### Abstract

This article presents the effectiveness of Virtual Reality Therapy (VRT) in addressing specific phobias and anxiety disorders within a demographic specific to Western Romania. This research analyses data from 637 VRT patients conducted over a three-year period of active clinical practice. The study primarily focuses on measuring the outcomes of VRT in treating all kinds of phobias and anxiety and provides the first dataset on VR therapy efficacy for phobias in Romania. Additionally, it evaluates the optimal duration and frequency of VRT sessions to maximize therapeutic benefits while minimizing adverse reactions like fatigue and anxiety. The findings indicate that a certain minimal number of sessions are required for specific phobias and that VRT sessions ideally last one hour, spaced several days apart, to allow adequate cognitive and emotional processing by patients. It offers unique regional insights into the effectiveness of VRT, and it presents an exciting opportunity for future research and potential expansion into treating a broader range of phobias.
