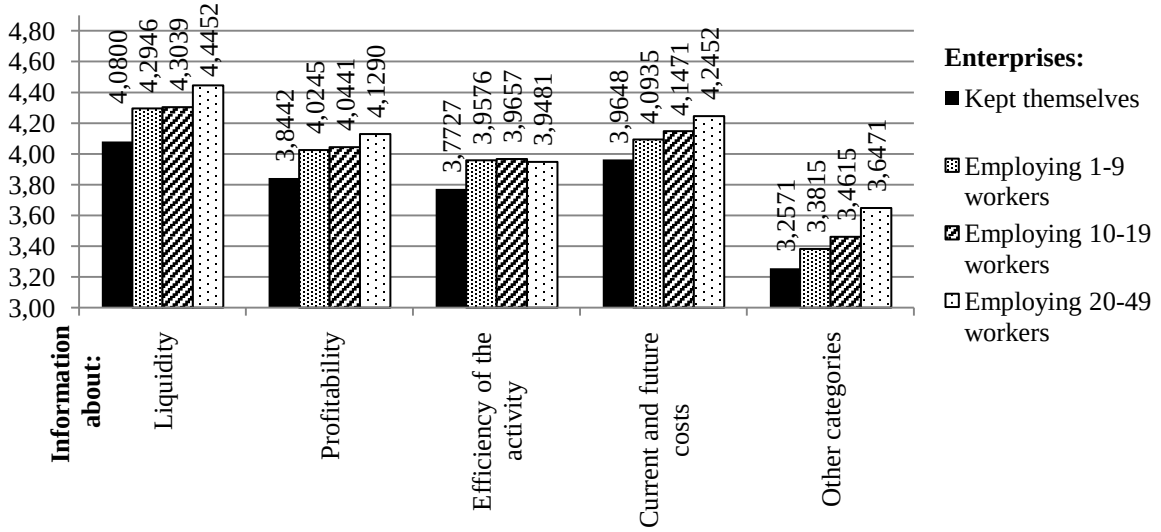

Diagram 3: Distribution of Assessment of Information in Short-term Management According to Size of Enterprise.

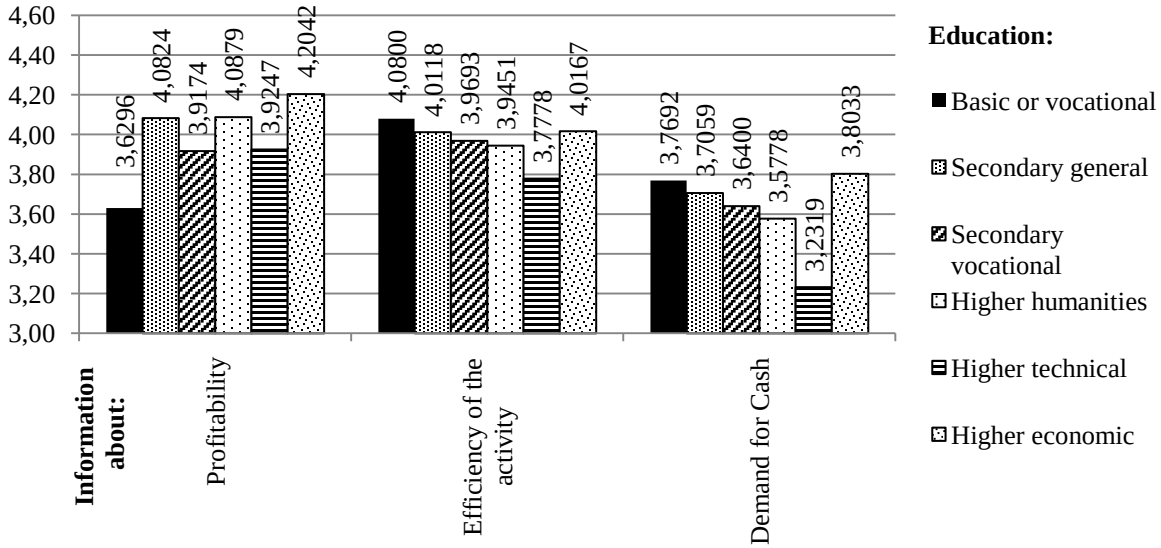

Diagram 4: Distribution of Assessment of Information in Short-term Management According to Manager's Education.

The life-cycle phase affects the information needs only in two areas (Diagram 5). For all companies the information about the costs level is more important. This is particularly true for companies in the entry and growth phases. In the stability and end-stage phases, entrepreneurs are especially interested in the demand for cash.

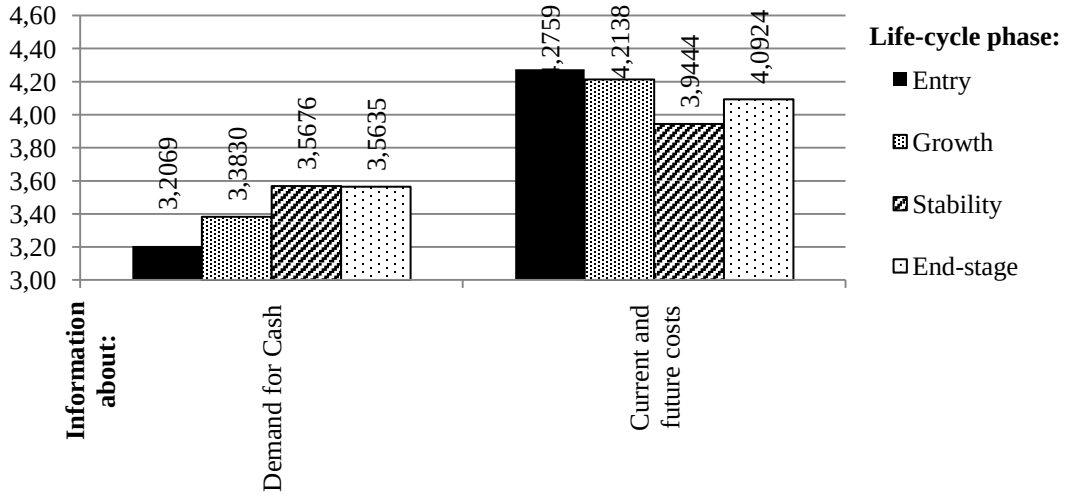

Diagram 5: Distribution of Assessment of Information in Short-term Management According to Life-cycle Phase.

Table 6 presents calculations of Chi-square statistics and contingency coefficients for selected factors in long-term management.

Entrepreneurs' information needs in long-term management, similarly to the short-term management depend on the size of the enterprise, managers' education and the life-cycle phase of the company. In the first case, it concerns six types of information (level of debt, cost of capital, profitability of investments, value of the company, expected results of long-term activities and other categories). In the second case, the dependences are diagnosed in five types of information (level of debt, cost of capital, value of the company, financial condition and expected results of long-term activities). The last case concerns only two areas – value of the company and expected results of long-term activities. In addition, I have diagnosed the dependence of information needs on the nature of business. It concerns the information about the level of debt and about financial condition in relation to the company's competitors and business sector. The distribution of entrepreneurs' answers is presented on Diagram 6 to 9.

Assessment of the information in the long-term management confirms the trand that the larger size of the enterprise determines the increased information needs of its manager (scores of the largest enterprises are the highest – Diagram 6). Differences in ratings range from 4.7% (information about profitability of investments) to 8.7% (information about the level of debt). The information about the level of debt is the most important for the largest enterprises. For the smallest ones – about profitability of investments. The rest of the assessments did not differ from the average (Diagram 2).

For entrepreneurs with higher education, information about the expected results of long-term activities is the most important. The information about financial condition in relation

to competitors and the business sector is the most significant for managers with lower education (see Diagram 7). Assessments of other types of information are more diversified. However, the lower demand for information is typical of entrepreneurs with vocational (technical) education, regardless of the level.

Table 6: Influence of Endogenous Factors on Entrepreneur's Information Needs in Long-Term Management.

Information about	**Level of debt**	**Cost of capital**	**Prof. of invest.**	**Value of company**	**Finan. Cond.**	**Expected results**	**Other**

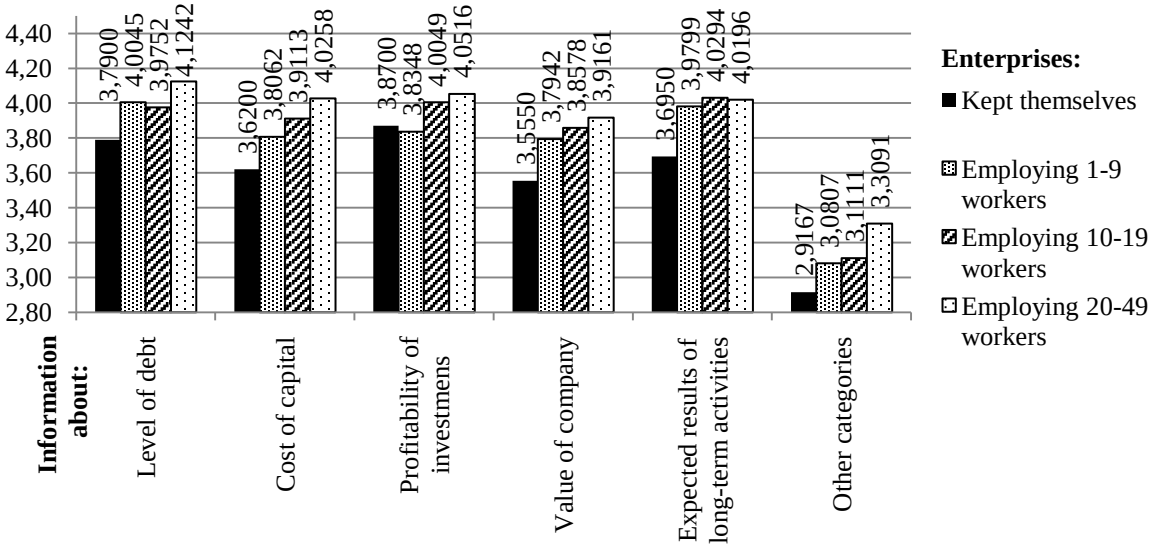

Diagram 6: Distribution of Entrepreneurs' Assessment of Information in Long-Term Management According to Size of Enterprise.

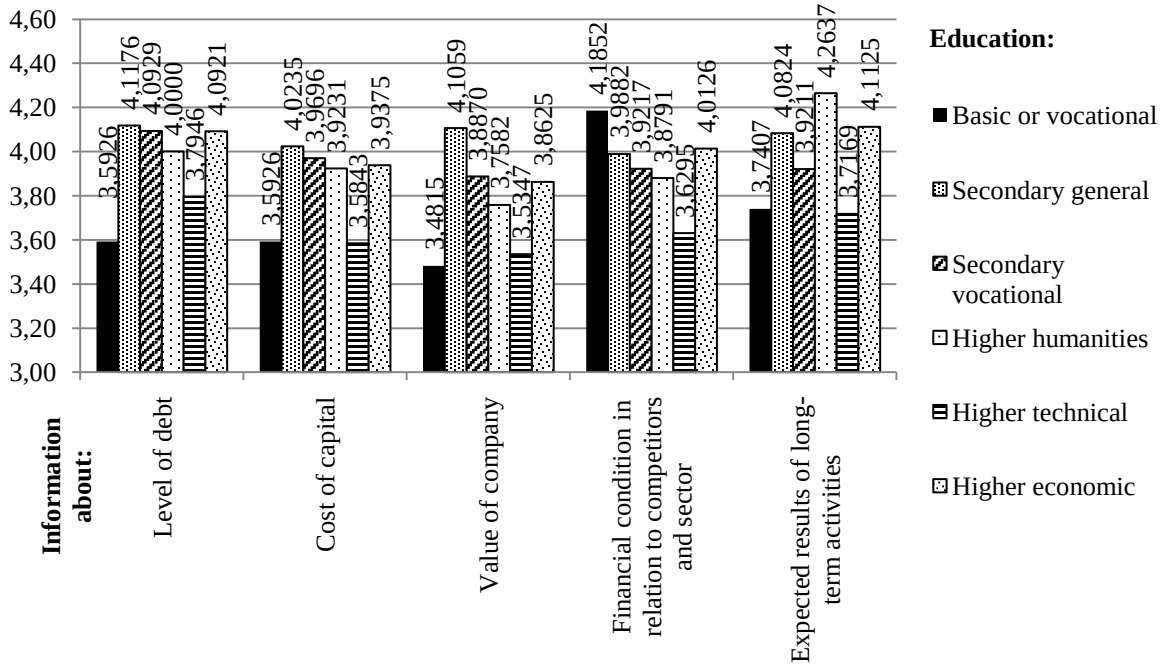

Diagram 7: Distribution of Assessment of Information in Long-Term Management According to Entrepreneur's Education.

Diagram 8 shows that the importance of information about the company's value increases relatively to the phase of the life cycle. As regards the information about the expected results of long-term activities, the situation is reversed. The demand for both kinds of information is very similar for the companies in growth and stability phases of the life-cycle.

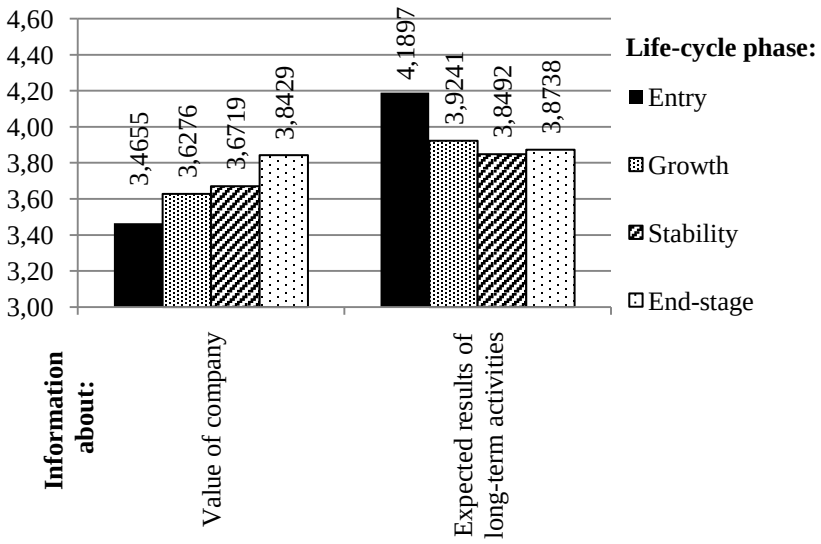

Diagram 8: Distribution of Assessment of Information in Long-Term Management According to Life-cycle Phase.

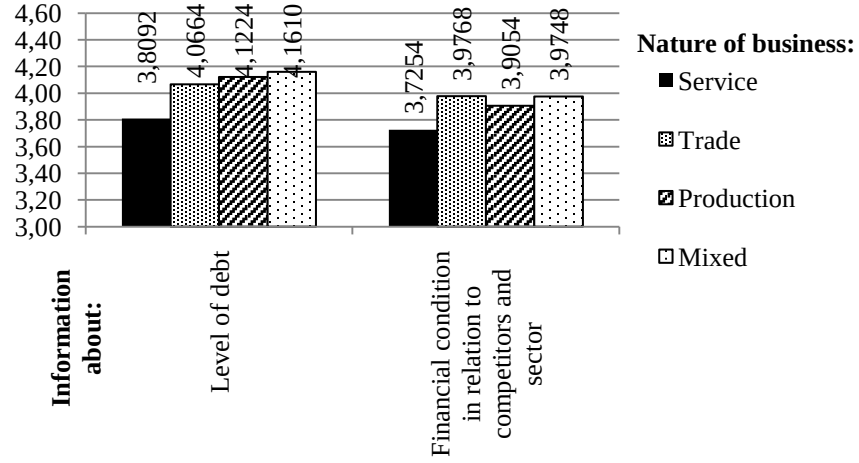

Diagram 9: Distribution of Entrepreneurs' Assessment of Information in Long-Term Management According to Nature of Business.

The research results (Diagram 9) show that the information about the level of debt (4.1610) and about financial condition in relation to competitors and business sector (3.9748) is mostly needed by companies running mixed types of business activities (ca. 4.01 and 3.95). Not much lower level of information needs is reported by production and trading companies**.** However, this information is evidently less important for service companies (3.8092 and 3.7254 respectively).

CONCLUSIONS

Research results are the important characteristics of the small enterprise sector in Poland. They describe the use of various types of financial information in decision making, and

thereby they determine the information needs of entrepreneurs. They allow us to assess the role of financial information in managing a small company, and its owner's managerial competence.

Taking into account general results, entrepreneurs have assessed highly the usefulness of financial information in the company management. The scores for the short-term management exceed 4.0 on the five-point scale. As regards the long-term management, they do not much diverge from that level. It means that managers of small companies often use financial information during decision making and the demand for this information type is significant among them.

In short-term management, information about liquidity (ability to pay current liabilities) is the most important aspect for managers. It shows that for small companies, the maintenance of liquidity is a key short-time problem. In this area, the information about current and future costs is the second on the list of entrepreneurs' information priorities. It follows that the costs are an important and sensitive subject of management in small enterprises. Entrepreneurs have also assessed information about revenues and about the profitability of the company as relatively high. It means that in the short term, in addition to maintenance liquidity, managers try to maximize profit.

The information about the level of debt and about the expected financial result of long-term activities is the most significant in strategic management. Indebtedness and its growth become the primary determinant of long-term policy of a small enterprise. Managers shape its level on the basis of the expected results of taken decisions. In this managerial area, entrepreneurs rated the usefulness of information about cost of capital quite low. In their opinion, the information about the financial condition in relation to competitors and business sector is more significant.

The assumed hypothesis about the relationship between information needs and selected factors (see Table 3) was only partially positively verified. In short-term management these needs depend on the size of the enterprise, entrepreneur's education and the life-cycle phase in which the company is. In addition to those aspects, the dependence on the nature of business is diagnosed for long-term management. In all cases of dependence the strength of correlation is weak. Information needs do not depend on the company's age.

There is a noticeable trend that in larger enterprises their managers assess the usefulness of each types of financial information as higher. This usefulness is evaluated as high by managers with higher economic and humanistic education. Financial information seems to be underestimated by managers with vocational education regardless of its degree. Only selected types of information needs depend on the life-cycle phase and on the nature of business.

Undoubtedly, a very important aspect of management is both the quantity and quality of information used by managers. They expect relevant, significant, full and reliable information. In this context, it can determine the assumption that optimal information system for small enterprises is vital. It will be the aim for my further research.

IDENTIFYING MARKET TAKEOFF IN HIGH TECH INDUSTRIES

Dr. Yi-Nung Peng, Yuan Ze University, Taiwan
pengyn@saturn.yzu.edu.tw

Dr. Susan Sandrson, Rensselaer Polytechnic Institute, USA
sandes@rpi.edu

ABSTRACT

This research we collect US data from both the personal computer (PC) and portable digital music player (commonly referred as MP3 players) industries and used derivative approximation by finite differences method to identify market takeoff. In addition, we examined the relationship between market takeoff and product innovations in the PC and MP3 markets. The derivative approximation by finite differences method eatables researchers to identify the market takeoff at a timely fashion which is an important advantage over the traditional statistical methods which can only perform the task in a retrofitting manner.

Keywords: Market takeoff, Method, PC industry, MP3 industry

INTRODUCTION

Although entry timing often depends on a firm's resources and capabilities (Kerin, Varadarajan, 1992;Lambkin, 1988;Lieberman and Montgomery, 1988;Lieberman and Montgomery, 1998), firms are often confused about which stage of the product life cycle an industry is in and whether it is too early or too late to enter.

The transition between the early commercialization and growth stages has been defined as market takeoff (Golder and Tellis, 1997). On the other hand, Agarwal and Bayus (2002) described market takeoff as "the first large increase in sales," or "the hockey-stick pattern of sales growth also seems to be popular among industry pundits." They used discriminant analysis to determine the timing of takeoff. Similar statistical methods have also been used by other scholars in distinguishing different stages of innovations (Agarwal and Gort, 1996;Gort and Klepper, 1982).

Recognition of market takeoff (the period in which the entire product category has reached the growth stage) is important given the perceived advantage of entering a market just before or at the growth stage (Lilien and Yoon, 1990;Shankar, Carpenter, 1999). The stream of literature describing the dual market development of the early stage innovations (Moore, 2002;Muller and Yogev, 2006) also pointed out the importance of market take off from the aspect of characteristics of customers.

Factors such as economic, and cultural factors (Tellis, Stremersh, 2003), firm promotional activities and timing (Delre, Jager, 2007), social network characteristics (Delre, Jager, 2010;Hohnisch, Pittnauer, 2008) and price drop (Hohnisch, Pittnauer, 2008) can impact the timing of takeoff.

Product innovation may also trigger the market takeoff. A product innovation can provide relative advantages that can increase the adoption rate (Rogers, 2003;Tornatzky and Klein, 1982).

Because this period of takeoff is so significant, it would be helpful for firms to understand the factors that trigger market takeoff. A better understanding of what triggers takeoff and how to recognize it would aid managers in becoming more proactive and effective in their product development efforts and in understanding how timing of product introduction may affect their success (Foster, Golder, 2004;Tellis, 2008).

Employing statistical methods to identiy market takeoff is rigorous but it relies on 20/20 hindsight. One needs to have many data points to determine the market takeoff time. An industry participant during the early stage of an innovation might face difficulties in identifying market takeoff using their method.

Addressing this issue, Golder and Tellis (1997) provided an alternative method to identify market takeoff. They developed a threshold for takeoff defining takeoff as the first year in which an individual category's growth rate, relative to base sales, crosses this threshold. According to the authors, this method identifies 90% of the takeoffs correctly. Further, visual verification helps to ensure the correct identification of takeoff. Their method used a minimum of 50,000 unit sales as a threshold because they found that a relatively large percentage increase could occur without signaling real takeoff. Their method has the advantage in identifying takeoffs in real-time even during the early stages of an innovation. However, is there other method we can use to identify market takeoff in a proactive manner? The market takeoff, it is a *"sudden"* increase in sales. It is essentially a *"big acceleration"* in market sales. The industry sales of the PC innovation was increasing every year. Can we identify the *"big acceleration"* in the PC industry mathematically instead of statistically? We are proposing to use the derivative approximation of finite differences (Eberly, 2001) as an alternative method for the takeoff identification. To achieve this goal, we collected the US PC and MP3 player industry data to examine the possibility of using derivative approximation of finite differences as a market takeoff identification method.

DATA

US Personal Computer Data

In searching for a consistent source for market information for US Personal Computer (PC) industry, I utilized the annual publication of Datamation, the "Datamation 50 and the Datamation 100." Datamation magazine was the key professional magazine for "data processing" industry during the time frame of the study. It was widely subscribed by information technology professionals. I used the following sections of Datamation to construct the quantitative aspect of the industry.

1. The Datamation 50 (1979) conducted by Datamation magazine, is an annual systematic revenue summary of the top 50 Data Processing firms including computer hardware, software, peripherals, and etc.

2. Datamation 100 (1980-1989).

The Datamation 100 is similar to Datamation 50 but includes top 100 firms. (timeframe) Datamation data helped in estimating annual sales for the PC industry which were hard to get from other sources. It was used by Chandler (2001) for his history of the electronics industry (citation). I obtained market share data of the companies through various secondary sources which will be discussed in detail in following sections.

In calculating firm market share I used the following:

Virhe.

I used this relationship to calculate "annual industry sales" by multiplying "annual company sales" (from Datamation) and "company market share (from other sources and books mentioned above). This is a reasonable method for estimating industry sales as it is difficult to get access to this data for the early stage of the industry in any other way. Datamation's data helped to determine the progression of personal computer industry sales over time.

US Portable Digital Music Players Data

Due to the lack of well-organized texts, I performed two broad-term keyword searches on ABInform Database to promote an understanding of technology advances and market size data. The two keywords were 1) MP3, and 2) digital music. The market sales data is thus assembled. The publications on which I performed keyword search can be categorized as 4 types:

1. Business Magazines: 1) Business Week, and 2) Fortune
2. Newspapers: 1) New York Times, and 2) Wall Street Journal
3. Two Popular Technology Magazines: 1) PC Magazine and 2) PC world
4. One Popular Music Magazine: Rolling Stone Magazine

ANALYSIS

Before we presenting our analysis details, we must clarify what is the *"big acceleration"* in sales means. An analogy to concepts in physics is helpful. The annual sales number is actually the *"speed of sales"* because the annual sales of an innovation represents its sales per year (sales/year). Therefore, it is the *"speed of sales"* if we think of the annual industry sales as the displacement of an object. Following this analogy, the annual increase in sales is the "acceleration of sales". This analogy helps in the identification of the *"big acceleration"* of sales. Following this line of thinking, the *"big acceleration"* of sales is actually *"the maximum change"* on the acceleration of sales.

However, mathematically how can we identify *"the maximum acceleration of sales"*? The concept of *derivative approximation of finite differences (Eberly, 2001)* is helpful.

The detail analysis and rationales are presented as follow:

Derivative Approximation of Finite Differences

$S(t)$ is the unit sales of an innovation; where *t* represents time;
The maximum change in the acceleration of sales is the maximum of $S''(t)$; that is the maximum rate of change in the speed of sales. To calculate the $S''(t)$, we must fist understand the calculation of $S'(t)$ under the notion of derivative approximation of finite differences, the derivate of $S'(t)$ can be calculated by forward, backward, and centered difference approximations. Similarly, $S''(t)$ also can be found.
To approximate the derivatives of a univariate function $f(k)$ by finite difference, given a small value of *h*, where *h*>0, the $f'(k)$and $f''(k)$ can be calculated as follow:

Forward difference approximation

$$f'(k)=\frac{f(k+h)-f(k)}{h}$$

Where $h=1$

$$f'(k)=f(k+1)-f(k) \tag{1}$$
$$f''(k)=\frac{\Delta f(k+1)-\Delta f(k)}{1}$$
$$f''(k)=\left[f(k+2)-f(k+1)\right]-\left[f(k+1)-f(k)\right]=f(k+2)-2f(k+1)+f(k) \tag{2}$$

Backward difference approximation

$$f'(k)=\frac{f(k)-f(k-h)}{h}$$

Where $h=1$

$$f'(k)=f(k)-f(k-1) \tag{3}$$
$$f''(k)=\frac{\Delta f(k)-\Delta f(k-1)}{1}$$
$$f''(k)=\left[f(k)-f(k-1)\right]-\left[f(k-1)-f(k-2)\right]=f(k)-2f(k-1)+f(k-2) \tag{4}$$

Centered difference approximation

$$f'(k)=\frac{f(k+h)-f(k-h)}{2h}$$

Where $h=1$

$$f'(k)=\frac{f(k+1)-f(k-1)}{2} \tag{5}$$

$$f''(k)=\frac{\left[\Delta f(k+1)-\Delta f(k-1)\right]}{2}=\frac{\left[f(k+2)-f(k)\right]/2-\left[f(k)-f(k-2)\right]/2}{2}$$

$$f''(k)=\frac{f(k+2)-2f(k)+f(k-2)}{4} \quad (6)$$

To identify the market takeoff of the PC innovation we apply the equations 1 to 6. Where $S(t)$ is the unit sales of an innovation; *t* represents year; *h*=1 (year)
Forward difference approximation

$$S'(t)=S(t+1)-S(t)$$
$$S''(t)=S(t+2)-2S(t+1)+S(t) \quad (7)$$

Backward difference approximation

$$S'(t)=S(t)-S(t-1)$$
$$S''(t)=S(t)-2S(t-1)+S(t-2) \quad (8)$$

Centered difference approximation

$$S'(t)=\frac{S(t+1)-S(t-1)}{2}$$
$$S''(t)=\frac{S(t+2)-2S(t)+S(t-2)}{4} \quad (9)$$

For the purposes of this analysis, market takeoff is defined as the year the maximum increase in sales rate. This point can be estimated from the discrete sales data using the centered difference approximation

$$S'(t)=\frac{S(t+1)-S(t-1)}{2}$$
$$S''(t)=\frac{S(t+2)-2S(t)+S(t-2)}{4}$$

where S(t) is the unit sales in year t.

Takeoff Identification for PC and MP3 Markets

To identify the time of takeoff, given the method's different approaches, we must discuss the advantages of approaches. By plotting the industry sales and maximum peak of three approximation approaches for the PC (Figure 1) and MP3 innovations (Figure 2), we can see that the market takeoff of the PC innovation is identified to be in 1980, 1981, and 1982 respectively by the forward, centered and backward approximations. The year of takeoff for MP3 players were in 2003, 2003 and 2005 respectively.

The Determination of the Proposed Approach—Backward Difference Approximation

However, which of the 3 approximation approaches is correct? We believe that the backward difference approximation because its first order and second order derivatives are generated by the comparison of current and the previous periods. Therefore, the output is more concurrent which is the major purpose of this study—proactive takeoff identification.

Figure 1: PC Industry Unit Sales Evolution and Takeoff Identification.

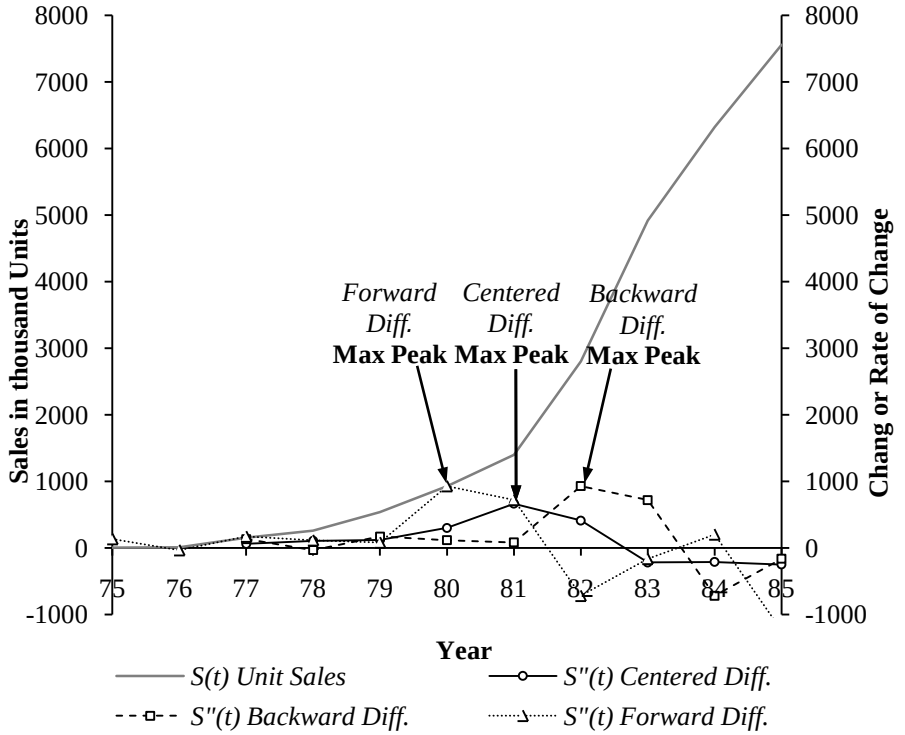

Figure 2: US MP3 Player Sales Evolution and Takeoff Identification.

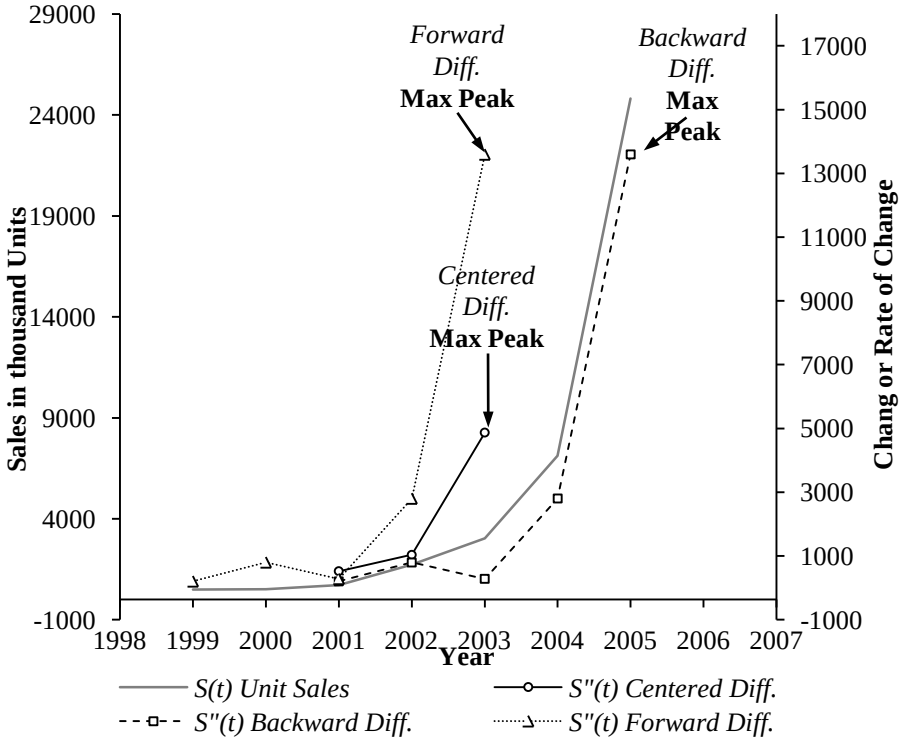

Figure 3: Multiple Takeoffs of the U.S. PC Industry under the Backward Difference Approximation.

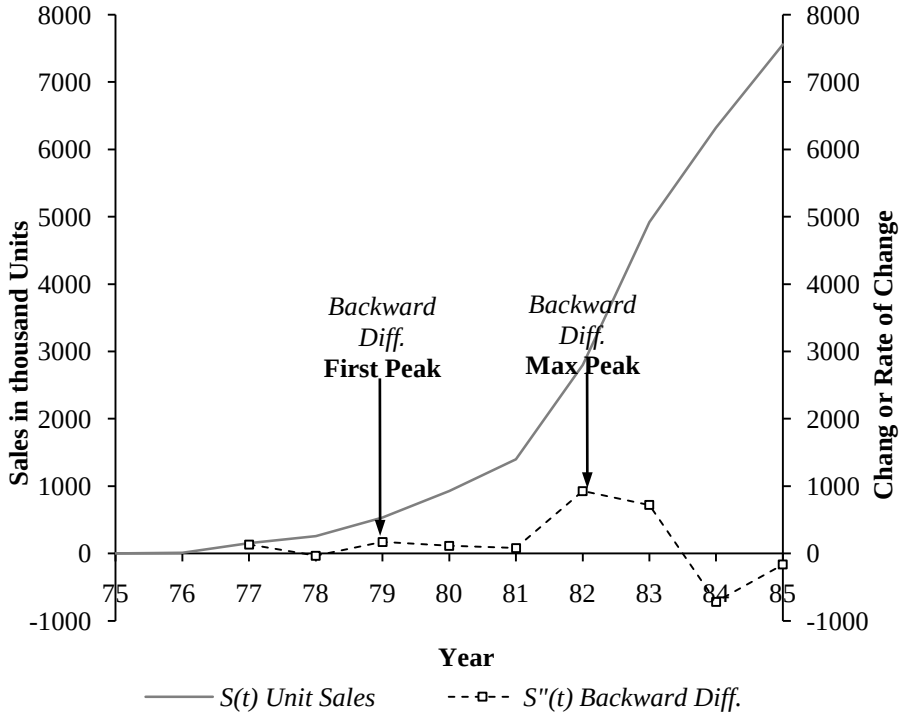

Figure 4: Multiple Takeoffs of the U.S. MP3 Players Industry under the Backward Difference Approximation.

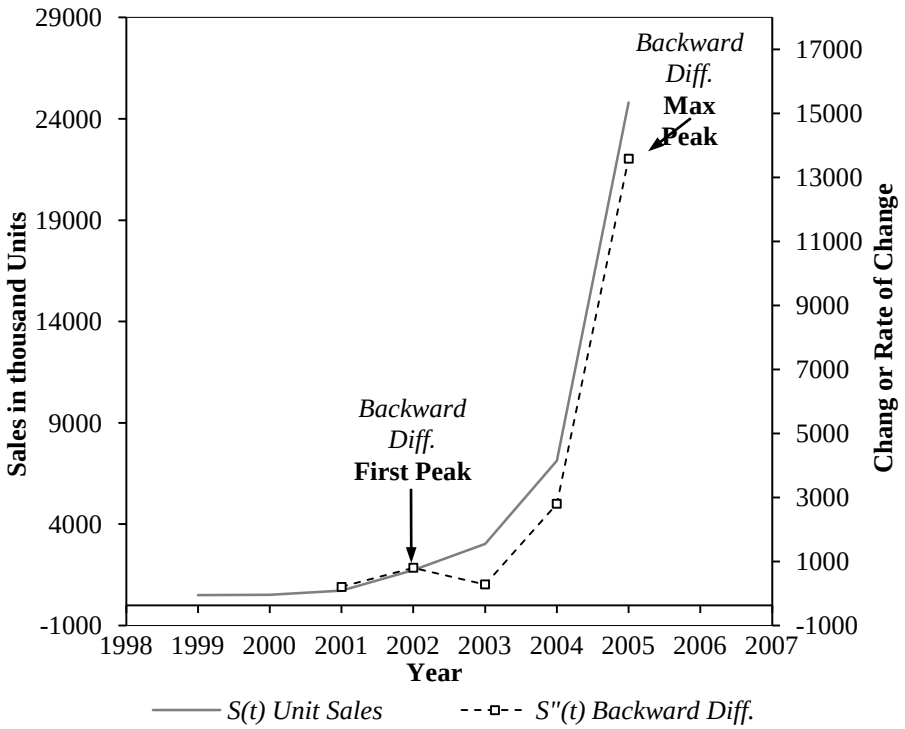

Multiple Takeoffs

Peng (2006) pointed out that , theoretically speaking, there maybe multiple take offs in the product life cycle of an innovation. Such pheromone has been confirmed by Muller and Yogve (2006) using the market takeoff identification tool developed by Golder and Tellis (1997). Muller and Yogve (2006) observed three takeoffs in various consumer electronic industries such as PC, printers, and remote controls. The multiple-takeoff characteristic of innovations impacts our analysis profoundly.

Our identification of the peak of the rate of change on the acceleration of sales is only try to identify the *"the maximum rate of change"* on the acceleration of sales. The *"the of change"* on the acceleration of sales is naturally time-based. Therefore, the *"the maximum change"* on the acceleration of sales is contingent upon the period of time which one studies.
Given this notion, to really identify the time of market takeoff, we must examine the first peak of the curve of the rate of acceleration of sales. Figure 3 and Figure 4 show the first peak and the maximum peak of the curve under the backward difference approximation approach. We can see that the first takeoff for the PC and the MP3 player innovations are actually in 1979 and 2002 respectively.

CONCLUSTION AND DISCUSSION

Market takeoff is an important phenomenon in the course of an innovation's development. Scholars in the field of technology and innovation management had developed statistical tools (Agarwal and Bayus, 2002) and graphical tool (Golder and Tellis, 1997) to facilitate the identification of market takeoffs.

The statistical method, though rigorous, can only identify the takeoffs in the retrospect. Researchers need to collect a more complete sales data for the takeoff identifications. That is why the graphical tool developed by Golder and Tellis (1997) is being used by practitioners in the real world setting (Foster, Golder, 2004). However, we still rely on human visual confirmation for the correct identification of market takeoffs and the method still can miss-identify the market takeoffs (Golder and Tellis, 1997).

Therefore, we proposed to use the derivative approximation of finite differences method as a new market takeoff identification method. This method can identify the takeoff earlier than the traditional statistical methods given its only demand sales data of the next period. Given its numeric nature, we can identify market takeoffs objectively.

We identify 1979 as the year of market takeoff for the PC innovation. Although differ from the conclusion from Agarwal and Bayus (2002). However 1979 is one year after the introduction of the complete package of the Apple II (Peng, 2006) in the PC innovation. And 2002 is one year after the introduction of the iPod. This shows that takeoff may be closed related to the product innovation which is consist with existing diffusion literature. We still need to examine more innovations and compare the conclusions draw from the new method with existing methods to better evaluate the validity of identifying marketing using the derivative approximation of finite differences method.

ABSTRACT

The article investigates the investment and financial constraints for French, Hungarian and Slovenian farms using FADN panel data with different econometric estimation approaches. Farm gross investment is positively associated with real sales growth and cash flow implying the absence of soft budget constraint. Gross farm investment is positively associated with investment subsidies. Specific results by country are found depending on farm indebtedness. Investment subsidies can mitigate some capital market imperfections in short-term, while on long-term what is crucial is farm sale ability to successfully compete in the output market gaining sufficient cash flow for farm competitive survival and investment.

Keywords: farm investment, soft budget constraint, investment subsidy, panel data analysis
JEL classification: D81, D92, O12, Q12, C23

INTRODUCTION

There is a wealth of literature on the presence of capital market imperfections and their effects on firm investment in transition countries (e.g. Budina et al., 2000; Konings et al., 2003; Lizal and Svejnar, 2002; Rizov, 2004), and a few papers focusing on this issue for the agricultural sector in these countries (Petrick, 2004; Latruffe, 2005; Bojnec and Latruffe, 2007; Bakucs et al., 2009; Latruffe et al., 2010). This research provided evidence for existence of capital market imperfections during transition and after accession to the European Union (EU) (Rizov et al., 2001). In addition, some studies tested the persistence of soft budget constraint in transition economies. If soft budget constraint is still persistent, it may lead to a postponed restructuring (Kornai, 2001, Kornai et al. 2003). Soft budget constraint may be more important in agriculture because government supports to the farm sector are much higher than to firms in manufacturing. Cross-country comparison of investment behaviour is limited in the agricultural economics literature (except Benjamin and Phimister, 2002). Previous empirical analyses on investment activity in agriculture are mainly based on the augmented accelerator model or Euler equations.

The aim of this paper is to analyse the existence of soft budget constraint and credit market imperfections in three different EU countries, France, Hungary and Slovenia, using the augmented accelerator model with dynamic panel estimations. The historical development and the evolution of farms in the EU vary by countries, not only between Eastern and Western Europe, but also inside both regions. Within Eastern Europe these differentials in farm size and its growth are caused by the initial conditions that are linked to the agricultural history during the previous communist system and later institutional and policy reforms, while in Western Europe they are caused by the long-term institutional and policy evolutionary factors and market conditions. During the communist system Hungarian agriculture was collectivised and the average farm size has been all the time among the largest in Europe. In Slovenia the communist collectivisation failed and small-scale farm structure has remained among the smallest in Europe. In France farm structure has developed under market conditions and policy support, in particular the Common Agricultural Policies (CAP) measures introduced after the Second World War (Piet et al., 2010). While its farms are among the largest in Western Europe, they are smaller than in Hungary. Transition from centrally-planned to market economy in Slovenia has strengthened further development of small-scale family farms, while in Hungary a bi-modal farm structure has emerged with a greater number of small-scale family farms and a smaller number of large-scale corporate farms. The proportion of small farms in Slovenian agriculture is much higher than in Hungary. Therefore, our comparative analysis includes three countries with different historical-institutional developments and different farm structures: small-scale farms in Slovenia, medium-sized farms in France, and bi-modal small-scale and large-scale farms in Hungary.

Our analysis is based on data from the French, Hungarian and Slovenian Farm Accountancy Data Networks (FADN). Previous research has provided evidence of capital market imperfections in these countries during transition (Bojnec and Latruffe, 2007; Bakucs et al., 2009). Our paper highlights whether such imperfections persist after accession to the EU.

METHODOLOGY

The starting point of our empirical analysis is the standard augmented accelerator model in the following specification (Fazzari et al., 1988):

$$\frac{I_{it}}{K_{it-1}} = \alpha_i + \alpha_1 \frac{Q_{it}}{K_{it-1}} + \alpha_2 \frac{CF_{it-1}}{K_{it-1}} + \varepsilon_{it} \qquad (1)$$

where subscript *i* denotes the *i*-th farm and subscript *t* denotes the *t*-th period, while ε is a stochastic element. I_{it} denotes gross investment of the *i*-th farm between periods *t* and *t-1*, which is calculated as the change in capital stock (net investment) plus depreciation in values; values in period *t* were deflated by the agricultural input price index for goods and services contributing to agricultural investment K_{it-1} is the stock of capital, measured by all tangible assets, in the period *t-1*; values in the current period *t* are deflated by the agricultural input price index. Q_{it} is the change in output sales value between period's *t* and *t-1*; values in period *t* were deflated by the harmonized indices of consumer prices. CF_{it-1}

denotes the real cash flow of the *i*-th farm, defined as before tax profits plus depreciation; values in period *t* were deflated by the harmonized indices of consumer prices. Dependent and explanatory variables are normalised by the stock of capital in time *t*-1 to control for size effects.

The positive regression coefficient α_2 on the cash-flow variable is generally interpreted as a sign for credit rationing, as firstly proposed by Fazzari et al. (1988). In addition, Lizal and Svejnar (2002) suggested to consider the coefficient α_2 as an indication of the presence of the soft budget constraint, and proposed two interpretations for the latter: first, the weak version when the coefficient α_2 is zero; firms have access to credit for investment irrespective of their profitability. Second, the strong version of the soft budget constraint, when the coefficient α_2 is negative; firms with poor financial performance can access bank loans more easily.

Following Konings et al. (2003) we estimate equation (1) in first differences to control for unobserved farm level fixed effect and possible measurement error:

$$\Delta \frac{I_{it}}{K_{it-1}} = \alpha_1 \Delta \frac{Q_{it}}{K_{it-1}} + \alpha_2 \Delta \frac{CF_{it-1}}{K_{it-1}} + \Delta \varepsilon_{it} \qquad (2)$$

In our econometric estimations the baseline model is the standard augmented accelerator model (equation (2)). We then extend our model specification to include investment subsidies related to capital stock as an additional explanatory variable in a separate model.

In addition to full sample estimate, we use farm characteristics to classify farms by increasing vs. decreasing real sales, and by high debt and low debt farms. Similar as Benjamin and Phimister (2002), we define high debt and low debt farms with debt-to-asset ratio greater than 0.3 and less than 0.2 respectively, to test the sensitivity of our estimation. We also imposed outlier rules by removing farms from econometric estimates if the investment capital ratio is above 99% in absolute value (Benjamin and Phimister, 2002).

In the empirical analysis we use three econometric estimators. First, we employ standard static panel models using a Hausman test to identify whether a random or a fixed effect model is appropriate. Second, we employ the generalized method of moments (GMM) estimator developed by Arellano and Bover (1995) and Blundell and Bond (1998), also referred to as GMM-system estimator. Windmeijer (2005) proposes a finite sample correction that provides more accurate estimates of the variance of the two-step GMM estimator. As the t-tests based on these corrected standard errors are found to be more reliable, the paper estimates the coefficients using the finite sample correction. Finally, we have an unbalanced panel dataset for the five year length period between 2003 and 2007 for France and between 2004 and 2008 for Hungary and Slovenia. Thus to correct the unbalanced nature of our data, in a third model, we estimate equation (2) with a generalised version of bias corrected LSDVC estimator proposed by Bruno (2005a)[1]. The author defines a selection indicator r_{it} such that r_{it} =1 if (y_{it}, x_{it}) is observed and r_{it} =0

[1] We apply the Stata programme xtlsdvc developed by Bruno (2005b) using Blundell and Bond (1998) estimator.

otherwise. From this the dynamic selection rule s (r_{it}, $r_{i,t-1}$) is created, that selects only the observations that are usable for the dynamic model, namely those for which both current values and one-time lagged values are observable. As it is good practice to check the sensitivity of empirical results, we will present and compare the results from the fixed effects estimator, GMM estimator, and LSDVC estimator. The French sample being too large for such estimator, it is applied to a random sample of half the size of the initial size.

DATA

The data analysis is based on French, Hungarian and Slovenian FADN that includes farms above two European Size Units (ESUs; one ESU is equivalent to 1,200 euros of gross margin). The time span used for analysis is 2004-2008 for Hungary and Slovenia and 2003-2007 for France. Table 1 presents descriptive statistics of the data used. Gross investment to capital is the highest for Hungarian and the lowest for Slovenian FADN farms, but of course varies by farms. The data shows disinvestments by some farms in Slovenia and France, but not in Hungary. Real sale growth to capital is the highest for French and the lowest for Slovenian FADN farms. Real cash flow to capital is the highest for Slovenian and the lowest for French FADN farms. Similarly as real sale growth to capital, also real cash flow to capital vary by farms from negative to positive values. Real investment subsidy in period t-1 to capital is on average similar for French, Hungarian or Slovenian FADN farms.

Table 1: Descriptive statistics for the whole period 2004-2008.

Variable		Obs	Mean	Std. Dev.	Min	Max
				Hungary (in euro)		
Investment to capital	$\frac{I_{it}}{K_{it-1}}$	8367	0.096	0.220	0.000	11.633

				France (in euro)		

Investment to capital	$\frac{I_{it}}{K_{it-1}}$	25782	0.076	0.174	-3.440	12.500
Sale growth to capital	$\frac{Q_{it}}{K_{it-1}}$	25782	0.299	0.292	-0.729	12.049
Cash flow to capital	$\frac{CF_{it-1}}{K_{it-1}}$	25782	0.131	0.246	-12.325	9.370
Investment subsidy in period *t*-1 to capital		25782	0.004	0.019	0.000	0.868

ECONOMETRIC RESULTS

Results of the Hausman test suggest using fixed effect models. The standard augmented accelerator model confirms a positive association between farm investment and real sale growth and cash flow variables, respectively (Table 2). Therefore, our econometric results reject the validity of the soft budget constraint for French, Hungarian and Slovenian farms. However, they reveal the presence of capital market imperfections. Farm investments are positively associated with investment subsidies in time *t* in France, Hungary and Slovenia, but negatively for investment subsidies in time *t-1* for France and Hungary. This implies that current investment subsidies are important for investment decisions, but except for Slovenia, they are not anticipated as a factor for long-term farm investment behaviour, where a more crucial role is plaid by farm output market conditions with real sales to growth and cash inflow into the farm household.

Dependent variable: gross investment$_{t,t-1}$ to capital. All explanatory variables are divided by capital. N: number of observations. ***/**/*: statistically significant, respectively at the 1%, 5%, and 10% levels.

Following Benjamin and Phimister (2002) we impose outlier rules to exclude farms if their investment to capital ratio is above 99% in absolute value (Table 3). The results do not change substantially. The regression coefficients for real sale growth are of a positive sign and significant in all specified cases. The regression coefficients for the cash flow variable remains with the positive sign. For Slovenia, the regression coefficients are slightly lower and closer to zero. The regression coefficients for investment subsidy in the current period *t* are of a positive sign and significant, but the coefficients for investment subsidy in the previous period *t-1* are not significant for Hungary and Slovenia, and negative and significant for France.

Moreover, we split our FADN sample into two sub-samples depending on farm indebtedness to classify farms as high debt vs. low debt farms that can be considered to differ in their financial constraints. Similar as Benjamin and Phimister (2002) we define high debt and low debt farms with debt-to-asset ratio greater than 0.3 and less than 0.2, respectively.

The results differ by countries and by these two debt groups of farms. For France, gross farm investment is positively and significantly associated with real sale growth in the current period *t* for both groups of farms with high and farm with low debts (Table 4). This finding holds also for farms with low debt in Hungary and Slovenia, but the regression coefficients for these two countries are insignificant for high debt farms. While investments in low debt farms are market driven, it is less clear for high debt farms in Hungary and Slovenia.

Dependent variable: gross investment$_{t,t-1}$ to capital. All explanatory variables are divided by capital. N: number of observations. ***/**/*: statistically significant, respectively at the 1%, 5%, and 10% levels.

The regression coefficients for the cash flow variables, irrespective to the model specification, are of a positive sign and significant implying an absence of soft budget constraint but a presence of capital market imperfections. In Hungary and France, the coefficient is much higher for farms with low debt than for farms with high debt, revealing that lower indebtedness constrains more investment decisions in these countries. However, the opposite is found for Slovenia. The regression coefficients for the investment subsidy variable are mixed. They are of a positive sign and significant when pertaining to investment subsidy at time *t* for Hungary and France as well as for Slovenia in the case of farms with low debt. On the contrary, for Hungary they are insignificant for lagged investment subsidy variable. For Slovenia, for high debt farms the regression coefficient pertaining to lagged investment subsidy variable is insignificant, while for low debt farms they are significant, but of a negative sign. The opposite holds for French FADN farms: of a negative sign and significant for farms with high debt and insignificant for farms with low debt. The regression coefficients for the lagged investment subsidy variables imply different long-term

investment behaviour of farm by countries and by the degree of indebtedness of farms. While for Hungary there is less significant long-term farm investment behaviour for these two groups of farms, the Slovenian low debt farms and French high debt farms seem to be a cautious in their long-term farm investment behaviour.

The re-estimated adapted standard augmented models by the dynamic panel data model (GMM-SYS) confirm the positive and significant association between farm gross investment and farm real sale growth (Table 5). These results clearly imply that the FADN farm investment behaviour are driven by competitive output market conditions and the farm abilities to sell output and invest in such a market environment. Moreover, except for Slovenia, farm gross investment is positively and significantly associated with cash flow, confirming for France and Hungary the absence of the soft budget constraints for the FADN farms. For Slovenia, the regression coefficients for the cash flow variable are insignificant. Finally, farm gross investment is found to be a positively and significantly associated with investment subsidies for France, Hungary and Slovenia. To sum up, these GMM-SYS results

reject the validity of the soft budget constraints for French and Hungarian FADN farms and confirm the presence of capital market imperfections in these two countries.

The sample selection models based on the bootstrapped standard errors estimates provide all significant regression parameters at 1% significance level except for cash flow coefficient in France (Table 6). The positive association between gross farm investment and real sale growth is confirmed in all three countries, confirming that farms based their investment decisions on market conditions. The positive association between gross farm investment and cash flow also rejects the validity of the soft budget constraints but confirms the presence of capital market imperfections in Hungary and Slovenia. No significance is found for the French sample. Finally, gross farm investment is positively associated with investment subsidies in the three countries.

CONCLUSION

We use an adapted augmented accelerator model of gross farm investment for a panel data of French, Hungarian and Slovenian FADN farms to investigate the impact of real sale growth, cash flow and investment subsidy on gross farm investment, during the period 2003-2007 for France and 2004-2008 for Hungary and Slovenia. We use different econometric estimation approaches to test the sensitivity and robustness of our econometric results.

In a spite of different nature of FADN farms in France, Hungary and Slovenia, their investment behaviour does not differentiate substantially. Farm gross investment is positively associated with real sale growth suggesting that farm investment decisions are

based on market conditions in all the three countries. The association is also of a positive sign for the cash flow variable in general, implying the absence of the soft budget constraints and the presence of capital market imperfections limiting investment expenditures. As expected, some differentials are also found between farms with low and high debts, which vary between the analysed countries. Gross farm investment is positively associated with investment subsidies. Public programmes to support farm investment (investment subsidies) seem to be successful in enhancing investment in these countries in short-term, but farms investment behaviour pertaining to investment subsidies is more cautious on long-term. This implies that investment subsidies can mitigate some capital market imperfections such as interest rate volatility, but on long-term what is crucial is farm competitiveness and ability to successfully compete in the output market gaining sufficient cash flow for farm competitive survival and investment and thus also farm growth.

ABSTRACT

The purpose of this study is to examine whether listed firms in Taiwan use discretionary accruals and financial instruments regulated under Statement of Financial Accounting Standards No.34 as complement tools in reporting earnings. We estimate a set of simultaneous equations that captures managers' incentives to enhance earnings performance through financial instruments usage and accrual management. The empirical results of two-stage least squares regressions reveal that, as conjectured, the financial instruments usage is positive associated with the magnitude of discretionary accruals and support the complement hypothesis. It suggests that managers jointly use financial instruments and discretionary accruals to increase earnings and, besides the risk hedging purpose, provides alternative explanation for the multi-goals of financial instruments usage. These results remain robust to various specification tests.

Keywords: Complement hypothesis, Discretionary accruals, Earnings management, Financial instruments usage,

INTRODUCTION

The participants in financial derivatives market include hedgers, speculators and arbitrageurs. Hedgers use financial instruments to lock-in prices in order to avoid exposure to adverse movements in the price of an asset. Speculators take short-term positions in the market and consider derivatives as instruments of profit making, instead of as risk hedging tools. The arbitrageurs enter simultaneously into contracts in two or more markets to lock-in riskless profit by exploiting price differentials or imbalances. Nonetheless, how financial instruments are actually used by non-financial firms is still largely unknown in the literatures. Although firms can use financial instruments to speculate and/or to arbitrage on private information, extant empirical studies highlight the risk hedging motive and ignore the important roles of the other two participants.

The purpose of this study is to examine the possible complement relationship between the financial instruments usage and aggressive discretionary accruals in enhancing earnings (hereafter, the complement hypothesis) for listed firms who recognized the usage of financial instruments regulated under Statement of Financial Accounting Standards (SFAS) No.34 (Financial Accounting Standards Board 2004) in Taiwan. Before the enactment of SFAS No.34, firms only disclosed some of the financial instruments information in the footnotes and these disclosures were not uniform. Therefore, there was a lack of visibility or transparency for financial instruments usage. Because SFAS No. 34 requires firms to recognize all financial instruments as assets or liabilities in the balance sheet and also requires them to adopt mark to market approach to recognize the resulting gains or losses from the changes of financial instruments' fair value at the end of fiscal year in their income statements. Thus, the magnitude of financial instruments usage to some extent would have an effect on listed firms' reported earnings. Rather, the active usage of financial instruments is thought to add value by alleviating a variety of market imperfections through hedging (Adam & Fernando, 2006). Recently, Gèczy et al. (2007) suggest that financial derivatives involve real action which plays an important role in strategically boosting firm's earnings and view speculation as a positive profitability activity. Inspired by the study of Gèczy et al. (2007), the present study is motivated to examine whether listed firms jointly use financial instruments and discretionary accruals to manipulate their earnings.

Since earnings have two components, cash flows from real operations and accruals, the earnings reporting choices can result from cash flows and/or accruals. Facing increasing pressure to meet benchmark earnings, managers have incentives to use both discretionary accounting choices and real operation activities, such as using financial instruments, to manipulate earnings. In other words, except using the discretionary accrual, managers also can manipulate earnings through purchase and/or sell financial instruments. Recently, Gèczy et al. (2007) suggest that financial derivatives can be used to hedge market risk exposures or to speculate on movements in the value of the underlying asset. The authors argue that the speculation hypothesis generally implies that the derivative transactions are undertaken with the primary intention of making a profit. Adam & Fernando (2006) also document that gold mining firms have consistently realized economically significant cash flow gains from their derivatives transactions. Thus, if managers rather use financial instruments to increase earnings (and/or cash flow) but to smooth earnings, the substitution relationship between financial instruments usage and discretionary accruals is called for

further examinations.

Recent studies document that managers' market views influence their attempting to time commodity markets with derivatives usage decisions (Stulz, 1996; Faulkender, 2005; Brown et al., 2006; Adam & Fernando, 2006). Stulz (1996) calls this practice "selective hedging". He claims that selective hedging will increase shareholder value if managers have an informational advantage relative to other market participants. Thus, it is possible that managers believe that they can create shareholder value by incorporating speculative elements into their financial instruments usage decisions. Hitherto, many studies view discretionary accruals as the primary tools to manipulate earnings. However, managers also can increase earnings by using financial instruments that boost their firms' cash flows. Once managers believe they have a comparative information advantage relative to the market and, hence, to view speculation as a positive profitability activity, the magnitude of financial instruments usage will be enlarged. In such case, financial instruments usage will play an important role in strategically boosting firm's earnings. It is expected that both the financial instruments usage and aggressive discretionary accruals play important roles in elucidating firms' income-increase reporting behaviors. Inspired by the studies of Adam & Fernando (2006), Gèczy et al. (2007) and among others which view speculation as a positive profitability activity, the present study examine the possible complement relationship between the financial instruments usage and aggressive discretionary accruals in enhancing earnings for listed firms with active financial instruments usage under SFAS No.34 in Taiwan.

The empirical results of the two-stage least squares regression indicate that, as conjectured, financial instruments usage is positive association with the magnitude of discretionary accruals and supports the complement hypothesis. It suggests that managers use financial instruments and discretionary accruals jointly to increase earnings, which is inconsistent with the studies of Barton (2001) and Wang & Kao (2005). Reporting requirements on financial instruments usage may potentially affect firms' behavior with respect to production and risk management, and thus the derivative instruments usage. Sapra (2002) demonstrates that it is possible for mandatory financial instruments disclosures to result in excessive speculation in the financial instruments market. Our empirical results to some extent evidence the possible potential multi-purposes of financial instruments usage and support the findings of Sapra (2002). These results remain robust to various specification tests.

Overall, the present study documents that financial instrument has cash flows effect, then influence reporting earnings, and provides feedback for regulators with respect to the subsequent reporting requirement in capital market. The present study enriches the financial instruments related research from two angles. First, although Barton (2001) finds that derivatives serve as a partial substitute role to discretionary accruals subject to managers' income smoothing assumption, the potential cash flows effect of financial instruments can be a potentially important motive for firms to use financial instruments. We examine whether financial instruments usage is a complement tool for discretionary accruals to manipulate earnings. The second angle, this study contributes to the literature by examining, besides the prevailing hedging risk hypothesis, financial instruments can be used to speculate on movements in the value of the underlying asset. If managers can boost earnings by using multiple tools, i.e., financial instruments and aggressive discretionary

accruals, the question naturally arises regarding how managers combine these instruments to gain benefits. This examination, to some extent, provides evidence to understand the substitute or complement nature of financial instruments usage strategy in earnings increase and assists regulators to evaluate the possible policy effect of SFAS No. 34 in Taiwan.

This paper is organized as follows: Section 2 describes the related prior studies and develops the empirical hypothesis. Section 3 presents the empirical design. Section 4 presents and discusses the empirical results. Section 5 discusses the robustness test and Section 6 concludes the study.

BACKGROUND AND LITERATURE REVIEWS

Accounting for Financial Instruments in Taiwan

The ongoing growth in the use of financial instruments accompanying with the financial instruments abuses have motivated accounting regulators to develop and stretch financial instrument-related disclosure requirements in Taiwan. First, The Financial Accounting Standards Committee of the Accounting Research and Development Foundation in Taiwan issued SFAS No.14 regulating the accounting treatments of *Foreign Currency Translation* transactions in December 1998. Subsequently, SFAS No.27 (*Disclosure of Financial Instruments*) was issued in 1997 and aimed to improve the transparency of listed firms' financial instruments usage. Namely, it required the disclosure of the extent (i.e., the contractual or notional amount), nature, terms, and the concentrations of credit risk for all financial instruments. Since the requirements of disclosing of financial instruments were not clear and uniform, the disclosures about financial instruments in financial statement are obscure and discretionary. SFAS No.34, *Accounting for Financial Instruments*, was issued in December 2004 and was effective for fiscal years beginning after 2006. This new standard requires all financial instruments owned by the listed companies to be initially recognized in the balance sheet as either liabilities or assets at their fair values. It also requires them to adopt mark to market approach to recognize the resulting gains or losses from financial instruments' fair value changes at the end of fiscal year in their income statements or in equity section of the balance sheet, depending on the intentions of financial instruments usage and the types of hedging. This standard setting provides the present study with a unique opportunity to identify a distinct financial instruments users sample that recognized financial instruments in their annual reports during 2006~2007 to examine the alternative motivation of financial instruments usage, besides the risk hedging motivation.

Related Research

Firms normally make plans based on expectations of what foreign exchange rates, interest rate, and commodity prices will be over the near time. If prices or rates change, the result of operations and cash flows will also differ from expectations. When firms have incentives to reduce the volatility of cash component of earnings through real risk-management activities, one possible way is to use derivatives to hedge the risks inherent in commodity prices,

foreign currencies, and interest rate (Nance et al., 1993; Tufano, 1996; Gèczy et al., 1997). That is, firms can use properly structured hedging derivative forms, whose rate or price moves in the opposite direction of the rate or price of the underlying item being hedged, to reduce the magnitude of differences. Breeden & Viswanathan (1998) find that hedging reduces noise related to exogenous factors and hence decreases the level of asymmetric information regarding a firm's earnings and its quality. This finding again is supported by the study of Dadalt et al. (2002). There are substantial studies examining the using of derivatives to smooth earnings/cash flows volatilities. For examples, Smith & Stulz (1985) show that the use of derivatives to hedge can maximize shareholder value because hedging may be reduce expected tax and expected costs of financial capital by reducing the probability that the firm encounters financial distress. In advance, there are rich bodies of studies exploring the various channels through which financial derivatives hedging can contribute to increase firm value (e.g., Froot et al., 1993; DeMarzo & Duffie, 1995; Allayannis & Ofek, 2001; Graham & Rogers, 2002). It seems the usage of financial derivatives is associated not only with smoothing earnings but also with enhancing firm's value.

Another line of research examines the tradeoffs managers make between derivatives and other risk management tools. For example, Schrand & Unal (1998) document that managers of thrift institutions integrate derivatives and the composition of loan portfolios to manage overall risk. Petersen & Thiagarjan (2000) using gold mining companies and Pincus & Rajgopal (2002) using oil & gas firms as sample examine the interaction of accounting choice and derivatives hedging and evidence similar tradeoffs pattern. Barton (2001) uses sample firms of *Fortune 500* non-financial companies and estimates a set of simultaneous equations that captures managers' incentives to maintain a desired level of earnings volatility through hedging and accrual management. The author concludes that managers use derivatives and discretionary accruals as partial substitutes for smoothing earnings. Following Barton (2001), Wang & Kao (2005) based on Taiwanese listed companies sample also find the substitution relationship between discretionary accruals and derivatives in earnings smoothing. However, the finding of Wang & Kao (2005) is based on SFAS No.27 (*Disclosure of Financial Instruments*) and on relative small hand-collected sample size (109 sample firms with 327 firm-year observations). Their underlying premise is also based on the comparative cost and benefit of discretionary accruals and derivatives as Barton' (2001) U.S. capital market setting. Recently, Kim et al. (2006) examine whether operational hedging (firms reporting foreign sales) can be viewed as either a substitute or a complement role to financial derivatives hedging when a firm intends to reduce the volatility of future cash flows and, thus, to possibly increase firm value. The authors find that non-operationally hedged firms use more financial hedging relative to their level of foreign currency exposure and suggest operational hedging is complement to financial derivatives hedging. According to above, to some extent, managers have incentives to smooth and/or enhance earnings and financial instruments can be an effective tool to meet their earnings management goals.

Hypothesis Developments

Prior studies document that financial instruments can be treated as a mean to strategically manipulate firm's earnings. Barton (2001) and Wang & Kao (2005) propose the income smoothing hypothesis and suggest both derivatives and discretionary accruals can be used for reducing earnings volatility. Recently, Adam & Fernando (2006) suggest that the active

usage of derivatives is thought to create firm value by alleviating a variety of market imperfections through hedging. Gèczy et al. (2007) also point out that derivatives can be undertaken with the intention of making a profit. Based on the above arguments, financial instruments usage can be viewed as either a substitute or a complement tool to a firm's discretionary accruals when it intends to reduce a firm's volatility of future cash flows or to possibly increase a firm's earnings. In the income smoothing hypothesis, it is expected that financial instruments usage can be partially substituted by the use of discretionary accruals. As for the earnings increasing hypothesis, it is expected that financial instruments usage is a complement tool to the use of discretionary accruals. Thus, that the goal of strategically uses of financial instruments is earnings smoothing or earnings increasing, to some extent, is an empirical issue in differential capital market setting.

Although Ewert & Wagenhofer (2005) develop an analytical model and demonstrate that real activities manipulation increases when tightening accounting standards make accruals management more difficult. However, accruals management and real activities manipulation (e.g., financial instruments usage) are not mutually exclusive strategies for managers and multiple tools can achieve the same earnings objective. Firms can use both accruals management and real activities manipulation to boost or constrain earnings and obtain the greatest effect through a coordinated approach (Mizik & Jacobson 2007, 2008). In other words, both accruals management and financial instruments manipulation play important roles in concurrently strategically boosting and/or suppressing firm's earnings.

As for the relative cost determination of alternative earnings management tools, prior studies show that the reporting and/or litigation costs in U.S. are relatively higher than that in other developed economies (e.g., Antle et al., 1997). The higher reporting and/or litigation costs bring about the cost-benefit consideration of accruals management and financial instruments usage manipulation an important issue in managers' strategic earnings reporting decisions. However, the relative cost-benefit of accruals management and financial instruments usage manipulation bonded by the lower reporting and/or litigation costs may make the earnings management incentives effect dominate the relative cost-benefit effect, and then, weaken the effect of cost determination in the selection decisions of alternative earnings management tools. Yet, the institutional consideration for managers to incorporate the relative cost-benefit of alternative manipulating tools into strategic earnings reporting decisions are likely to be less in Taiwan, where reporting and litigation costs are relatively lower.[1] Thus, without higher reporting and litigation costs to trigger the relative cost-benefit advantage consideration between accruals management and financial instruments usage manipulation, we expect the earnings management incentives effect will dominate the relative cost-benefit effect in managers' accruals management and financial instruments usage manipulation decisions.

Stulz (1996) documents that managers' market views influence their attempting to time commodity markets with financial derivatives usage decisions. The author claims that selective hedging will increase shareholder value if managers have an informational

[1] Taiwan is characterized as a smaller stock markets, weaker investor protections, and lower disclosure requirements (Chin et al., 2009). Chin et al. (2007) and Duh et al. (2009) also documented that the auditor litigation costs in Taiwan are lower than those in other developed economies. Thus, both the lower disclosure requirements and auditor litigation costs form a somewhat relative weaker financial reporting costs environment.

advantage relative to other market participants. Thus, it is possible that managers believe that they can create shareholder value by incorporating speculative elements into their financial instruments decisions. Sapra (2002) suggests that greater transparency about a firm's derivative activities is not necessarily a panacea for imprudent risk management strategies. The author shows that transparency actually induces the firm to take excessive speculative positions in the derivative market. In other words, after SFAS No.34 is enforced in Taiwan, once managers believe they have a comparative information advantage relative to the market and, hence, view speculation as a positive profitability activity, the magnitude of financial instruments usage will enlarge. In such situation, besides the aggressive discretionary accruals, financial instruments usage, involving real actions which have cash flows effects, play an important role in strategically boosting firm's earnings. It is expected that both the financial instruments usage and aggressive discretionary accruals play important roles in elucidating firms' income-increase reporting behaviors. Inspired by the studies of Sapra (2002), Adam & Fernando (2006), Gèczy et al. (2007) that view financial instruments usage as positive profitability activities, the present study conjectures that firms with active financial instruments positions will simultaneously use discretionary accruals to boost their earnings. Namely, this study examines the complement relationship between the financial instruments usage and aggressive accruals management in enhancing earnings. From the above discussions, we therefore establish our hypothesis as follows:

H1: The financial instruments usage regulated by SFAS No.34 is positive association with the magnitude of discretionary accruals.

RESEARCH DESIGN

Data and Sample Selection

Years 2006 and 2007 are chosen as the observation years because SFAS No.34 was enforced on 2006 and later annual reports in Taiwan. The sample firms used in this study are composed of publicly traded companies listed on the Taiwan Stock Exchange (hereafter, TSE) and Gre Tai Securities Market (hereafter, OTC) in Taiwan. That only TSE-listed and OTC-listed firms are considered is due to the feasibility of collecting the necessary reliable data. The empirical data are retrieved from both the Taiwan Economic Journal Database (TEJ) and the Open Market Observation Post System (MOPS) of the TSE and OTC in Taiwan.

Because there are insufficient sample firms in some industries for estimating discretionary accruals, except food (code 12), textile (code 14) electronic (codes 23, 24, 30) industries, we follow the study of Chang et al. (2003) and group some resembling industries into one integrated industry to obtain larger firm sample and avoid the inefficiency problem of regression coefficients estimation. Electric machinery (code 15) and electric wire (code 16) are combined as "electric" industry; plastics (code 13), chemical (code 17), and rubbery (code 21) are combined as "plastic and chemical" industry; cement (code 11), iron (code 20), and construction (code 25) are combined as "construction and building materials" industry; tourism (code 27) and general merchandise (code 29) are combined as "service and sales" industry. Table 1 reports the resulted seven industries in the study.

Table 2 presents the sample selection process of the present study. Consistent with extant

literature, finance-related institutions (codes 2801 to 2888) are excluded as they are subject to different disclosure requirements and regulations that make using industry cross-sectional Jones model to estimate discretionary accruals problematic. The total observations of firms traded in TSE and OTC during 2006~2007 are 2,459 firm/years. The present study follows the study of Chang et al. (2003) and deletes glass-ceramic, paper, automobile industries, shipping and transport industry, oil industry, and other industries because of too few listed firms causing trouble in estimating discretionary accruals. We also deleted 394 observations for data deficient or unavailable. These selection procedures yield a final sample of 1,834 firm/years, which include 837 firms in year 2006 and 997 firms in year 2007, respectively.

Table 1: Integrated Industry Analysis.

Integrated or Individual Industry	Industry Composition
Construction and Building Materials (11,20,25)	Construction, Steel, and Building
Plastic and Chemical (13,17,21)	Plastic, Chemical, Rubber and Tire
Electric (15,16)	Electric Machinery, Electric Wire and Cable
Service and Sales (27,29)	Tourism and General Merchandise
Electronic (23, 24, 30)	Electronic
Foods (12)	Foods
Textile (14)	Textile and Fiber

Table 2: Sample Selection.	2006	2007	Total
Firms listed on TSE and OTC during 2006~2007	1,229	1,230	2,459
Less:			
Too few listed firms industry:			
Shipping and Transport industry	(22)	(22)	(44)
Oil industry	(12)	(12)	(24)
Paper industry	(7)	(7)	(14)
Glass and Ceramic industry	(7)	(5)	(12)
Automobile industry	(5)	(5)	(10)
Other industries	(64)	(63)	(127)
Firms' data unavailability:	(275)	(119)	(394)
Final samples	837	997	1,834

Variables Measurement and Empirical Model

This section presents the methodology implementing to examine the hypothesis. Since the usage of financial instruments regulated by SFAS No.34 and discretionary accruals may be endogenous, the simultaneous equations are developed to avoid bias and the inconsistent coefficients estimation of ordinary least squares (OLS). Following Barton (2001) and Wang & Kao (2005), the relationship between financial instruments usage and discretionary accruals is tested by the following simultaneous equations estimated by two-stage least squares (2SLS) regression. To test our hypothesis, the present study uses the following simultaneous equations:

$$|\mathbf{DIC}|_{it} = \alpha_0 + \alpha_1 \mathbf{DER}_{it} + \alpha_2 \mathbf{COMP}_{it} + \alpha_3 \mathbf{STOCK}_{it} + \alpha_4 \mathbf{DEBT}_{it} + \alpha_5 \mathbf{RD}_{it} + \alpha_6 \mathbf{FS}_{it} + \alpha_7 \mathbf{IDR}_{it} + \alpha_8 \mathbf{IND}_{it} + \alpha_9 \mathbf{DPR}_{it} + \alpha_{10} \mathbf{FLEX}_{it} + \alpha_{11} |\mathbf{OCF}|_{it} + \alpha_{12} \mathbf{ROA}_{it} + \alpha_{13} \mathbf{SIZE}_{it} + \alpha_{14} \mathbf{MILLS}_{it} + \zeta_{it} \quad \text{.....(1)}$$

and

$$\mathbf{DER}_{it} = \beta_0 + \beta_1 |\mathbf{DIC}|_{it} + \beta_2 \mathbf{COMP}_{it} + \beta_3 \mathbf{STOCK}_{it} + \beta_4 \mathbf{DEBT}_{it} + \beta_5 \mathbf{RD}_{it} + \beta_6 \mathbf{FS}_{it} + \beta_7 \mathbf{IDR}_{it} + \beta_8 \mathbf{IND}_{it} + \beta_9 \mathbf{QR}_{it} + \beta_{10} \mathbf{CYCLE}_{it} + \beta_{11} \mathbf{DIV_YIELD}_{it} + \beta_{12} \mathbf{ST_DEBT}_{it} + \alpha_{13} \mathbf{MILLS}_{it} + \xi_{it} \quad \text{.....(2)}$$

where:

$|\mathbf{DIC}|$ and $\mathbf{DER}$ are the proxies for discretionary accruals and financial instruments usage regulated by SFAS No.34, respectively. In simultaneous equations, $|\mathbf{DIC}|$ and $\mathbf{DER}$ are endogenous variables, concurrently, the other variables are control variables and will be defined in section 3.3. Furthermore, the possible self-selection problem is corrected by adding the inverse Mills ratio (MILLS) variable, which suggested by Heckman (1979), into the simultaneous equations.

Because the sample firms do not have sufficient time series data to estimate the parameters of the Jones (1991) model when determining $|\mathbf{DIC}|$, we measure discretionary accruals (DA) via the cross-sectional version of the Jones (1991) model as reported in DeFond & Jiambalvo (1994)[2]. Subramanyam (1996) and *Bartov et al.* (2001) indicate that this approach is generally better specified than the time-series model. Recently, Kothari et al. (2005) suggest that incorporating a performance measure into Jones model to estimate the parameters of the nondiscretionary accruals can effectively enhance the model specification. Therefore, we estimate the discretionary accruals (DA) by the prediction errors from the cross-sectional Jones model of Kothari et al. (2005). As discussed above, we follow the study of Chang et al. (2003), grouping some resembling industries into one integrated industry to come up with a larger sample, thus to avoid the inefficiency of regression coefficients estimation when getting the estimates of nondiscretionary accruals.

The financial instruments regulated by SFAS No.34 include: financial assets/liabilities at fair value through profit or loss, held-to-maturity investments, available-for-sale financial assets, hedging derivative assets/liabilities, financial assets/liabilities carried at amortized cost, financial assets carried at cost. Thus, in order to catch the earnings management intention of the financial instruments usage, our second pivotal variable DER is measured as the change in sum of notional amount of financial assets and financial liabilities regulated by SFAS No.34 scaled by lagged total assets. It is described as follows:

$$\mathbf{DER} = \left(\mathbf{TFA}_{it} - \mathbf{TFA}_{it-1}\right) / \mathbf{A}_{it-1}$$

[2] The modified Jones model proposed by Dechow et al. (1995) is also used to enhance the robustness of our study. The result is discussed in the robustness check.

where:

TFA is defined as the sum of notional amount of total financial assets plus total financial liabilities regulated by SFAS No.34. According to the definition, the DER may be positive or negative. Positive DER indicates that there is an increasing usage of financial instruments regulated by SFAS No.34. On the other coin, negative DER reveals that there is a decreasing usage of financial instruments regulated by SFAS No.34.

Definitions of Control Variables

Inverse Mills Ratios

To measure the inverse Mills ratio, we first estimate the following equation to explain the decision to use financial instruments:

$$USER_{it} = \gamma_0 + \gamma_1 COMP_{it} + \gamma_2 STOCK_{it} + \gamma_3 DEBT_{it} + \gamma_4 RD_{it} + \gamma_5 FS_{it} + \gamma_6 IDR_{it} + \gamma_7 IND_{it} + \gamma_8 QR_{it} + \gamma_9 CYCLE_{it} + \gamma_{10} DIV_YIELD_{it} + \gamma_{11} ST_DEBT_{it} + \nu_{it} \ldots.(3)$$

where:

USER is a binary variable and coded 1 if the firm uses financial instruments, 0 otherwise. We use probit regression on the full sample of 1,834 firm-years to estimate equation (3). Following Greene (2004), γ and W are denoted as the coefficient vector and the explanatory variable vector in the financial instruments user model respectively. And let $\hat{\gamma}$ be the estimate of γ. Then, the inverse Mills ratio is defined as: $\mathbf{MILLS} = \phi(\hat{\gamma}'\mathbf{W}) / \Phi(\hat{\gamma}'\mathbf{W})$ if **USER** variable equals 1 and $\mathbf{MILLS} = \phi(\hat{\gamma}'\mathbf{W}) / [\Phi(\hat{\gamma}'\mathbf{W}) - 1]$ if **USER** variable equals 0, where: $\phi(\bullet)$ and $\Phi(\bullet)$ are denoted as the standard normal probability density function and the standard normal cumulative distribution function, respectively. We include MILLS as an additional control variable to correct for potential self-selection bias in the empirical equation.

Common Explanatory Variables for both $|\mathbf{DIC}|$ *and* $\mathbf{DER}$ *Equations*

Cash compensations for managers are increased with the firm's performance such as profit. The interest conflicts exist between managers and shareholders conditional on maximizing managers' self-interests. Managers might want to increase their cash compensations by increasing earnings myopically. It is expected that cash compensations (COMP) will be positively associated with the pivotal variables, i.e., $|\mathbf{DIC}|$ and $\mathbf{DER}$. COMP is measured as the directors', supervisors', and CEOs' salaries and bonuses, scaled by lagged total assets. It is also found that managers have incentives to increase earnings to raise their values brought from ownership. Thus, we expect managers' stock holdings to be associated with $|\mathbf{DIC}|$ and $\mathbf{DER}$. Stock holdings (STOCK) are measured as the sum of percentages of the stock ownerships owned by directors, supervisors, and CEO. In addition, managers may avoid violating the debt covenants based on accounting performance. DeFond & Jiambalvo (1994) provide evidence that managers tend to increase earnings when the leverage is raised. We use debt-to-assets ratio (DEBT), defined as total liabilities divided by total assets, to proxy for leverage risk. It is expected that DEBT will be associated with our two pivotal variables, i.e.,

$|\mathbf{DIC}|$ and $\mathbf{DER}$.

Baber et al. (1991) point out when pre-R&D earnings are low, managers may strategically prune away investment in R&D expenditures. It suggests that R&D intensity will be positively associated with $|\mathbf{DIC}|$ and $\mathbf{DER}$. Thus, we incorporate R&D intensity into empirical models to capture the relationship between R&D intensity and two explained variables. R&D intensity is defined as the ratio of R&D expense to equity market value. Moreover, Jorion (1990) documents that foreign sale is positively associated with the absolute value of exposure to foreign exchange rate risk. Since exports sale is an important revenue for listed firms in Taiwan, we expect firms with international diversification have more opportunity to manage earnings by way of $|\mathbf{DIC}|$ and $\mathbf{DER}$. We thus use ratio of foreign sales to total sales (FS) to measure firms' business diversification to capture the possible influences of diversification on $|\mathbf{DIC}|$ and $\mathbf{DER}$. Wang & Kao (2005) reveal that interest-rate risk is positive associated with $|\mathbf{DIC}|$ and $\mathbf{DER}$. Following Wang & Kao (2005), we use the absolute value of the difference between interest revenues and interest expenses scaled by net sales (IDR) to measure interest-rate risk and expect IDR will be positive with $|\mathbf{DIC}|$ and $\mathbf{DER}$. Naturally, the percentage of firms belonging to electronic industries is 64.89% in our empirical data, thus, an electronic industry dummy variable (IND) is used to control for the industry characteristics. IND is coded 1 if the sample firm belongs to electronic industry and 0 otherwise.

Control Variables for the Discretionary Accruals Model

Previous studies document that when pre-management earnings are low, managers might myopically increase earnings to maintain the common dividend payout levels. Dividend payout ratio (DPR) is defined as the ratio of cash dividends to earnings per share before discretionary accruals. In addition, managers in industries with more accounting flexibility are likely to manage accruals to a greater extent (Barton, 2001). The present study follows Barton (2001) and uses the root mean squared error of equation (4) as a proxy for industry accounting flexibility (FLEX). It is expected that FLEX will be positively associated with the magnitude of discretionary accruals.

The literature related to discretionary accruals are based on the *maintained hypothesis*; however, Dechow et al. (1995) point out that the modified Jones model will overstate the magnitude of discretionary accruals for firms with extreme operating cash flows. The absolute value of operating cash flows scaled by lagged total assets (|OCF|) is used to control for the potentially measurement error. If ROA of a firm is high, the manager is less likely to myopically increase earnings (Bowen et al., 1995). ROA in this paper is measured as the ratio of net income before interest and depreciation net of tax to average total assets. The relation between ROA and $|\mathbf{DIC}|$ is predicted to be negative. In the view of economics of regulation, large firms tend to manage earnings to avoid the monitors from capital market regulator and the government. DeFond & Park (1997) provides evidence on the positive relation between firm size and the magnitude of discretionary accruals. The natural logarithm of net sales, denoted as SIZE, is the proxy of firm size in this paper.

Control Variables to Financial Instruments Usage Regulated by SFAS No.34

Firms with large current assets face less financial distress (Nance et al. 1993). Froot et al. (1993) also indicate that the liquidation of assets is negatively associated with the use of derivatives. Therefore, quick ratio (QR), defined as the ratio of quick assets to current liabilities, is used to be a proxy for a firm's liquidation. Firms with long cash conversion cycles are more likely to benefit from hedging because their cash flows are exposed to volatility in market prices (Barton 2001). Cash cycle (CYCLE) is measured as the average collection days of accounts receivables, net of the average payment days of accounts payables, plus average days of inventory sell-out. CYCLE variable is predicted to be positively related with **DER** . In addition, Barton (2001) documents that large expected dividend yield increases the firm's cash need, managers tend to hedge against the volatility in cash flows. Hence, we expect that dividend yield (DIV_YIELD), measured as the ratio of cash dividends to market value of common stocks, will be positively correlated with **DER** . Finally, firms with shorter debt maturity are more likely to use interest rate swaps to hedge risk exposure, thus, a positive correlation between short maturity debts and DER is expected (Barton 2001). Short maturity debts (ST_DEBT) are measured as current liabilities divided by total liabilities.

EMPIRICAL RESULTS

We first present the summary statistics and correlation analyses of related variables in this study. Second, two-stage least squares regression results for the DER and |DIC| simultaneous equations are presented.

Descriptive Statistics

Table 3 reports the descriptive statistics for the related variables in this study. The average absolute discretionary accruals (|DIC|) is 0.073, which is statistically significant at 1% level. The average financial instruments usage (DER) is 0.019. The average ratio of cash compensations (COMP) is 0.9%. It indicates that managers receive relative moderate cash compensations in the sample. The average ownership of managers (STOCK) is 23.8% (median is 20.9%) and show the ownership structures of firms in Taiwan are characterized by a higher degree of concentration. The average ratio of leverage and average R&D intensity are approximately 0.37 and 0.024, respectively. More than half of revenues come from foreign sales documents that international business activities play an important role in the revenues structure in our sample. The average ratio of interest difference is 0.014. The mean of FLEX is 0.017 and documents that there is little difference in the flexibility of GAAP in different industries. The average ROA of the sample is approximate 6%. The average cash conversion cycle is about 101 days. The average dividend yield is 3%. Finally, the average SH_DEBT is 0.758 which reveals half of the total liabilities are short maturity debts in the sample of this study.

Table 3: Descriptive Statistics of Related Variables (n=1,834).

Legends:
|DIC|=discretionary accruals. DER=financial instruments usage regulated by SFAS No.34. COMP=cash compensations for managers scaled by lagged total assets. STOCK=the ownership owned by managers. DEBT=the ratio of total liabilities to total assets. RD=the ratio of R&D expenditures to market value of common equity. FS=the ratio of net foreign sales to net sales. IDR=the absolute value of difference between interest revenues and interest expenses scaled by net sales. IND=1 if the sample firm belongs to electronic industry, and 0 otherwise. DPR=the ratio of cash dividends to earnings net of discretionary accruals per share. FLEX=the root mean squared error of equation (4). |OCF|=the absolute value of operating cash flows scaled by lagged assets. ROA=the ratio of net income before interest and depreciation net of tax to average total assets. SIZE=nature log of net sales. QR=the ratio of quick assets to current liabilities. CYCLE=the average collection days of accounts receivables, net of the payment days of accounts payables, plus average days of inventory sell-out. DIV_YIELD=the ratio of cash dividends for common stock to market value of common equity. ST_DEBT=current liabilities scaled by total liabilities.

Correlation Analysis

According to the study of Barton (2001), earnings is the sum of cash flows and accruals, thus, the variance of earnings (σ_E^2) is a function of the variance of cash flows (σ_C^2), the variance of accruals (σ_A^2), and the correlation coefficient of cash flows and accruals (ρ_{CA}). In other words, the equation $\sigma_E^2 = \sigma_C^2 + \sigma_A^2 + 2\rho_{CA}\sigma_C\sigma_A$ will be hold. Therefore, it is reasonable to observe that managers smooth earnings volatility by adjusting cash flows volatility, accruals volatility, and/or the correlation between cash flows and accruals. However, when the myopic earnings increase motivation replaces the possible earnings smoothing behavior by managers, it is expected to find distinct relationship between financial instruments usage and discretionary accruals, which is different with those observed in Barton (2001) and Wang & Kao (2005). The present study first follows the procedure suggested by Barton (2001) and correlates the earnings volatility with $|\mathbf{DIC}|$ and $\mathbf{DER}$ variables to provide preliminary comparison evidences. We use sample firm's quarterly data to calculate the coefficient of variation (CV) to measure volatility. Panel A in Table 4 presents the descriptive statistics for the coefficient of variation for earnings, operating cash flow, and total accruals. The average coefficients of variation of earnings, operating cash flow, and total accruals are 2.660, 4.926, and 8.948, respectively. It is found that total accruals are more volatile than operating cash flows and earnings.

Panel B in Table 4 presents the correlations between **DER** (|**DIC**|) and the coefficient of variation (CV) of related variables. It documents that **DER** is insignificantly negative-associated with the volatilities of cash flows and accruals. But the rank correlations between **DER** and the volatilities of earnings is 0.058 which is statistically significant at 5% level. This result is inconsistent with the finding of Barton (2001) and does not support the **DER** smoothing earnings volatility conjectures. The correlation between |**DIC**| and volatilities of earnings is 0.005 which is positive but not statistically significant. Operating cash flows and total accruals are both negatively associated with |**DIC**| and again are inconsistent with the finding of Barton (2001). Overall, the fact that financial instruments usage regulated by SFAS No.34 (i.e., DER) and discretionary accruals (i.e., |DIC|) are positively associated with the volatility of earnings suggests that managers do not use both financial instruments and discretionary accruals to smooth earnings volatility. Thus, the conclusion that the usage of financial instruments can smooth earnings volatility, which is suggested by Barton (2001), is called for further examinations.

Although the untabulated Pearson/Spearman correlation matrix for the related variables in equations reveal most of the independent variables are correlated with others, the variance inflation factors (VIF) of the explanatory variables (unreported) in the regressions are less than 10 and do not suggest severe multi-collinearity problems (Neter et al., 1989).

Table 4: Rank Correlations between |DIC| and DER and the Coefficient of Variation.

Panel A. Descriptive Statistics for the Coefficient of Variation(n=1,834)

Variables	Mean	Standard deviation	First quartile	Median	Third quartile
Coefficient of variation for the variable: [a]					
Earnings	2.660	18.774	0.305	0.570	1.196
Operating cash flows	4.926	23.029	0.803	1.704	3.704
Total accruals	8.948	46.213	1.239	2.431	5.375
Correlation between operating cash flows and total accruals	-0.857	0.292	-0.993	-0.970	-0.875

Panel B. Correlations between |DIC|, DER and the Coefficient of Variation (n=1,834) [b]

CV of variables	|DIC|	DER
CV of earnings	0.005	0.058**
CV of operating cash flows	-0.025	-0.002
CV of total accruals	-0.053**	-0.005
Correlation between operating cash flows and total accruals	-0.031	-0.007

Legend:

a. The coefficient of variation is the standard deviation of the variable divided by the absolute value of its mean, based on quarterly data for 2006 and 2007.

b. *, **, *** denote significance at the 10%, 5%, and 1% levels respectively, based on two-tailed tests.

Simultaneous Regression Results

From Table 5, the coefficients of DER in Equation (1) and |DIC| in Equation (2) are 3.067 (t=29.28) and 0.256 (t=7.00), respectively, and both positively statistically significant at 1% level. It documents that managers use both financial instruments and discretionary accruals to increase earnings, yet, not to smooth earnings. It is reasonable to conclude that managers

use financial instruments and discretionary accruals as complement tools rather than substitute tools in create firms' net income. Our hypothesis is empirically supported.

The empirical results from common control variables are discussed as follows. The coefficients of COMP variable are -0.501(t=-2.43) and -0.193 (t=-0.67) in the DER and |DIC| models, respectively. It is unexpected to find that COMP is negatively associated with DER and |DIC|. This may be due to the fact that cash compensation in many Taiwanese firms is replaced with stocks or stock options in recent years. The coefficients of STOCK variable are -0.046(t=-4.27) and 0.003 (t=0.21) in the |DIC| and DER models, respectively. The coefficient of STOCK is negative statistically significant associated with |DIC| at 1% level. It implies that the interest conflict between shareholders and the managers holding large shareholdings is not severe and consistent with the argument of Jensen and Meckling (1976). However, in the DER model, the coefficient of STOCK is positive but not statistically significant. The coefficient of DEBT is 0.281(t=24.07), which proxy of leverage risk, is positive statistically significant associated with |DIC|. Consistent with the finding of DeFond & Jiambalvo (1994), this result reveals that the firms with higher leverage are more inclined to manipulate earnings.

Table 5: Regression Results for Simultaneous Equations (n=1,834).

$$|\mathbf{DIC}|_{it} = \alpha_0 + \alpha_1 \mathbf{DER}_{it} + \alpha_2 \mathbf{COMP}_{it} + \alpha_3 \mathbf{STOCK}_{it} + \alpha_4 \mathbf{DEBT}_{it} + \alpha_5 \mathbf{RD}_{it} + \alpha_6 \mathbf{FS}_{it} + \alpha_7 \mathbf{IDR}_{it} + \alpha_8 \mathbf{IND}_{it} + \alpha_9 \mathbf{DPR}_{it} + \alpha_{10} \mathbf{FLEX}_{it} + \alpha_{11} |\mathbf{OCF}|_{it} + \alpha_{12} \mathbf{ROA}_{it} + \alpha_{13} \mathbf{SIZE}_{it} + \alpha_{14} \mathbf{MILLS}_{it} + \zeta_{it} \cdots (1)$$

Legends:

1. MILLS is the inverse Mills ratio obtained from Equation (4). Other variables are defined in Table 3.
2. *, **, *** denote the significance on 10%, 5%, and 1% levels respectively, based on two-tailed tests.

The coefficients of RD variable are 0.383(t=8.35) and -0.116(t=-1.82), which statistically significant at 1% and 10% level respectively, in the |DIC| and DER models. The statistically significant positive relation between R&D intensity and discretionary accruals reveals that managers with more growth opportunities tend to manage earnings to prevent underinvestment problems. However, the negative relationship between RD and DER suggests that the usage of financial instruments is decreased for managers with more growth opportunities. It is interesting to find that FS is statistically significant positively related with |DIC|, yet, statistically insignificant negatively related with DER. It implies that managers with higher exchange rate risk increase the use of discretionary accruals. However, a distinct pattern is revealed by the IDR variable empirical findings. The coefficients of IND variable are -0.050(t=-14.150) and 0.006(t=1.170) in the |DIC| and DER models, respectively. The empirical results reveal that the use of discretionary accruals is decreased for firms belonging to electronic industry when comparing with firms in other industries. Nevertheless, managers in electronic industry use slightly more financial instruments. The reason for this result may be attributed to the fact that there is strong demand for cash flow hedge for firms in electronic industry and managers use financial instruments to smooth cash flows volatility, then, decrease the usage of discretionary accruals.

As to the exclusive variables in the |DIC| model, the coefficients of FLEX and |OCF| are 1.631(t=8.38) and 0.362(t=23.84), respectively, which are both positive and statistically significant at 1% level. It reveals that firms with more FLEX and larger magnitude of operation cash flows tend to use discretionary accruals to manipulate earnings. The coefficients of DPR, ROA and SIZE are -0.009(t=-2.44), -0.045 (t=-2.78) and -0.003(t=-2.54), both negative and statistically significant at 5%, 1% and 5% level, respectively. As to the exclusive variables in the DER model, the coefficient of QR variable is 0.005(t=4.36), positive and statistically significant at 1% level. The coefficient of CYCLE variable is -0.00004(t=-2.37), negative and statistically significant at 5% level. The coefficients of DIV_YIELD and ST_DEBT are statistically insignificant.

ROBUSTNESS TEST

The present study implements some diagnostic checks (untabulated) to confirm our initial findings. First, we know that three-stage least squares (3SLS) extend 2SLS and include all equations estimation at the same time. In order to gain confirmatory evidence to support our empirical results, the 3SLS regression is implemented in this study to estimate more efficient coefficients. The result of 3SLS regression reveals that the coefficients of DER in Equation (1) and |DIC| in Equation (2) are 0.689(t=2.74) and 0.079(t=2.15), both positive and statistically significant at 1% and 5% level, respectively. This additional evidence suggests our empirical result is robust to the 3SLS regression examination.

Second, the present study further examines DER and |DIC| models independently by traditional ordinary least squares (OLS) to gain comparing evidence. These further examination results reveal that the coefficients of DER in Equation (1) and |DIC| in Equation (2) are 0.060(t=3.27) and 0.101(t=4.33), again, both positive and statistically significant at 1% level, respectively. The significantly positive relation between DER and |DIC| indicates that the primary results do not topple by separated OLS estimations of Equation (1) and (2).

Third, the present study replaces the discretionary accruals measured from cross-sectional Jones (1991) model by the discretionary accruals measured from cross-sectional modified Jones model. In the 2SLS regressions, the coefficients of DER in Equation (1) and |DIC| in Equation (2) are 3.146(t=30.38) and 0.257(t=7.25), respectively, both positive and statistically significant at 1% level. In the 3SLS regressions, the coefficients of DER in Equation (1) and |DIC| in Equation (2) are 0.796(t=3.55) and 0.085(t=2.18), which are positive and statistically significant at 1% and 5% level in the |DIC| and DER models, respectively. The additional evidence suggests that the positive correlation between DER and |DIC| unlikely results from the misspecification of discretionary accruals.

Finally, in order to gain comparative results with Barton (2001), we further use the stock concept to measure the position of financial instruments held by sample firms. Accordingly, DER variable is redefined as the sum of notional amount of financial assets and financial liabilities regulated by SFAS No.34 scaled by lagged total assets. The 2SLS regression empirical results show that the coefficients of DER and |DIC| are 0.988 (t=13.32) and 0.220(t=4.73), respectively, when discretionary is measured by Jones model. Alternative, the 2SLS regression empirical results report the coefficients of DER and |DIC| are 1.039 (t=13.95) and 0.224(t=4.97), respectively, when discretionary is measured by modified Jones model.

In summary, we obtain supportive evidence on our hypothesis that managers view derivatives and discretionary accruals as partial complement tools in enhancing earnings. The above additional diagnostic checks demonstrate that our empirical results are robust to different estimating methods and specifications of variables.

CONCLUSION

Prior studies document that firms can use derivative instruments to speculate and/or to arbitrage on private information, yet, few studies highlight the risk hedging motive and ignore the important roles of the other two key participants. Adam & Fernando (2006) argue that the active usage of derivatives is thought to add value by alleviating a variety of market imperfections through hedging. Gèczy et al. (2007) also suggest that financial derivatives involve real action which plays an important role in strategically boosting firm's earnings and view speculation as a positive profitability activity. Although Barton (2001) and Wang & Kao (2005) evidence managers appear to trade-off derivatives and discretionary accruals for incentives to smooth earnings. The present study alternatively use the financial instruments usage regulated under SFAS No.34 in Taiwan to examine the hypothetical complement relationship between financial instruments usage and discretionary accruals in enhancing earnings.

The empirical result indicates that financial instruments usage is positive associated with the magnitude of discretionary accruals and supports our complement hypothesis. It suggests that managers use financial instruments and discretionary accruals jointly to increase earnings, contrary to the conclusions of Barton (2001) and Wang & Kao (2005). Our empirical results to some extent evidence the possible potential multi-purposes of financial instruments usage and support the findings of Sapra (2002). These results remain robust to various specification tests.

ABSTRACT

This study concentrates only silicon wafer laser dicing. It has the major problem which is meandering. According to the very narrow saw street in silicon wafer, only 15 µm, the saw kerf from laser dicing process exceed into chip circuit that will be the defect. The objective of the research study is to find the optimal settings for silicon wafer laser dicing process in order to achieve the target of 3 µm maximum fluctuation of meandering.

Keywords: meandering; laser dicing; design of experiment; fractional experiment.

INTRODUCTION

Nowadays, competition in the manufacturing industry is increasing in both domestic and international markets. Significant factors that make a manufacturing company competitive in the worldwide market are quality, delivery and cost. It is generally agree that the quality and cost represent an essential factor in business's growth. Therefore, the thought of quality and cost are highly important.

With ongoing miniaturization of IC's the ratio of the functional wafer surface gets lower and lower. The non functional wafer area for the next generation of RFID chips rises up to 30% with smallest conventional saw lane design available. Therefore new chip separation technologies were evaluated to enable a significant reduction of the saw lane width and thus a significant increase of the number of dies per wafer.

Currently, the conventional concept to separate chip is blade dicing, which has saw blade to saw on wafer saw lane. However, the capability of blade dicing is limitation. This method can support at 50 µm saw lane width in minimum. And with mechanical sawing on silicon might lead to generate the chipping or crack on wafer as well.

Therefore, laser dicing machine, the high accuracy and high capability machine used to separate wafer, is applied to improve quality and reducing cost. That's can support the silicon wafer which are 15 µm saw lane width. The concept of laser dicing is laser diode will generate the

pulse to destroy silicon structure and breaking the wafer again after laser pulse. With this concept there is no chip or crack happen compare to blade dicing method. Since this is quite new concept machine so, sometimes the unforeseen problem might be happen.

As mentioned above there are some serious defects happened. Meandering is one of the most critical. The characteristic of defect is look like wavy kerf. That's still acceptable if the maximum fluctuation is not over than 3 µm. In fact we faced about 4 to 5 µm. Since the new type of wafer, the saw lane width was decreased to 15 µm to gain more and more chip in one wafer. That's mean this kind of defect can be destroyed of whole wafer. And those defect silicon wafers will be scraped.

As a conclusion, the meandering was a major problem in laser dicing process. The fault tree analysis is applied to find the potential root cause of meandering. Next, the Design of Experiment (DOE) is applied to reduce this kind of defect. After the experiments are conducted, the best setting is selected. Next, the confirmation experiment are conducted in order to confirm the settings that the maximum fluctuation us not over 3 µm.

BACKGROUND

In the past silicon wafers have been diced by using blade saw. This method is called blade dicing method. Kumagai et al. (2007) the blade dicing process causes undesirable mechanical vibrations and stress in the wafer which make damage in the wafer consisting of cracks, chippings, etc. When the dicing processing speed increases or wafer thickness decreases, the defects increase as well. However, the semiconductor wafers are becoming thinner and thinner in advanced manufacturing. Moreover, the processing speed is important characteristics for the productivity. In order to solve blade dicing problems, laser dicing methods have been developed (Hermanns, 2005). Stealth dicing method is one kind of laser dicing methods (Fukuyo et al, 2005). The laser beam is focused into the interior of the work wafer as well as the laser processing only occurs inside the wafer. The coolant and washing water are not necessary at all for this stealth dicing method since it does not cause any frictional heat and debris. The stealth dicing method has three advantages as follows (Kumagai et al., 2007).

1) High-speed dicing for thinner wafers without any chipping.

2) No debris contaminants that are caused by blade dicing or laser ablation;

3) Completely dry process.

METHODOLOGY

In order to search for the optimal setting of the laser dicing process, the following steps are performed:

1. Determine the potential factors affected to the fluctuation of meandering by using fault tree analysis.
2. Conduct the screening experiment with 3 replications to eliminate the factors which is not affected the fluctuation of meandering.
3. Conduct the following experiment to determine the best settings which give the smallest maximum fluctuation of meandering.
4. Conduct the confirmation experiment in order to confirm the settings that the maximum fluctuation us not over 3 µm.

RESULTS

By brainstorming with process and manufacturing engineers, four major areas 1) product 2) machine 3) process and 4) materials, are used as the focused area for fault tree development.

The fault tree analysis for meandering is shown in figure 1.

Figure 1: Fault tree analysis for meandering.

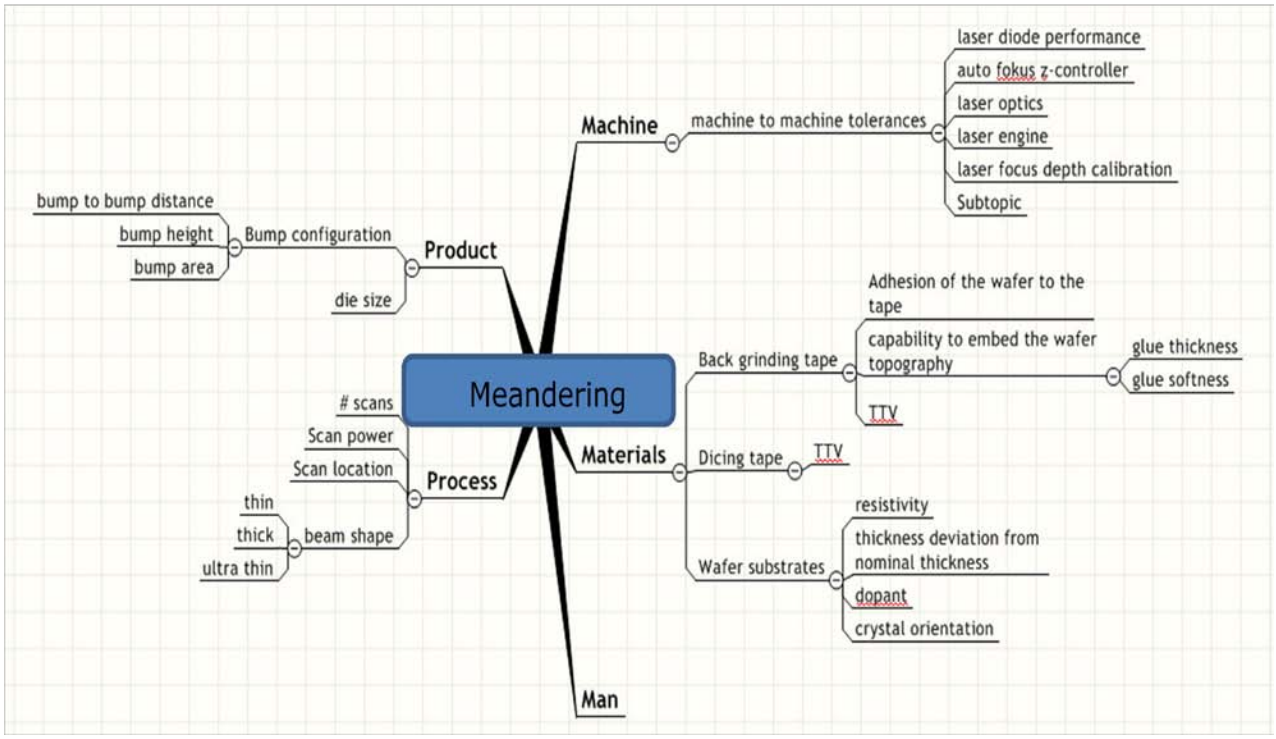

Figure 1: Fault tree analysis of meandering.

For the product, there is only one product type for experiment and they are from the single source. For machine, machine was calibrated to make sure that it is ready for running. For

materials, there is only one type of backgrind tape, dicing tape and wafer substrates. Therefore, the potential factors affected to the fluctuation of meandering are from process which are scanning height (factor A), scan power 1 (factor B), scan power 2 (factor C), beam shape (factor D) and scanning speed (factor E). These factors are considered at two levels each. The levels for all factors are shown in table 1.

Table 1: Factors and Levels of 2^5 factorial experiment.

Factors	Level	
	Low	High
scanning height (A)	10,9	16,3
scan power 1 (B)	0.12 Watt	0.36 Watt
scan power 2 (C)	0.18 Watt	0.54 Watt
beam shape (D)	Ultrathin	Thick
scanning speed (E)	100 mm/s	300 mm/s

The results are shown in table 2.

Table 2: Results of 2^5 factorial experiment with 3 replications.

Scanning Height (A)	Scan Power 1 (B)	Scan Power 2 (C)	Beam Shape (D)	Scanning Speed (E)	REP I	REP II	REP III	Average

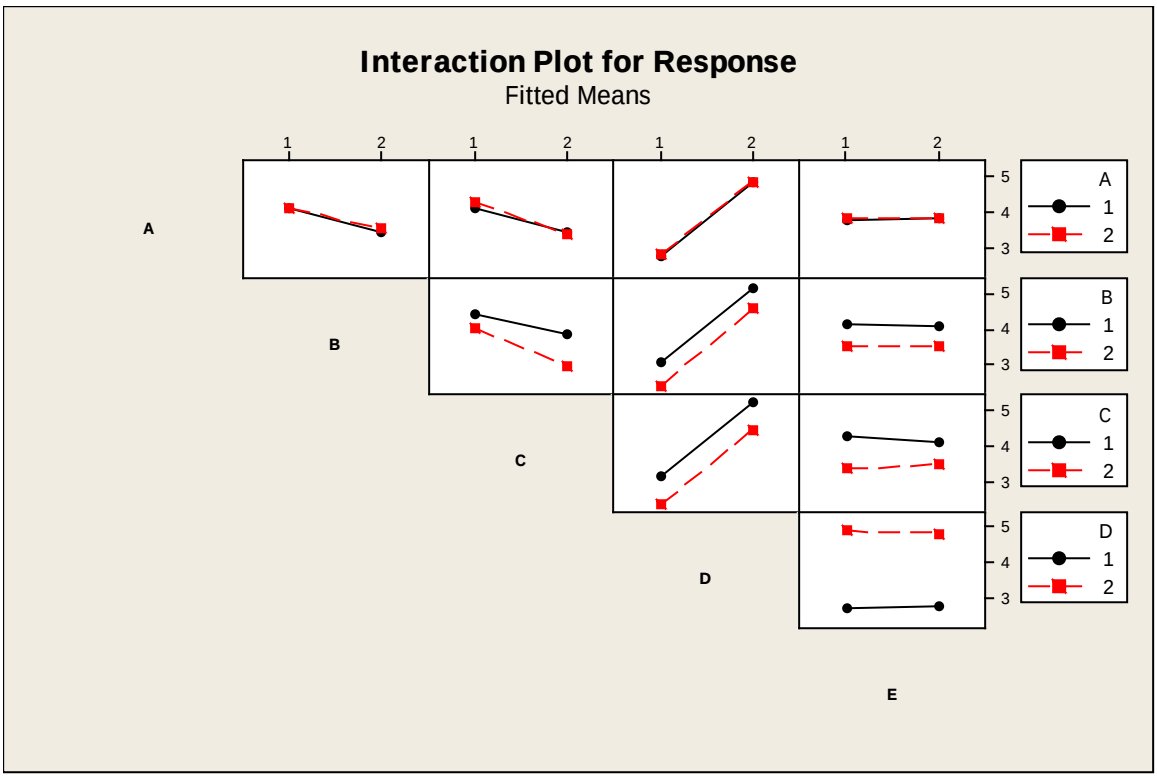

Figure 2: Interaction plot for response 2^5 factorial experiment.

According to table 3, the factors which affect to fluctuation of meandering is factor B,C, D and interaction of factor B and C by using 0.01 significance level. For the following experiment, factor B and C is conducted with four levels. However, factor D is conducted with two levels. According to figure 2, interaction plot of factor D with factor A, B, C and E at level 1 (ultrathin) give the smaller responses than level 2 (thick). Therefore, the following experiment is conducted with two levels which are ultrathin and thin for factor D. Next the $4^2.2^1$ factorial experiment with 5 replications is conducted. The levels for each factor are shown in table 4.

Table 4: Factors and Levels of $4^2.2^1$ factorial experiment with 5 replications.

Factors	Level			
	1	2	3	4
scan power 1 (B)	0.12	0.24	0.36	0.48
scan power 2 (C)	0.18	0.36	0.54	0.72
beam shape (D)	Ultrathin	Thin		

For the factors which are not affected to the fluctuation of meandering, they are fixed at the appropriate value. Scanning height (factor A) is fixed at the middle value of 10,9 and 16,3 which is 13,6. Scanning speed (factor E) is fixed at 300 mm/s because this is the maximum value of scanning speed which gives the highest productivity. The results are shown in table 5.

Table 5: Results of $4^2.2^1$ factorial experiment with 5 replications.

Scanning Height (A)	Scan Power 1 (B)	Scan Power 2 (C)	Beam Shape (D)	Scanning Speed (E)	REP I	REP II	REP III	REP IV	REP V	Average

R-Sq(adj) =78.35%

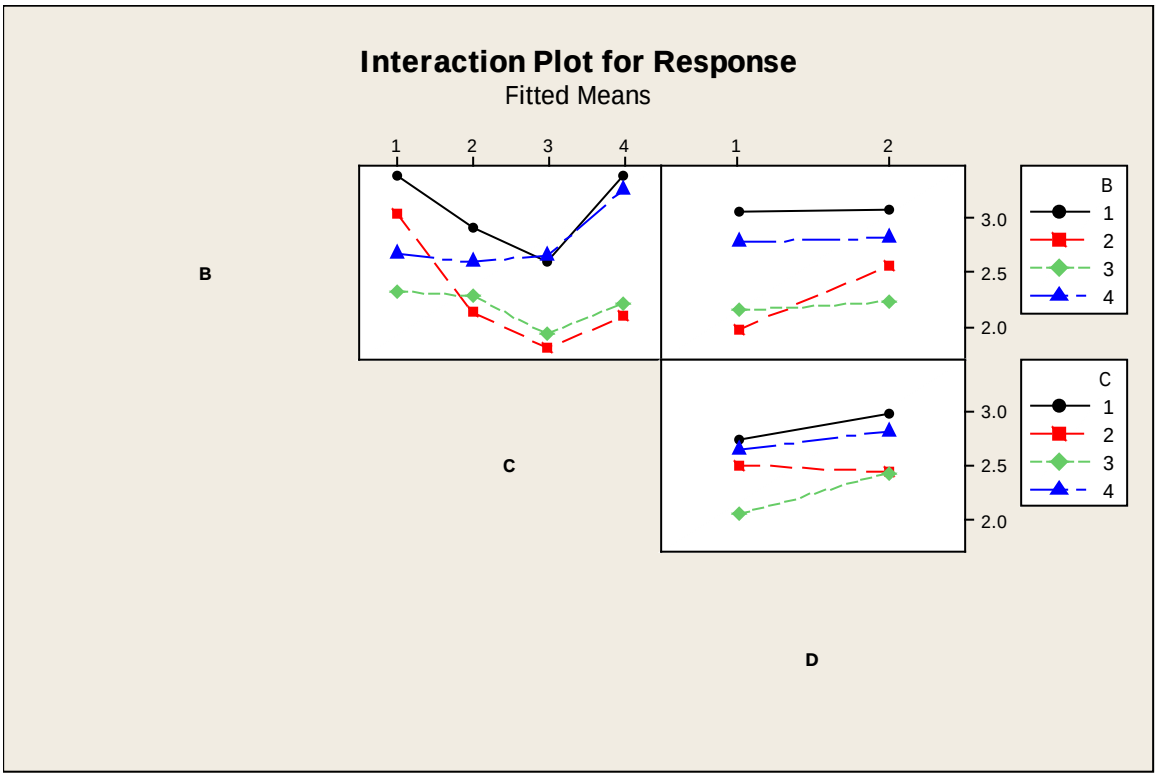

Figure 3: Interaction plot for response of $4^2.2^1$ factorial experiment.

According to table 6, the factors which affect to fluctuation of meandering is factor B, C, D, BC interaction, BD interaction and CD interaction by using 0.01 significance level. According to figure 3, the best settings which give the smallest maximum fluctuation of meandering are level 2 (0.24 Watt) of factor B, level 3 (0.54 Watt) of factor C and level 1 (ultrathin) of factor D.

Next, the confirmation experiment is conducted in order to confirm the settings that the maximum fluctuation us not exceed 3 µm. The results are shown in table 7.

Table 7: The results of the confirmation experiment with 40 replications.

Wafer no.	Response	Wafer no.	Response	Wafer no.	Response	Wafer no.	Response
1	0.93	11	0.77	21	2.79	31	1.66
2	2.40	12	0.90	22	2.37	32	2.48
3	**3.38**	13	1.31	23	2.48	33	0.58
4	1.57	14	0.93	24	1.65	34	0.84
5	1.74	15	2.61	25	0.45	35	1.40
6	2.17	16	2.26	26	2.31	36	1.21
7	1.76	17	0.41	27	0.74	37	0.91
8	1.29	18	2.61	28	1.39	38	0.94
9	0.80	19	2.02	29	1.80	39	0.83
10	1.76	20	0.27	30	0.98	40	2.64

According to table 7, there is only one slice which is shown the maximum fluctuation of meandering exceeds the target. This can be acceptable.

CONCLUSIONS

The factors affected to the fluctuation of meandering are scan power 1, scan power 2 and beam shape. The best setting of scan power 1 is 0.24 Watt, scan power 2 is 0.54 Watt and beam shape is ultrathin. The benefit after implemented the new settings is shown in table 8

Table 8: The benefit after implemented the new settings.

Process	Average loading	% reject	wafer amount	cost/wafer (k.euro)	Reject cost	Saving
Past parameter	520	4.62	24	14	336	45.83%
New parameter	520	2.5	13	14	182	

After implemented new parameters to shop floor, specimen silicon wafers from 40 slices. There is 1 from 40 slices which shown defects from meandering. That is 2.5 %. Typically, average loading is 520 wafers per month, average rejected wafers per month are 24 slices that is 4.62%. Comparing to defect rate of the new parameter, the numbers of rejected wafers are 2.5% or 13 wafer slices per month by using the same average loading per month. Wafer cost is totally 14,000 euro per slice. Therefore, it can be save cost up to 45.83%.

TQM PRACTICES IN PUBLIC SERVICE ORGANIZATIONS CASE OF HEALTHCARE AND ACADEMIC LIBRARIES

Ville Tuomi, University of Vaasa, Finland
ville.tuomi@uwasa.fi

Mian M. Ajmal*, Abu Dhabi University, United Arab Emirates
mian.ajmal@adu.ac.ae, *corresponding author

ABSTRACT

Purpose *–This study aims to discuss the evolution, principles, and stages of total quality management (TQM) in health care and academic libraries. It points out the discrepancies between these two types of service organizations by elaborating their present strengths, weaknesses, possibilities and threats while making TQM practices in their organizations. It also makes a comparison that how case organizations think about the definition of quality and TQM philosophy along with its applicability within public sector.*

Design/methodology/approach *–The study can be categorized as qualitative research. The data is collected from semi structural interviews of the informants and the concerning documents, which consist of strategy, policy papers and audit reports of the case organizations. Altogether there are four case organizations, two of these are from health care and two from academic libraries. Furthermore, data is analyzed with the help of content analysis.*

Findings *–It is obvious from the results that the most vital issues in TQM practices are its comprehensiveness, and its application in such a way which is appropriate for the organization, with a logical way of operation and the participation of management and personnel. TQM is seen as quite applicable to the service sector however, it requires being reconciled with strategic management initiatives.*

Managerial implications *–Training, guidance, teamwork, involvement and learning are imperative for achieving a continuous improvement culture and are vital elements when adopting TQM. Managers should learn from the experience of TQM implementers by studying expected challenges and pitfalls. They should also pay more attention to the crucial role of all stakeholders in the TQM implementation.*

Originality/value *–The study could be quite valuable from a strategic perspective in providing guidelines to build up a proper plan for TQM practices more promptly. The paper also manages to shed light on TQM practices of public service organizations by comparing their current approaches to quality.*

Keywords: TQM, Quality management systems, Service organization, Healthcare, Academic libraries

INTRODUCTION

In the past TQM used to be implemented in the manufacturing sector, but now it has also been widely applied in service organizations and the public sector (Fryer et al., 2007) e.g. higher education (Venkatraman, 2007) health care, libraries and information sectors (Moghaddan et al., 2008). All kinds of organizations in the private as well as the public sector are looking to be customer-oriented organizations to carry on their operations in a globally competitive environment. Therefore to compete as customer-oriented organizations it is necessary to offer quality products and services to their customers. Subsequently, TQM is such/specifically a philosophy that provides the tools and the direction to improve the quality of their products and services.

However, TQM implementation in manufacturing firms is not considered a novel and multifaceted strategy, but TQM implementation and practice particularly in public service organizations like healthcare and academic libraries are really quite a recent and composite undertaking. The introduction of the TQM term in health care is well established, but there is still lack of such a supporting framework that can make it easier for newcomers to follow the boulevard. Likewise, academic libraries have always been committed to provide high quality services to its subscribers. Although previously, consuming more resources, buying more books, and moving to larger premises were considered as improving quality, this approach is not valid today. One of the good solutions to improving quality is to provide the right information to the right user at the right time. This requires a thorough change in the approach – an approach based on user requirements and user satisfaction. It is believed that this can be achieved by implementing TQM. Thus, TQM approach is slowly achieving popularity in today's libraries. Regardless of this current recognition, many service organizations seem to be perplexed by their TQM practices. They give the impression that TQM approach is being properly practiced but the real scenario is quite different in most of these service organizations.
Therefore, the objective of this research is to study which kinds of TQM practices there are in public sector services, whether they are applying a fully-fledged TQM approach or only some parts of the TQM are being employed? More specifically, this research proceeds to examine the implementation of TQM in the public service organizations in the attempts to:

- present an overview of TQM initiatives in service organizations
- identify the level of understanding and knowledge about TQM in health care and academic libraries
- make comparisons of TQM practices in both health care and academic libraries

To accomplish the objective mentioned above and to achieve sub goals of the study, the paper will analyze the distinctiveness of the TQM practices in each target organization. First, it will carry on by providing an up to date literature review of the associated terms individually with more emphasis on quality, TQM and its applicability in service organizations. Second, it will elaborate on the methodological approach which has been employed during this study and a description of all target organizations. Third, it will illustrate the results along with discussion and managerial implications. Finally, it draws some conclusions based on the present results and discussions in light of previous literature. It also includes an appendix that portraits an overview of TQM practices and approaches of all case organizations.

DEFINITIONS

Service Quality

Quality is concerned with fulfilling the needs, wants and expectations of the valued customers. One of the key and stable definitions may be that, 'quality is suitability for purpose'. Quality is also defined as 'satisfying customer's requirements' or 'fitness for purpose' (Ghobadian et al., 1994). However, it is complex to define service quality rather than the quality of goods. Service quality can be defines as an attitude of the consumer relating to the results from comparisons between expectations of service with his perceptions of actual performance (Grönroos, 2007). The quality of services executed can only be appraised during or after consumption (Audhesh et al., 2005). The more composite and personal the service, the more detective effort customers will perform (Berry et al., 2006). The primary source of value creation for a service quality is performance by the service provider. It is often the small things that influence a customer's overall perception of service quality, be it the tangibility associated with the service or the behavior or technical performance by the service provider (Kumar et al., 2010).

Service Quality Dimensions

The most commonly stated set of service quality was offered by Zeithaml et al. (1990), who using factor analysis, condensed the dimensions of service quality into five categories:

1. Tangibles (facilities, equipment and appearance of staff);
2. Reliability (ability to perform the promised service dependably and accurately);
3. Responsiveness (willingness to help customers and provide prompt service);
4. Assurance (knowledge and courtesy of staff and their ability to convey trust and confidence);
5. Empathy (caring, individualized attention the organization provides to its customers).

Total Quality Management

According to British Standard BS 7850, TQM is defined as management philosophy and company practices that endeavor to strap up the human and material resources of an organization in the most efficient way to accomplish the organizational objectives. In general, the overall scope of quality, total quality and TQM can be classified as follows (Kanji):

Quality: – is to satisfy customer's requirement persistently
Total Quality: – is to achieve quality at low cost
Total Quality Management: – is to obtain total quality by involving everyone's daily commitment.

According to Vouzas and Psychogios (2007) there are two substantial aspects of TQM that can be identified; the 'hard' side and the 'soft' side. The hard (or technical) side refers to management tools and practices, while the soft (or philosophical) is associated with

management concepts and principles. The hard aspects of TQM consist of clear and well documented methods while the soft aspects compose its whole theory, combining its background and philosophical elements. It is argued that TQM has to evolve. Four stages can be identified in the evolution of TQM:

- Inspection-based System
- System of Quality Control
- Quality Assurance
- Total Quality Management

Quality Management initiated with a simple Inspection-based system, where a product was compared with a product standard by a team of inspectors. First revolutionary charge – System of Quality Control came along with World War II. At that time quality was achieved through control systems, product testing and documentation control. In the Quality Assurance stage, there was a change from product quality to systems quality. Typical of this stage were quality manuals, quality planning and advanced document control. Quality assurance is prevention-based. The fourth stage of development was TQM. A clear and unambiguous vision, few interdepartmental barriers, staff training, excellent customer relations, emphasis on continuous improvement, and quality of the company as a whole are typical in a TQM environment.

Over time the definitions of quality management have been widened to incorporate the wellbeing of society, the environment and future generations. A large part of the development of quality concept and quality management has taken place without much consideration of what quality management really is or should be. It has been claimed, that quality management should focus on customers and their satisfaction and not concentrate on stakeholders and interest parties who are affected by the products and processes (Klefsjö et al., 2008), but on the other hand TQM is in many researches said to be implemented with the help of quality awards, which are considered as excellence models (Bou-Lusar et al., 2008; Vernero et al., 2007).

TQM can be described as the development of an organizational culture, which is defined by, and supports, the constants attainment of customer satisfaction through an integrated system of techniques and tools. TQM is a way of managing to improve the effectiveness, efficiency, flexibility, and competitiveness of a business as a whole. There are eight most common principles in the TQM: leadership and management, strategic planning, focus on customer, focus on employees, focus on suppliers, focus on material resources, process management and performance results (Rad, 2006).

Total Quality Management in Healthcare

In exceedingly competitive healthcare environments, hospitals similar to all other public or private organizations and institutions, are confronted with the stipulation of measuring both their financial (costs, revenues, profitability) and non financial performance (quality of their services), in order to improve their functions and increase their competitiveness (Chaniotakis and Lymperopoulos, 2009). Performance measurement is not an easy task in health services, where a wide range of stakeholders are involved. Lim and Tang (2000) argue

that customer based determinants and perceptions of service quality play an important role in hospitals. Hence, Wisniewski and Wisniewski (2005) revealed that service quality from the patients' perspective should be consistently monitored and assessed. Silvestro (2005) proposes the development of a tool for measuring the gap between patients' priorities and their perceptions and the match between the patient and management perspective.

Ovretveit (2001) has found seven components in integrated quality development in hospitals, which is an application of total quality management in a hospital. The components are based on longitudinal empirical research in European hospitals. The components are as follows:

1. Four coordinated organization-wide programs to develop professionals' competencies, managers' competencies, organization and processes, and a new role for patients;
2. Three-dimensional definition of quality (patient, professional and management quality);
3. Patient pathway and process development;
4. Quality data gathering;
5. Team quality projects;
6. Patient focused system development; and
7. Creating 'soulful spirals' and preventing 'soulless spirals'.

These seven components aim to combine effective established professional quality assurance methods with newer quality improvement methods, simultaneously by improving patient, professional and management quality, and describing and developing the system of care experienced by the patient in a soulful way.

Conceptualization of Critical Dimensions of TQM in Hospitals

Considering the relevance of TQM in health care, an instrument that identifies the operating elements of TQM in hospitals from the viewpoint of the health-care service providers is developed and validated in the present study. The following critical factors of provider-perceived TQM in hospitals have been identified in this paper (Duggirala et al., 2008):

1- Top management commitment and leadership
2- Human resource management in the hospital
- Selection
- Training
- Employee involvement

3- Process management
- Ease of access to the hospital, and ease of admission processes and procedures
- Administrative services
- Processes: administrative and clinical
- Exit
- Clinical outcomes of medical care

4- Hospital facilities and infrastructure
5- Patient focus
6- Employee focus

7- Measurement of hospital performance
8- Hospital information system
9- Errors, safety and risk management
10- Service culture
11- Continuous improvement
12- Benchmarking
13- Union influence
14- Governance and social responsibility

According to Bassand et al. (2007) TQM in healthcare is a relative concept that requires comparison either with the performances of others or with the standards. The measurement of quality needs to be relevant for both service providers and patients, and also the process of care should be measured. There should be regional and/or national programs to measure performance indicators systematically and provide feedback to individual hospitals.

Total Quality Management in Academic Libraries

The mission of academic libraries is to collect and store scientific publications and register, analyze and organize them in a way, that researchers and students can use them. The quality of the academic library is depended mostly on how well a library can support the members of a academic community to work successfully. On the other hand the quality of a university depends partly on the quality of library operations, because high quality research requires wide and updated collections with efficient services. Service is the key value of academic libraries (Sinikara 2007). The services of an academic library could be classified into four groups, in the same way as in marketing literature. First are 'cash cow-services', which are widely used and require little investments, like book lending services. The second are 'star-services', with a high relative market share operating in a high growth market, like the provision of e-content. The third group is 'problem children' which have not achieved dominant position, but have potential to move in this direction, like Really Simple Syndication (RSS) in libraries. The fourth group is 'dog services' for which there is a low need and level of effectiveness, like physical collections of printed abstracts and indexes (Walton 2007).

Quality management in academic libraries can be defined as all of the processes, activities and measures that contribute to the management of the quality of the products, service or other outputs from the organization. There is tension between externally-focused quality assurance and internally-focused quality enhancement and a big challenge for the public sector management is to combine these. Quality assurance is more focused on output standards and measured performance, while quality enhancement is more focused on internal processes as well as the assessment of these. The consequences of quality assurance are funding, accreditations, achievement of quality marks and branding. The consequence of the quality enhancement is quality service delivery. While implementing quality management, a library has to take into consideration the sector (e.g. higher education or local authorities), organization (e.g. university or local authorities), division or strategic business unit, library and information service (e.g. academic or public library), and functions or departments and projects (e.g. new building or new services) (Rowley 2005).

The university libraries in Finland are open for everyone, which is not the case in every European country. The libraries are valuable not only for education and research at the University, but also for the society (Sinikara 2006).

However, due to the nature of the services provided, academic libraries encompass additional complexity to the implementation of any quality management system. The libraries are embedded in larger organizations, they have a high level of engagement with users, they have a wide range of stakeholders, they form complex co-operations with many partners, they increasingly deliver services electronically and they are affected by the public sector services policies (Kostagiolas & Kitsiou, 2008; Rowley, 2005). Table 1 below provides an overview of previously selected related studies to TQM implementation in academic libraries.

Table 1: Previous studies.

Kostagiolas & Kitsiou, 2008	**Purpose:** It aims to empirically assess the current issues and the perceptions for quality management systems implementation in Greek academic libraries.
	Design/methodology/Approach: A qualitative survey based on the development of a questionnaire for semi-structured interviews with the directors of Greek academic libraries.
	Results: An interest for ISO 9000:2000/ISO 9001:2000 has been observed in academic libraries in Greece.
Rowley, 2005	**Purpose:** To review the quality, performance management and impact assessment regimes that currently impact on public and academic libraries in the UK by exploring the challenges for managers in finding their path through this quality maze.
	Design/methodology/Approach: An opinion piece that offers some conceptual frameworks, based on an analysis of literature, practice and web sites gathered over many years' investigation and observation. The tension between externally-focused quality assurance and internally-focused quality enhancement is taken as a point of departure.
	Results: A review of the approaches for collecting customer evaluations of service quality, enhancing quality and performance illustrates the complexity associated with accommodating agendas arising from different contexts, and the competing notions of quality that are embedded in these different approaches.
Kauar et al., 2006	**Purpose:** To describe the steps in attaining the ISO 9001:2000 quality management system certification at the University of Malaya Library.
	Design/methodology/Approach: Case study in four university libraries by including the description of planning, implementation and maintenance of the quality management system along with continual improvement efforts to provide quality service.
	Results: The move towards a quality management system within quality standard requirements, such as the MS ISO 9001:2000 proved challenging to obtaining the management commitment and the reorganization of services. Customer feedback becomes the focus of on-going planning to fulfill customer requirements. A quality management system has brought about informed decision making and increased customer satisfaction.
Dadzie, 2004	**Purpose:** The research examines the possibilities, challenges and constraints faced by top management in a bid to introduce total quality as a management tool to enhance the services provided to the university community.
	Design/methodology/Approach: Case study in one university library. Qualitative study made by using interviews, which were analyzed with help of content analysis.
	Results: The librarians were quite committed to their jobs. The major hindrance to the execution of their strategies and policies has been that of financial resources.
Wang, 2006	**Purpose:** To provide retrospective overview of TQM in the context of library services
	Design/methodology/Approach: Conceptual study/ literature review
	Results: The process of implementing TQM in libraries involves a conceptual change in library professionals and a cultural transformation in the organizational operations. Teamwork is important for successful implementation of TQM. Every step of the process

	depends upon the constant support of the top management.
Moghaddam & Moballeghi, 2008	**Purpose:** To present an overview of TQM in the library and information sectors
	Design/methodology/Approach: Literature review focusing on TQM implementation in the library and information sectors.
	Results: TQM philosophy is increasingly being applied in the service sector, including libraries.
Chim, 2007	**Purpose:** To trace the development and implementation of the quality assurance system and its continuous review process.
	Design/methodology/Approach: Descriptive case study
	Results: To set up a successful QA system requires commitment of both staff and management, and customer focus which means understanding and educating the customers and reacting to customer feedback.
Juntunen et al., 2005	**Purpose:** To present the process of creating quality management system of the Kuopio University Library (Finland).
	Design/methodology/Approach: Case study with some survey-based material
	Results: Quality management can be used as a tool for leadership within the Library, improving the Library's processes and marketing.
Saarti & Balague, 2009	**Purpose:** To benchmark ISO 9001:2000 quality management based systems in Spanish, and in Finish Universities.
	Design/methodology/Approach: Case study in which two libraries' approach to build their quality management system is compared.
	Results: The ISO 9001:2000 guides institutions to develop their quality management systems and it has helped them to develop their services and analyze how they have succeeded in this task.

METHODOLOGY

Despite being a qualitative study, a contingency approach is used in this paper. This is because the approach offers a good way to consider what kind of situational factors should be taken into consideration while implementing a quality management system; but at the same time the theory should be developed in order to consider the level of human actors and not only the organization level (Donaldson, 1996). This study is qualitative also because of the study subject, quality management subject that is a vague subject, given that the term quality has many dimensions (Garvin, 1988) and a hospital is a complex organization with multiple goals (Kast & Rosenzweig, 1970).

A qualitative approach allows a researcher to deal with complexity, context and persona and a multitude of factors and fuzzy phenomena. For example, holistic case studies are applicable in these kinds of situations (Gummesson 2006, 167). Qualitative methods are also very suitable for studies concerning organizational change, because they allow the detailed analysis of the change and by using the qualitative methods we can assess how (what processes are involved) and why (in terms of circumstances and stakeholders) the change has occurred (Cassell & Symon, 1994- 5). However this research process consists of the following steps applied from the study of Lukka (2003):

1. Find a practically relevant problem which also has potential for theoretical contribution.
    - This study also aims to find out which kind of TQM practices there are in public services, and from the theoretical viewpoint it is a question of how to take into consideration all situational factors and special characteristics of a

public service organization when applying quality management which is said to be universalistic.

2. Examine the potential long-term research co-operation with the target organization(s).
3. Obtain deep understanding of the topic area both practically and theoretically.
    - During this study we tried to develop one of the organizations also in practice by building a process measurement system into the heart unit of the hospital.
4. Innovate a solution idea and develop a problem solving construction, which also has potential for theoretical contribution.
    - Because of the universalistic tradition of quality management, a situational quality management model is constructed.
5. Implement a solution and test how it works.
    - A weak market test is made by showing the results to the informants of the each target organization.
6. Ponder the scope of applicability of the solution.
    - The model is constructed in such a way that it could be used in building quality systems in the other public service organizations.
7. Identify and analyze the theoretical construction.
    - The nature of the quality management is considered in the continuum of universalistic theory vs. situational approach to quality management
    - The major types of potential theoretical contributions are the novel construction itself as well as applying and developing the existing theoretical knowledge about quality management features emerging in this case.

The study material consists of semi structural interviews of the informants, audit reports, strategies and other documents available. All the material is analyzed with the help of content analysis. Some previous studies, which have used the same approach, are for example Kunkel & Westerling (2006). Interview made from the following informants:

- Central Hospital of the Vaasa Hospital District (CHV); general manager, manager doctor, quality manager, manager of the heart unit, politician
- Central Hospital of the Keski-Pohjanmaa Hospital District (CHK); general manager, manager doctor, quality manager, manager of the heart unit and worker (group interview), politician
- Kuopio University Library (KUL); quality manager, manager of the library, service manager
- Helsinki University Library (HUL); administrative managers (group interview), manager of the library, quality manager of the student library

The content analysis can be defined as any methodological measurement applied to text (or other symbolic materials) for social science purposes (Duriau et al., 2007). Content analyzes are most successful when they focus on facts that are constituted in language, in the uses of particular texts which the content analysts are analyzing. Such linguistically constituted facts can be divided into four classes: attributions, social relationships, public behaviors and institutional realities. Attributions are concepts, attitudes, beliefs, intentions, emotions, mental states and cognitive processes which ultimately manifest themselves in the verbal attributes of behavior. They are not observable as such. Institutional realities, like the government, are constructions that rely heavily on language. See the exact description of

the content analysis of the study in appendix I and II. Data was collected with the following three sources:

Target Organizations

Altogether there are four target organizations. Two of them are regional hospitals and in both hospitals managers of the units are chosen for examples of sub-units of hospitals because of their supposed quality management experiences. Two libraries are also included which are attached to two different academic universities. Below is a short overview of each exploring their strengths, weaknesses, possibilities and threats regarding TQM practices.

Central Hospital of the Vaasa Hospital District, (CHV)

The Central Hospital of the Vaasa has an administrative role in the Vaasa Hospital District, which consists of three hospitals. The District is owned by 23 municipalities and it is a bilingual organization (both Swedish and Finnish speaking personnel, customers, and owners). The number of the personnel in the year 2006 was 1997, which consisted of nursing staff (1060), physicians (183), research staff (240), and maintenance staff (109). Services are offered for 166,000 inhabitants in the area of the municipalities (SHQuality, 2007). This Hospital District is one of the 20 Finnish hospital districts.

Table 2: Strengths, weaknesses, possibilities and threats concerning TQM.

Strengths	**Weaknesses**
• Enough know-how • A tradition of systematic working • It is easy to learn new theories and models • Well educated personnel • Ethical background • Language of the SHQS is suitable for the health care industry • Much experience of development work • Commitment towards TQM (nursing staff) • Sufficient human resources • Planning of strategies, security policy and risk management (*) • Customer focus(*) • Meeting practices (*) • Human resources management practices, like taking care of well-being of the personnel, recruitment • Benchmarking (*) • Quality management is getting better (*)	• There is insufficient know-how concerning quality work • Traditionally every patient and diagnosis are considered as unique cases without any point of view of production (no production management or sizing) • Multidimensionality of health care, lack of standardized products, rapidly increasing amount of knowledge, which makes it hard to handle the situation and to see the totality • A big organization • Everything must be communicated in Swedish and in Finnish communication • Lack of commitment of physicians and other personnel • There are only a few quality systems in primary health care in this region • Modeling and measurement of processes in hospital and unit levels (*) • Goals and measures of operation and levels and goals should be defined (*) • Part of planning practices (*)

Possibilities	Threats
• Changes in the operation environment force to improve the organization • Changes in the structure of municipalities and services can help hospitals to improve their operations • All the social- and health care units use the same kind of (quality) system and thus it is possible to create a unitary system • To find the process owner for the social and health care services across the organization boundaries • Top management of the central hospital is committed to quality work • Functionality of communication among the special fields	• Border lines between professions • The aim has been to offer almost everything to essentially everybody for free. This leads to a continuous gap between the needs and possibilities of the whole public administration and falls heavily on health care. • Operation environment is changing and resources are needed to follow-up the changes. Maintenance of a quality system requires work on an almost daily basis. • Lack of resources • Cooperation between hospital districts and outpatient care: there is no motivation to improve quality in every place. • More and more specialized health care leads to a situation in which the patient's viewpoint disappears and totality becomes vague

(*) = audit report (SHQuality 2007)

According to the quality policy and strategy, good quality in CHV is defined as service processes which are from the customer's or patient's point of view, high level, available, efficient and economic, and during which the well-being of the personnel and expectations of the stakeholders are taken into consideration (Vaasa Hospital District, 2007). In the strategy there is a decision to establish a quality system for the hospital (Vaasa Hospital District, 2003). In the heart unit of the CHV (8.10.2004) there is a quality manual which is made according to ISO 9001:2000 quality management standard. However, the hospital is still using the SHQS quality system (SHQuality, 2007).

Central Hospital of the Keski-Pohjanmaa Hospital District (CHK)

The Keski-Pohjanmaa Central Hosital has an administrative role in the Keski-Pohjanmaa Hospital District. The District is owned by 13 municipalities and it is a bilingual organization (both Swedish and Finnish speaking personnel, customers, and owners) (Keski-Pohjanmaa hospital District 19.11.2007). The number of the personnel in the year 2006 was 1143 and in the year 2007 it was 1164 (Keski-Pohjanmaa hospital District 2007).

Table 3: Strengths, weaknesses, possibilities and threats concerning TQM.

Strengths	Weaknesses
• Electronic appointment in the laboratory • Citizen's acceptance • Networking with educational institutions • Long traditions of SHQS since the year 1996 • Qualified and committed internal audit group • Positive attitude of the personnel towards development (**) • Small size of the organization (flexibility) • Big volumes and clear procedures of operations	• Funding system and attitudes concerning it • Appointment problems • Lack of commitment • Quality management is not applied on daily basis • No full-time development and quality manager • Small size of the organization • It is difficult to change (bureaucracy, trade-unions, etc.) • Complicated organization • Lack of physicians • No consideration about the totality of the social-

• Commitment of the personnel (*) • Customer focus (*) • Cost awareness (*) • Regional cooperation (*) • Commitment to values (*) • good job satisfaction survey (*)	and health care services • Lack of quality policy (*) • Information systems and knowledge management (*) • risk management (*) • process measurement (*)
Possibilities	**Threats**
• Integrated clinical pathways can become more flexible and efficient while the organization is growing • Quality management may encompass the whole social and health care services	• Belief in extremely big organizations • Recruitment of competent personnel fails • Municipalities don't understand SHQS • Cure is improved on an economic basis instead of the need of patients • Prioritization of the health care • Quality management is applied only partially and the totality is forgotten

(*) = audit report (SHQuality, 2006), (**) = both audit report (SHQuality, 2006) and interviews

In the strategic plan of the hospital, high service quality was mentioned as one of the key values of the hospital. The service quality is based on hearing the needs of the customer and patient, high-quality services, effectiveness, and taking care of knowledge, readiness of operation and facilities of operation (Keski-Pohjanmaa Hospital District, 19.11.2007).

Helsinki University Library (HUL)

Table 4: Strengths, weaknesses, possibilities and threats concerning TQM.

Strengths	**Weaknesses**
• Size of the organization • Commitment towards TQM (**) • Comprehensiveness of the quality management system (**) • Balanced management • Networking inside the organization • Critical thinking • Traditions of overall evaluations • Knowledge • Clear quality assurance operations (*) • Utilization of intranet (*) • Management tools for quality assurance (*) • Utilization of customer feedback in the student library (*)	• Size of the organization • Multifold decision making procedure • Disconnectedness of HRM • Different kinds of resources in the units of the library • There is no material concerning TQM practices in English • Measurement and evaluation (*) • Relationship between support services (like the library), research and education should be developed further for quality assurance (*)
Possibilities	**Threats**
• Internationalization • Benchmarking between the university libraries in the future national structural development • Becoming an improved expert- and service organization with the help of organizational changes and personnel development	• Internationalization • Efficiency is emphasized more and more increasingly • New Universities Act • Structural development • Co-operation between libraries and organization may not work anymore

(*) = audit report (Vuorio et al 2008), both interviews and audit report (Vuorio et al 2008)

The library institution of the University of Helsinki comprises of two large entities until the year 2010: the national Library of Finland and the University of Helsinki Libraries. The student library is one of the libraries in the city center campus. There has been a quality

system since the year 2005 and different kinds of evaluations from the beginning of the 1990´s (Sinikara 2006).

Kuopio University Library (KUL)

Table 5: Strengths, weaknesses, possibilities and threats concerning TQM.

Strengths	**Weaknesses**
• Commitment towards TQM • Providing resources to quality work • Documentation • Co-operation inside the university • The university has developed its quality system in a systematic way based on ISO 9001 quality management system (*) • Good cooperation between quality manager and staff correspondent for quality of the units at the university (*) • Intranet used effectively for quality management (*) • Students' participation in quality work	• Too much documentation • Intranet must be developed • Deficiencies of the intranet • Difficulties in measurement/evaluation at the time when quality system was established, there were four other big projects going on (this is becoming a strength) • Measurement systems should be improved: both measurement and performance indicators (*)
Possibilities	**Threats**
• Benchmarking • They can get savings with help, or develop confidential relationships by merging the universities (Kuopio and Joensuu)	• Eminent decisions may be made too hastily which are considered impossible by other organizations • The cooperation inside the university may disappear

There are 35 staff members in the UKL (Saarti & Balaqué 2009), which is much less than in Helsinki. According to the Research Library Statistics in 2007 there are more recourses (personnel, financial recourses etc.) at the University of Helsinki Library per parent organization than at the University Library of Kuopio. At the Kuopio ththe uey have made more investments on electronic publications than University of Helsinki, which is the biggest university in the Finland (KOTA database 26.4.2010).

FINDINGS

The development of a quality system is the most adopted initiative in all the case organizations. The least adopted TQM initiative is the application of statistical process control. This can be explained by the respondents' lack of knowledge about the exact control methods used by the Quality Improvement departments or, because some hospitals lack the financial resources and expertise to implement these statistical process control methods.

According to the interviews the most important issues in TQM practices are comprehensiveness, a systematic way of operation, the participation of management and personnel, high quality cure processes, reporting and reacting, the implementation of high-level goals (ethics and values), focus on development as well as measurement and goal levels. TQM is seen as quite applicable or very applicable to (a) hospitals and libraries but there are several issues, which foster the implementation of TQM. Language used in the implementation should be familiar and suitable to the target organizations, and unfamiliar

language should not be used by force. SHQS is an example of translating the language of TQM into a language familiar to the healthcare industry. This requires it to be accommodated to healthcare.

In all the case organizations, they claimed that there is no TQM but simultaneously ISO quality standard is implemented there. TQM is usually seen as a method for practicing quality. However, TQM is not applied in every single part of the organization – except maybe in Kuopio Library. In every organization they applied TQM in a way that is typical to the industry: in hospitals they used SHQS and in university libraries they used quality assurance recommended by the Finnish Higher Education Evaluation Council. In the heart unit of the Vaasa Central Hospital and The University of Kuopio, they also applied ISO quality management standard. Furthermore, the heart unit were evaluated by medical experts. In Kuopio they used ISO standard, because it was seen as more suitable for international associations.

It is visible that everybody is talking about quality assurance instead of quality management or TQM. The most important issue in TQM is the totality, participation, continuous improvement and organizational learning process. It was seen as quite easy or very easy to apply in university settings. The context of the university must be taken into consideration and only tools/techniques suitable to the organization should be used. According to the audit reports of the universities, there are problems in measuring quality management at their libraries. In the interviews most problems were seen in the measurement processes of the TQM in such organizations.

An organization should take care of its strengths, get rid of their weaknesses, utilize the possibilities and avoid threats. Cooperation between different organizations was seen as a possibility in every case organization. Commitment of at least part of the staff was seen as strength and measurement of processes was a weakness in every case. Hospitals were more worried about resources than libraries and both libraries considered disappear of co-operation as a threat. Situational factors in operation environment were seen in many different ways: size of an organization was seen as a strength and weakness, like internationalization at the University of Helsinki Library.

DISCUSSION AND IMPLICATIONS

TQM is considered to be a generic management model that is applicable to every organization, but on the other hand it is also suggested that the operation environment of an organization should be taken into consideration while implementing quality management. It is crucial to persuade quality as early as possible, preferably at the initial stage of organizational operations. Organizational structure modification supports the success of TQM which must always be considered. Leadership and top management support are keys to TQM implementation and practice. Upper management must always conduct continuous improvement activities with the consensus of all employees. They should also make use of selective application of TQM tools and techniques by appraising their suitability with the organization. There must also be sufficient financial resources available for TQM initiatives.

Training, tutoring, teamwork and staff involvement are important for achieving a continuous improvement culture and are vital elements when adopting TQM. This claim is supported by Fung's (1998) study which showed that the learning team approach assists in accomplishing an educational organization and attains TQM. It is noted from the findings that most of the staff members from case organizations are not familiar with the approach of TQM, so providing appropriate training for employees and support from top management are considered vital success factors by most researchers (Ennis & Harrington, 1999). This result is consistent with the results of Rad (2005) concerning the key success factors for TQM implementation.

Successful TQM implementation requires top management commitment, employee involvement and empowerment, customer focus and continuous improvement, training for TQM throughout the organization and increased communication. Furthermore, there is a need for patience and tolerance as it is a time-consuming process and it is not easy to change an organization. An increased focus on the area of organizational change related to TQM is also needed. To conclude, the successful TQM implementation requires a thorough understanding of critical success factors, barriers to achieving these factors, and managerial tools and techniques to overcome these barriers along with continuous organizational learning. The barriers of the implementation of the TQM are resistance to change and people's attitudes, problems in finding funding and time for training, while maintaining current services in the library. It is also difficult to make a change in organizational structures, yet TQM requires institutions to restructure themselves (Moghaddam & Mogalleghi 2006) and be ready to learn each and every thing that occurs over the passage of time.

Finally, the results of research argue that TQM initiative implementation may seem to be an easy task, but this is a very illusory deliberation. The dilemma is not only how to implement the agenda, but how to make it work effectively and efficiently. Managers as well as quality policy makers should pay more attention to the vital role of all stakeholders in the TQM implementation and success stages. A non-implementer of the TQM philosophy should learn about the expected challenges and pitfalls from the experiences of TQM implementers.

CONCLUSION

From the assessment of present practices of TQM in public healthcare units and academic libraries, it is apparent that TQM or narrowly associated approaches are not just a 'fashion of the day'. Case organizations are practicing quality in the form of quality assurance, continuous improvement, user satisfaction, etc., if not exactly in the appearance of TQM. The resolutions of TQM may fluctuate from service organization to organization, as each is unique in itself. The certainty of the modern service organization indicates that quality improvement is indispensable not only for survival, but for facing major changes and growth required for organizations of the present and of the future.

It is concluded from the research findings, that there is a considerable divergence regarding the development of a quality system and TQM practices in case service organizations. This advocates the need for enhanced communication between all level managers in order to

attain an environment of quality improvement and a TQM system that requires the full integration between each stakeholder of the organization. It also argues that changing to a TQM idea requires a new administrative view, a change in the organization structure to eliminate the barriers, and improved communication through information systems with a long-term organizational learning perspective.

Future Research

Future research is vital in appraising the understanding and the critical success factors for TQM based on the customers' point of view. Also, further studies need to be undertaken concerning the detailed impact of organizational culture and structure, top management support and employee training and involvement of TQM implementation in service organizations.

Appendix I. Description of the analysis of the study material

The study material consists of qualitative data gathered from interviews and documents concerning the target organizations. Interviews referred frequently to the documents during the interviews, and therefore the study material is analyzed separately. The study material was gathered in the following ways:

Target organization	Helsinki University Library	Kuopio University Library	Keski-pohjanmaa Central Hospital	Vaasa Central Hospital
Interviews Type	Semi-structured	Semi-structured	Semi-structured	Semi-structured
Documents	Strategy, audit report (Vuorio et al 2008)	Strategy, audit report	Strategy, audit report	Strategy, audit report, quality policy

Interviews took from 30 minutes to 2 hours. Every interviewee was presented with questions beforehand so they were prepared. They also had key documents in the interview with them or they remembered them so well, that they could refer to them (for example quality policy, strategy and audit reports if available).

All the interviews were recorded and afterwards the recording material was transcripted. The transcripts of the recordings were analyzed with the help of content analysis. The results of the analysis were interpreted with the help of previous literature. After this analysis, a weak market test was made with the key informants in the beginning of the year 2010. Part of the study material had already been tested in two separate single case studies, which helped in the analysis of this study.

Appendix II. Comparison of the cases

Definition of the quality and approach to TQM

	HUL	KUL	CHK	CHV
Definition of quality	Operation appropriate to situation and high level results	Best possible results, products and operation attainable with the available resources. Support services' (like library services) are of appropriate size to support key processes (teaching and research) and are lean, open and flexible. These should be appropriate, free from defects with short lead times and support good enough facilities and equipment. The quality of a library consists of a combination of management and professional services. It can be viewed as the customers´ subjective view of the quality of service, as well as the pedagogic point of view, defined as the customer learning to find information and using the library independently	Best possible cures in a cost-effective and appropriate way including the availability of the service. Small amount of defects, combination of different kinds of viewpoints, i.e. experience of the patient, technical quality of the cure, management and personnel; all good operations; systematic operations, enough documentation and well-defined regulations	Good available cure based on patients/customers needs, effective and economic service processes, and operations in which the well-being of the personnel and expectations of the stakeholders are taken into consideration. Quality is based on the values of the health care industry. Everybody has a different point of view to the meaning of quality.
Approach to TQM VS strategy *Why quality is needed? *Most important issues in total quality	Quality is based on strategy and strategy is based on quality. Quality must be improved to get better results, which calls for the development of operations and continuous improvement. The most important issues in QM are totality, participation, continuous improvement and learning	QM is part of strategic management, is based on it and very closely connected to it. QM is made for both internal and external reasons. The most important issues in QM are the following: to support strategic management, participation of the personnel, to work with QM and improve results.	QM supports the establishment of a strategy by giving information. There has to be 4-6 key goals in a smaller unit and well thought out meanings to these goals in their operations. The goals in the units have to be concrete and connected to time, resources and economy. QM is needed because of the following reasons: To get an overall view of operation: economy + personnel + process/customers viewpoint. Only operations of good quality are sensible. Operations can't be improved without	Quality system and strategy are closely interconnected. The quality system calls for clear strategic goals and vision. Quality work is based on values, which in turn are included in strategy. QM is needed for the following reasons: - to control totality - to implement values - On the other hand it is a management fad, but it is also needed a) to guarantee cure for customers and to show what kind of working place it is. - low quality work

	processes. The word quality assurance is used instead of quality management		evaluation and documentation. The most important issues in QM are the following: - patient centeredness, communication with personnel, being in the right place at the right time from the operations point of view - to find measures and to develop evaluation - follow-up - Clear management system based on information and documentation generated by quality management	must be avoided - required regulations The most important issues in QM are the following: - comprehensiveness - applying QM in a way which is suitable for the organization - systematic way of operation - participation of management and personnel - high quality cure processes - reporting, reacting - nothing is forgotten (because the SHQS is a type of check list), implementation of high-level goals (ethics and values), finding focus on development, measurement and goal levels

Applicability to the public sector

	HUL	KUL	CHK	CHV
How easy it is to apply in the public sector?	quite easy or very easy	quite easy or very easy	quite easy	quite easy or very easy
Reasons why it could be applicable	Context is taken into consideration; such quality tools/techniques are used, which are suitable to the organization, and the usage is thoroughly thought out		- the existence of an organization depends on quality - if the special characteristics of the context of the public sector are taken into consideration while applying QM, it is well applicable because evaluation is so important.	total quality management – thinking is very applicable to pubic administration, if it is reconciled with health care
Issues which make it difficult to apply QM:	If the context of the university is not taken into consideration		If innovativeness is decreasing because of the ”quality”. If the total situation of a patient with multiple problems is nor taken into consideration.	Organizational structure as a mixture of service and production organization, difficulties in standardization and more dramatic understanding of deficiencies in health care compared to the production of goods.

Total quality management in practice

	HUL	KUL	CHK	CHV
State of art	Quality work is almost institutionalized	Quality work is more like everyday work	Quality work is both every day work as well as a separate project.	Quality work is both every day work (like in the heart unit) and distinct development work.
Practical implications in quality work	The use of manual operation systems, networking and group work	Evaluation, education of personnel and students, and work of self-directed teams	Education and projects in which clinical pathways and service chains are identified and described together with stakeholders efficiency of personnel is increasing patients stay a shorter time in hospital, implementation of SHQS and evaluation	Establishment of quality systems into different units of the hospital is most important. Other implications are process improvement and documentation concerning risks
Quality tools	Different kinds of evaluations, statistics, and work groups.	Documentation (quality manuals etc.), different kinds of evaluations, education and group work methods, ISO 9000, and check lists in customer service.	SHQS and quality tools, which include flow charts and cause-and-effect diagrams	SHQS (includes self-evaluations and audits), ISO quality management standards, and group work methods

The roles of the personnel and management in the TQM

	HUL	KUL	CHK	CHV
The role of personnel	The implementation of change	Commitment and participation Nothing can be done without personnel	To do the work as well as possible, participate in development projects, work as a member of an expert team, consider feedback in an appropriate way and not emotionally	Commitment, good work and know how concerning continuous improvement
The role of management	Commitment To work in the interface of the parent organization, changing environment and personnel.	Commitment, providing resources and to take the lead To motivate and to get personnel to work in self-directed manner	To provide resources, emphasize the importance of quality and work as a role model. To provide information on statistics, and reward appropriately	To motivate personnel, commitment, work as a role model and provide resources

Evaluation and measurement in the organization

	HUL	KUL	CHK	CHV
Measurement and evaluation in general	Evaluations, audits, customer surveys, statistics, and other follow-up´s, check lists	At university level, mainly teaching and research are measured	SHQS, and medical evaluations Because they are made on the side, it is	SHQS (includes self-evaluations and audits), evaluations of authorities, follow-up

		There are 25 indicators, and unit specific indicators	important to consider how much time can be spent on evaluations; what are the benefits compared to the time used on evaluations	of statistics, benchmarking etc.
Measurement of customer satisfaction	surveys are coordinated, other operations are not	different kinds of surveys spontaneous customer feedback is analyzed by the evaluator and results are discussed in the meetings of the workplace	Common surveys; clinic specific evaluations, like questionnaires, calling to patients and feedback boxes; utilization of ICT will come in the future Evaluations must have some kinds of consequences i.e. the possibility to change things	twice annually in a systematic way there are paper surveys and possibilities to give feedback on the internet, follow-up of quality deviations, and reports of a patient representative feedback is discussed in the different units of the hospital
Process measurement	Both qualitative and quantitative measurement, and measurement of effectiveness	customer satisfaction, cost-effectiveness, importance of the service, and quality	delay (time), patient satisfaction, technical quality, economy/costs, personnel, lead time, efficiency, effectiveness, medical evaluation etc., measurement of both diseases and patients' service processes	There should be measurement instruments with many viewpoints and correct amount of measures Measurement should be connected to merit pay Measurement and analysis should be as automatic as possible (electric equipment are needed). Quality of life could be measured The need for both quantitative and qualitative measures
Problems in the utilization of the evaluations and measurements	utilization of the gathered data measurements of effectiveness are difficult, for example the kinds of impacts the library has on learning reliability choosing of the measures systematic operation in measurement and evaluation	It is difficult to find qualitative indicators There are too many indicators There are too few respondents Uncertainty whether measures are reliable.	utilization of information technology is underdeveloped Interpretation of the feedback is difficult More services should be measured; less diagnosis, and there should only be 5-20 measures Finns are not in the habit of complaining (too polite)	all the measures should not be chosen at the hospital level The effectiveness of the units can't be measured and is the right thing being done some things can be changed slowly (for example lack of physicians) and others quickly measurement is not automatic enough and not part of normal operation,

				measures don't measure processes properly (mortality is a measure, but it doesn't happen)

Process improvement

	HUL	KUL	CHK	CHV
Importance of the processes for good quality. How to improve processes?	Processes are important Processes should be improved by modeling them and increasing productivity (more work with less staff).	Processes are important Processes should be improved by: modeling and getting to know the processes, documented instructions, planning the processes for the future for the merger of the university of Kuopio and University of Joensuu, development of measurement and concentrating on the most important issues	Processes are important It is important to increase service oriented development instead of diagnosis centeredness, to get rid of queues and use more information technology. A clinical pathway is a wider concept than a process; there must be compatibility between processes and clinical pathways.	Processes are important Processes should be improved by identifying, describing and measuring them. Very long traditions of some professions make development work difficult and optimizing the work of one group may not guarantee the quality of the whole process. Knowledge of how many services are needed (volume of orders), what capacity and resources this requires, and costs of production. The goals of the hospital are vague: to make patients healthy. The decisions of what is produced and how much are made inside the hospital independently of customers' needs and owners' wants.

AN EMPIRICAL ANALYSIS OF THE RELATION BETWEEN BOARD STRUCTURE AND FIRM VALUE : CASE STUDY OF THAI LISTED COMPANIES IN SET 100

ABSTRACT

The objective of this study is to analyze the relationship of a firm value with the structure of board members of firms that are listed in Thailand SET 100. The independence variables are board size, percentage of independent director, percentage of financial or accounting expertise in audit committee, independent chairman, CEO duality, and percentage of female directors. The dependent variable is firm value which is estimated by using Tobin's Q. The data used for the analysis are from financial statement between the years 2007 to 2009. There are 87 companies being investigated in this study. The study also excludes financial, insurance, property fund, and banking sectors. The result suggests that the structure of board members of a firm has the relationship with the value of a company and only CEO duality that show the statistical significant.

Keywords : Corporate Governance, Thailand, Firm Value, Tobin's Q, Board Structure

INTRODUCTION

Given the increasing importance of corporate governance in Thailand, many researches have studied the role of corporate governance. Corporate governance consists of the set of processes, customs, policies, laws and institutions affecting the way a corporation is directed, administered or controlled. Corporate Governance also includes the relationships among the many stakeholders involved and the goals for which the corporate is governed. Organization for Economic Co-operation and Development (OECD, 2004) defines corporate governance as the system by which business corporations are directed and controlled. The corporate governance structure specifies the distribution of rights and responsibilities among different participants in the corporation such as, the board, managers, shareholders and other stakeholders, and spells out the rules and procedures for making decisions on

corporate affairs (Kajola, 2008). In conclusion, corporate performance structure comprises internal control, market control, board control, corporate charter, law and regulation

About the Code of Corporate Goverance (2004) in the Thailand Securities and Exchange Commission stated that the Board of Director is responsible for governing the firm through an objective, independent check on its management. Solomon (2004) also Vander Bauwhede & Willekens (2003) stated that there should be accurate and free-flowing information going in and out of the board to promote a healthy, functioning corporate body; more than just assuming responsibility for the financial statements. Fama and Jensen (1983) theorize that the board of directors is the highest internal control mechanism responsible for monitoring the actions of top management.

According to the meaning, principles and empirical research of corporate governance, those illustrate the important of corporate governance to organization. In Thailand, corporate governance is the concentrate area in the Securities and Exchange Commission (SEC) and the Stock Exchange of Thailand (SET), both institutes have disbursed to corporate governance. The SET focuses on internal control in improving its corporate governance of Thai firms, especially on the structure of board of directors (Yammeesri and Herath, 2010).

Many empirical researches provide evidence about the important of including outside directors on the board for purposes of monitoring management in agency problem. The relation between board of director composition and firm value is particularly important to the accounting profession. Fama's (1980) and following research conducted by Fama and Jensen (1983) also stated board composition and board of director's recommendations propose that having higher percentage of outside directors increases the board's effectiveness as a monitor of management. Fama and Jensen (1983) acknowledged that the board toned down the agency problem by acting as advisors to the CEO and executive managers, and to be boundary spanners in expanding the company linkage with the external environment, as well.

According to the limited local studies on this accounting phenomenon also the increased importance of corporate governance in Thailand, this study empirically examines by attempting to assess the role of corporate governance practices, particularly those involving the structure of board of directors, in explanatory the firm value listed in the SET 100, Thailand. This study intent to provide the beneficial results to several stakeholders for bringing these knowledge to improve the feature of corporate governance.

THEORETICAL BACKGROUND AND DEVELOPMENT OF HYPOTHESES

A number of studies based on the relation between the structure of board of director and firm value argued that the structure of board of directors have the relation with the firm

value. Various researches were conducted from a number of methodologies. The conceptual framework of this study is identified in Appendix A.

According to the conceptual framework in appendix A, we define the structure or characteristics of board of directors as independence variable and dependence variable is firm value, which measure by using Tobin's Q. Tobin's Q is calculated in the period that fit with the timeframe. Chung and Pruitt (1994) reported that Tobin's Q measures firm performance under decision making in asset investment.

The independence variables that fit with how to measure the broad structure in this study are as follows: 1. Board Size, 2. Percentage of Independent Directors, 3. Percentage of Financial or Accounting Expertise of Directors in Audit Committee, 4. Independent Chairman, 5. CEO Duality, and 6. Percentage of Female Directors.

As mentioned, several independence variables are defined to examine the relation between board structure and firm value: Case Study of Thai Listed Companies in SET 100, which approaches from literature reviews, can be explained as follows:

1. Board Size (BS): Board size is measured by using total board of director at the end of period. Total board of director will examine whether it can increase the value added of the firm. Pfeffer and Salancik (2003) suggested that the higher the number of directors, the higher financial performance. These findings also matched with what Delton et al. (1999) concluded that the number of the board members has correlations with financial performance which includes accounting measurement and current market value. Moreover, the board members also bring in outside expertise that can improve the effectiveness of a firm. The information about the board members also gets published in the annual report. The hypothesis is proposed as follows:
H1a: The Tobin's Q of firm listed in SET 100 is positively associated with board size.

2. Percentage of Independent Directors (ID): Percentage of independent directors is measured as independent director to the entire number of board of director, it indicates responsibility of directors to make sure that agency problem and the possibility of having nominees may reduce (Beiner et al., 2006; Helland and Sykuta, 2005; Lee and Carlson, 2007). The hypothesis suggests the follow:
H1b: The Tobin's Q of firm listed in SET 100 is positively associated with Percentage of Independent Directors.

3. Percentage of Financial or Accounting Expertise of Directors in Audit Committee (FAE) : Carcello et. Al. (2006) and DeFond et al. (2004) suggest that the proportion between numbers of financial or accounting expertise of directors in audit committee supports the

transparency and the competence of the company. Education background is used to determine the qualification of experts. The hypothesis is as follow:

H1c: The Tobin's Q of firm listed in SET 100 is positively associated with Percentage of Financial or Accounting Expertise of Directors in Audit Committee.

4. Independent Chairman (ID): Independent chairman who has no personal involvement with the company prior joining the board is more likely to protect the benefit of an organization. The chairman position that is held by an independent chairman would also raise the visibility of practicing corporate governance. The information mentioned is also published in the annual report or 56-1 form. The hypothesis is as follow:

H1d: The Tobin's Q of firm listed in SET 100 is positively associated with Independent Chairman.

5. CEO Duality (CD) : Finkelstein and D'Aveni (1994) points out that if CEO has multiple duties and assume double positions such as being a president and a CEO together at the same time, it may encourage him to be able figure out the way to deceive the company. The problem of CEO duality also complements with Mallette and Fowler (1992) about the possibility of passing information to outsiders. Thus, segregation of duties principle is very important for the company. The hypothesis is as follow:

H1e: The Tobin's Q of firm listed in SET 100 is negative associated with CEO Duality.

6. Percentage of Female Directors (FD) : Smith et al. (2006) suggests that multiple genders allow company to increase competitiveness and lead to higher profit. Carter et al. (2003) supports the idea and also conclude that different gender generate mechanism to establish a check and balance system for a company. The following hypothesis is trying to prove the extent to which the proportion of female directors has an effect on the profit and market value of the company. The proportion of female and male director can also be seen in the annual report. The hypothesis is as follow:

H1f: The Tobin's Q of firm listed in SET 100 is positively associated with Percentage of Female Directors.

In this study, the four control variables are defined in order to identify the specific impact of board structure on firm value. The control variables use in this study, have also been included in several researches in the literature.

1. Firm Size (FS): Firm Size is measured as the natural logarithm of book value of total assest. Majummdar (1977) reported that there is a positive relation between firm size and firm performance.

2. Gearing Ratio (GEAR): Gearing Ratio is measured as total liabilities divided by total stockholder's equity. Grossman and Hart (1982) and Jensen (1986) reported that

leverage (measured by total liabilities divided by total assets) shows the positive signal of firm value and management.

3. Percentage of Sale Growth (SG): Percentage of Sale Growth is measured as the total sales of the current year minus total sales of the previous year divided by total sale of previous year. Mak and Kusnadi (2005) stated that sales growth is positively related to firm value.

4. Lagged Return on Assets (ROA): Lagged Return on Assets is measured as operating profit divided by average total assets. By the mean, average total assets are calculated as average of total assets of current year and total assets of previous year.

According to dependence variable, independence variable and control variable, the regression model is defined as follows:

Regression Model :

$$Q_t = \alpha_t + \beta_1 BS_t + \beta_2 ID_t + \beta_3 FAE_t + \beta_4 IC_t + \beta_5 CD_t + \beta_6 FD_t + \beta_7 FS_t + \beta_8 GEAR_t + \beta_9 SG_t + \beta_{10} ROA_{t-1} + \varepsilon_t$$

Where:

Q_t : Tobin's Q in the period of firm *i* in year *t* (Tobin's Q);

α_t : Constant at time *t* (Constant);

β : Coefficient of independence variables at time *t* or time *t-1* (Coefficient);

BS : Total board of director of firm *i* at time *t* (Board Size);

ID : Percentage of independent directors divided by total board of director of firm *i* at time *t* (% Independent Directors);

FAE : Percentage of financial or accounting expertise of directors divided by total board of director of firm *i* at time *t* (% Financial or Accounting Expertise of Directors in Audit Committee);

IC : A Dummy variable which a value of one if chairman of firm is the independence board and a value of zero otherwise, of firm *i* at time *t* (Independent Chairman) ;

CD : A Dummy variable which a value of one if there is not a spilt between chairman of firm and CEO and a value of zero otherwise, of firm *i* at time *t* (CEO Duality);

FD : Percentage of female directors of firm *i* at time *t* (% Female Directors)

FS : The natural logarithm of book value of total assets of firm *i* at time *t* (Firm Size)

$GEAR$: Total liabilities divided by total stockholder's equity of firm *i* at time *t* (Gearing Ratio)

SG : Total sales of the current year minus total sales of the previous year divided by total sale of previous year of firm *i* at time *t* (%Sale Growth)

ROA : Operating profit divided by average total assets of firm *i* at time *t* (Lagged Return on Assets)

ε_t : Residual at time t (Error Terms)

RESEARCH DESIGN

In this study, the causal or explanatory approach will be applied. A cross-sectional analysis will be conducted in this research. The sample size will be collected in Thailand SET 100 during year 2007-2009. Anyway the firms in the Banking, Insurance, Financing and Property Fund sector will not be included in this study because the transactions of those industries will be different to other industries. The data will be collected on December 29, 2009, total 80 firms, which have been shown in Appendix B. The secondary data is applied as source of data in this study. Appendix C shows the details of source of secondary data such as the SET, SEC, Website of listed firms, etc.

Focusing in measurement of variables for Regression model can explained as follows (Appendix D):

BS : Total board of director at time t (Board Size), will be calculated by counting the number of board of director shown in report 56-1 at the year ended under the title "board of director and management team"

ID : Percentage of total independence director at time t (% Independent Directors), will be calculated by counting the number of board of director and the number of independence director, shown in report 56-1 at the year ended under the title "board of director and management team"

According to SET regulation, independence director (or outside director) will have outstanding share in that firm not more than 0.05%. Also independence director must not be the management team, employee or advisors who have the fixed salary. Under SET regulation, the listed firm must have at least 3 independence directors.

$$ID = \frac{\text{Total independence director} \times 100}{\text{Total director}}$$

FAE : Percentage of financial or accounting expertise of directors in audit committee at time t (% Financial or Accounting Expertise of Directors in Audit Committee), will be calculated by counting the number of board of director and the number of financial or accounting expertise of directors in audit committee, shown in report 56-1 at the year ended under the title "board of director and management team". Under SET regulation, the financial or accounting expertise of directors in audit committee must have knowledge in financial or accounting field must have at least a bachelor degree in financial or accounting, or have experience in financial or accounting field.

$$FAE = \frac{\text{Financial or accounting expertise of directors in audit committee} \times 100}{\text{Total audit committee}}$$

IC : Dummy variable which a value of one if chairman of firm is independence board and a value of zero otherwise, at time t (Independent Chairman), will be calculated by checking whether chairman of directors is independence board, which shown in report 56-1 at the year ended under the title "board of director and management team".

CD : Dummy variable which a value of one if there is not a spilt between chairman of firm and CEO and a value of zero otherwise, of firm *i* at time *t* (CEO Duality), will be calculated by checking whether there is not a spilt between chairman of firm and CEO, which shown in report 56-1 at the year ended under the title "board of director and management team".

FD : Percentage of female directors at time t (% Female Directors), will be calculated by counting the number of board of director and the number of female directors, shown in report 56-1 at the year ended under the title "board of director and management team".

$$FD = \frac{\text{Percentage of female directors x 100}}{\text{Total directors}}$$

Q : According to theory of Tobin's Q, Lindenberg and Ross (1981) studied about the valuation, they stated that the firm valuation can measure with market value of stock. Chung and Pruitt (1994) defined to calculate Tobin's Q as market value of firm, they stated that Tobin's Q is measured as market value of common stock (market price of common stock multiply outstanding share volume) plus market value of preferred stock and market value of liabilities, also book value of assets will be used instead of replacement cost.

$$Q = \frac{(MP \times OSV) + MV_{p/s} + MV_l}{BV_a}$$

Where:

MP : Market Price of common stock

OSV : Outstanding Share Volume

$MV_{p/s}$: Market Value of Preferred Stock

MV_l : Market Value of Liabilities

BV_a : Book Value of Assets

DATA ANALYSIS

The statistic used in this study consists of descriptive statistics, which are Mean and Standard Deviation, Pearson's Product Moment Correlation Coefficient, Inferential Statistics with Multiple Regression Analysis, shown in Appendix E.

EMPIRICAL RESULTS

Table 1 presents descriptive statistics of the variables which average for 3 years. The results show that the mean for 3 years of Tobin's Q is 1.36, minimum is 0.34 and maximum is 7.20. Average total number of board size is 12, which the maximum is 18 whereas the minimum is 5. Average percentage of total independence director is 38, which shown the maximum 80 and the minimum is 18. When focus on percentage of financial or accounting expertise of directors in audit committee, it shows the average is 34. Also when concentrate on percentage of chairman of firm is independence board, the average shows 36.5. Whereas the descriptive statistic shows the average percentage is 9.6 when there is not a spilt between chairman of firm and CEO. About average of percentage of female directors is shown 10.4.

Focusing on control variables, the statistic shows that average ROA is 10.7, whereas the maximum is 55 percent and the minimum is minus 22 percent. Average market value of total assets is 54,839 million baht. The gearing ratio which is measured as total liabilities divided by total stockholder's equity and the average sales growth are 1.32 percent and 9.6 percent, respectively.

Table 1: Descriptive statistics, average for 3 years (2007-2009).

(N = 249)

Variables	Variable Description	Min	Max	Mean	Std. Dev.
Q	Tobin's Q	0.34	7.20	1.36	0.81

SG	% Sale Growth	-60	369	9.6	39.89

Appendix F presents descriptive statistics of the variable for each year during year 2007-2009. It shows the Tobin's Q is 1.61, 1.08 and 1.07 for year 2007-2009, respectively. Average number of board size for each year is 12 persons, the maximum of every year is 18, whereas the minimum of year 2008 and year 2009 is 6 person and the minimum of year 2007 is 5. The average percentage of independence director of year 2007, 2008 and 2009 are 36.7, 38.5 and 38.7 percent, respectively. The minimum of percentage of independence director in year 2007 is 19 percent and the maximum is 69 percent. Whereas the maximum

and the minimum of percentage of independence director in year 2008 and 2009 is equal, the minimum is 18 percent and the maximum is 73 percent.

Focusing on average percentage of financial or accounting expertise of directors in audit committee of year 2007, 2008 and 2009 are 35.6, 33.6 and 33.6, respectively. Whereas, the maximum and the minimum is 100 percent and zero percent is equal for all years. For average percentage of chairman of firm is independence board of year 2007, 2008 and 2009 are 33.8, 36.9 and 36.5, which the maximum and the minimum is 100 percent and zero percent, which is equal for all years. The descriptive statistic shows the average percentage of year 2007, 2008 and 2009 are 10.0, 9.5 and 9.3 when there is not a spilt between chairman of firm and CEO which the maximum and the minimum is 100 percent and zero percent, which is equal for all years. About average of percentage of female directors of year 2007, 2008 and 2009 are 10.7, 10.2 and 10.4, which the maximum and the minimum is 38 percent and zero percent, which is equal for all years.

Focusing on control variables, the statistic shows that average ROA of year 2006, 2007 and 2008 are 12.2, 11.9 and 9.6, whereas the maximum of year 2006, 2007 and 2008 are 38.0, 42.0 and 55.0, whereas the minimum of year 2006, 2007 and 2008 are -12, -3 and -22 percent. Average market value of total assets of year 2007, 2008 and 2009 are 51,216 million baht, 54,839 million baht and 53,262 million baht, whereas the maximum of year 2007, 2008 and 2009 are 891,524 million baht, 885,192 million baht and 1,103,589 million baht, respectively. The minimum of year 2007, 2008 and 2009 are 2,018 million baht, 2,935 million baht and 2,582 million baht, respectively. The average gearing ratio which is measured as total liabilities divided by total stockholder's equity of year 2007, 2008 and 2009 are 1.30, 1.39 and 1.38 percent, respectively. Whereas the maximum and the minimum of year 2008 and 2009 are equal, which are 16.83 and 11.10 percent. The maximum and the minimum of gearing ratio of year 2007 are 11.46 and 0.07. Finally, the control variable which is the percentage of sale growth, the average of year 2006, 2007 and 2008 are 13.17, 16.06 and 15.82. Whereas the maximum and the minimum of year 2008 and 2009 are equal, which are 369 and - 60 percent. The maximum and the minimum of average percentage of sale growth of year 2007 are 300 and - 36 percent.

Before testing for the Multiple Regression Analysis, we need to test correlation between all variables in order to check for auto-correlation, singularity and multicollinearity. Table 2 shows correlation coefficients for 3 years (year 2007- year 2009). It shows that there is no correlation among testing variables.

Table 2: Correlation Coefficients for 3 years (year 2007- 2009).

Variables	Variable Description
Q	Tobin's Q
BS	Board Size
ID	% Independent Directors
FAE	% Financial or Accounting Expertise of Directors in Audit Committee
IC	Independent Chairman (%)
CD	CEO Duality (%)
FD	% Female Directors
ROA	Lagged Return on Assets (%)
FS	Firm Size (Book Value of Total Assets)
GEAR	Gearing Ratio
SG	% Sale Growth

Moreover, we test the error of data. The histogram figure indicates that the distribution is abnormal. The probability plot has deviation. Besides, this study uses Durbin-Watson Test for checking autocorrelation, the Durbin-Watson Test shows d = 1.743. It means there is degree of freedom among the variables. For testing regression standardized residual with regression standardized predicted value, the results states that there is no pattern on plots. Multicollinearity also is tested, all independence variables shows that all VIF is less than 5, it means board size, percentage of independent directors, percentage of financial or accounting expertise of directors in audit committee, percentage of independent chairman, CEO Duality (%) and percentage of female directors do not relate for each other.

Table 3 and table 4 shows the result of pooled - data Multiple Regression Analysis (R Square = 0.406), stated that independence variables have significant influence to dependence variable (p = 0.000, which is less than 0.05). In other word, board structure has an influence on a firm value.

Focusing on coefficient between dependence variable and independence variable, we find that CEO Duality and Lagged Return on Assets have significant (p = 0.014 and p = 0.000, which is less than 0.05, respectively), whereas, the other independence variables do not show the significant statistic and the incremental significant.

Results from the multiple regression shows that there are 3 variables consistent with H1, the coefficient on board Size (BS), percentage of financial or accounting expertise of directors in audit committee (FAE)) continue to be positive and significant (p < 0.05). Whereas, the hypothesis about CEO duality (CD), which there is not a spilt between chairman of firm and CEO, is not consistent with H1, it means that there is positively relation between Tobin's Q and CEO duality at level 0.05.

Furthermore, the Tobin's Q is negatively relation with percentage of independent directors (ID), independent chairman (IC) and percentage of female directors (FD), which these hypotheses will be rejected at level 0.05. Whereas, the Tobin's Q is positively relation with lagged return on assets (ROA) and Gearing Ratio (GEAR), which are control variables. The Tobin's Q is negatively relation with percentage of sale growth (SG) and Firm Size (FS).

However, the regression model with dependence variable and independence variables without including 4 control variables in the model indicates that one hypothesis is rejected (Hypothesis H1e), which means there is a positively relation between Tobin's Q and CEO Duality (CD). This findings suggests that CEO who is also acting as a chairman has the influential effect on the firm value.

Moreover, the result of regression model with 4 control variables indicates that two hypotheses are rejected. The two hypotheses are H1d and H1e. There is positively relation between Tobin's Q and CEO Duality (CD) but negatively relation between Tobin's Q and percentage of Independent Directors (ID).

According to the regression analysis for each year, the results of regression analysis of year 2007 and 2009 have a statistic significant at 0.05. The result of regression analysis of year 2007 and year 2009 shows the similar findings with pooled - data regression.

IMPLICATION TO RESEARCH RESULTS

For Pooled-Data result, R Square is equal to 0.406. Considering this result with our hypotheses, the findings, using F-test, suggest that there is statistical significant difference. However, if we consider the coefficient parameters of each variable, the results show that only one selected variable, CEO Duality, has the effect to the value of a company (*p*-value = .014). Using t-test, findings show there is negatively statistical significant different. The outcome suggests that the CEO who is also acting as a chairman of a company can influence the way the firm is run. The objective of a company would also be fulfilling if the two positions are held by the same person. This finding is similar with Anderson and Anthony (1986). The result also indicate the larger the company, the more benefit and lose if a company has the leader that held two position as CEO and chairman (Brickley et al. 1997). In conclusion, the reverse relationship between CEO Duality and Firm value happen and no statistical significance for these other variables.

The results shows that there is no statistical significant in board size, Mak and Kusnadi (2005) also supported the idea that more board of directors will not increase financial performance. Their findings stated that co-operation will be problematical if there is more board of directors. They also argue that it is not guarantee that more board of directors will generate financial performance.

For the percent of independent directors and percentage of financial or accounting expertise of directors in audit committee, the board member with freedom to make any decisions without involving self interested may not reflect the higher revenue than those

that have less independent directors. One explanation of this outcome is the degree of freedom that independent director have in making decisions. For the number of independent directors, the right amount depends on the work or expertise that the firm may request from these directors. Moreover, the agency theory also suggests that the independent directors should not hold more than 0.05 percent of stock. That said, this group of directors might not contribute to the price of a company stock. Bhagat and Black (2002) also concluded that a firm that has independent directors may not have anything to do with a company stock price.

The results shows that the independence chairman is no statistical significant. Donaldson and Davis (1991) also supported the idea that independent director who serves as CEO is more likely to help increase the productivity of a company. There is also no statistical significant between male and female director. Williams and O'Reilly (1998) suggested that to have directors from both sex would not allow better communication and will increase the emotional judgment. Lau and Murnighan (1998) argued that the higher the numbers of different sex in the board the higher the possibility of having the longer discussion and time need to make decision.

CONCLUSION

The findings of this study suggest that structure of board of director has a direct effect on the value of a firm. The result suggests that CEO duality has a incremental significant. Nevertheless, we can conclude that CEO Duality has positive relationship with the value of a firm while other variables have no influence to the firm's value. However, the regulator that is responsible for set up the rule and regulation should apply the board structure concept. The results of this project can enhance the company performance. The future research should focus on the relationship among other independent variables, and concentrate more on how the structure of a board of director is form and the method to measure firm value.

IT GOVERNANCE TRANSITION ANALYSIS FROM ITIL TO COBIT: CASE STUDY BANKING INDUSTRY IN THAILAND

Saksri Zuurbier, Kasetsart University, THAILAND

Pornthep Anussornnitisarn, Kasetsart University, THAILAND

Bordin Rudsameetas, Kasetsart University, THAILAND

ABSTRACT

The purpose of this study is to identify the key difference among two well-known IT governance standards: Information Technology Infrastructure Library (ITIL) and Control Objectives for Information and Related Technology (COBIT). The setting of this study is the information technology systems in Financial Institutions of Thailand where many institutions have been applied ITIL as their IT risk management but considering COBIT implementation. The results provide a guideline for moving from ITIL to COBIT.

Keywords: Information Technology Risk Management, COBIT, ITIL, IT best practice.

INTRODUCTION

During 1997 and 1998, Thai financial crisis was the most severe in Thai economy. The Thai Baht currency had been weakened by several attacks from international funds. Finally, the Thai Government at that time was forced to float the currency. The Baht immediately dropped significantly in value, losing 20 percent in one month, and falling to less than half its former value within six months.

Due to the financial crisis during 1997-1998, Bank of Thailand (BOT) enforced the financial institute implement an international risk management framework such as BASEL I. Basel I was published by the Basel Committee (BCBS) in Basel, Switzerland in 1988. It was the results from the round of deliberations by central bank representatives from around the world. BASEL I only focused on a credit risk problem by setting minimal capital requirements for financial institutes. Later, BASEL II was developed in 2004 as a guideline for broader financial and operational risk management for financial institutes (Hamaker, 2004; Reghavan, 2006). At time of developing this article, all of Thailand financial institutes are on the process of implementing BASEL II.

Even though, the financial risk management primarily focuses on the financial operations like loan, credit and debt issues. The raising of applications in Information Technology (IT) as part of supporting tool in back-office operations and new customer outreach operation for the front office (Boritz, 2005; Klamm and Watson, 2009). The availability and reliability of the IT system has become a critical to the entire operations of the major Thailand banks. Therefore, the effort in implementing risk management, such as BASEL II, has included the issues of IT risk management into it. At that time, an Information Technology Infrastructure Library (ITIL) which

are developed and promoted by the United Kingdom's Office of Government Commerce (OGC) in 1989 for its first version, has been popular among the international firms in developed countries. Following the recognized IT risk management framework, it is the quickest way for Thailand banks to ensure the confidence of both Thailand central bank and foreign rating agencies in part of the corporate good governance campaign after the financial crisis. As a result, ITIL has been widely adopted in Thailand financial institutes.

With a rapidly developed and changes in Information technology including the popularity of using information technology in daily life of the ordinary people, in U.S., 95 million U.S. households use the Internet; 72.5 million of those households participate in online banking, with 36.4 million using online bill pay, it was a 51 percent increase in Internet usage per household since 2000, and an even more increase of 84 percent in online banking and 78 percent in online bill payment. Many Thailand banks has been aggressively rolled out many services related with information technology throughout the country, such as an Automatic Teller Machine (ATM), telephone Banking, Internet Banking, mobile Banking, e-billing and e-payment etc. The trend of using computer system to scan customer profiles & transactions to match with new financial products is very popular and very demanding in computing capability. In addition, many banks in Thailand now operate seven days a week in shopping center or community center.

As a result, most of Thailand financial institutes have increased in their IT resource capability and capacity (Hardware, Software, and People) to provide an adequate service level for both of their front and back office operations. With many new IT initiatives as new financial products or services, project management and system evaluating and monitoring have become critical to determine the success of overall initiative. According to ISACA (2008), ITIL is a best practice but at the implementation level, ITIL often lacks of the detail on how to operate a certain practice. Since the IT systems and their complexity grew larger and larger in recent years, IT department has been look for more detail standard. The Control Objectives for Information and related Technology (COBIT) is considered by many Thailand banks as more detail alternative of ITIL. The scope of COBIT framework is more widely than ITIL process as show in Figure 1.

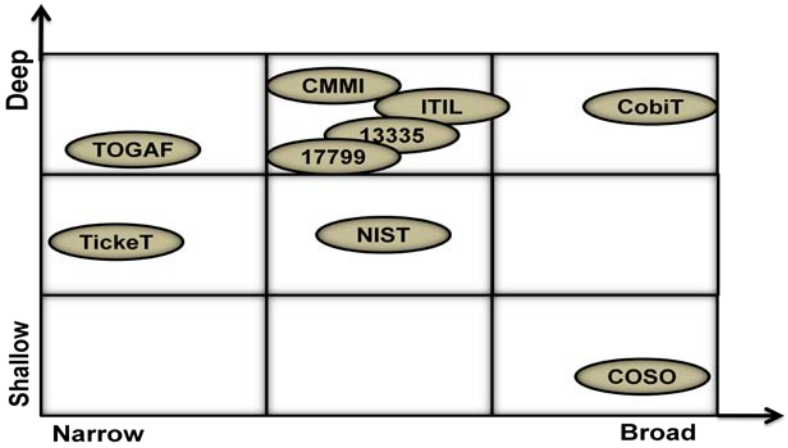

Figure 1: IT Standard Address adopted from www.itgi.org.

Control Objectives for Information and related Technology (COBIT) is developed and released by the Information Technology Governance Institute (ITGI) as an IT process and control framework linking IT to business requirements. With the addition of management guidelines in 1998, COBIT is often referred as a management framework or IT governance framework, providing management tools, such as metrics and maturity models, to complement the control framework. COBIT gives managers, auditors, and IT users with a set of measures, indicators, processes and best practices, to assist them in maximizing the benefits of their information technology systems/projects/initiatives (Hardy, 2006). The current version is COBIT 4.1.

Since, many banks have implemented ITIL. Moving to another framework like COBIT can be confusing and time consuming transition. However, both ITIL and COBIT are considered as a good and comprehensive framework. Therefore, the purpose of this research is to identify the areas of ITIL and COBIT which are similar which will required less effort in transition. And, identify the areas that need an effort including new activities, documents etc. in the transition from ITIL(version 3) to COBIT(version 4.1). Moreover, this research also check if there is an area where COBIT missed and but exists in ITIL. The benefits of this research are to reduce time in transition and to provide guideline about where IT department need to put an effort to ensure the success of obtaining COBIT certificate.

BACKGROUND

Information Technology Infrastructure Library (ITIL)

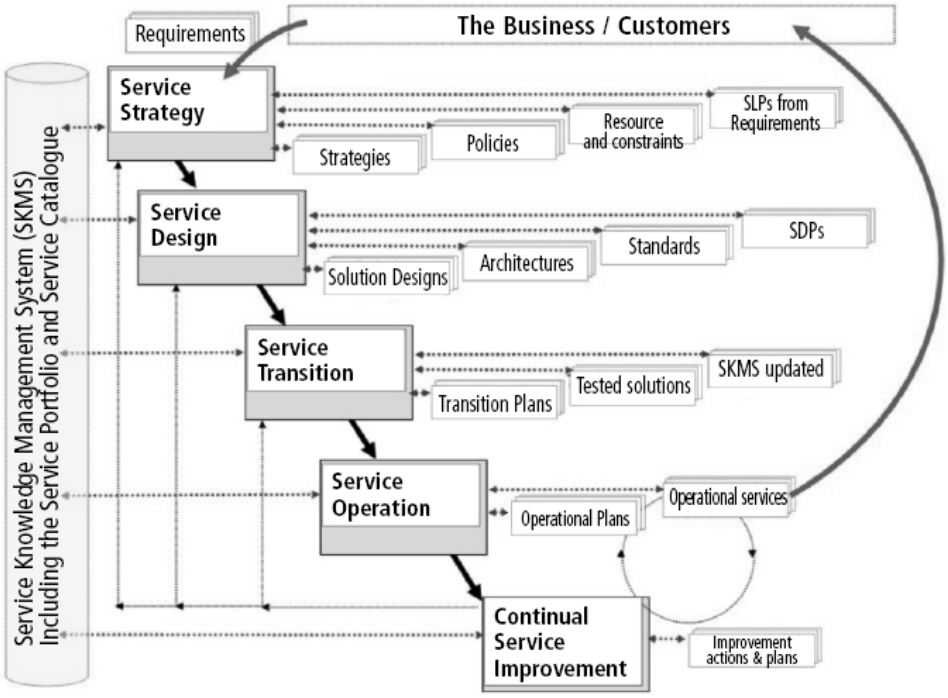

Figure 2: ITILv3 IT service lifecycle stages.

ITIL was developed by the effort of Her Majesty's Stationery Office (HMSO), United Kingdom on behalf of the Central Communications and Telecommunications Agency (CCTA) to provide a public framework and best practice for managing IT services and their environment. From its first published in 1989, ITIL has known as a comprehensive IT management best practice. The latest version is ITIL v3 which released in May 2007 (Cannon and Wheeldon, 2007; Iqbal and Nieves, 2007; Shirley and Macfarlane, 2007; Vernon and Rudd, 2007). ITIL v3 consists of five building blocks in IT system life cycles: 1) Service strategy 2) Service design 3) Service transition 4) Service operations and 5) Continual service improvement as shown in Figure 2.

In general, the development of IT system starts from the change in requirements of the business. The service strategies of IT system are formulated and aligned to meet business requirements within a service level package (SLP) to achieve a defined set of business outcomes. Then, the IT service design begins by involving with system architectures, solutions and standards in order to produce IT solution with a service design package (SDP). In service transition stage, the IT service is evaluated, tested and validated while relevance details are updated into the service knowledge management system (SKMS). When IT service is ready to be used (live environment), it enters the service operation stage. In addition, the search for continual service improvement is the key to overall system success by identifying the weaknesses or failures within any of IT life cycle stages.

Control Objectives for Information and related Technology (COBIT)

A control objectives for information and related technology (COBIT) is an IT governance framework which developed by the Information Systems Audit and Control Association (ISACA) in 1996. Later, ISACA set up the IT Governance Institute (ITGI) as a principle to promote, research, and develop the IT governance best practices and standards including the later version of COBIT. Currently, ISACA has planned to issue COBIT version 5 in 2011. However, the research conduct in this article has been worked under the framework of COBIT version 4.1 (IT Governance Institute, 2005).

In general, COBIT is a business-focused IT framework that guides organization management team by closing the gap among control requirements, technical issues, business risks, and stakeholder communications. With COBIT, the company executives can develop coordinated policies in both IT and business perspectives throughout the organization. The COBIT conceptual framework and principles begin with business requirements. With essential information provided by organization IT systems, the enterprise can utilize the received information to achieve its objectives and goals. Therefore, the enterprise needs to provide enough IT resources. Then, IT resources must be managed and monitored based on a structured set of processes in order to deliver the required enterprise information. The COBIT processes help ensure alignment between IT operations and business requirements. The fundamental concept of COBIT is illustrated in Figure 3.

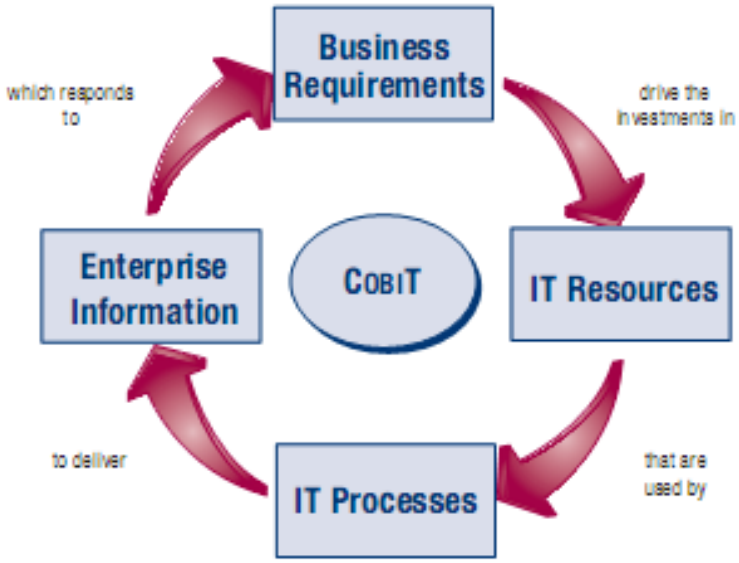

Figure 3: COBIT fundamental concept.

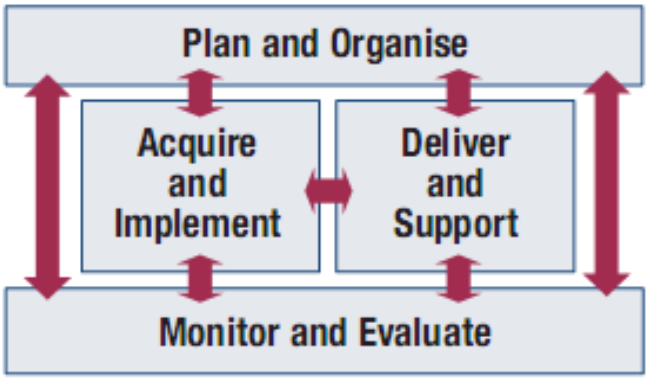

Figure 4: Four inter-related COBIT process groups.

COBIT classifies its generic processes and activities into four main groups: 1) Plan and Organize, 2) Acquire and Implement, 3) Deliver and Support and 4) Monitor and Evaluate as shown in Figure 4. These four main COBIT process groups are mapped and aligned with traditional IT development concept of plan, build, run and monitor. In Plan and Organize (PO) process group, it provides direction to solution delivery. In Acquire and Implement (AI) process group, it provides the solutions and hands them over to be turned into services. In Deliver and Support (DS) process group, it receives the solutions from AI process group and makes them available for end users. In Monitor and Evaluate (ME) process group, it monitors all processes to ensure that the direction provided is followed and IT operations still aligned in respond to the business objectives and goals.

The COBIT framework provides a reference process model and common language for everyone in organization to view and manage IT activities. Incorporating an operational model and a common language for all parts of the business involved in IT is and initial steps toward IT good governance. It also provides a framework for measuring and monitoring IT performance, communicating with service providers and integrating best management practices (Von Solms, 2005).

METHOD

In this research, COBIT's 34 processes are mapped with the ITIL v3 processes descriptions. By analyzing the detail description of ITIL v3 processes in comparison with individual process of the COBIT's 34 processes, the similarity of process scope and activities are identified using numeric rating scale shown in Table 1.

Table 1: Rating of the similarity of requirements between COBIT 4.1 and ITIL v3.

Rating	Description
1.0	All/almost of requirements of the control objective are covered the guidance in ITIL v3
0.8	Many aspects of the control objective are addressed by ITIL v3, but the key activity areas are not covered completely.
0.6	Some aspects of the control objective are addressed by ITIL v3, but the key activity areas of the control objective are more than 50% but not greater than 80%
0.4	Some aspects of the control objective are addressed by ITIL v3, but the key activity areas of the control objective are not greater than 50%
0.2	A few aspects of the control objective are addressed by ITIL v3.
0	There is no match between the requirements of COBIT and ITIL v3.

RESULTS

Due to the limited pages, the comparison between ITIL and COBIT by linking the activity stated in ITIL v3 to COBIT 4.1 is shown only the activity in the PO process group in Table 2.

Table 2: Result of linked activity areas between ITIL and COBIT

COBIT		Link	Similarity Rating between ITIL and COBIT
Group	**Process**	**Activity Area**	
PO 1.0	Define a Strategic IT Plan	IT strategic planning is required to manage and direct all IT resources in line with the business strategy and priorities. The IT function and business stakeholders are responsible for ensuring that optimal value is realized from project and service portfolios. The strategic plan improves key stakeholders' understanding of IT opportunities and limitations, assesses current performance, identifies capacity and human resource requirements, and clarifies the level of investment required. The business strategy and priorities are to be reflected in portfolios and executed by the IT tactical plan(s), which specifies concise objectives, action plans and tasks that are understood and accepted by both business and IT.	0.8
PO 2.0	Define the Information Architecture	The information systems function creates and regularly updates a business information model and defines the appropriate systems to optimize the use of this information. This encompasses the development of a corporate data dictionary with the organization's data syntax rules, data classification scheme and security levels. This process improves the quality of management decision making by making sure that reliable and secure information is provided, and it enables rationalizing information systems resources to appropriately match business strategies. This IT process is also needed to increase accountability for the integrity and security of data and to enhance the effectiveness and control of sharing information across applications and entities.	0.2

COBIT		Link	Similarity Rating between ITIL and COBIT
Group	**Process**	**Activity Area**	
PO 3.0	Determine technical Direction	The information services function determines the technology direction to support the business. This requires the creation of a technological infrastructure plan and an architecture board that sets and manages clear and realistic expectations of what technology can offer in terms of products, services and delivery mechanisms. The plan is regularly updated and encompasses aspects such as systems architecture, technological direction, acquisition plans, standards, migration strategies and contingency. This enables timely responses to changes in the competitive environment, economies of scale for information systems staffing and investments, as well as improved interoperability of platforms and applications.	PO 3.0
PO 4.0	Define the IT Processes, Organization and Relationships	An IT organization is defined by considering requirements for staff, skills, functions, accountability, authority, roles and responsibilities, and supervision. This organization is embedded into an IT process framework that ensures transparency and control as well as the involvement of senior executives and business management. A strategy committee ensures board oversight of IT, and one or more steering committees in which business and IT participate determine the prioritization of IT resources in line with business needs. Processes, administrative policies and procedures are in place for all functions, with specific attention to control, quality assurance, risk management, information security, data and systems ownership, and segregation of duties. To ensure timely support of business requirements, IT is to be involved in relevant decision processes.	0.8
PO 5.0	Manage the IT Investment	A framework is established and maintained to manage IT-enabled investment programs and that encompasses cost, benefits, prioritization within budget, a formal budgeting process and management against the budget. Stakeholders are consulted to identify and control the total costs and benefits within the context of the IT strategic and tactical plans, and initiate corrective action where needed. The process fosters partnership between	0.8

COBIT		Link	Similarity Rating between ITIL and COBIT
Group	**Process**	**Activity Area**	
		IT and business stakeholders; enables the effective and efficient use of IT resources; and provides transparency and accountability into the total cost of ownership (TCO), the realization of business benefits and the ROI of IT-enabled investments.	
PO 6.0	Communicate Management Aims and Direction	Management develops an enterprise IT control framework and defines and communicates policies. An ongoing communication program is implemented to articulate the mission, service objectives, policies and procedures, etc., approved and supported by management. The communication supports achievement of IT objectives and ensures awareness and understanding of business and IT risks, objectives and direction. The process ensures compliance with relevant laws and regulations.	0.2
PO 7.0	Manage IT Human Resources	A competent workforce is acquired and maintained for the creation and delivery of IT services to the business. This is achieved by following defined and agreed upon practices supporting recruiting, training, evaluating performance, promoting and terminating. This process is critical, as people are important sets, and governance and the internal control environment are heavily dependent on the motivation and competence of personnel.	0.2
PO 8.0	Manage Quality	A quality management system (QMS) is developed and maintained that includes proven development and acquisition processes and standards. This is enabled by planning, implementing and maintaining the QMS by providing clear quality requirements, procedures and policies. Quality requirements are stated and communicated in quantifiable and achievable indicators. Continuous improvement is achieved by ongoing monitoring, analysis and acting upon deviations, and communicating results to stakeholders. Quality management is essential to ensure that IT is delivering value to the business, continuous improvement and transparency for stakeholders.	0.6

COBIT		Link	Similarity Rating between ITIL and COBIT
Group	**Process**	**Activity Area**	
PO 9.0	Access and Manage IT Risks	A risk management framework is created and maintained. The framework documents a common and agreed-upon level of IT risks, mitigation strategies and residual risks. Any potential impact on the goals of the organization caused by an unplanned event is identified, analyzed and assessed. Risk mitigation strategies are adopted to minimize residual risk to an accepted level. The result of the assessment is understandable to the stakeholders and expressed in financial terms, to enable stakeholders to align risk to an acceptable level of tolerance.	0.6
PO 10.0	Manage Projects	A program and project management framework for the management of all IT projects is established. The framework ensures the correct prioritization and co-ordination of all projects. The framework includes a master plan, assignment of resources, definition of deliverables, approval by users, a phased approach to delivery, QA, a formal test plan, and testing and post-implementation review after installation to ensure project risk management and value delivery to the business. This approach reduces the risk of unexpected costs and project cancellations, improves communications to and involvement of business and end users, ensures the value and quality of project deliverables, and maximizes their contribution to IT-enabled investment programs.	0.2

CONCLUSION

Based on the comparison between ITIL and COBIT as stated in Table 2, the overall similarity between ITIL and COBIT can be summarized based on COBIT process group as shown in Figure 5-8.

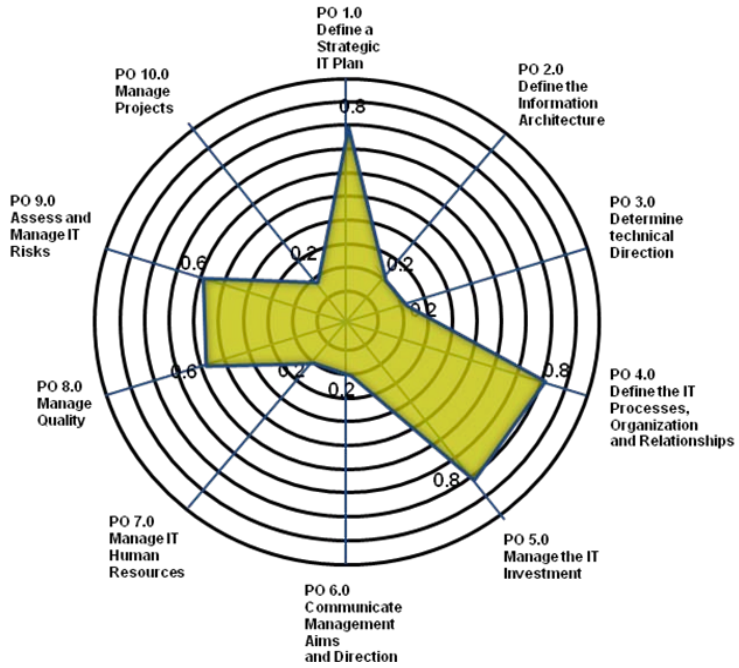

Figure 5: A similarity comparison between ITIL v3 and COBIT 4.1 process group PO.

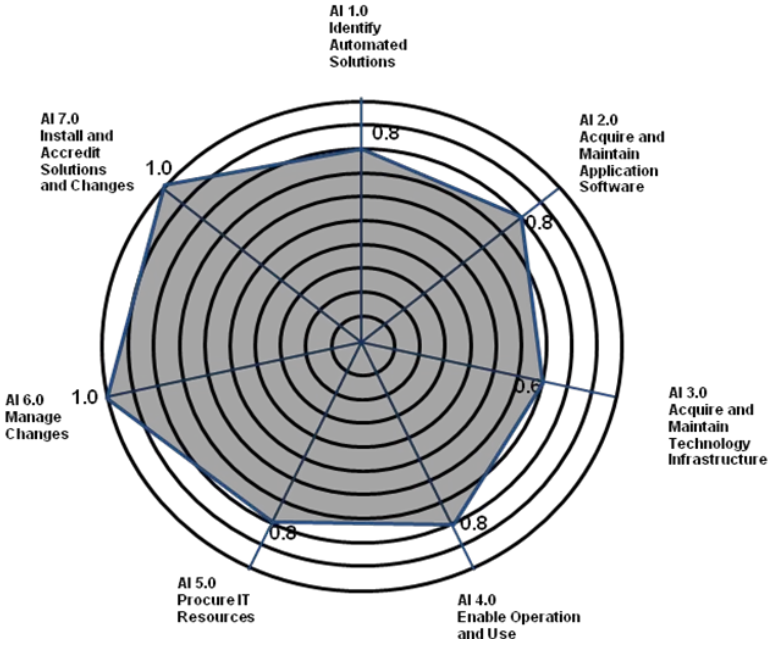

Figure 6: A similarity comparison between ITIL v3 and COBIT 4.1 process group AI.

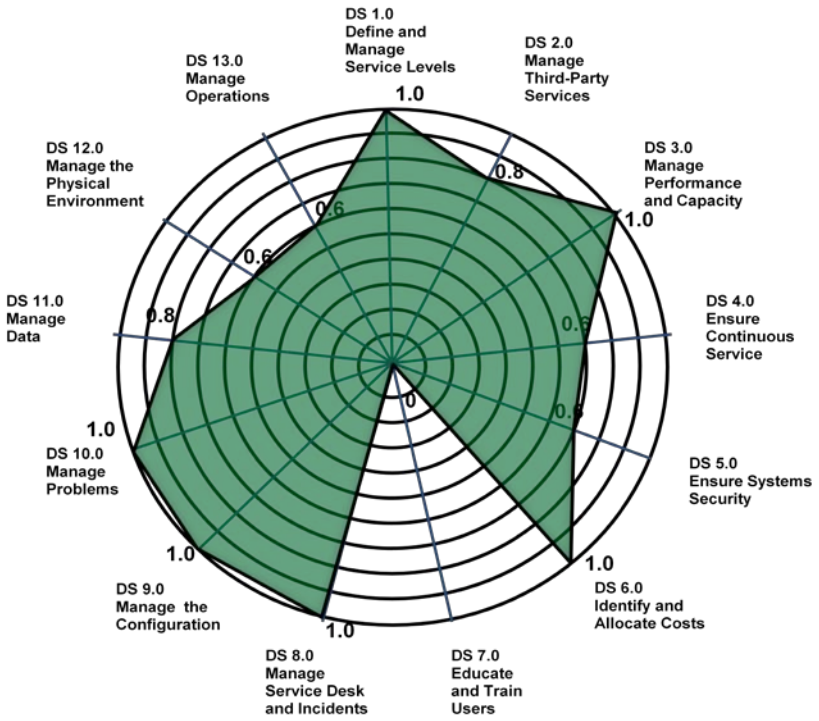

Figure 7: A similarity comparison between ITIL v3 and COBIT 4.1 process group DS.

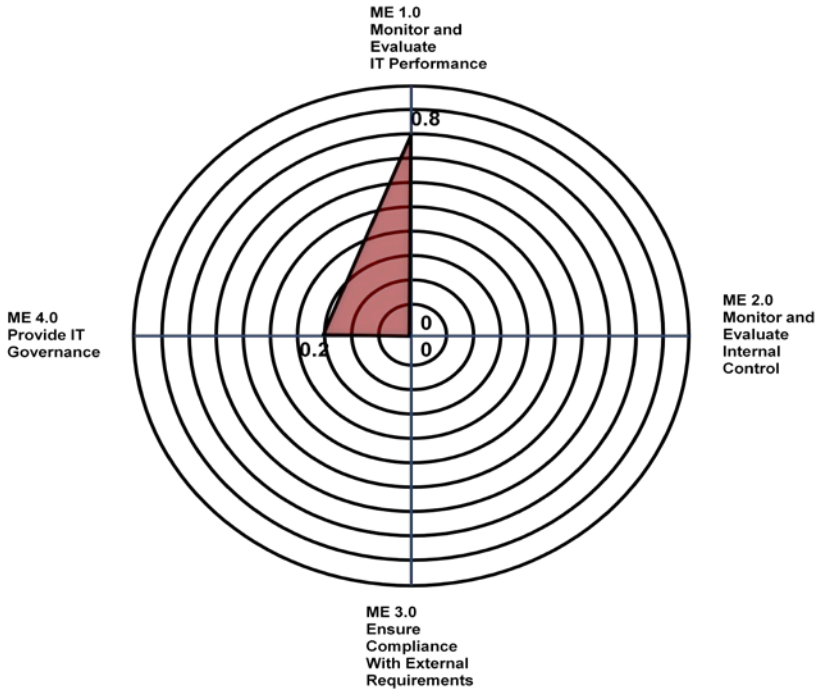

Figure 8: A similarity comparison between ITIL v3 and COBIT 4.1 process group ME.

Based on Figure 5-8, ITIL processes can be considered as similar processes to COBIT in AI and DS. However in Planning (PO) and Monitoring (ME) processes, COBIT has broader processes perspectives than ITIL. In addition, based on the results, when comparing COBIT and ITIL processes with the information system development life cycle (Strategy-Requirements-Design-

Develop-Test-Deploy-Operate-Monitor-Optimize), ITIL less focuses (lighter color) on monitoring and optimizing phase in compare to COBIT as shown in Figure 9.

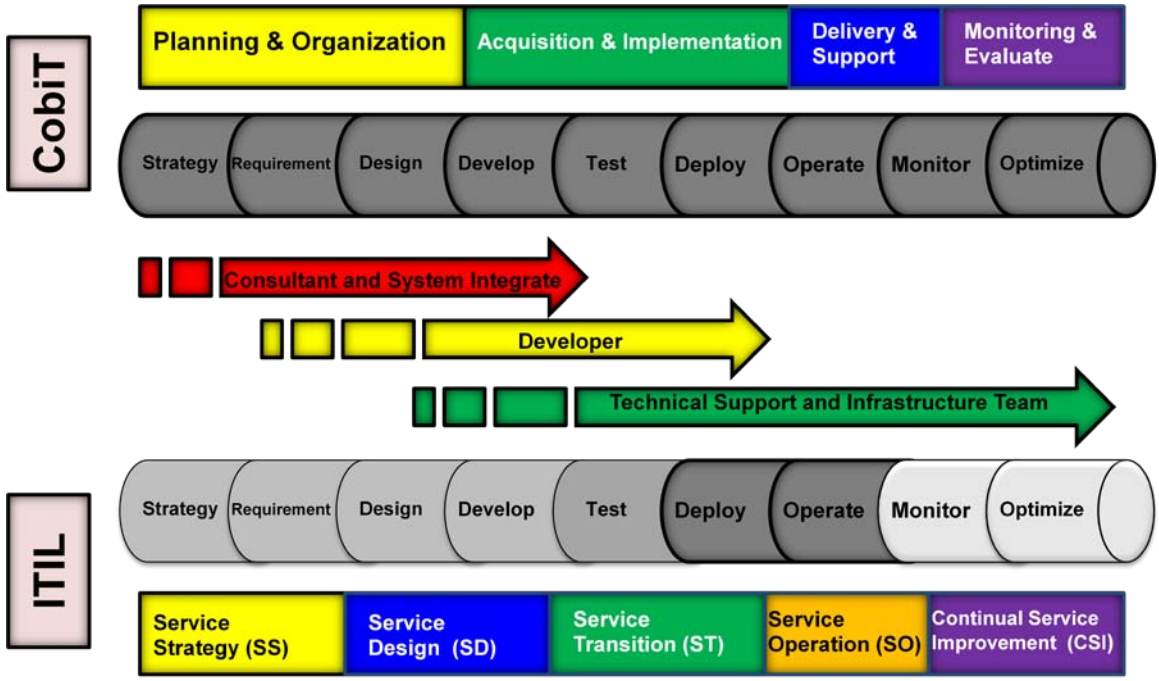

Figure 9: Comparing IT project development life cycle with COBIT and ITIL.

In conclusion, this research did not intend to compare the performance between COBIT and ITIL. It intended to identify the similarity and difference in case if there is a change in organization policy regarding IT governance standard in this case, Thailand banking industry.

If Thailand Banks has considered moving from ITIL to COBIT, the area they need to focus is the monitoring and evaluating processes. Several new procedures have to be developed and deployed. Moreover, the connection between IT strategy and organization strategy are needed to be identified and realigned including work procedures that enable theses connections.
